The total receipts amounted in round numbers to 506,000*l.*, that amount being thus made up: subscriptions 67,800*l.*, entrance fees 425,000*l.*, casual receipts (*i. e.* refreshment and catalogue contracts, royalty on medals, washing-rooms, &c.) 13,200*l.* The total expenditure connected with the Exhibition was about 330,000*l.*, leaving a surplus of 176,000*l.* in the hands of the Commissioners, but the final balance, including interest on Exchequer Bills and additional small receipts was 186,436*l.* How to apply this large surplus was a most important question. The original announcement to the subscribers was to the effect that, should any surplus remain, it was the intention of the Commissioners "to apply the same to purposes strictly in connection with the ends of the Exhibition, or for the establishment of similar exhibitions for the future." This latter purpose they were however led on more mature reflection to abandon, and they arrived at the conclusion that instead of applying it to any purposes of a temporary, partial, or local character, they could in no way so properly act in the spirit of the pledges held out to the public as by assisting in carrying out a comprehensive scheme which should have for its object to "increase the means of industrial education and extend the influence of science and art upon productive industry:" they having been compelled by their experience, in connection with the Exhibition, to regard as a matter of urgent importance the "systematically imparting instruction in science and art to the industrial classes of the community, to enable them to maintain their pre-eminence in the markets of the world." In their Second Report (1852) the Commissioners review the existing means and deficiencies of the country in respect to these matters, and develope their idea of the means required to supply the deficiencies which they have pointed out. Properly to carry into execution any comprehensive scheme would require the liberal co-operation of the public and the government. The sum in the hands of the Commissioners would go but a small way towards meeting the requirements of the case. It would suffice however to prepare the ground, and they determined so to employ it, leaving it to the public to complete the work when its importance and necessity shall have become fully understood and appreciated. They say, "The Commissioners feel it their duty to deal with the funds in their hands in such a manner as may ensure the greatest amount of advantage being derived from the mode of their application; and they consider that in no manner could this be ensured so well as by carefully preparing the basis and framework of a large and comprehensive plan, and securing facilities for its execution, leaving it to the various interests concerned to give substance to it, whilst the perfect development of the system must be left to the progressive action of time, commencing with the wants at present manifested, and extending it as those wants become greater and find expression on the part of the public. In investigating the causes which have led to the deficiency in England of larger institutions of the character alluded to, and the reasons why the great amount of private exertion and of State endowment already mentioned has not operated with all the advantage that might have been looked for, we have found two, which have more especially attracted our notice: the first being the want of that harmony of system which would admit of an economic and combined action of the forces already in existence towards a common end; and the second, the want of actual space for their development in this overcrowded metropolis." And having enlarged on these points at some length, they add that it appears to them that, "The two things to be aimed at are the adoption of a *system* and the securing of a *locality* where that system may be developed. We feel that we are best discharging the duties intrusted to us by her Majesty, by submitting for consideration and discussion on the part of the public such a system, and by ourselves providing such a locality, bearing in mind that the filling up of the plan that may be adopted must be left to the wants expressed, to the interest felt by the public at large, and to the voluntary efforts of institutions, societies, and individuals, aided by the efforts of the Government to develope more fully the institutions already founded by it, and which are so much appreciated by the public."

Acting on the suggestions of this report, the Government in the speech from the Throne at the opening of the session of 1852-53 invited the "aid and co-operation" of parliament in promoting a "comprehensive scheme" for the advancement of the Fine Arts and of Practical Science, which was in effect the scheme of the Commissioners. After some discussion the House of Commons voted the sum of 150,000*l.* towards the purchase of a site on which a National Gallery and Museum might be erected, and which should be available for the other purposes indicated. An equal sum was provided by the Commissioners out of the surplus remaining at their disposal. The land purchased by the Commissioners consisted of the well-known Gore House estate of 21 acres, situated nearly opposite the site of the Exhibition of 1851; the Villars estate of 48 acres, and some other adjacent land, which "were deemed indispensable for the completeness and development of the capacities of the property." Altogether it formed a compact estate of about 86 acres, its extreme length being half a mile, its average width a quarter of a mile. The Commissioners were anxious to secure other adjoining property to the extent of about 80 acres then obtainable, making in all about 170 acres, but the Government demurred, and the opportunity was lost, it being speedily purchased for building purposes. For the completion of the purchases the government subsequently obtained an additional vote of 27,500*l.*; and the Commissioners, having obtained the necessary powers from parliament, have formed upon the estates lines of road, sewers, &c. The total expenditure upon the Kensington estate up to Jan. 31, 1858, has been 312,036*l.*, and 54,716*l.* remains to be paid in completion of one of the purchases. The Commissioners wish to retain in their hands a balance of 20,000*l.*, which they consider to be "the minimum which they could safely retain for the purpose of meeting current expenses and providing for contingencies." The Commission itself has been incorporated as a permanent body, and certain members of the Government are now *ex officio* members of it.

The "comprehensive scheme" of the Commissioners proposed eventually to bring together, upon the locality they have purchased, all the existing metropolitan institutions, whether dependent on government or on private support, which have in view the advancement of science and art in their various branches, and to "establish a central point of union for those who in so many ways devote their energies to the same ends, especially in respect of the practical application of science and art to productive industry." They thus, in connection with the enlarged system of industrial instruction of which they urged the necessity, hoped that instead of being behind most other European nations we might take the lead in industrial science and art, as well as in manufacturing industry and enterprise. But the Commissioners have been doomed to see their scheme, like so many another castle in cloudland, reduced to much humbler dimensions than that in which it at first presented itself to their imagination. As a first step it was proposed to remove the National Gallery, and a noble site with a frontage of a thousand feet (the depth being practically unlimited) nearly facing the site of the Exhibition of 1851, was proffered by the Commissioners. A Committee of the House of Commons in 1853 reported unanimously in its favour, and the Government appeared to be inclined to support the proposition, but the Commissioners appointed to consider the subject in 1857 decided by a majority of three votes to one against removing the national collection from Trafalgar Square; and in consequence of their report a survey has been made of the ground in the rear, and estimates given of the cost of enlarging the present building, or erecting a new one on its site. So with reference to the Art-Collections in the British Museum, the feeling of the Trustees has been decidedly expressed against any removal. So again, a new building has been erected for the collection of vegetable products at Kew, which were proposed to be taken to Kensington. Then the Learned Societies were averse to migrating so far westward, and provision has been made for their accommodation at Burlington House, Piccadilly, which was purchased by the Government.

But a very definite advance has been made. By manufacturers and artisans, and by the general public, as well as by the Commission, the great importance of systematic art instruction is now generally admitted. A new department of the Government has been created, whose special duty is the promotion of Industrial Art and Science; and to which was intrusted the direction of all previously existing government scientific and art institutions, and the encouragement of all local institutions of a similar order. [SCIENCE AND ART, DEPARTMENT OF, *S.* 2.] Upon the estate purchased by the Commissioners a great practical step towards the realisation of a main feature of their scheme has been taken. In a building which has been adapted to the purpose, instruction in practical art and science by professors and teachers of the highest standing is regularly given, and an excellent library has been formed for the use of the students; more strictly scientific courses of lectures are at the same time delivered at the Metropolitan School of Science, in Jermyn Street —the two institutions making together a school nearly resembling that desired by the Commissioners. In a spacious temporary iron building at the south-eastern angle of the estate have been brought together for public exhibition industrial, educational, and art collections, which, though as yet necessarily very incomplete, and in some cases only rudimentary, are all of great value and interest; and having been arranged and shown so as most to suit the convenience of the industrial classes, they have proved remarkably attractive. These collections include a Museum of Patent Inventions, a Trade Museum, a Museum of Ancient and Modern Manufactures, a Museum of Animal Products, a Museum of Domestic Economy, the Architectural Museum formerly exhibited in Cannon Row, the fine collection of paintings by British artists presented to the nation by Mr. Sheepshanks, and collections of British sculpture, drawings, etchings, &c. At the present moment [March 1858], a collection of models and drawings submitted in competition for the Memorial to be erected in commemoration of the Great Exhibition is also being exhibited in the 'South Kensington Museum,' but the true memorial of the Exhibition of 1851 will be the Exhibition Estate, with the Museums of Art and Industrial Science collected upon it.

EXOCETUS. [FLYING FISH.]

EYEBRIGHT. [EUPHRASIA.]

F

FABER, REV. GEORGE STANLEY, was born on the 25th of October 1773. He was the eldest son of the Rev. Thomas Faber, who was descended from a French refugee who came over to England after the revocation of the edict of Nantes. He was educated at the grammar-school of Heppenholme, near Halifax in Yorkshire, where he remained till 1789, when he was entered of University College, Oxford. He took his degree of B.A. in 1792, and before he had reached his twenty-first year, was elected a Fellow and Tutor of Lincoln College. He took his degree of M.A. in 1796, served the office of Proctor in 1801, and in the same year, as Bampton Lecturer, preached the discourses which he shortly afterwards published under the title of 'Horæ Mosaicæ.' He took the degree of B.D. in 1803, and married in the same year. Having by this step relinquished his fellowship, he went to reside with his father at Calverley, near Bradford in Yorkshire, where for two years he acted as curate. In 1805 he was collated to the vicarage of Stockton-upon-Tees, in the county of Durham, which he resigned in 1808 for that of Redmarshall, in the same county. In 1811 he was collated to the vicarage of Long-Newton, where he remained till 1831, when Bishop Burgess presented him to a prebend in the cathedral of Salisbury. In 1832 Bishop Van Mildert gave him the mastership of Sherburn Hospital, near the city of Durham, when he resigned the vicarage of Long-Newton. During his mastership he considerably increased the value of the estates of the Hospital. He rebuilt the chapel, the house, and the offices, and greatly improved the grounds; he augmented the incomes of the incumbents of livings under his patronage, restored the chancels of their churches, and erected agricultural buildings on the farms. He died at his residence, Sherburn Hospital, on the 27th of January, 1854.

The theological writings of Mr. Faber, particularly those on prophecy, have had a very wide circulation. One of the principles for the interpretation of prophecy which he chiefly laboured to establish and exemplify, was, that the delineations of events in prophecy are not applicable to the destinies of individuals, but to those of governments and nations. His writings are numerous, and we can only mention a few of the most important:—'Horæ Mosaicæ, or a View of the Mosaical Records, with respect to their Coincidence with Profane Antiquity, their internal Credibility, and their Connexion with Christianity,' 2 vols. 8vo, 1801; 'A Dissertation on the Mysteries of the Cabyri, or the great gods of Phœnicia, Samothrace, Egypt, Troas, Greece, Italy, and Crete,' 2 vols. 8vo; 'Dissertation on the Prophecies that have been fulfilled, are now fulfilling, or will hereafter be fulfilled, relative to the great Period of 1260 Years,' 2 vols. 8vo, 1806; 'A General and Connected View of the Prophecies relating to the Conversion, Restoration, Union, and future Glory of Judah and Israel,' 2 vols. 8vo, 1808; 'The Origin of Pagan Idolatry,' 3 vols. 8vo, 1816; 'A Treatise on the Genius and Object of the Patriarchal, the Levitical, and the Christian Dispensation,' 2 vols. 8vo, 1823; 'The Sacred Calendar of Prophecy, or a Dissertation on the Prophecies which treat of the Grand Period of Seven Times,' 3 vols. 8vo, 1828; 'Eight Dissertations on certain connected Prophetical Passages of Holy Scriptures bearing more or less upon the Promise of a Mighty Deliverer,' 2 vols. 8vo, 1845.

FAIRFORD. [GLOUCESTERSHIRE.]

FALKINGHAM. [LINCOLNSHIRE.]

FAREHAM. [HAMPSHIRE.]

FAREY, JOHN, civil engineer and draughtsman, was born at Lambeth on March 20, 1791, and was educated at Woburn, where his father was agent to the Duke of Bedford, who took much interest in the progress of agriculture. John Farey, senior, was frequently employed in making reports on geological questions; wrote a 'General View of the Agriculture and Minerals of Derbyshire,' &c., (2 vols. 8vo, London, 1811,) a work which had some reputation, and contributed to the 'Agricultural Magazine.' Farey, junior—with his brothers and sisters, becoming at an early age attached to kindred pursuits—was engaged in making drawings for the plates of 'Rees's Encyclopædia,' 'The Edinburgh Encyclopædia,' 'Tilloch's Magazine,' 'Gregory's Mechanics,' and 'Mechanical Dictionary,' the 'Pantalogia,' and many other publications, some of which he contributed articles to, or edited. To him, in conjunction with the Messrs. Lowry, the engravers, has been ascribed in a great degree, the merit of introducing a better explanatory style of illustration in scientific works, and which has not since been improved upon in the bulk of publications, in a ratio commensurate with mechanical facilities. His avocations connected him with eminent scientific men of the time; and thus with Huddart, Jessop, Mylne, and Rennie, he was engaged in the publication of Smeaton's reports and drawings. In 1807 he had received the silver medal of the Society of Arts for an instrument for making perspective drawings, described in their 'Transactions;' and in 1813 the gold medal was awarded to him on the invention of his machine for drawing ellipses. This last he afterwards improved upon, besides effecting many improvements in the scales and drawing instruments now in use. In 1819 he went to Russia, and was engaged in the construction of iron-works. In Russia he first saw a steam-engine indicator—an instrument which it was attempted to keep secret—and on his return he had similar contrivances manufactured, and was often employed to use them in disputed cases. In 1821 he resigned his professional engagements in favour of his brother, and embarked in a lace manufactory in Devonshire, but gave that up in 1823. In 1825 he took the engineering direction of flax-mills at Leeds; but in 1826, on the failure of his brother's health, he returned to London, and from that time to near his death, which took place in his sixty-first year, on the 17th of July 1851, he was employed as a consulting engineer, or referee, in most of the novel inventions and litigated patent cases, during the quarter of a century. For such duties he was peculiarly qualified from retentive memory as to details of machines and processes, names and dates, and from habits of conscientious and laborious research into authorities for cases. In his investigations and in the preparation of drawings for specifications, he was assisted by his wife, a lady of great scientific attainments. From the shock of her decease he never wholly recovered. Some time before, part of his library and documents had been burnt with his house in Guildford-street. Farey commenced a 'Treatise on the Steam-engine, Historical, Practical, and Descriptive,' (4to, London, 1827, with plates,) a valuable work, but which did not get beyond a first volume, and he was an active member of the Institution of Civil Engineers, from whose Report of 1851-52 many of these particulars are derived.

FARINGDON. [FARRINGDON.]

FAT. [TISSUES, ORGANIC, *S.* 1.]

FAUCHER, LÉON, an ex-minister of the French government, and a writer on subjects of political economy and social progress, was occupied during the greater part of his life as a journalist. His connection with the periodical press of Paris commenced about the year 1830; from 1836 to 1843 he was a contributor to the 'Courrier Français,' and was afterwards a leading writer in the 'Revue des Deux Mondes,' which is published on the 1st and 15th of every month, and occupies an influential place among those periodicals which are chiefly devoted to the discussion of questions of political economy and the investigation of the actual condition of the various nations of the world. M. Léon Faucher was, during the last ten years of the dynasty of Louis Philippe, a member of the Chamber of Deputies for the department of Marne. He was re-elected by the same department in 1848 as one of its representatives in the National Assembly of the French Republic. He became Minister of the Interior, December 29, 1848, and held the office till May 14, 1849. He was again appointed Minister of the Interior, April 10, 1851, and was succeeded by the Comte de Persigny, January 22, 1852. M. Léon Faucher died on the 15th of December 1854, at Marseille.

M. Léon Faucher published in 1845 'Études sur l'Angleterre,' 2 vols. 8vo, Paris, a work descriptive of the social and industrial condition of certain districts of England—Whitechapel, St. Giles's, the City; Liverpool, Manchester, Leeds, Birmingham, and adjoining districts—together with dissertations on the Bank of England, the Lower Classes, Middle Classes, Aristocracy, the Corn-Laws and the League, and the Balance of Powers. Several portions of this work had appeared in 1843 and 1844 in the 'Revue des Deux Mondes,' and the description of Manchester had been translated into English under the title of 'Manchester in 1841; its Present Condition,' 12mo. The work is written in a fair and impartial spirit, and affords evidence of diligent research and patient investigation; but contains many mistaken views and exaggerated descriptions. Other dissertations by M. Léon Faucher are the following:—'De l'Impôt sur le Revenue;' 'Du Système de M. Louis Blanc.' 'De la Situation Financière et du Budget,' 8vo, 1850, appeared originally in the 'Revue des Deux Mondes,' in 1849. 'Remarks on the Production of the Precious Metals and the Demonetization of Gold in several Countries in Europe, by Mons. Léon Faucher; translated by Thomas Hanley, Junior,' 8vo, Lond., 1852. These remarks appeared first in the 'Revue des Deux Mondes,' and were subsequently published, somewhat modified, in the Reports of the Académie des Sciences Morales et Politiques.

FAUJASITE. [MINERALOGY, *S.* 1.]

FERRIER, MISS, was born at Edinburgh, about 1782, the daughter of a writer to the signet, and who was one of Sir W. Scott's colleagues as clerk of the Court of Session. This association almost necessarily produced an intimacy with the Scott family, and she had early access to the company of the best literary society of her native city. She was the author of 'Marriage,' published in 1818; 'The Inheritance,' in 1824; and 'Destiny, or the Chief's Daughter,' which appeared in 1831. They were all published anonymously, and thence Sir Walter Scott spoke of his "Sister shadow," at the end of his 'Legend of Montrose,' as one peculiarly fitted to excel in the depicting of Scottish character, as proved by "the very lively work entitled 'Marriage.'" In the latter part of his life, when Miss Ferrier was one of his most trusted friends, her name occurs in his diary. Her novels are not entirely national; the characters are vigorously drawn, and thoroughly individualised; the plots tolerably well imagined and ingeniously developed; and the dialogues are spirited and life-like, sometimes humorous, and occasionally witty. The use of the Scottish dialect is occasionally introduced with good effect, the dialect actually spoken and not the imitation which was occasionally heard upon the stage. All her novels were successful, and have become standards; but she seems to have written because she had accumulated observations and materials, and not from the love of either fame or profit. Sir Walter Scott, indeed, says of her, that in conversation "she was the least *exigeante* of any author, female at least, whom I have ever seen." He adds: "she was simple, full of humour, and exceedingly ready at repartee; and all this without the least affectation of the blue-stocking." This appears to be a good representation of her whole character: acute and observant, she was too kind to wish to give pain, and too placid and contented to seek for applause. Though her satire is sometimes sufficiently coarse and caustic upon the grosser errors of human conduct, the sketches are relieved by scenes of humour, which, if sometimes exaggerated, like those of Miss Burney, are certainly laughable.

Miss Ferrier passed a peaceful and quiet life in her native town, associated with all the more distinguished of her contemporaries, and respected for her kindness and urbanity by every one who knew her. She died, aged seventy-two, in November 1854.

FIELDFARE. [THRUSHES.]

FIELDING, COPLEY VANDYKE, was born about 1787, and belonged to a family several of the members of which were artists of greater or less ability. Copley Fielding exhibited his first pictures at the Artists' Exhibition, Spring Gardens, in 1810. It was by his water-colour landscapes that he first attracted notice, and though he subsequently made many attempts to achieve success as a painter in oil, it is by his paintings in water-colours that he will be remembered. Mr. Fielding began the practice of the art about the time that Girtin and Turner had succeeded in raising the practice of water-colour painting almost to a level with that of oil-colours, and Fielding devoted himself with thorough earnestness of purpose to the new art.

From an early period in his career he became a teacher, and he had in that line an unusual measure of success, as well in the progress of his pupils as in their nnmber and social position. His success as a teacher of conrse did mnch to secure for him a wide circle of patrons and friends, which the merits of his works effectnally maintained. His course was one of steady prosperity, quite devoid of adventure. His time was constantly occupied either in teaching or painting, or in those sketching excursions which were to furnish him with the materials for new pictnres. For many years Mr. Fielding held the office of President of the Society of Painters in Water-Colours, and his position was generally recognised as that of the head and representative of this branch of art in England; the more readily, no donbt, in conseqnence of the estimation in which his personal as well as professional qualities were universally held. He died March 3, 1855, in his sixty-eighth year, at Worthing, Sussex, where, or at Brighton, he had for a long period been accnstomed to spend his autumns.

FIGITES. [GALLICOLÆ.]

FI'LICES, or FILICA'CEÆ, a natnral order of Plants, being the highest gronp of the class *Cryptogamia*, or Acrogens. The species are flowerless plants, consisting of leafy fronds, which are produced from a rhizoma unfolding in a spiral manner, and traversed hy veins which form definite parts on the under surface, and produce unilocular, rarely multilocular, cases containing reproductive sporules.

The parts of these plants which reqnire most attention in their stndy, and on modifications of which modern classifications depend, are the veins and organs of reproduction. The veins are either produced equally from both sides of a midrib, or they radiate from the base or axis of development, or from one side of an eccentric or unilateral costa. They are either simple, or once or repeatedly dichotomously branched, or the primary veins are pinnate; the branches are simple or forked. Their apices are either free, or they are combined by varions forms of anastomosis. The organs of reproduction consist of a sporangiferous receptacle, which is a thickened point or lengthened portion of the nltimate venules or veinlets. It is generally superficial, sometimes immersed in the snhstance of the frond, or considerably elevated, and then glohose or colnmnar. The sporangia, thecæ, or spore cases, are transparent, globose, oval, or pyriform unilocular cases, each girded by a more or less complete elastic articulated ring, or destitnte of a ring; then sometimes oblong, opaqne, and multilocular, and usually pedicillate. The sori are collections of sporangia, and have the same form, position, and direction as the receptacles. They are either naked, or each sorus is fnrnished with a membranaceous covering of varions forms which rises from the receptacle. This covering is called an indusinm, and is a plane, or vanlted, or cnp-shaped membrane, produced from the receptacle of each sorus, and is generally decidnous as it becomes replicate. Often the entire margin (or lobnles of the frond) is changed in texture, and forms an accessory indusium. Sometimes the whole of the sori of each segment are included within a universal indusinm which is formed by the revolnte margin of fertile contracted fronds.

The following acconnt of the reprodnction of the Ferns is given in a Report to the British Association in 1851, on the higher Cryptogamous Plants, by Mr. Henfrey. Speaking of the Ferns, Mr. Henfrey says:—

"This class formed for a long time the great stumbling-block to those who songht to demonstrate the existence of sexuality in plants. The yonng capsules were generally considered to be the analogues of the pistillidia of the Mosses, and the yonng abortive capsules which frequently occur among the fertile ones were supposed by some authors to represent the antheridia. Mr. Griffith noticed a structure which he was inclined to regard as the analogue of the antheridium in certain of the ramenta upon the petioles.

"In the year 1844 Professor Nägeli published an account of his observations on the germination of certain ferns, and announced the discovery of moving spiral filaments closely resembling those of the *Charæ*, on certain cellular structures developed npon the pro-embryo or cellular body first produced by the spore. It is not worth while to enter into an analysis of his observations, as they have since been clearly shown to have been very imperfect; it is sufficient to state that he only described one kind of organ, and from his description it is evident that he confonnded the two kinds since discovered, regarding them as different stages of one structnre. The announcement of this discovery seemed to destroy all grounds for the assumption of distinct sexes, not only in Ferns, bnt in the other Cryptogams, since it was argned that the existence of these cellular organs, producing spiral filaments, the so-called spermatozoa, upon the germinating fronds, proved that they were not to be regarded as in any way connected with the reproductive processes.

"But an essay published by the Count Suminski in 1848 totally changed the face of the qnestion, and opened a wide field for specnlation and investigation on this snbject, jnst as it was beginning to fall into disfavonr. Connt Suminski's paper gives a minute history of the course of development of the Ferns, from the germination of the spore to the production of the regular fronds; and he fonnd this development to exhibit phenomena as curious as they were unexpected. The cellnlar organs seen by Nägeli were shown to be of two perfectly distinct kinds, and moreover to present characters which gave great plausibility to the hypothesis that they represented reproductive organs; moreover, this author expressly stated that he had obtained absolute proof of sexuality by observing an actual process of fertilization to take place in the so-called ovules, through the agency of the spiral filaments or spermatozoa. The main points of his paper may be briefly summed np as follows:—The fern-spore at first produces a filamentary process, in the end of which cell-development goes on until it is converted into a Marchantia-like frond of small size and exceedingly delicate textnre, possessing hair-like radicle threads on its under side. On this under side become developed, in variable nnmbers, certain cellnlar organs of two distinct kinds. The first, which he terms antheridia, are the more numerons, and consist of somewhat globnlar cells seated on and arising from single cells of the cellular Marchantia-like frond. The globular cell produces in its interior a number of minute vesicles, in each of which is developed a spiral filament, coiled up in the interior. At a certain epoch the globular cell bursts, and discharges the vesicles, and the spiral filaments moving within the vesicles, at length make their way ont of them, and swim abont in the water, displaying a spiral or heliacal form, and consisting of a delicate filament with a thickened clavate extremity; this, the so-called head, being said by Count Suminski to be a hollow vesicle, and to be furnished with six or eight cilia, by means of which the apparently voluntary movement of the filament is snpposed to be effected.

"The second kind of organ, the so-called 'ovules,' are fewer in number and present different characters in different stages. At first they appear as little round cavities in the cellular tissne of the pro-embryo, lying near its centre, and opening on the nnder side. In the bottom of the cavity is seen a little globnlar cell, the so called 'embryo-sac.' It is stated by Count Suminski, that while the ovule is in this state one or more of the spiral filaments make their way into the cavity, coming in contact with the central globular cell. The four cells bounding the month of the orifice grow ont from the general snrface into a blnnt cone-like process, formed of four parallel cells arranged in a squarish form, and leaving an intercellular canal leading down to the cavity below. These four cells become divided hy cross septa, and grow ont until the so-called ovule exhibits internally a cylindrical form composed of four tiers of cells, the uppermost of which gradually converge and close np the orifice of the canal leading down between them. Meanwhile the vesicular head of one of the spiral filments has penetrated into the globular cellule of the embryo-sac, enlarged in size and undergone multiplication, and in the course of time displays itself as the embryo, producing the first frond and the terminal bud, whence the regular fern-stem is developed. In considering the import of these phenomena, the anthor assumes the analogy here to be with the process of fertilisation in flowering plants, as described by Schleiden, regarding the prodnction of the embryo from the vesicular head of the spermatozoa as representing the prodnction of the phanerogamons embryo, from the end of the pollen tube after it has penetrated into the embryo-sac.

"The promulgation of these statements naturally attracted great attention, and since they appeared we have received several contribntions to the history of these remarkable structures, some confirmatory, to a certain degree, of Suminski's views; others altogether opposed to them.

"In the early part of 1849, Dr. Wigand published a series of researches on this subject, in which he subjected the assertions of Suminski to a strict practical criticism; the conclusions he arrived at were altogether opposed to that author's views respecting the supposed formation of the organs, and he never observed the entrance of the spiral filaments into the cavity of the so-called ovnle. About the same time M. Thuret published a series of observations on the 'Antheridia of Ferns.' In these he merely confirmed and corrected the statements of Nägeli respecting the antheridia, and did not notice the so-called ovules.

"Towards the close of the same year Hofmeister confirmed part of Suminski's statements, and opposed others. He stated that he had observed distinctly the production of the young plant (or rather the terminal bud for the new axis) in the interior of the so-called ovule; but believed the supposed origin of it from the end of the spiral filament to be a delusion. He regards the globular cell at the base of the canal of the ovule as itself the rudiment of the stem, or embryonal vesicle (the embryo originating from a free cell produced in this), analogous to that produced in the pistillidia of the Mosses. He also describes the development of the ovule differently, saying that the canal and orifice are opened only at a late period by the separation of the contiguous walls of the four rows of cells.

"About the same time appeared an elaborate paper on the same subject by Dr. Hermann Schacht, whose results were almost identical. He found the young terminal bud to be developed in the cavity of one of the so-called ovules, which were developed exactly in the same way as the pistillidia of the Mosses. He stated also that the cavity of the ovule is not open at first, and he declares against the probability of the entrance of the spiral filament into it, never having observed this, much less a conversion of one into an embryo. In the essay of Dr. Mettenius, already referred to, an account of the development of the so-called ovules is given. His observations did not decide whether the canal of the ovule, which he regards as an intercellular space, exists at first, or only subsequently, when it is entirely closed above. Some important points occur in reference to the contents of the canal. The contents of the canal in a mature condition consist of a continuous mass of homogeneous tough substance, in which fine granules, and here and there large corpuscles, are embedded. It reaches down to the globular cell, or embryo-sac, and is in contact with it. This mass either fills the canal or diminishes in diameter from the blind end of the canal down to the embryo-sac; in other cases it possesses the form represented by Suminski, having a clavate enlargement at the blind end of the canal, and passing into a twisted filament below; in this latter shape it may frequently be pressed out of the isolated ovules under the microscope, and then a thin transparent membrane-like layer was several times observed on its surface. In other cases the contents consisted of nucleated vesicles, which emerged separately or connected together.

"The embryo-sac consists of a globular cell containing a nucleus, and this author believes that the commencement of the development of the embryo consists in the division of this into two, which go on dividing to produce the cellular structure of the first frond.

"With regard to the contents of the canal the author says, 'Although I can give no information on many points, as in regard to the origin of the contents of the canal of the ovule, yet my observations on the development of the ovule do not allow me to consider them, with Suminski, as spiral filaments in course of solution; just as little have I been able to convince myself of the existence of the process of impregnation described by that author. It rather appears to me that the possibility of the entrance of the spiral filaments and the impregnation cannot exist until the tearing open of the blind end of the canal in the perfectly-formed ovule, as after the opening of the so-called 'canal of the style' in the pistillidia of the Mosses.

"Another contribution has been furnished by Dr. Mercklin, the original of which I have not seen, but depend on analyses of it published in the 'Botanische Zeitung,' and the 'Flora' for 1851, and further in a letter from Dr. Mercklin to M. Schacht, which appeared in the 'Linnæa' at the close of last year.

"He differs in a few subordinate particulars from M. Schacht, in reference to the development and structure of the prothallium, or pro-embryo, and of the antheridia and spiral filaments; but these do not require especial mention, except in reference to the vesicular end of the spiral filament described by Schacht, which Mercklin regards as a remnant of the parent vesicle, from which the filament had not become quite freed. The observations referring to the so-called ovule, and the supposed process of impregnation, are very important; they are as follows:—

"'1. The spiral filaments swarm round the ovule in numbers, frequently returning to one and the same organ.

"'2. They can penetrate into ovules. This was seen only three times in the course of a whole year, and under different circumstances; twice a spiral filament was seen to enter a still widely open young ovule, then come to a state of rest, and after some time assume the appearance of a shapeless mass of mucilage; the third case of penetration occurred in a fully developed ovule through its canal; it therefore does not seem to afford evidence of the import of the spiral filament, but certainly of the possibility of the penetration.

"'3. In the tubular portion of the ovule, almost in every case, peculiar club-shaped granular mucilaginous filaments occur at a definite epoch; these filaments, like the spiral filaments, acquiring a brown colour with iodine. These mucilaginous bodies sometimes exhibit a twisted aspect, an opaque nucleus, or a membranous layer, peculiarities which seem to indicate the existence of an organisation.

"'4. These club-shaped filaments are swollen at the lower capitate extremity, and have been found in contact with the embryo-sac, or globular cell, which forms the rudiment of the future frond.

"'5. The spiral filaments, which cease to move and fall upon the prothallium, are metamorphosed, become granular, and swell up.'

"Hence the author deduces the following conclusions:—

"'That these clavate filiform masses in the interior of the ovule are transparent spiral filaments, which at an early period, while the ovule was open, have penetrated into it; which leads to the probability that—

"'1. The spiral filaments must regularly penetrate into the ovules; and, 2. They probably contribute to the origin or development of the young fruit frond (or embryo). In what way this happens the author knows not, and the details on this point given by Suminski remain unconfirmed facts.'

"An important point in this essay is the view the author takes of the whole process of development in this case. He regards it as not analogous to the impregnation in the *Phanerogamia*, since the essential fact is merely the development of a frond from one cell of the prothallium, which he considers to be merely one of the changes of the individual plant, while all the other authors who have written on the subject, with the exception of Wigand, call the first frond, with its bud and root, an Embryo, and regard it as a new individual; or at all events, even a distinct member of a series of forms, constituting collectively the representatives of the species.

"Finally, Hofmeister, in his notice of this essay in the 'Flora,' declares that the development of the so-called embryo, or first frond, commences not by the subdivision of the globular cell, or embryo-sac, but by the development of a free cell, or embryo vesicle in this, like what occurs in the embryo-sac of the *Phanerogamia;* and he asserts that this is the first stage of development from the globular cell in all the vascular Cryptogams, including that found in the pistillidia of the Mosses."

The position of the Ferns in a natural system of classification has not been a matter of much difference. Their imperfect organs of reproduction have at once led to their being placed by most botanists among *Cryptogamia;* nevertheless Bory St.-Vincent elevates Ferns to the rank of a class intermediate between Monocotyledons and Acotyledons, or *Cryptogamia;* at the same time he rejects the view of Jussieu, who, from the mode of germination of their sporules, placed the Ferns among the Monocotyledons. Their relation with the flowering-plants is seen through *Cycadaceæ*, with which order they agree in their gyrate vernation and their pinnate leaves. Their affinity with Cryptogamic plants is obvious in the *Equisetaceæ* and *Lycopodiaceæ*. The order of Ferns may be divided into the following sub-orders, which Lindley regards as of the rank and value of orders:—

I. Gleicheniaceæ. The thecæ with a transverse or obliquely transverse complete elastic annulus or ring, bursting vertically. The species are tropical, or extra-tropical only in the Southern Hemisphere, of a harsh and rigid texture, simple or generally with copious dichotomous branches and gemmæ in the axils; the ultimate branches pinnatifid. None of the genera of this order, as understood by Hooker, are British. It includes about forty species.

II. Polypodiaceæ, with the sori dorsal, often near or at the margin, various in form, sometimes constituting an uniform linear or spreading mass, naked or furnished with an involucre, the thecæ 1-celled, with a longitudinal or oblique elastic articulated generally incomplete ring, bursting transversely and irregularly. This is a very extensive sub-order: the species inhabit almost every part of the world, from the tropics to the arctic and antarctic regions; they are exceedingly variable in size and appearance, including the largest tree-ferns and the smallest herbaceous species. It contains by far the largest number of genera of any of the sub-orders of Ferns. Many of these are very extensive, and have no British representatives, as *Cyathea, Hemitelia, Alsophila, Dicksonia,* &c.

III. Osmundaceæ has the thecæ with an operculiform ring, or without one, reticulated, striated with rays at the apex, bursting lengthwise, and usually externally. The species of this sub-order are not numerous.

IV. Danæaceæ. The thecæ sessile, without any ring, concrete into multilocular sub-immersed masses, opening at the apex. This is also a small sub-order, with three genera —*Danæa, Marattia,* and *Kaulfussia.*

V. Ophioglossaceæ. The thecæ single, roundish, coriaceous, opaque, without ring or cellular reticulation, half 2-valved, with a straight vernation. It embraces the genera *Ophioglossum, Helimnthostachys,* and *Botrychium.*

The following is an arrangement of the British genera of Ferns;—

Sub-Order *Polypodiaceæ.*

Tribe *Polypodieæ.* The sori nearly circular, without an indusium.
Genera, *Allosorus, Polypodium, Woodsia.*

Tribe *Aspidieæ.* The sori nearly circular, covered by an indusium.
Genera, *Lastrea, Polystichum, Cystopteris.*

Tribe *Asplenieæ.* The sori oblong or linear, covered by an indusium opening longitudinally on one side.
Genera, *Athyrium, Asplenium, Scolopendrium.*

Tribe *Grammitideæ.* The sori elongate, without an indusium.
Genus, *Ceterach.*

Tribe *Adiantariæ.* The thecæ covered by a marginal or sub-marginal elongated part of the frond, or by a separated portion of the cuticle, resembling an indusium.
Genera, *Blechnum, Pteris, Adiantum.*

Tribe *Hymenophylleæ.* The thecæ opening irregularly; the ring oblique, eccentric, transverse, complete; the receptacle terminating a vein at the margin of the frond.
Genera, *Trichomanes, Hymenophyllum.*

Sub-Order *Osmundaceæ.*

Tribe *Osmundeæ.* The vernation circinate; the rachis solid; the thecæ stalked.
Genus, *Osmunda.*

Sub-Order *Ophioglossaceæ.*

Genera, *Ophioglossum, Botrychium.*

The Ferns have a wide geographical distribution, the herbaceous and shrubby kind being found towards the north and south poles; whilst the tree-ferns rival the gigantic palms in the forests of tropical climates. It is these last which give a peculiar character to the vegetation of the countries where they grow, as their foliage and stems differ altogether from any that are observed amongst flowering plants. The proportion which they bear to other plants varies much in different parts of the world. In Jamaica they are in the proportion of 1 to 9; in New Guinea as 28 to 122; in New Ireland as 13 to 60; in the Sandwich Islands as 42 to 160; on continents they are less numerous; in equinoctial America 1 to 36; in Australia 1 to 37; in France 1 to 63; in Portugal 1 to 116; in the Greek Archipelago 1 to 227; in Egypt 1 to 971. In the north their proportions are greater; they form in Scotland 1 to 31; in Sweden 1 to 35; in Iceland 1 to 18; in Greenland 1 to 10; and the North Cape 1 to 7.

The properties and uses of the Ferns are not in proportion to their numbers in the vegetable kingdom. Many of them deposit starch in their rhizomata, from which food may be prepared. The roots of *Nephrodium esculentum* are eaten in Nepaul; those of *Angiopteris evecta* are used in the same manner in the Sandwich Islands. *Diplazium esculentum, Cyathea medullaris, Pteris esculenta,* and *Gleichenia dichotoma,* all yield starch, and are employed as food in different countries. The *Adiantum Capillus Veneris* yields astringent and aromatic secretions. Some of the American polypodiums are said to possess powerful medicinal effects, and are used as anti-rheumatic, anti-venereal, and febrifugal remedies. The *Angiopteris evecta* yields an aromatic oil, which is used in the Sandwich Islands to perfume the fixed oils, as cocoanut oil. The stems of many species contain bitter principles, and have hence been used as tonics. Species of *Aspidium* and *Asplenium* have been used in European medicine. The Brazillian negroes form tubes for their pipes from the stems of *Mertensia dichotoma. Osmunda regalis* had at one time a great reputation in medicine.

FILLANS, JAMES, sculptor, was born at Wilsontown, Lanarkshire, on the 27th of March, 1808. His father having become reduced in circumstances, removed into Renfrewshire while James was yet a child, and the boy was early set to the keeping of sheep and similar employments, and consequently received scarcely any school education. When old enough he was apprenticed to a weaver at Paisley; but disliking the occupation, was at the end of a year placed with a stonemason. At this business, after having served his apprenticeship, he for awhile worked as a journeyman. But he had, during his spare hours, even when engaged as a weaver, been teaching himself to draw and to make clay models, and by perseverance he attained sufficient skill to win some local celebrity. Motherwell, the poet, was at this time the editor of the 'Paisley Advertiser,' and he warmly encouraged the young man's tastes, and judiciously guided his aspirations. Fillans found in Paisley, at his moderate prices, patrons for small portraits, busts, and fancy figures; but he determined to try the wider field of Glasgow, as much in order to avail himself of the additional facilities that city afforded for improvement in art, as in the expectation of increased patronage. He however met with both, and after a time was in a condition to visit Paris for the purpose of further study. On his return in 1836 he established himself in London, where he found many warm Scotch friends, among others Allan Cunningham, who sat to him for his bust, and introduced him to Chantrey.

At the exhibition of the Royal Academy in 1837, Fillans had seven busts, including one of Allan Cunningham, which attracted some attention. He now produced a Tam o' Shanter jug; 'The Birth of Burns,' an alto-rilievo, and other designs of a similar kind, forming a Burns' series, which have been more than sufficiently praised; and he received a commission for a bust of Mr. Oswald of Auchincruive, for his tenantry, which led him to visit Italy, Mr. Oswald being then resident on the continent. While still depending upon portrait busts for his means of support, Mr. Fillans was not negligent of loftier subjects. His chief work of this order was a life-sized group in marble, 'The Blind teaching the Blind,' a work of real merit and some originality: it was exhibited in Glasgow, where it produced a great sensation. His 'Boy and Fawn' was another admirable production. But the works which established his fame were his colossal statue of Sir James Shaw, for the baronet's native town of Kilmarnock, and the bust of John Wilson—both characteristic works, that of Wilson being indeed by far the most striking head of the poet which has been produced. In Scotland they were received with enthusiasm, and the sculptor was congratulated with two or three public dinners given in his honour. Still, though so far successful, he found his income insufficient to maintain establishments in London and Glasgow, and he resolved to quit the metropolis, his commissions having been chiefly derived from his countrymen. He removed to Glasgow in 1851, but his health, already impaired, became gradually worse; and at length an attack of rheumatic fever carried him off on the 12th of September 1852. He had been engaged as long as his strength permitted upon a colossal statue of 'Rachel weeping for her Children,' but left it unfinished.

A life of James Fillans, by James Paterson, was published at Paisley in 1854, in a handsome quarto volume. It contains engravings of his principal statues, of his designs for Motherwell's tomb, the Burns' series, an elaborate series of designs of 'Taming the Wild Horse,' and a set of designs illustrative of a tale by a friend. It also contains several pieces of poetry, in which Mr. Paterson finds much to admire, but which would have been as well left in the manuscript, except as evidence of the sculptor's kindheartedness. Fillans used the pencil as well as the chisel, but with by no means equal success.

FINANCE. [Revenue and Taxation, *S.* 2.]

FINDEN, WILLIAM, line engraver, was born in 1787. He was apprenticed to Mr. Mitan, an engraver of shop-bills, coats of arms, &c., but by devoting his leisure to the study of the works of James Heath, and others, he acquired, by his own industry and intelligence, so much facility in the use of the burin, and displayed so cultivated a taste, that after he began to work on his own account he soon found ample employment in engraving book plates. Among his first successes in this line, his engravings of Smirke's illustrations of 'Don Qoixote' have been singled out for special commendation.

Being very industrious, and always remarkable for a certain neatness of line and smoothness of finish, he grew in course of time to be one of the most popular engravers of the day; and he was selected to engrave 'the royal portrait' by Lawrence, of George IV. seated on the sofa. It was a plate of large size, and for engraving it Mr. Finden received the sum, unparalleled for a portrait, of 2000 guineas. Finden bestowed upon it the utmost care, and it was so extremely popular that proofs and prints are said to have been advertised for at a large advance of price. But both the picture and the engraving were in an essentially false style of art, and, the fashion having passed away, they have sunk in general estimation even below their proper level. Among Mr. Finden's other more celebrated large engravings, may be mentioned the 'Village Festival,' from the well-known picture by Wilkie, now in the National Gallery, which, with something of effeminacy in the handling, is much his finest engraving; and the 'Highlander's Retnrn,' also after Wilkie.

Still his greatest success had been in small plates, especially in book-plates, and the great request in which he was with publishers, led him to call in the assistance of inferior hands for the completion of his many engagements. To such an extent did he carry this, that he had at length, in conjunction with a younger brother, Mr. Edward Finden, also a skilful engraver, established a complete manufactory for line engravings on steel and copper. The effect was, of course, mischievous to art; injurious to his own reputation, as necessarily tending to destroy individuality of style; and eventually it was ruinous to his fortune, by inducing him to undertake—partly no doubt to keep his establishment in full employment, and partly to secure to himself a share of the profits which he fancied belonged of right to the engraver rather than to the publisher—the publication of various extensive series of engravings. Of these, the first and most successful was the popular 'Byron Gallery.' Other galleries and sets of illustrations followed with less success; and ultimately by far the best of the whole 'the Gallery of British Art'—a generally well selected, well-engraved, and characteristic series of engravings from our best painters—on a larger and more costly scale than any of his previous speculations, was undertaken at an unfortunate time, and, being persevered in, in hopes of eventually retrieving the losses, swept away the fruits of all his previous labour.

After this, Mr. Finden's only important work was a large engraving, executed for the Art Union, of Hilton's 'Crucifixion'; but it was the work of a man broken in spirit, and is a very unsatisfactory production. He completed it shortly before his death, which occurred on the 20th of September, 1852.

FLAGS. [Iris, *S.* 1.]

FLIXWEED. [Sisymbrium.]

FLORIS, an island in the Indian Archipelago, lying between 8° and 9° S. lat., 120° and 123° E. long. Its length is about 200 miles from east to west, and its average breadth about 35 miles. The surface of the island is hilly, particularly on the south side, where there are several high volcanic mountains, from one of which there was an eruption in 1810. Cotton is one of the products. Sandal-wood, bees'-wax, horses, and slaves are exported to Singapore. The principal port, Endé, is on the south side of the island: it has an excellent harbour. Larantuka, a town on the east side, on the straits of Larantuka, in 8° 45′ S. lat., 123° E. long., is in the possession of the Portuguese, who have succeeded in bringing many of the natives to the profession of the Roman Catholic faith. This is the only part of the island in possession of Europeans. Endé was formerly subordinate to the Dutch presidency at Coopang in the island of Timor; but in 1812 the Bugis inhabitants succeeded in expelling all Europeans. The coast is mostly colonised by Bugis and Malays, but the interior is inhabited by aborigines, a dark curly-headed race, who resemble the Papuas of New Guinea. The island gives name to the strait of Floris, which separates it from the islands of Solor and Adenar on the east.

FLOWER, that part of a plant in which the organs of reproduction are placed. The flower originates from a bud, and is nothing more than a particular modification in the perfecting of the parts contained in the bud; namely, the several foliar organs and internodes. Only two essential processes of development can exist, and from those only two essential organs, as fundamental organs, can be formed in the plant; namely, the Axis and the Leaf. All the several parts of the flower must therefore be referrible to these fundamental organs, and be traced back to them. Since Göthe's time this tracing back has been termed the Metamorphosis of Plants. Originally this mode of considering the flower rested solely on Comparative Morphology, and the observation of cases in which the interruption of the usual processes of development, in some or all parts of the flower, caused those parts to reassume forms in which it was not difficult to recognise the nature of the fundamental organ from which they had been produced. This latter has been termed Retrogressive Metamorphosis. As examples of it, we may mention the different monstrosities, the doubling of a flower through the transition of the stamens into petals, the transition of the petals and sepals into the common leaves of the plant, &c. This mode of establishing the foundations of the doctrine of metamorphosis has however two essential faults: since, in the first place, it seeks to obtain individual facts by means of hypotheses and comparisons; while, secondly, its progress depends entirely npon favourable circumstances. The only correct and sure ground on which to rest this doctrine is the history of development.

In Phanerogamic Flowers the following parts are distinguished, proceeding from without inwards:—1. The Floral Envelopes, as the External Calyx (Epicalyx), of which the parts are Leaves (Phylla); the Calyx, the parts of which are Sepals; the Corolla, the separate portions of which are Petals; or, instead of these three, the Perianth (Perianthium), whose separate parts are Leaves (Phylla): 2. The Stamens (Stamina), around and within which some stunted accessory foliar organs appear under very various names: and lastly, 3, in the centre of the flower, the Pistil (Pistillum), the separate foliar organs of which are Carpels (Carpella). In the stamens the lower thread-like portion, which is termed the Filament (Filamentum), is distinguished from the upper thick and hollow part, containing the Dust (Pollen), called the Anther (Anthera). In the pistil, the lower part surrounding the Ovules or Seed-Buds (Gemmulæ) is called the Germen; the upper free part, which is usually covered with papillæ, is termed the Stigma, and between these two frequently a stalk-like elongation of the germen occurs, called the Style.

The flower of *Phanerogamia* is the only physiologically determinate organ of the plant, since it contains the apparatus for the regular propagation. But to this only two parts contribute—namely, the stamens, as generators and receptacles of the pollen: and the seed-bud or ovule, as the place in which the pollen is developed into the embryo. All the remaining parts of the flower—namely, the envelopes of the whole perianth, the calyx and corolla, the receptacles containing the seed-bud (the germens, styles, and stigma), are not, in a physiological sense, essential, and they may be absent, without the flower losing its correspondence to the character by which a flower is defined.

In the correct (morphological) view of the flower, there is no distinction between essential and inessential forms, and therefore it is necessarily more proper to divide it into axial and foliar organs. The following relations should be borne in mind:—The axis and its modifications are the basis of the flower, because to them the foliar organs are attached. Attached to the outer part of the axis of the flower occur several forms of true foliar organs, the floral envelopes, accessory leaflets, and stamens. The innermost part is occupied by organs which are formed from true axial organs, or an intimate blending of these with foliar organs, which are termed the female apparatus, or better, the rudiment of the fruit. At the same time the parts of the flower are usually grouped together and treated generally, according to the relations of number and position, as well as of duration. Thus we obtain this plan for our following investigations:—

A. The Axial Organs of the flower.

B. The number, relative position, and duration of the parts of the flower.

C. The true Foliar Organs of the Flower.

a. The Floral Envelopes.

b. The Stamens.

c. The Accessory Foliar Organs.

D. The Rudimentary Fruit.

a. The Pistil.

b. The Spermophore.

c. The Seed-Buds.

The Anthers have been called the male organs of a plant (with the superfluous collective term Andrœceum); the Seed-Buds and their receptacle the Pistil, the female parts (together the Gynœcum). A flower that contains both parts is termed Hermaphrodite (Flos Hermaphroditus). Flowers that contain only one of those kinds of organs are termed Unisexual Flowers (Flores Unisexuales, Diclini). When, in the last case, male and female flowers (mas et femina) appear on the same individual plant, such plant is termed Monœcious (Planta Monoica); when they appear on separate individuals the plant is termed Diœcious (Planta Dioica). An Inflorescence which contains both male and female flowers, also is termed Inflorescentia Androgyna. Here again it must be distinguished whether the male and female blossoms are formed upon different plans, as in the *Cupuliferæ* (Diclines); or whether, through the suppression of one or other part, a pseudo-diclinous condition appears in a flower formed on the plan of a hermaphrodite. This latter condition, which is never found to run through all the examples of any species of plant, brings monœcious and diœcious species into hermaphrodite genera, and suggested to Linnæus the establishment of his 23rd class, *Polygamia*, where in one and the same species male, female, and hermaphrodite flowers are present.

There are very few flowers of so simple a structure that they consist only of one simple essential part, so that no formation of internodes is possible within the flower; and the extremity of the pedicels immediately supports the floral parts existing. This is the case in the male flower of the *Euphorbiæ*, where the end of a pedicel bears one single stamen; also in the male flower of the *Abietineæ*, where one single foliar organ, converted into a stamen, constitutes the entire flower. It is also the case in the female flower of *Taxus*, where the small pedicel, clothed with bracts, terminates immediately in the naked seed-bud. In the generality of flowers however several parts are united which do not stand at equal heights on the axis, and thus more or fewer undeveloped internodes take part in the structure of the flower. The original condition of the internodes, is here also most frequently permanent; and the pedicel, after the detachment of all the parts of the flower, frequently ends in a small slightly thickened knot, which represents the collective internodes of the flower in an undeveloped condition,—the simple base or receptacle of the flower (Torus). Examples in which individual internodes become elongated are rather rare. In some families they are elongated between the inner floral envelopes and the stamens (Androphorum), and between the stamens and the germen (Gynophorum). The latter is generally termed Germen Stipitatum. There are examples of both in the *Passifloraceæ* and the *Capparidaceæ*.

A considerably longer part, without elongation of the individual internodes, frequently occurs as a gynophore in flowers which contain many germens (as in the *Rosaceæ*, the *Ranunculaceæ*, *Magnoliaceæ*, &c.) Again the gynophore is often presented as a hemispherical or cushion-like part, as in some other *Rosaceæ* and *Ranunculaceæ*. A very rare form of it is that of a reversed cone, which bears the germens upon a base turned upward, as in *Nelumbium*. In the rarest instances, with the exception of this case, the axis of the flower is elongated within the floral parts even without ending as a germen; but this does sometimes occur, as in the male flowers of some Palms and other plants; for example *Chamædorea*, where the points of the petals unite with the apex of the axis of the flower which passes up through them.

In very crowded inflorescences, the torus of an axillary bud developes obliquely, and rises up on one side, especially beneath the germen, so as to appear as a part of its side-wall; this happens with most of the Grasses. A similar circumstance, arising from a similar cause, happens when many single germens are present in one flower, by the division of the torus, which forms the basis of each of those germens, and thus assumes the appearance of forming a part of the wall of the germen (as in *Potamogeton* and *Dryadaceæ*).

But the development of the internodes into a Disc, or in a hollow cup, is far more frequent in the flower. If the collective internodes of the flower form a hollow body, or even a cylindrical elongated tube, which incloses only seed-buds, and bears all the floral parts upon its upper edge, all this is the so-called Inferior Germen or Ovary (Germen Inferum).

Every other similar expansion of the internodes of the flowers which does not immediately bear seed-buds, is called the Disc (Discus). This may be situated beneath the rudiment of the fruit (Discus Hypogynus), and then may be flat, as in *Potentilla* and *Fragaria;* or cup-shaped, as in *Rosa*, *Populus* (*mas*), &c. This latter may be free (*Rosa*), or may be blended with the germen situated inside it (*Pyrus*); or it may pass off from the middle of the (half-inferior) germen (Discus Perigynus), as in many *Myrtaceæ;* or, lastly, it may rise above the (inferior) germen, and stand upon it (Discus Epigynus). Here it is very rarely (or never?) flat, but funnel-shaped, as in *Godetia;* in the form of a long tube, as in *Œnothera:* or resembling a style, as in the *Orchidaceæ* and *Aristolochiaceæ*. In all these cases the foliar organs of the flower may be situated in very different places. Usually, indeed, they collectively form a zone around the edge of the flat or concave discs; then the discs may be said to correspond to as many discs lying one above another as there are internodes implied by the number of foliar organs. Frequently the true foliar organs stand around the edge of the disc; and upon its inner or upper surface the germens are arranged in one or more circles (as in *Rosa*, *Punica*, *Onagraceæ*). More rarely the floral envelopes alone stand on the border, while the stamens are then at a distance from them, upon an internal prolongation of the disc, as in the *Orchidaceæ*.

The disc is by no means always regularly developed, but sometimes enlarged at one side only, whereby the whole flower appears oblique, thus in *Reseda*. The most remarkable structure is in *Pelargonium*, where the disc forms a cavity to one side of the peduncle, and in *Tropæolum*, where the spur is formed solely by the disc.

There are but few special observations to be made respecting the structure of the internodes of the flower; it is in general like that of annual stems; but it should be remarked that they often possess fewer vascular bundles, and these of simpler development. The internodes (as also some of the foliar organs) within the flower, frequently do not have the epidermis developed, but, instead of this, a delicate soft cellular tissue, somewhat yellowish in colour, and often containing a saccharine secretion, forms the investment of the surface (Nectarium).

It is very rarely that a flower consists of one part only, as in the male flowers of *Euphorbia*, *Lemna*, and *Wolffia*, which are formed of one foliar organ, the anther; or the female flower of *Taxus*, which is formed of one axial organ, the seed-bud. Usually more parts unite to form a flower: thus the female flower of most of the *Araceæ* consists of one or more seed-buds, and a carpel surrounding them. The male flower of the *Salicaceæ* consists of a scale-like disc and several stamens. In the generality of cases, both male and female organs are present in the same flower: they are seldom naked, as in *Hippuris*, but usually surrounded by floral envelopes.

In axillary flowers, those parts which are turned towards the peduncle are termed the upper, and those turned towards the bract, where it is present, the lower. Some plants exhibit the peculiarity that the pedicel, until the time of the blooming, makes a half turn (analogously to the twining stem), and it may be the true pedicel, as in *Calceolaria* and some *Orchidaceæ;* or the inferior germ, as in most of the *Orchidaceæ*. By this curve, the upper parts of such a flower (in those plants the lip) become apparently the under; and such flowers are termed Flores Resupinati. The term is sometimes falsely applied to those *Orchidaceæ* in which no such twisting takes place, but in which the lip stands regularly as the upper part of the flower, as, for example, in *Epipogium*.

The individual organs of the flower taken generally, according to the common view, and known by collective names, may originally consist either of one piece or of more than one: in the first case they are partes monomeræ; in the second case partes di-, tri-, or polymeræ. In the latter case the parts may be entirely separated and independent of one another, or they may be grown together in various ways. These coherent sets were formerly also called partes monomeræ. De Candolle better termed them partes gamomeræ; as, for example, *Hemerocallis* = perianthium gamo- (mono-) phyllum, hexamerum; *Salvia*, corolla gamo- (mono-) petala, pentamera; *Rosa*, corolla pentapetala, &c.

The coherence occurs here in the same manner as in the stem-leaves, but on account of the crowded position in the flower-bud, much more frequently. It happens either that a single foliar organ grows together by its edges into a tubular or cup-like organ, as, for example, occurs frequently in the so-called monomerous floral envelope (Bracteole); or that several foliar organs grow together by their edges: this commonly affects all the edges of a circle of leaves, but sometimes two edges remain ununited, as with the calyx of *Gentiana lutea*. So, again, this process is usually simultaneous in development at all the edges of a circle; but it sometimes happens very much later—*a*, on two uppermost leaf-edges, whereby the single-lipped forms arise, as in the corolla of *Teucrium* and the flores ligulati of the *Compositæ;* or, *b*, with each pair of leaf-edges at the side of the leaf-circle, whereby the two-lipped forms (partes bilabiatæ) of descriptive botany arise. Another kind of blending also occurs in the flower, of which no example occurs in the stem-leaves, and only one in the bracts and bracteoles, namely, the cupula of the *Capuliferæ;* this is, the blending together of two or more circles, as in the two circles of the floral envelopes of many *Liliaceæ;* or in these and the two circles of stamens, in the circle of petals and stamens, in the *Labiatæ*, &c.; and in general in all flowers to which are ascribed stamina perianthio vel corollæ (not calyci) inserta.

The coherence of the stamens of one or more circles has been well termed, since Linnæus's time, fraternity (Adelphia); and, according to the number of brotherhoods in a flower, Monadelphia, Diadelphia, Polyadelphia. When the foliar organs of the flower are coherent, the blended part is termed the Tube (Tubus Perianthii, Calycis, Corollæ, &c.); the free parts, the Limb (Limbus); and the boundary of the two, the Throat (Faux). One of the most striking examples of coherence, which also has no analogue in the stem-leaves, is found in the blending of the foliar organs of the flower at the point only, the union never extending farther; so that the foliar organs are connected above, but free below, as in the corolla of the male flowers of *Chamædorea*, *Casuarina*, and in the androphore of *Symphyonema montanum* (?).

Abortion in the flower means that some part present in the rudimentary condition is arrested during the development and gradual perfecting of the flower, and thus at last retires from observation. There is no other kind of abortion. So soon as the individual parts of a flower become distinct members, the foliar organs appear arranged around an ideal and real axis of the flower (the axial organs of the flower), and in the rudimentary condition always regularly. Through subsequent unequal development of the single parts, the flower frequently becomes unsymmetrical, or, as it is called, irregular. This irregularity is always such that the upper part of a flower becomes developed differently from the under. Such irregularity very seldom affects the germen, which almost universally remains regular even in unsymmetrical flowers; yet there are cases in which this is the only symmetrical part, as in many of the *Scrophularaceæ*, *Acanthaceæ*, and *Cryptocoryne spiralis*. If the unsymmetrical flower, with or without coherence of its parts, is divided into two halves, an upper and under, developed in different ways, they are generally termed bilabiate; but if only one single foliar organ is developed in an aberrant form, that leaf acquires the name of Labellum, or Lip. Rare indeed are the cases where the entire flower is unsymmetrical, as in *Goodyera discolor*.

It is not possible to state in general terms the number of parts which may unite to form a flower. We find of foliar organs alone sometimes as many as fifty or sixty united in one flower. Certain combinations, on the contrary, are rarely met with: no monomerous flower possesses double floral envelopes. When the various parts of the flower are present in large numbers, these arise universally in one or more circles (Whorls) at the same height on the axis, and at the same time. When circles containing members of equal number follow in succession, the members of the one circle usually stand opposite the interspaces between the members of the preceding circle (the circles and their members alternating); they seldom stand precisely before them (the circles and their members opposite). But it by no means is to be assumed that the members of each circle are always of equal number in a flower. The number of members often increases up to the stamens, and thence diminishes; it is rare for the circle of the carpel to contain the greatest number, as in the *Malopeæ* and *Malvaceæ*. The generality of monocotyledonous plants with perfect individual flowers have regular homomerous circles through the entire flower: in dicotyledonous plants this is relatively rarer; the outermost and innermost circles have usually fewer members. Again, respecting the number of circles which follow one another, no general statement of importance can be given. Seven different forms of foliar organs may possibly exist in the same flower, namely, the epicalyx, calyx, corolla, accessory corolla, the stamens, accessory stamens, and the carpels; but there is no flower in which all occur in conjunction. All these foliar organs may be present in one or more circles, with the exception of the epicalyx, in which there is no example of a double circle. Perianth, calyx, corolla, accessory corolla, and carpels occur in one, or more rarely in two circles. Stamens may be present in one, two, three, or possibly even four circles; more circles than this are not exhibited in the normal condition of the flower. If the number is increased, which seldom happens except in stamens and carpels, as in *Ranunculaceæ* and *Dryadaceæ*, the *Magnoliaceæ*, &c., they stand no longer in circles but in a spiral. In monocotyledonous plants with perfect individualised flowers, with the single exception of some *Scitaminaceæ*, five trimerous circles of foliar organs of the flower appear to be formed in those where a second circle of petals exists. The greatest multiplicity of forms occurs in the dicotyledonous plants. *Lavatera*, for example, has an epicalyx, calyx, corolla, stamens, and carpels in five circles, with increasing numbers of members; those of the calyx and corolla alone are equal. *Gnidia virescens* has perianth, stamens, accessory stamens, and carpels, but in eight circles, which are throughout composed of two members each. It is by no means necessary that all the parts of a circle of floral foliar organs should be ultimately developed in the same manner; and many floral structures which have hitherto been apparently inexplicable, may probably, by keeping this truth in mind and following out the history of the development, be readily traced back to the original type.

The duration of the individual parts of the flower is very various; the axial organs, so far as they support the rudiment of the fruit or aid in its formation, persist naturally at least until the ripening of the seed, then fall away with it; or if it becomes disengaged from them, die away with the remainder of the plant. When axes bear only male organs, or flowers, their duration is different; sometimes they are cast off at a true articulation, sometimes they remain upon the parent plant, and gradually die away. The foliar organs of the flower are equally various in their duration. Perianth, corolla, and accessory corolla commonly perish soon after the perfecting of the flower; either they are cast off by true disarticulation, or they wither upon the parent plant. The epicalyx and the calyx frequently share the fate of the axial-organs supporting the rudiments of the fruit; the carpels almost invariably. The carpels are rarely destroyed before the perfecting of the seed, as in *Leontice*, and according to Robert Brown in *Peliosanthes Theta*. The stamens die away almost immediately after the dispersion of the pollen; either they are cast off, or they dry up and die away within the flower.

The terminology in use is as follows:—Those parts which fall away immediately, when their perfect formation is but scarcely completed, are termed caducous or fugacious (partes caducæ); those which endure somewhat longer are termed, if they are cast off by disarticulation, deciduous (partes deciduæ); if they retain their position, and die by gradual withering and drying up, marcescent (partes marcescentes); those parts which remain long, still vegetating, are termed persistent (partes persistentes); if they change their forms by further growth they are termed excrescent (partes excrescentes).

As among the floral envelopes are usually reckoned the perianth, the calyx, and the corolla, we may also include here the epicalyx. Under the term perianth, in its narrowest sense, only those foliar organs fall which, at least two in number, are applied closely to the flower and upon one level; so that all individual foliar organs on the axis of the flower, which only inclose stamens or germens, may be termed bracts. All these bracts have this in common, that they are merely foliar organs peculiarly modified; and consequently all the peculiarities of form which occur in the latter naturally appear in the former also. It is not often that the leaves of the floral envelopes have great thickness; they are almost always more or less flat. But the forms analogous to the pitchers or pouches are here frequent, much more so than is the case with the stem-leaves; and these are termed, according to their various resemblances to objects, cup-shaped, as in the lower petal of *Polygala;* hood-like as in the upper leaf of the perianth of *Aconitum;* and so on. If a long sac-like appendage is formed at the basis of a perianthial leaf expanded above, it is called a spur (calcar), as in

Orchis, Delphinium, Fumaria, &c. The formation of the spur is frequently conjoined with the formation of a symmetrical flower, where one upper or lower foliar organ forms a spur. The flattened expanded form, which is connected with the axis by a linear prolongation, frequently occurs in the sepals (?). This expanded surface is termed the limb or blade of the leaf (lamina); the narrowed base is not termed petiole but claw (unguis). True articulation is frequent between the floral envelopes and the axis, but it never occurs in the continuity of these leaves (?); thererefore there are no true compound perianthial leaves, though a simply divided limb is frequent, as the petala palmatifida in *Reseda*, the petala pinnatifida in *Schizopetalum*, &c. An indication of true articulation may probably be afforded in the separation of the upper part of the tube of the flower in *Mirabilis*, of the calyx of the *Datura* from the lower, and in some similar cases.

True stipules are not met with in the floral envelopes, but appendages analogous to the ligula appear, to which indeed a part of the structure described as the corona belongs. As in the *Narcissus* and the *Lychnis*, the scales of the throat of the *Boraginaceæ* also belong here. These parts are formed in very various fashions on the floral envelopes, and such appendages are sometimes exhibited standing upon the surface of the foliar organ, in three or more rows, one above another. Almost all parts recognised as corona and accessory corolla (paracorolla) belong here, in particular a part of those elegant forms exhibited in the *Stapeliaceæ* and the *Passifloraceæ;* so also does a portion of the so-termed nectaria, as, for example, in the petals of *Ranunculus*. All these are mere dependent appendages of the foliar organs, which are developed originally simple and flat, all these parts being produced from them subsequently. Here also occurs the one-sided development of a foliar organ: this is seen frequently in the petals of the *Apocynaceæ* (*Vinca, Nerium*, and *Cerbera*)

The collective form of one or more circles, whether coherent with each other or not, is more accurately designated according to further peculiarities, as tubular (tubulosum), bell-shaped (campanulatum), funnel-shaped (infundibuliforme), salver-shaped (hypocrateriforme), rotate (rotatum), &c.

Five kinds of floral envelopes are easy to be distinguished. When all the foliar organs are similarly or nearly similarly developed in a circle of one evident form, colour, and structure, they are described under the general name of perianth, the single organs of which are called perianthial leaves. If in the floral envelopes of one flower we can distinguish two circles differing in form, colour, and structure, the outer is named the calyx, its component organs being sepals; while the inner is termed the corolla, its single parts petals. Then if three circles of forms are distinguishable the outermost is called the epicalyx, the leaves of which may be denominated phylla. When between the simple or manifold floral envelopes and the stamens other independent foliar organs occur which exhibit a structure very imperfect and abnormal compared with the true envelopes, these are called a paracorolla, of which it will be necessary to speak further on, among the accessory parts of the flower.

The Perianth consists, according to the preceding considerations, of one or more circles of leaves, which are developed so as to be similar in colour, form, and structure. The following series of its forms may be more minutely characterised:—

The individual foliar organs are always expanded in a flattened form, seldom divided into limb and claw, and, at least when they are not coherent, usually oval or lanceolate. They may be green, as in the male flower of *Urticaceæ*, or of various colours, as in *Thymeliaceæ;* they may be firm and solid, and that especially when green, as in *Elæagnaceæ:* or of delicate texture, as in *Aristolochiaceæ;* or they may be developed as delicate sapless scales (paleæ), or bristles and hair, as in the *Typhaceæ* and *Cyperaceæ*. The perianth is almost universally regular, rarely (in some *Ranunculaceæ* and *Orchidaceæ*) symmetrical; in these cases never (?) 2-lipped, but often with one lip, as in the *Orchidaceæ*. This is then not unfrequently developed, hollow (cucullatum in *Aconitum*, calcaratum in *Orchidaceæ*), and it is commonly the uppermost leaf of the perianth. Its foliaceous portions may be free, as in *Juncaceæ;* or coherent, as in *Funkia, Hemerocallis*, &c.: they may consist of one circle, as in *Urticaceæ;* or of more, as in *Liliaceæ*. The parts are frequently blended with the stamens: in the coherent perianth the tube is sometimes straight, as in *Narcissus;* sometimes curved, as in *Aristolochia*. The mouth is mostly naked; sometimes, but seldom, as is the case in *Narcissus*, furnished with appendages which form a corona, which however are rare in the perianth, and in free foliar organs only (?) occur on the lip: the inner circle often has a beard.

The structure of Perianthial Leaves, is, on the whole, that of very simple leaves, which exhibit no special peculiarities, particularly if they are green. The ramifications of the vascular bundles are therefore simple; the separation into an upper and under parenchyma layer is seldom exhibited; but the epidermis usually. In the coloured and delicate parts the cells of the parenchyma contain colouring matter. In general the parenchyma is very loose and almost spongy, with homogeneous transparent fluid contents, and large intercellular cavities filled with air; hence the white colour. The epidermis is less developed in coloured leaves, and more resembles the structure of epithelium; stomates are sometimes present, especially upon the under surface, but the epidermal cells of the upper surface are often raised in shorter or longer papillæ, which give the upper surface a peculiar velvet-like appearance. It is very frequent here to find the secreted layer of the epidermis (cuticle) regularly and delicately striated (aciculatus), which certainly contributes to heighten the brilliancy of the colour, and perhaps, by its effect upon the rays of light, to the production and modification of the peculiar tints.

Occasionally, especially at the base of hollow parts, no epidermis is produced at certain points, and the parenchyma assumes a peculiar structure, to perform the function of secretion of a juice containing much sugar; as, for instance, the nectary at the base of the perianthial leaves of *Fritillaria*, very various parts on the labellum of the *Orchidaceæ*, &c. In rare cases the texture is hard and almost woody from the interspersion of many thickened porous parenchymatous cells, as in the species of *Banksia* and *Dryandra* (?). In paleaceous perianths the spiral and other vessels are not found in the usually simple vascular bundles, and in hair-like perianths even the vascular bundles themselves are wanting.

The Calyx only exists when a corolla occurs with it; it therefore can never be confounded with it. It is always the external of two dissimilar sets of envelopes. Its series of forms very much resembles those of the perianth; perhaps it is not so frequently delicate in structure and colour, as in the *Scitaminaceæ, Musaceæ, Butomaceæ, Ranunculus, Tropæolum*, &c. Usually it consists of one circle of sepals, more rarely of two (as in the *Berberidaceæ*). These sepals are always very simple, oval, or lanceolate, seldom pinnatifid, very frequently broad at the base and tapering to a point, or very small (dentes calycis obsoleti); sometimes they appear only as dry scales, or as tufts of hair (the pappus of the *Compositæ*). Appendages seldom occur upon the sepals, but they are frequently of hollow or concave form. The number of the sepals in each circle is in Monocotyledons, frequently three, more rarely four or two; in the Dicotyledons it is most frequently five, but also two, three, or four, and perhaps sometimes more. Coherence of the sepals with one another may occur in every way, but never with the corolla and stamens nor with the germens; that which is so called being quite another condition. Both in free and in coherent sepals, regularity and symmetry are met with; the latter often exhibit the bilabiate structures.

That which has been said of the structure of the perianth applies also to the calyx, only that here green foliaceous sepals are the more frequent.

The corolla, which only exists as the inner set of floral envelopes accompanying a calyx, may be compared to a very delicate and coloured perianth. No true corolla occurs perfectly green and resembling the leaves; its series of forms is greater than that of any other of the floral envelopes. In the Monocotyledons it presents in general only simple, round, oval, or lanceolate leaves, very seldom having claws. In the Dicotyledons the forms are infinite, as are also the variety and splendour of the colour. The following are the main points in the structure of this organ:—

The individual petal exhibits, on a reduced scale and in a delicate condition, almost every variety of form of the leaf, with the exception of the truly compound. Concave forms are here frequent, such as the hood-shaped, pitcher-shaped, or spurred petals, &c.; these latter very often on individual petals of an otherwise regular corolla, as in *Fumaria*. Fringed and feathered forms, as well as variously lobed petals, are also by no means rare. The limb and the claw are often clearly to be distinguished. Parts analogous to the ligule, and every imaginable form of appendage, with the exception only of the stipules, occur frequently, and characterise genera and families.

On this account it is indispensable to distinguish the simple appendages of the petals from the independent foliar organs. To the former belong the scales (fornices) of the *Boraginaceæ*, the scales of the corona of the *Silenaceæ*, the formations generally described as coronæ in the *Stapeliaceæ* and some other *Asclepiadaceæ*, the nectaria of *Ranunculus*, *Parnassia*, &c.

The corolla consists of one circle, rarely of two (three series in *Berberis*), or more (four series in *Nymphæa*). In Monocotyledons the number of members is equal to those of the calyx; in Dicotyledons the number of five in a circle predominates, though it is sometimes composed of two, or four, or of a greater number in *Dryas*. The number of members is equal to that of the calyx, or greater; very rarely indeed it is smaller; this last case occurs with *Hibiscus*. Suppression is not infrequent, and sometimes involves all the foliar organs of a corolla at once, as in the summer flowers of many species of *Viola*, in *Lepidium ruderale*, and in some species of *Acer*. The coherence of organs in every way is still more frequent; never indeed with the calyx or the germens, but frequently with the stamens.

The corolla, whether with free or with coherent petals, may be regular or only symmetrical. In the latter the bilabiate formation is the most frequent, especially in five-membered circles, in such a way that, according as the odd petal is on the upper or the under side of the flower, the upper lip consists of three or of two petals. In the latter case these two are very often little or not at all coherent, as in *Teucrium*, the so-called radiated flowers of the *Compositæ* (floribus ligulatis vel radiatis). Peculiar forms of symmetrical flowers are, for instance—the personate flowers (corolla personata), in which the upper petals of a coherent corolla are so curved inward that they close the entrance of the tube (as in *Antirrhinum*), the incurved portion is termed the palate (palatum); the true bilabiate or mouth-like corolla (corolla ringens), in the *Labiatæ*, in which the two petals forming the upper lip often present a concave form overhanging the lower lip, termed galea; the so-called papilionaceous flowers of the *Leguminosæ*, in which the uppermost leaf, which is broad and large, surpassing the others, is termed the standard (vexillum), whilst the lateral petals, as wings (alæ), are usually dissimilarly developed, and the two undermost, very frequently coherent, also developed unequally at the two sides, approach each other in a concave form, so as to form the keel (carina). Sometimes all the petals of the papilionaceous flowers become coherent at the lower part, and form a tube, as in *Trifolium*; or individual petals are abortive, &c. The most irregular of all the forms have hitherto received no names; such as appear for instance in the *Polygalaceæ*, the *Balsaminaceæ*, *Tropæolaceæ*, &c.

All that was said respecting the structure of the perianth holds also for the structure of the corolla, remembering only that this is more delicate. The contents of the cells vary much in colouring matter, and their distribution in groups is sometimes very remarkable. Very dense texture, in consequence of the presence of much-thickened porous cells, as in the *Amarantaceæ*, is infrequent. The structure of the epidermis, and its development into papillæ, hairs, &c. is very manifold. Development into surfaces secreting nectar, both at the bottom of concave forms and upon the appendages, is especially common. The petals also occasionally secrete a viscous substance, in consequence of which they adhere together, as happens at the points of the inner petals of the *Fumariaceæ*.

The Epicalyx is seen where three separate series of foliar organs are distinguishable in the floral envelopes, and it is the outermost of these. There are not many plants which exhibit an epicalyx. In form and structure it much resembles the calyx. It occurs with free leaves (as in *Passiflora*), and coherent leaves (as in *Lavatera*). Its leaves are seldom delicate, such as are seen in the corolla, but are often dry and membranous (as in *Scabiosa*), but generally green and leafy (as in the *Malvaceæ*).

For an account of the other organs of the flower, see STAMENS; FRUIT, *S.* 2; STIGMA; SEED. For the functions of the flower, see REPRODUCTION IN PLANTS AND ANIMALS, *S.* 2.

(Schleiden, *Principles of Scientific Botany*.)

FOOD. The materials taken into the system of organised beings, and by which their functions are maintained, and out of which their bodies are formed, are called Food. Food in its widest sense is the raw material out of which plants and animals are manufactured. We shall confine ourselves here to the consideration of the food of animals, and of man in particular.

The great cause of the necessity of a constant supply of new matter or food to the body is the waste of the materials of which the blood and organs are composed, during the performance of their functions. The result of this waste is seen in the form of the various excretions which are thrown off from the body by the skin, liver, kidneys, and bowels. We shall find, then, that the food, the blood, and the excretions, represent each other, that they contain substances of the same nature, and are all composed of the same ultimate elements.

If we take a portion of human flesh or blood, and seek for its ultimate elements, we shall find that, on accurate analysis, they will yield the following elements:—

Carbon.	Potassium.	Aluminum.
Hydrogen.	Sodium.	Copper.
Nitrogen.	Calcium.	Chlorine.
Oxygen.	Magnesium.	Fluorine.
Sulphur.	Iron.	Silicon.
Phosphorus.	Manganese.	

Few or none of these elements occur in the human body in their pure form, but are combined variously with one another, forming compounds having very different physical properties and chemical relations. These elements may be divided, for physiological purposes, into two classes; the first four, carbon, hydrogen, oxygen, and nitrogen, being called Organic, whilst the remainder are called Inorganic elements. The first are called organic elements because they are found universally present in plants and animals, and because no animal cell and no vegetable cell can grow unless the whole of these elements exist. Hence, as they lie at the foundation of all organic existence, they are properly designated by this term.

The inorganic elements, though very generally present in large classes of animals and plants, are not universal. Man requires phosphorus and calcium in the form of phosphate of lime for his bones; but many of the lower animals contain no phosphate of lime. Sea-animals and plants will not live without chlorine and sodium in the form of common salt; but fresh-water plants, and plants away from the sea-shore, do not require this constituent. The term inorganic, then, is applied to these elements to express their different relation to plants and animals, and will also point out their frequent occurrence in the mineral world. The elements of man's body however are all derived from the mineral world, and are identical with the same bodies in inorganic substances. The carbon found in the human body is identical with that which forms, in its pure state, the diamond—which enters into the composition of graphite and various kinds of coal, and is found in limestone and chalk, forming a part of the carbonic acid of the carbonate of lime, of which these rocks are composed. The hydrogen of the human body is the same as the gas which, united with oxygen, forms water, and when combined with nitrogen produces ammonia. The oxygen of the animal is identical with the gas which, with nitrogen, forms a fifth part of the atmosphere, and which, combined with the metals, forms oxides, of which the greater portion of the earth's surface is composed. The nitrogen of the organic world is identical with that which constitutes so large a portion of the atmosphere. Nor are these elements alone identical in and out of the human body; but we find that they possess the same chemical properties, and that their agency in the human body depends on these properties. Thus, carbon and hydrogen are inflammable bodies, and have a great affinity for oxygen, with which they unite, forming carbonic acid and water, giving out heat during the process of union. This very process goes on in the animal body, and constitutes one of the most important functions of the body. The characteristic features of the functions and properties of animal and vegetable bodies depend on the chemical relations of the four organic elements.

These elements never enter the system in their pure form. Carbon, however needed in the animal frame, cannot be appropriated pure; and a man would starve with the Koh-i-Noor diamond in his mouth, were he not allowed to exchange it for more digestible forms of carbon. The gases hydrogen, oxygen, and nitrogen, would, any one of them in their pure state, destroy human life; and even when the two last are mixed with the atmosphere, they will not support life in that form. Again, we may mix them in various ways, and not be more successful. Carbon combines with oxygen to form carbonic acid, and hydrogen combines with nitrogen to form ammonia, and these two compounds nnite together to form common smelliug-salts, or carbonate of ammonia. But smelling-salts, though they contain all the organic elements, will not serve for human food. Nevertheless what is not food for man is nutriment for plants. Carbonic acid and ammonia supply plants with materials of growth. It is from these two bodies that the vegetable kingdom elaborates all the secretions which give to plants elegance of form, beauty of colour, deliciousness of scent, deadliuess as poisons, and nutritiousness as food. The plant stands between the mineral and animal kingdoms, prepariug the former for the service of the latter. Withont plants there could be no animals. In the whole range of natural history we are presented with no instance of an animal existing directly on mineral matter. It is true that many animals are carnivorons, and live on the flesh of lower animals. The lion and the tiger prey npon the deer and the antelope; but if we go one step further we still arrive at the vegetable kingdom as the source of animal nutrition. The deer and the antelope are herbivorous creatures, and the flesh of their body is formed directly from the plants they eat. So with the animals eaten by man; they are all grain or herb-eating animals, and supply to man the materials they have obtained from the vegetable kingdom. At the same time the best standard we can take of food is milk, which is derived from the animal. When human milk is examined, it gives the following results in every 1000 parts:—

Water	870
Butter	52
Sugar	63
Casein	10
Salts	5
	1000

These five constituents of milk may be regarded as typical of all kinds of food, whether obtained from the animal or vegetable kingdom. Hence we may class alimentary substances according as they are represented by one or other of these constituents of milk.

1. *Aqueous.* Water is required not only as the medium of conveying the other snbstances into the body, but it forms a prominent constituent of the body itself. Blood contains 790 parts of water to 210 parts of solid matter in every 1000. Muscles contain 770 parts of water to 230 parts of solid ingredients. The brain and nerves contain about 800 parts of water in 1000. If food does not contain water naturally, it is taken into the system in the form of tea, coffee, beer, and also in its pure state. The quantity of water taken with the food should be about in the proportion of four to one, as we find it in milk. We cannot however judge of the quantity contained in solid food till we know its composition. Thus many substances which appear solid contain large quantities of water. In potatoes, for instance, there are 75 parts of water in every 100.

2. *Oleaginous.* The butter of the milk represents oily and fatty matters in general, which seem to enter into the composition of all healthy food. They are taken by the inhabitants of tropical countries in the seed of the cocoa-nut, as well as by those of the polar regions from the fat of the seal and many kinds of fish. They are obtained from both the animal and vegetable kingdoms, being known by the name of suets, fats, and lards, from the former source, and oils and butter from the latter.

3. *Saccharine.* The sugar of the milk represents several snbstances obtained from plants and used as food. Sugar itself varies in its composition according to its sources; hence we have cane-sngar, grape-sugar, maple-sugar, &c. Sugar has also a composition nearly approaching that of starch, and this substance is very generally found in the vegetable diet of man; pure in the form of arrow-root, tapioca, and sago; combined in the flour of wheat and other cereal grasses. Of all the animal products used as food, sugar is found alone in milk.

4. *Proteinaceous.* The casein of the milk, which, when separated, is known by the name of cheese, has in common with two other vegetable and animal substances, called fibrine and albumen, a principle for their basis named Protein. These substances form the chief part of the fabric of the body, and in their capacity of food perform a very different function in the body to the butter and sugar before mentioned.

5. *Inorganic.* The salts of milk are the saline substances which, entering into the composition of various parts of the human body, are necessary to its integrity and health. The importance of the presence of these substances is freqnently overlooked in food, and many diseases of the human frame arise from their absence. They are conveyed into the system in both animal and vegetable food; but in common salt we have an instance of a substance belonging to this class taken directly from the mineral kingdom as food without the intervention of an organic body.

In addition to these forms of dietetic substances found in milk, the food of the adult human being constantly contains certain principles which do not appear to be represented in the milk. Thus, the snbstances called condiments, as the various spices, contain volatile oils, which, although not essential to the diet of man, seem to exert a very beneficial influence when taken into the system. In tea and coffee there is a principle called theine, which seems to be the active ingredient of these substances. In the fruit of plants also, we have acids, as the citric, tartaric, malic, and oxalic acids, which seem to act very beneficially in certain states of the system. As these snbstances seem to act medicinally rather than dietetically, they may be properly called, as a class, the medicinal constitnents of food. The following classification will give an idea of the kinds of food:—

Class I. *Alimentary Substances.*

Group A. *Aqueous*, containing water as a principal ingredient. Examples:—Tea, coffee, beer, wine.

Group B. *Carbonaceous*, containing carbon as a distinguishing ingredient.
1. *Saccharine.* Examples:—Sugar, starch, cellulose.
2. *Oleaginous.* Examples:—Oil, butter, fat.

Group C. *Nitrogenous*, containing nitrogen as a distinguishing feature.
1. *Vegetable.* Examples:—Flonr, oatmeal, maize.
2. *Animal.* Examples:—Butcher's meat, cheese.

Group D. *Inorganic.*
1. From organic sources. Examples:—Potash in fresh vegetables, phosphate of lime in flour and flesh.
2. From the mineral kingdom. Example:—Common salt.

Class II. *Medicinal Substances.*

Gronp A. *Acids.* Examples:—Citric acid in oranges, tartaric acid in grapes, oxalic acid in rhubarb-leaves.

Group B. *Volatile Oils.* Examples:—Mustard, pepper, nutmeg, cloves.

Group C. *Alkaloids.* Examples:—Theine in tea and coffee, theobromine in chocolate.

We shall here make a few general remarks on the nature of the substances in the groups indicated, referring for special information on the plants and animals yielding food to the various articles devoted to these subjects throughont the 'Penny Cyclopædia,' and its Supplements.

Under the head of WATER will be fonnd an account of Water and the substances it nsually holds in solution. In taking it as an article of diet, the following general remarks should be borne in mind:—

First, It may be taken in too large quantities to be carried off by the other emnnctories, and then it remains in the system to impoverish the blood, and to rednce the amount of solid matter that is necessary for the performance of the functions of the tissues of the body. This is one of the results that take place from what is called the 'water cure.' Unless persons have sufficient vigour to take the exercise necessary to throw off by the skin the water that is taken into the stomach, serious ill effects must necessarily arise. The good that is effected by this system of the treatment of disease must be attributed more to the exercise it renders necessary than to the unnatural quantities of water taken into the system.

Secondly, Water may not be taken in snfficient quantities to carry on the healthy functions of the system. If the food is taken too dry, it is only imperfectly digested, and many important constituents, such as the salts, are not taken into the body in sufficient quantity. A deficient quantity of water in the blood will also prevent the healthy process of nutrition, and wasting and degeneration of the solid parts of the body will occur. It would be difficult, perhaps, to lay down any law with regard to the quantity of water individuals should take, and perhaps it is safer to rely on the instincts of the body, which seem to point out how much we ought to take by the feeling of satiety that comes on after enough has been taken. We may, however, get at something like an approximation of the proportion of solids and fluids required by the system in food, by examining the composition of milk, in which we find the proportion of water to solid parts is as 870 to 130 in 1000 parts, or as about seven to one.

Thirdly, The good effects of water may be destroyed by the substances with which it is taken. Although the stomach has the power of separating water from the food in which it exists, it yet often happens that the fluid articles of diet are injurious. Water itself may contain so large a quantity of saline matters, or of organic matters in a state of decomposition, as to cause serious disease. The taking habitually water in the form of fermented liquors, as beer and wine, as also the admixture of distilled spirits, may cause irritation and congestion of the mucous membranes, and derangement of the nervous system.

We now proceed to speak of the Carbonaceous Group. This class of substances is sometimes called Respiratory and Combustible. They are called respiratory, because it is through the function of respiration that they become useful in the system. They are called combustible, because it is through the process of combustion that their effects upon the system are developed. This class of food does not, in fact, contribute directly to the nutrition of the body, but they are consumed in maintaining the animal heat. The temperature of the human body is always a fixed one; and if we place a thermometer upon the tongue, or under the arm, or in any other unexposed part of the body, we shall find that it stands at the point in the index of Fahrenheit's thermometer marked 98°. This heat the human body maintains equally at the poles and under the tropics. No external temperature alters it, and we have thus conclusive evidence that it is produced from within. The cause of this heat is the combustion of the carbon and hydrogen contained in the carbonaceous group of foods. Starch, sugar, and oil are conveyed from the stomach into the blood, and whilst in the blood they are brought in contact with oxygen gas which is taken in during respiration, and the consequence of this contact is the union of the carbon and the hydrogen with the oxygen, the formation of carbonic acid gas and water, and the giving out of heat.

The human body is preserved at the same temperature by the regulating action of the skin. When large quantities of heat are generated in the body, by exercise or other causes, then the extra heat is carried off by the perspiration from the skin; but when the body is exposed to a low temperature, and its heat is rapidly conducted away by surrounding cold, the heat is maintained by increased supplies of food belonging to the carbonaceous group. The animal heat of the lower animals varies according to the circumstances of the creature. Those performing great muscular exertions, and living in cold climates, have a higher temperature than man; whilst those which are not active in their habits, and live in hot climates, have a temperature lower than that of man.

The substances belonging to this group which enter into the food of man are cellulose, starch, sugar, and oil.

Cellulose forming the external membrane of the cells of all plants is found in all food derived from the vegetable kingdom. It has a composition almost identical with starch, but differs in being insoluble and indiffusible in water. There can be little doubt, however, that it is taken up extensively into the system in the food of the lower animals, especially of the *Herbivora*. When cells are very thick with cellulose they are indigestible, and this will account for many articles of food as carrots, turnips, radishes, uncooked vegetables, &c., not being readily digested. Cellulose is converted into starch by the addition of sulphuric acid, and it is not improbable that some change of this sort may take place when it is taken into the stomach. It is however seldom taken by human beings alone, although recommended by no less an authority than Benjamin Franklin, who showed by example that saw-dust puddings might be used as an article of diet.

Starch enters very largely into the diet of man, and of the lower animals. It is distinguished from cellulose by its ready diffusibility in water. On this account it appears to be much more readily absorbed from the stomach or converted into the forms in which food is taken up into the system. Its property of uniting with water and forming with it at a high temperature a gelatinous mass, explains the change which takes place in boiling the flour of the grains in which it is contained.

Starch is found in some plants in greater quantities than in others; it is however very generally found in perennial roots and rootstocks, in the stems and in the seeds of plants. There are few or no vegetables or parts of plants that are eaten that do not contain starch. It is found in turnips, carrots, potatoes, cabbages, parsnips, beans, peas, wheat, barley, oats, and the rest of the *Cerealia*; in chestnuts, walnuts, hazel-nuts, and all other seeds; in the apple, the pear, the plum, and cherry, and all other fruits. In many of these things however it is not the distinguishing alimentary ingredient, but it is often separated, and is used pure as an article of diet. The substances in which it occurs pure are arrow-root, sago, and tapioca.

What is sold under the name of arrow-root in the shops, is a form of starch procured from the rootstocks of various species of plants belonging to the family *Marantaceæ*. There are three kinds of arrow-root known in the shops, the West Indian and the East Indian arrow-roots, and Tous les Mois.

Although there is much difference in the price of arrow-root, its composition is always the same. Even the substances used to adulterate arrow-root, as potato and sago starch, are of the same composition; and though the appearance and flavour of the arrow-root may be impaired, its ultimate dietetical action is the same.

Although arrow-root, sago, tapioca, and potato starch, are all composed of the same constituent, their flavour is very different; hence the preference given to arrow-root as an article of diet. This flavour depends on some peculiar principle which is produced in the plant from which the starch is obtained, and by very careful preparing can be entirely got rid of. Arrow-root is used for making cakes, puddings, and a thick gelatinous fluid in great request in the sick room. It is a property of starch to combine with water at a temperature of 180°, and form a gelatinous compound. This property of starch renders it very useful in cookery, and seems to increase the digestibility of the starch itself.

Arrow-root is frequently regarded as nutritious; but it will be seen that it is not nutritious in the proper sense of that word. Those foods can alone be called nutritious that contribute to the building up of the fabric of the body by adding those materials to the tissues which are being constantly removed by the wear of the body. Now, starch does not perform this function, and is entirely consumed in the body in maintaining its animal heat. Arrow-root however and the other forms of starch, are frequently mixed with nutritious matters, such as milk and bread; and in this way the food into which they enter becomes nutritious.

Another form of starch is Sago. It is starch obtained from the inside of the trunks of palms, and other trees. Many plants yield starch in their stems, which, on being prepared, is called sago by Europeans. The sago which is sold in the shops of England is principally imported from the islands of the Indian Archipelago, and is the produce of a palm called the true Sago-Palm, or *Sagus lævis*. There is however another palm belonging to the same genus, the *S. Rumphii* (the Prickly Sago-Palm), which yields the sago that is consumed by the natives of India.

Sago is not generally so carefully prepared as arrow-root, and it is a much cheaper article of diet. Its ultimate action is perfectly the same as arrow-root. It is now often employed by starch-makers to procure the finer kinds of starch used by manufacturers. When thus prepared, it is used to adulterate arrow-root.

Tapioca is another form of starch. It is brought to Europe from South America, and is the produce of a plant known to botanists by the name of *Janipha Manihot*. It is a poisonous plant, and the Indians in the countries where it grows extract a poison from it, which they use to poison their arrows, before they obtain the starch. Cassava, which is eaten by the natives, is procured from the same plant, but is prepared in a different way from tapioca. The starch of tapioca does not differ in chemical composition from that of sago and arrow-root, and it is used in the same way, and for the same purposes.

There are many other well-known plants which owe their dietetical properties to the starch they contain; amongst these we may mention the potato, the carrot, the turnip, the parsnip, the cabbage, the Jerusalem artichoke. From any of these starch might be prepared. The roots of *Arum maculatum*, though acrid, contain much starch. When cooked, the acridity of the plant is got rid of, and they are eaten with impunity. These roots are employed in making the substance called Portland sago, which is the starch separated from the rest of the matter of the plant. This sago is used for the same purposes as the other kinds of sago.

The roots of *Orchis mascula*, which is a common plant of our meadows, form the substance called salep. When it is boiled, it forms an agreeable article of diet, which, before the introduction of tea and coffee, was very generally used in this country. It is now almost entirely disused in Great Britain.

Starch differs in some of its chemical and physical properties according to the plants whence it is obtained. In this way chemists have distinguished several kinds of starch. Inuline is a form of starch obtained from the *Inula Helenium*, a plant not uncommon in our own fields. Lichen-starch is another form, which is found in almost all kinds of *Algæ* as well as Lichens. This starch has the same power of thickening water at a high temperature as arrow-root and tapioca; and hence, when any of these plants are boiled in water, they form a thick mucilaginous decoction. The thickness of the fluid thus obtained, under the erroneous notion of its being nutritious, has led to the use of many species of sea-weeds and lichens as articles of diet.

One of the plants of this kind, which has been used most extensively and is still largely employed, is the Iceland-Moss (*Cetraria Islandica*). It belongs to the family of Lichens, and is a native of the northern parts of the world. This and other lichens probably contain other dietetical secretions besides starch, as we find they are capable of supporting animal life. The Rein-Deer-Moss (*Cenomyce rangiferina*) is an instance of this. In the northern parts of the world as well as in mountainous districts this lichen grows in great abundance, and during the winter season is the principal support of the rein-deer. In spite of the extreme cold to which it is subjected, this plant grows with vigour, and the rein-deer, in order to obtain it as food, is obliged to remove with its nose the snow with which it is sometimes covered for many feet. The Cup-Moss (*Cenomyce pyxidata*) of our own moors belongs to the same genus as the rein-deer-moss, and is also used as an article of diet in the same way as the Iceland-moss. The Tripe de Roche is another of these lichens which has been used as an article of diet. It has a melancholy interest attached to it, as it has so often formed the chief article of diet of our arctic navigators. Two species of lichens, the *Gyrophora proboscidea* and *G. erosa*, afford the Tripe de Roche. Although they are said to be nutritious, they are described as having bitter, nauseous, and purgative properties.

Amongst the sea-weeds which have been used as articles of diet none is better known than the *Chondrus crispus*, which under the name of Carrageen-Moss, Irish Moss, and Pearl-Moss has been for a long time used in Europe. It grows on the rocky sea-shores of Europe; and when washed and dried, and then boiled with water, makes a mucilaginous decoction, which, like the same preparation of the Iceland-moss, has been recommended in consumption, coughs, diarrhœa, and other diseases. It has however no bitter principle, and is probably less tonic than the lichen. This and other sea-weeds have been occasionally had recourse to by the poor inhabitants of the sea-shores of Europe, more especially Ireland, when the ordinary corn or potato crop has failed. They contain however but little nutritious matter, and persons soon famish who live upon nothing else. There are certain forms of sea-weed which are often eaten as an addition to other kinds of food. There is in all of them a certain flavour of the sea, arising probably from the saline matter they contain, which renders them very objectionable to some persons as articles of food, and which will probably always form an objection to their general use. Of those which are eaten in various parts of England we may mention:—

1. Laver, Sloke, Slokam (*Porphyra laciniata*). It is on all our sea-shores; and when employed as food is salted and eaten with pepper, vinegar, and oil.

2. Green Laver, Green Sloke, Oyster-Green (*Ulva latissima*). The *Ulva* is not so good to eat as the *Porphyra*, and is only had recourse to when the latter is not abundant.

3. Tangle, Sea-Ware, Sea-Girdles, Sea-Wand, Red Ware (*Laminaria digitata*). It is cooked by boiling for a long time, and adding pepper, butter, and lemon-juice. Cattle are fed on it when young in some parts of the British Islands.

4. Badderlochs, Hen-Ware, Honey-Ware, Murlins (*Alaria esculenta*). The part of the plant which is eaten is the thick middle rib which runs through the frond. It is sometimes called the Eatable Fucus.

5. The Dulse of the south-west of England is the *Iridea edulis* of botanists. It is eaten by the fishermen of the south-west coasts of England, who before eating it pinch it between red-hot irons. In Scotland it is cooked in the frying-pan. It is said to resemble in its flavour roasted oysters.

6. Dulse of the Scotch, Dellisk, Dellish, Duileisg, Water-Leaf (*Rhodomenia palmata*). The Highlanders and the Irish, before the introduction of tobacco, were in the habit of drying this weed and using it as a masticatory. The Icelanders use it as an article of diet under the name of the Sugar-Fucus. In the islands of the Mediterranean Archipelago it is employed as an ingredient to flavour soups, ragouts, and other dishes.

Several other sea-weeds have been employed as food, but these are the principal that are at present used in this country. In China the people are very fond of sea-weeds, and many kinds are collected and added to soups, or are eaten alone with sauce. One of these, the *Plocaria tenax*, is sometimes brought to this country under the name of Chinese Moss. The decoction it makes is so thick that it is used as glue. The Corsican Moss, which has a reputation in medicine as well as a diet, is the *Plocaria Helminthocortos*, and is found on the coasts of the Mediterranean. Another sea-weed was recently imported into London under the name of Australian Moss; but although affording a very thick jelly, it tastes too strongly of the sea to be rendered pleasant by any kind of cooking.

The next dietetical substance of which we have to speak is Sugar. Sugar is distinguished readily from starch by many properties. Sugar is soluble in water, whilst starch is only diffusible through it. Sugar is susceptible of fermentation, and of being converted into alcohol, which starch is not. Sugar has a peculiar sweet taste, whilst starch is insipid. It is on account of the solubility of sugar that we never, or very seldom, find it in plants in a solid condition. It is always dissolved in the water naturally contained in the plants in which it exists. Sugar is not so frequent a product of vegetable change as starch; but is, nevertheless, very generally found during some period of the growth of the majority of plants.

Sugar, like starch, is not nutritious, but is taken into the system with the object of maintaining animal heat. Persons may even get fat on sugar, but the living tissues are not nourished by any of the carbonaceous productions of plants. It is true, that in countries where the sugar-cane is grown, slaves and their children, during the period of its gathering, partake of it in large quantities, and are nourished upon it; but the sap of the sugar-cane, and the cane itself, contain other alimentary principles besides sugar, which assist in the nutrition of the body.

Sugar, being readily soluble in water, is more digestible than starch. Of the substances which maintain animal heat, it is the most easily digested; and hence we may see a reason why it is supplied to the young of the higher forms of animals. For this purpose it is secreted, by the female of all the *Mammalia*, in the milk, which is furnished universally to their young during the first months of their existence. The instinctive love of sugar, so well known as a distinguishing character of the child, seems to point out its adaptation to the wants of the infant system. Readily digestible however as sugar is, it is one of those substances which speedily undergoes decomposition. When taken into the stomach and the system, its elements seem to enter into secondary combinations, which are very injurious. This is why so many persons find it necessary to limit the quantity of sugar which they take in their diet. The changes however which it so frequently undergoes in the adult system, do not appear to take place in children; hence the child may eat sugar with impunity, although its parents may not.

Although there are various kinds of sugar, having a different composition, they seem all to act dietetically in the same way upon the system. The most common form of sugar in plants, and that which is most frequently eaten in diet, is Cane-Sugar, so called from its being yielded by the sugar-cane. It consists of—

	Atoms.
Carbon	12
Hydrogen	9
Oxygen	9
Water	2

The other kinds of sugar which are eaten, are milk-sugar, $C_{24}H_{19}O_{19}+5HO$; and grape-sugar, $C_{12}H_{12}O_{12}+2HO$. It will be seen that cane-sugar resembles starch in its composition, and it is probably formed in the plant from that body. Although cane-sugar is found in the sugar-cane, the beet, and the maple, it is not so frequent in plants as grape-sugar, which is the form in which sugar is found in the fruits and other parts of plants which may be sweet.

The sources of sugar, as an article of diet, are of course very various; it is only separated however from a limited number of plants. Of these the principal is the Sugar-Cane (*Saccharum officinarum*).

The sugar eaten by the inhabitants of France is principally obtained from the Beet (*Beta vulgaris*). In tropical countries it is obtained from the juice of palms, as from the Jaggary Palm (*Caryota urens*), the Cocoa-Nut Palm (*Cocos nucifera*), and others. It exists in the stems of all grasses, and is prepared in America from Maize (*Zea Mays*). The Birch (*Betula alba*) in this country, and the Sugar-Maple in America (*Acer saccharinum*), also yield it in their sap.

Grape-sugar, also called Glucose, is found in the fruits of most plants. It seems to act on the system in precisely the same way as cane-sugar.

The result of the fermentation of grape-sugar is the production of Alcohol, which does not differ much in composition from sugar. The following is the decomposition:—

	C.	H.	O.
2 Atoms of Alcohol	8	12	4
4 Atoms of Carbonic Acid . . .	4	0	8
2 Atoms of Water	0	2	2
One Atom of Grape-Sugar . .	12	14	14

Alcohol is taken as an article of diet in the form of beers, wines, and spirits. Although resembling sugar in its composition, its effects on the system are very different. It acts on the nervous system as a stimulant and narcotic, and might perhaps be regarded as one of the medicinal forms of food. A question has arisen amongst physiologists as to the action of this substance on the system. Liebeg, and with him many others, maintain that, like starch and sugar and oil, the elements of the alcohol unite with oxygen in the system, and thus by combustion assist in maintaining animal heat. On the other hand Dr. Carpenter, and those who repudiate the use of alcohol in diet, maintain that it is not destroyed during respiration, and consequently does not promote animal heat any further than as it stimulates the heart's action.

Alcohol when taken as an article of diet not only acts upon the nervous system, but on account of its chemical action on albumen exerts an injurious influence when taken in large quantities upon the mucous membrane of the stomach. It is thus that when indulged in, it becomes a source of indigestion, and lays the foundation of serious diseases. Taken in small quantities in the form of wine or beer, it seems to exert a favourable influence on the digestive function, and to belong to that class of foods to which spices and condiments are referred. Taken medicinally it is often capable of exerting powerful effects, on account of its rousing action upon the vascular system. It does not seem to be necessary to health, as there are many nations that never use it, and individuals, in countries where it is habitually taken as an article of diet, find their health not materially injured by debarring themselves from its use.

The quantity of alcohol contained in fermented beverages varies very much.

With regard to wines, when the juice of the grape contains large quantities of sugar in comparison with the water, and the fermentation is complete, then the alcohol is abundant, and strong wines are produced; whilst, when the sugar is in small quantities, or the fermentation is incomplete, weak or thin wines are the result. Ports and sherries are strong wines, whilst those of the Rhine are generally weak.

Sweet wines are those in which all the sugar is not converted into alcohol. This is mostly the case with wines made from other fruits besides grapes. Hence the well-known sweetness of what are called British wines. This does not however arise from an imperfect fermentation, but from the acid contained in other fruits not being tartaric acid. One of the most remarkable properties of tartaric acid is that it forms an insoluble salt (the cream of tartar) with potash, which is generally found in fruits; and in wines made from the grape this salt falls to the bottom of the cask, forming the tartar or lees of the wine. But other acids, as citric, malic, and oxalic acids, are not thus precipitated from their solutions, and they remain in wines, giving them a very acid flavour, which would render them unpleasant, unless sugar was added to cover their acidity. Sweet wines are objectionable as articles of diet, on account of the sugar they contain, which, when held in solution in wine, seems more likely to decompose, and thus prove injurious to the system, than when taken in its pure form. In wines made from other fruits besides grapes, the acid is also liable to objection.

Effervescing wines are those which are bottled before the fermentation is complete, so that a large quantity of the carbonic acid, which would be otherwise got rid of, is retained in solution in the wine, and escapes when the bottle is uncorked. Such is champagne. Effervescing wines are more liable to disagree with delicate stomachs than others, on account of their imperfect fermentation rendering them liable to further change in the stomach; and this state of change is probably communicated to the substances used as food contained in the stomach.

The skins and stalks of the grapes, if not the juice, contain tannin. This substance is a powerful astringent, and its presence seems to be the cause of the astringent character of many red wines, as port, claret, and others. There is also a difference in the quantity of free tartaric acid contained in wines; and those which have the largest proportion of this constituent have an acid flavour. Some of the wines made from grapes are so sour as to be very unpalatable: this is more especially the case with the poorer white wines of the Rhine.

The quality in which wines differ from each other most is what is called their bouquet, or flavour. It differs in wines made from different kinds of grapes, and differs in the same grape in different districts and in different seasons. It is well known that the vintage of one year produces a better or worse wine than that of another, and this depends on the development of the peculiar flavour of the wine. Liebig says that the bouquet is dependent on an acid which he calls œnanthic, and which, combining with the alcohol, forms an ether which gives the odour and flavour to wines.

The quantity of alcohol contained in wines differs very much. The ports and sherries consumed in England contain the largest quantity. But then much of this is added. It is added in the form of brandy. Brandied wines keep best, but are not the best to drink. Unless wines are naturally strong, they will not keep without the addition of alcohol. Clarets, hocks, and Moselles, are seldom brandied. Some of the hocks do not contain more than seven per cent. of alcohol, whilst port and sherry contain twenty-five per cent.

Ardent spirits, distilled liquors, differ from wine in their having been submitted to distillation after the fermentation, which produces the alcohol. Brandy is distilled from wine; and peach-kernels, or other vegetable matter containing oil of bitter almonds, are added to give it a flavour. All the parts of the plants belonging to the division of the order *Rosaceæ*, called *Amygdaleæ*, contain oil of bitter almonds. Rum is distilled from molasses or treacle in the West India Islands, and pine-apples are added to give a peculiar flavour. Gin is distilled in Holland, from rye; in this country from wheat, the grains of which are allowed to become saccharine, and then fermented. Juniper berries are employed to give the peculiar flavour to gin. Whiskey is distilled from wheat, barley, or oats, treated in the same manner as for gin. Nothing is added to flavour it; but the smoke of the peat, by the aid of which the distillation is effected in both Ireland and Scotland, gives a characteristic flavour to this liquor. Liqueurs belong to this division; they are distilled spirits containing large quantities of sugar, and are flavoured with all kinds of substances, as celery, bitter almonds, gentian, wormwood, &c.

Beers, ales, and porters, differ from wines in the addition of a bitter principle, most frequently the hop, to the fermented liquor. The saccharine matter for fermentation is obtained through barley. The grain of barley is steeped in water, and allowed to germinate. When the starch of the grain is converted into sugar, it is submitted to heat, and malt is formed. The malt is placed in boiling water, and hops added; when cooled, the process of fermentation is allowed to take place, and the beer is completed. When the malt is slightly charred during the process of drying, it gives a dark colour to the beer. It is then called porter. These fluids vary much in strength and bitterness, according to the quantity of malt and hops employed.

Beer is the safest of these beverages for habitual use; but even this may be indulged in too freely, and disease may be the result. Of the various kinds of beer, that which is to be most commended, is the weak form of bitter ale, which is now so generally employed in the households of London and its neighbourhood. Beer acts as a tonic on account of its bitter principle, as well as a stimulant, and is frequently, on this account, found to be a valuable addition to the ordinary diet.

The Oleaginous group of foods is somewhat peculiar. They are taken in various forms from both the vegetable and animal kingdoms, and are known under the name of butter, oil, lard, suet, fat, &c. The following formula will express the composition of this class of bodies:—

Carbon	11
Hydrogen	10
Oxygen	1

It will be seen that the oxygen is in considerably less proportion than in the foregoing substances of this group, and we may consequently conclude that the hydrogen as well as the carbon is consumed in the system in maintaining the animal heat. This is an important point, as it frequently happens that the value of the heat-giving group of foods is estimated by the quantity of carbon alone. That oil has more power in maintaining animal heat than sugar or starch, is seen in the fact that it is eaten in larger quantities by men who live in cold regions than by those who live in the warmer parts of the earth. Just as we pass north or south from the tropics, man adds oil to his food according to the degree of cold to which he is exposed.

Oil seems also to be deposited in the tissues of man and other animals as a source of combustible materials when these fail in their natural food. Thus the *Ruminantia* get fat in summer to supply them with their winter's store of fuel. Hybernating animals, which are fat when they commence their sleep, wake up quite thin. Their fat has been exhausted in maintaining their animal heat during hybernation.

Oil performs another function in the system. It is very evident from its general presence in every tissue of the body that it has an action in connection with the development of the proteinaceous tissues. It seems to assist their development, to act as a kind of preparation for their growth. In this way its curative action in certain forms of disease may be explained. There is no doubt of the beneficial action of cod-liver oil in scrofulous diseases, and its action can only be explained on the above supposition. In connection with the use of cod-liver oil it may be stated that animal oils appear to be in a different physical condition of aggregation from vegetable oils, and are certainly more readily digested and appropriated by the system.

The vegetable oils chiefly used as food are those obtained from the Olive (*Olea Europæa*) and the Almond (*Amygdalus dulcis*). Many seeds, as the Cocoa-Nut (*Cocos nucifera*), Almond (*Amygdalus*), Chestnut (*Castanea*), Walnut (*Juglans*), Hazel-Nut (*Corylus*), Brazil-Nut (*Bertholletia*), contain oil.

The fat of animals is the great source of oleaginous food from the animal kingdom.

We now come to speak of the Nutritious, Proteinaceous, or Nitrogenous articles of diet. The substance called Protein is the basis of these. It is the first element that appears in the development of the vegetable cell. It is consequently universally present in plants. It also constitutes the chief material of the tissues of animals. It assumes in both kingdoms various forms, and is called albumen, fibrine, and casein, according to its physical and chemical properties.

Some animals derive this constituent of their bodies directly from the vegetable kingdom, as all the herbivorous and graminivorous creatures; others derive it indirectly from the plant through the animal, as the various forms of *Carnivora*. Man obtains his supply of protein from both sources. As a sect has arisen of persons who deny the propriety of man's taking animal food, it may be well to examine the evidence on which his claim to be regarded as a flesh-eating animal rests. We shall dismiss the sentimental objection, that life ought not to be taken as unworthy of serious refutation, as every one must feel that for carnivorous animals to prey upon lower animals is a natural law.

"In the first place, the experience of the races and nations of men who partake of animal food is decidedly in its favour. Amongst the northern and European nations this practice is universal; and it is precisely amongst these people that we see the greatest amount of physical power, and moral and intellectual development existing. Amongst these nations, those individuals and classes who partake most largely or exclusively of a vegetable diet, are alike physically, intellectually, and morally degraded. It is a well established fact, that amongst those classes who get the least animal food, as also in those public establishments where meat is only sparingly allowed, mortality is greatest, and disease is most rife. One of the most common forms of disease generated by an exclusively vegetable diet is scrofula, and when traceable to this cause, the most speedy remedy is the addition of animal food to the diet. There are also many other forms of disease produced by the want of animal food, which require for their cure but an abundant supply of the needed material. I need not, I am sure, specify facts to verify this statement. The experience of every medical man would confirm it; and there is no surgeon or physician connected with the great medical charities of this country, but has every day, unfortunately, ample opportunities of witnessing the ill-effects of a vegetable diet, and the benefit, in such cases, of the administration of animal food.

"Nor are we at a loss in accounting for the beneficial action of the flesh of animals as food. From what I have before said, it will be recollected that the muscles and other tissues of animals are composed principally of protein; so that they truly constitute the most nutritious kind of diet. It has also been found, not alone as a matter of general personal experience, but by direct experiment, that animal food is more digestible than vegetable food. The experiments to which I allude are those performed by Dr. Beaumont of America, on a man that had received a gun-shot wound in such a position as to form a perforation into his stomach. This wound never healed, and enabled Dr. Beaumont to perform the experiments alluded to. By placing various kinds of food in the stomach of this man, he was enabled to ascertain how long each required to digest; and it was found that the flesh of animals was much more digestible than any of the more nutritious forms of vegetable food, as bread, and the preparations of flour.

"Could we not find reasons for partaking of animal food in its nutritiousness and digestibility, we might find ample justification from the structure of man as compared with some of the lower animals. To the comparative anatomist it is sufficient that he knows the structure of the teeth, jaws, or stomach of an animal, to tell whether it fed on vegetable or animal food; and when he finds the structure that characterises the one or the other combined, he likewise knows that the animal will require both kinds of food. Let us, then, for one moment glance at the structure of the teeth, jaws, and stomach of vegetable-feeding animals, and compare them with creatures feeding entirely on animal food. We may take the ruminant animals, as the sheep and the ox, as specimens of pure vegetable-feeding animals. On examining their teeth it will be found that they have broad surfaces, made rough for the purpose of rubbing on each other, and between those teeth the grass and grain they eat are well ground before they are swallowed. In order that these teeth may be moved with facility over each other, the jaw, in addition to the up and down movement, which is essential to the reception of the food into the mouth, has a lateral movement, by which the trituration of the food between the teeth may be effected. The food thus prepared passes down a long œsophagus, or gullet, into a complicated bag or stomach. In the ruminants, though not in all the vegetable-eating animals, a process of digestion or maceration is carried on previous to the final mastication of the food between the teeth, and its ultimate digestion in the stomach.

"If we turn now to the structure of flesh-eating animals, of which the *Carnivora*, embracing such animals as the lion, and the tiger, may be taken as the type, we shall find that instead of teeth furnished with broad surfaces, they have teeth with sharp points for holding and cutting their food. Their lower jaw has no lateral movement, but a powerful up and down action, by which their sharp teeth are brought over each other and made to act in dividing their food, something in the way of the blades of a pair of scissors when used in cutting. In passing to the stomach, we find the gullet short, and the stomach small and simple in its form, adapted for food that is readily digested and speedily conveyed into the system.

"On an examination of these organs in man, it will be found that they are a true mixture of these two classes. His teeth are partly adapted for grinding, whilst some of them are supplied with the sharp projections which are characteristic of the *Carnivora;* thus evidently adapting them for the mastication of both vegetable and animal food. A slight lateral movement of the lower jaw with the up and down action is expressive of the subserviency of his structure to a mixed diet. In the stomach also we find indications of the same intermediate position in its structure; and the same conclusion is forced upon us, that it is part of the apparatus of an animal intended for subsisting upon a diet composed of animal and vegetable substances.

"That man can live on food derived entirely from plants, or entirely from animals, is a well known fact. The natives of many parts of Asia never eat animal food, whilst the Hudson's Bay hunter, some tribes in the northern part of the world, and the Guachos of the Pampas of America, seldom or never have vegetable food; but neither the physical, moral, nor social condition of either the one or the other would prompt the suggestion that man attains his highest development exclusively on either vegetable or animal diet. In the various positions in which man is placed in the world, there can be no doubt that the relative quantities of flesh to food derived from plants, may vary much with great advantage; but there seems to be no position in which man in health can be pronounced to be the better with abstinence from either the one or the other kind of food. That man does subsist on either exclusively only proves the great range of his adaptation to the varying conditions in which he may be placed on the surface of the earth; but certainly it is no proof of his labouring under a necessity for the supply of one to the exclusion of the other." (Lankester 'Letters on Diet.')

Of the three forms of protein referred to above, fibrine is found in the flesh and blood of all animals, as gluten in wheat, barley, oats, rye, and the other *Cerealia.* Albumen is found in the juices of many plants, as cabbage, cauliflower, asparagus, &c.; it is also found in the nervous system and blood of animals. Casein is present in milk, also in the seeds of leguminous plants, as peas, beans, and lentils.

In the animal body is found a substance called Gelatin, which appears to be formed out of the proteinaceous tissues. This substance is necessary to the existence of the animal body, and what cellulose is in the vegetable kingdom, gelatin appears to be in the animal kingdom. Although often taken into the system with animal food, especially in soups and jellies, there appears to be no evidence that it is even converted into a proteinaceous tissue. Experiments on this subject have been performed both in France and Belgium on an extensive scale, and the conclusion arrived at was the same, that gelatin is not used for forming any of the proteinaceous tissues of the body; at the same time it is not improbable that the gelatin may be appropriated for the purpose of renewing the gelatinous portions of the tissues, which are very extensive in the animal body.

It will be thus seen that although gelatin cannot be said to be nutritious in the sense of nourishing the actively vital parts of the body, it may assist in keeping up certain parts of the fabric. It need not then be rejected from our food; but it cannot be too widely known, that, as the basis of soups and jellies, it may be administered under the supposition of its being nutritious, and thus lead, if used alone in diet, to disastrous results.

Of the forms of protein which occur in food, Casein demands a short notice. Although, as dissolved in milk, it is very digestible, it becomes, when separated and known by the name of cheese, very indigestible. When milk is deprived of its butter, and the pure casein made into cheese, as is the case with some English cheeses, as those from Suffolk, it becomes so hard as scarcely to be digestible. [CHEESE.] But in most cases the casein is curdled with the butter, and a large per-centage of this substance is found in all good cheeses. Stilton cheese is made by adding the cream of one milking to that of another, so that this cheese has double the quantity of butter that other cheeses possess. The indigestibility of separated or insoluble casein will perhaps explain the neglect of beans, peas, and lentils, as articles of diet, although they contain a much larger quantity of nutritious ingredients than most seeds.

In concluding these general remarks upon diet, we present our readers with a summary of the conclusions on this subject arrived at by one of our most recent physiological writers. Dr. Carpenter, in his 'Principles of General and Comparative Physiology,' thus concludes this part of his subject:—

"The waste of the tissues, of which gelatin is the basis, may be supplied either by albuminous, proteinaceous, or gelatinous compounds, since there is no doubt that albumen may be converted into gelatin, although the reverse process cannot be performed. As gelatin does not exist in plants, it must be formed in herbivorous animals at the expense of the albuminous elements of their food; whilst in carnivorous animals it is probably derived immediately from the gelatinous components of the bodies on which they prey. The materials of the adipose tissue, and the oleaginous particles which seem requisite in the formative operations of the system, generally are derived in the carnivorous races from the fatty substances which the bodies of their victims may contain; whilst the herbivorous not only find them in the oleaginous state in their food, but have the power of producing them by the conversion of farinaceous and saccharine matters.

"The foregoing statements are applicable to all tribes of animals 'cold-blooded' as well as 'warm-blooded.' We have now to consider the special case of the latter. In the carnivorous tribes the waste of the tissues is so great, in consequence of the restless activity which is habitual to them, that it appears to furnish a large proportion of the combustible material required for the maintenance of their proper temperature. The remainder is made up by the fat of the animals on which they feed; and it is to be observed that the amount of this is much greater in the bodies of animals inhabiting the colder regions of the globe than in the inhabitants of tropical countries. In the herbivorous tribes the case is different: they are for the most part much less active; and the waste of their tissues consequently takes place in a less rapid manner, and is far from supplying an adequate amount of combustible material, especially in cold climates. Their heat is in great part sustained by the combustion of the saccharine and oleaginous elements of their food, which are appropriated to this purpose without having ever formed part of the living tissues; and the demand for these will be larger in proportion to the depression of the external temperature, a greater generation of caloric being then required to keep up the heat of the body to its proper standard. Hence, cold-blooded animals can usually sustain the privation of food longer than warm-blooded, and this more especially when they are kept cool, so that they are made to live slowly, and death when at last it does ensue is consequent upon the general deficiency of nutrition. On the other hand, warm-blooded animals, whose temperature is uniformly high, must always live fast, and deprivation of food is fatal to them, not only by preventing the due renovation of their tissues, but also by destroying their power of sustaining their heat. The duration of life under these circumstances depends upon the amount of fat previously stored up in the body, and upon the retardation of its expenditure by external warmth, or by the inclosure of the body in non-conducting substances; and there is evidence that if this be duly provided for, and all unnecessary waste by nervo-muscular activity be prevented, the life even of a warm-blooded animal may sometimes be prolonged for many weeks without food."

It will be gathered from the foregoing general remarks that food may be divided into two great classes—the heat-giving and the flesh-forming; and we now present a table of some of the more ordinary kinds of food, in which one or the other, or both, of these classes of substances are found mixed.

[100 grains of Tea gives in an infusion 5 grains of theine and 26·5 grains of non-nitrogenous substances. (Peligot.)

By adding the first three columns of this table together, and deducting the sum from one hundred, it will give the quantity of water contained in each article of food. Thus, taking butcher's meat:—

Nitrogenous material	22·3
Carbonaceous material	14·3
Mineral matter	·5
	37·1
Water	62·9
	100·0

The quantity of carbon expresses the relative heat-giving power of the food. With foods containing fat the quantity of hydrogen should also be taken into consideration.]

Table of Composition of Food in 100 parts.

Food.	Nitrogenous Flesh-forming Ingredients.	Non-Azotised Heat-giving Principles.	Mineral Matter.	Carbon.
Milk	4·50	7·90	0·60	6·94
Butcher's Meat free from bone	22·30	14·30	0·50	21·56
Bacon, Pork	8·36	62·50	0·50	58·92
Fish	14·00	7·00	1·00	9·15
Flour	17·00	66·00	0·70	45·50
Barley Meal	14·00	68·50	2·00	40·50
Oatmeal	13·60	70·30	3·30	44·10
Indian Meal	10·71	72·25	1·04	36·41
Peas	23·40	60·00	2·50	35·70
Rice	5·43	84·65	0·52	36·00
Potatoes	1·41	22·10	1·00	12·20
Carrots	1.48	11·61	0·81	5·40
Turnips	1·64	10·00	1·62	5·20
Parsnips	2·10	17·70	0·80	8·63
Mangel Wurzel	1·60	12·26	1·14	5·50
Cabbage	1·75	4·05	2·20	2·65
Cocoa (nibs)	9·56	85·76	2·70	68·56
Sugar	0·00	100·00	0·00	42·58
Suet, Fat, Butter	0·00	100·00	0·00	79·00
Bread	6·83	48·65	1·51	25·19
Cheese	31·02	25·30	4·90	36·80
Beer	·85	9·17	0·20	4·33
Vinegar				

Such a table as this will be found useful in constructing dietaries for large institutions, which are very often erroneously constituted, and a large waste thereby entailed. The following table contains examples of dietaries, drawn up by Dr. Lyon Playfair, from various sources. This table accompanied an abstract of a lecture by Dr. Lyon Playfair on the 'Food of Man,' delivered at the Royal Institution in May 1853. The following extracts from this lecture will explain some of the valuable results obtained by Dr. Playfair:—

"It was now admitted that the heat of the body was due to the combustion of the unazotised ingredients of food. Man inspires annually about 7 cwt. of oxygen, and about 1-5th of this burns some constituent and produces heat. The whole carbon in the blood would thus be burned away in about three days unless new fuel were introduced as food. The amount of food necessary depends upon the number of respirations, the rapidity of the pulsations, and the relative capacity of the lungs. Cold increases the number of respirations and heat diminishes them; and the lecturer cited well-known cases of the voracity of residents in artic regions, although he admitted, as an anomaly, that the inhabitants of tropical climates often show a predilection for fatty or carbonaceous bodies. He then drew attention to the extraordinary records of arctic dietaries shown in the table, which, admitting that they are extreme cases even in the arctic regions, are nevertheless very surprising.

"Dr. Playfair then alluded to the second great class of food ingredients, namely, those of the same composition as flesh. Beccaria in 1742 pointed to the close resemblance between these ingredients of flesh, and asked, 'Is it not true that we are composed of the same substances which serve as our nourishment?' In fact the simplicity of this view is now generally acknowledged; and albumen, gluten, casein, &c., are now recognised as flesh-formers in the same sense that any animal aliment is.

"The old mode of estimating the value of dietaries, by merely giving the total number of ounces of solid food used daily or weekly, and quite irrespective of its composition, was shown to be quite erroneous; and an instance was given of an agricultural labourer in Gloucestershire, who in the year of the potato famine subsisted chiefly on flour, consuming 163 ounces weekly, which contained 26 ounces of flesh-formers. When potatoes cheapened he returned to a potato diet, and now eats 321 ounces weekly, although his true nutriment in flesh-formers was only about 8 or 10 ounces. He showed this further by calling attention to the six pauper dietaries formerly recommended, to the difference between the salt and fresh meat dietary of the sailor, &c., all of which, relying on absolute weight alone, had in reality no relation in equivalent nutritive value.

"Taking the soldier and sailor as illustrating healthy adult men, they consumed weekly about 35 ounces of flesh-formers, 70 to 74 ounces of carbon, the relation of the carbon in the flesh-formers to that of the heat-givers being 1 : 3. If the dietaries of the aged were contrasted with this it would be found that they consumed less flesh-formers (25—30 ounces), but rather more heat-givers (72—78 ounces); the relation of the carbon in the former to that of the latter being about 1 : 5. The young boy about 10 or 12 years of age consumed about 17 ounces weekly, or about half the flesh-formers of the adult man; the carbon being about 58 ounces weekly, and the relations of the two carbons being nearly 1 : 5½. The circumstances under which persons are placed influence these proportions considerably. In workhouses and prisons the warmth renders less necessary a large amount of food fuel to the body; while the relative amount of labour determines the greater or less amount of flesh-formers. Accordingly it is observed that the latter are increased to the prisoners exposed to hard labour. From the quantity of flesh-formers in food we may estimate approximately the rate of change in the body. Now, a man weighing 140 lbs. has about 4 lbs. of flesh in blood, 27½ lbs. in his muscular substance, &c., and about 5 lbs. of nitrogenous matter in the bones. These 37 lbs. would be received in food in about eighteen weeks; or, in other words, that period might represent the time required for the change of the tissues, if all changed with equal rapidity, which however is not at all probable.

"All the carbon taken as food is not burned in the body, part of it being excreted with the waste matter. Supposing the respirations to be 18 per minute, a man expires about 8·59 ounces of carbon daily, the remainder of the carbon appearing in the excreted matter."

The substances used as food which we have called medicinal are very numerous. They include acids, volatile oils, and the vegetable alkaloids.

The acids are eaten in fruits, such as the citric, malic, tartaric, and oxalic acids. It is possible they may be decomposed in the system, and furnish the materials of animal heat. They seem however to perform a more important part in dissolving up the mineral ingredients taken into the system as food. This seems one way in which carbonic acid acts beneficially when taken in wines, beers, and effervescing waters. Acetic acid, or vinegar, acts probably in the same manner as the other acids.

The volatile oils are added to other kinds of food, and, as condiments and spices, form a conspicuous feature in diet. We may class these, with alcohol, as stimulants of the mucous membrane of the stomach.

The use of tea, coffee, chocolate, and Paraguay tea, in infusion, constitutes a curious class of alimentary substances. In tea, coffee, and Paraguay tea, a principle is found identical in every instance, to which the name Thein or Caffein has been given. A substance very similar, Theobromine, is found in chocolate. It is undoubtedly upon the action of these substances that the dietetical uses of these plants depend.

Two theories have been advanced to explain the action of this principle. Liebig suggested that the taurin found in the bile was formed from the waste tissues of the body carried into the blood; and that this taurin was necessary for the production of carbonic acid gas, or rather to get rid of the carbonaceous matter in the system in the form of carbonic acid gas. The taurin must be constantly formed, otherwise the heat of the body is not maintained, the carbonaceous matter not got rid of, and disease is engendered. If persons have not sufficient food, or if the digestive organs do not enable them to carry a sufficient quantity of nutriment to the system, the tissues of the body are consumed to form taurin. Liebig found that thein had a composition identical with taurin, or so nearly as to render it a sufficient substitute for taurin, and thus by the use of thein, he supposed we were actually preventing the waste of the body, and so maintaining health at less expense than we could by taking more solid food.

Persons who cannot consume a sufficient quantity of food to yield the carbon necessary for generating animal heat, have recourse to tea, and find it actually a nutritious article of diet; and it is only, says Liebig, "by such means as this that it can act as a nutritious agent." But another theory has been advanced by Dr. Playfair. He says thein has a composition very similar to nervous matter. Now, seeing that every operation of the mind must be attended with a loss of nervous matter, there is a necessity for a supply of that nervous matter to enable the mind to carry on its operations. A large quantity of proteinaceous matter would be required to be supplied to form the nervous matter with proper constituents if taken in by means of meat or bread. But these alkaloids at once become a constituent of nervous matter; and this accounts for the agreeable stimulus and permanent effect on the mind produced by the use of tea and coffee, particularly by studious persons, as well as those whose nervous systems are exhausted from various causes.

In any just estimate of diet the mineral ingredients should be considered. The forms which they assume in the system are not well known, but we have a capital instance in the phosphate of lime, which, forming a part of the bones, we know must be supplied through the diet. This substance is found in the cereal grasses, and perhaps one reason that man takes these grasses everywhere for the substantive articles of his diet is the possession of this substance. Iron is another substance which is frequently deficient in the blood. It is naturally supplied in the food; but this failing, iron is given medicinally. Potash in combination with vegetable acids seems to have the power of preventing scurvy. Chloride of sodium is another well-known instance of the necessity of mineral ingredients in the food.

A few plain rules for taking food will properly conclude this article.

In the first place, food should be properly cooked. Many substances which are very indigestible when in the raw state are rendered perfectly digestible by cooking. Although the stomach is capable of digesting fruits and some kinds of seeds without any exposure to heat, yet, as a general rule, the breaking down of the tissues which occurs in cooking greatly facilitates the digestion of both animal and vegetable food. But whilst that cooking is proper which enables the stomach more easily to reduce the food to the condition of chyle, there are extremes of preparation which however palatable are to be avoided. Food that is much prepared, so as to reduce it to a fluid condition, as soups, stews, and various made dishes, do not present sufficient solid matter for the healthy process of digestion to be carried on. When the object is to prevent the stomach from doing duty such food is proper. It may also be taken occasionally with advantage as a variety in diet, but food taken long together in this form is injurious.

Much indigestible food at a time should be avoided. Many of the articles of our diet are less digestible than others, and when taken in small quantities are not injurious. It is when such substances are made the principal constituents of a meal that danger is likely to arise. To mention only a few of the less digestible kinds of foods:—Unfermented bread and biscuits, uncooked vegetables eaten as salad, unripe fruits, cheese, pie-crust, fat meats smoked, as bacon, and the fat of meat, some kinds of fishes, especially the *Crustacea*, crabs, lobsters, &c. Heavy meals of any one of these articles of diet, or mixtures of them, may be very injurious, and produce serious attacks of indigestion, if not other diseases.

Solid food should be well masticated before it is swallowed. The teeth are organs given us on purpose to perform this function, and its accomplishment is attended also with the mixture of the saliva with the food, which seems to be an important step in the process of digestion. Although by hasty mastication persons in business hope to save their time, they should know that at least it is a loss of food, if not immediately a loss of health. Much more food is digested when it is well masticated than when it is swallowed very hastily in large masses. Food that is imperfectly masticated is digested with difficulty, and remains sometimes so long in the stomach as to produce irritation of the stomach, and remaining unacted upon it putrifies, producing pain and tainting the breath.

Even where mastication is very complete it is always better to swallow slowly, as by this means every part of the food is brought more fully under the influence of the gastric acid of the stomach, by which it is prepared for absorption into the blood.

Full and heavy meals should be avoided. It is better to get up from table with an appetite than to feel that no more food could be taken. It is always difficult to say how much should be with propriety taken. Some systems will bear twice as much food as others, whilst there are those who require twice as much food as others. Scales and weights are dangerous instruments at table, as some men will starve on what others will thrive. There is an instinct which, if obeyed, constantly cries "Hold, enough;" which if men would listen to would always guide them right. The feelings after eating should be those of refreshment and comfort—feelings that are not often present when too large a meal has been eaten. All food taken into the system and not wanted is likely to be in the way, and the processes adopted by nature for getting rid of the incubus are not unfrequently attended by disease and death.

Persons who habitually over-eat are frequently obliged to have recourse to medicines to correct the errors of their indulgence. Such an unnatural way of correcting the evils of an unnatural habit is itself likely to produce disease in the system.

Active bodily exertion should not be taken immediately after the principal meal. The stomach requires a supply of blood to perform its functions. If the current is diverted to other organs digestion is prevented. On this account reading at meals is an objectionable practice. The brain in this process gets the blood which the stomach requires. Long walks and hard study should both be avoided after a full meal.

Long fasting is bad. It is bad when the body is resting; it is much worse when the body is actively engaged. The stomach, like all other organs, performs its functions in virtue of the stimulus afforded it by the blood. If the blood is allowed to go a long time without a renewal of its constituents it no longer supplies the nervous system with energy; the stomach, and even other organs, flag in the performance of their duty, and as a consequence digestion is imperfectly performed. How often should man eat in the day? In the morning, at noon, and at night, is the answer given by the instincts of man.

The body can go longer without food whilst resting than when awake; hence persons may with safety go a longer number of hours between the night and morning meal than between the morning and noon, or the noon and night meals.

There are no rules without exceptions in certain cases, and there are many circumstances which must modify the application of the foregoing rules, as well as in other ways regulate the taking of food.

Age is a perpetually modifying influence. The new-born infant requires the food which nature has provided for its use every hour or two. As it grows older the intervals at which it takes its food become longer; but it should be always recollected, that as a rule children should have more eating times than adults. Grown-up people are too apt to assume that what is good for themselves is good for children; hence as great an amount of suffering is entailed on children by restricting the quantity and times of taking their diet amongst the rich as come upon them from absolute want amongst the poor. The craving appetite of children is no vice of fallen human nature, but the incessant demands of an ever-wasting yet ever-growing human body. Bread and butter, or treacle, or common cake, should always be allowed if asked for by rapidly growing boys and girls between the hours which adults find convenient for their meals. An evil however arising out of the healthy appetite of youth should be guarded against; it is, that whilst growing a habit is acquired of eating large quantities of food which are no longer required when growth has ceased. If the appetite is not checked by reason at this period of life, the habit of eating more than is necessary may be productive of evil results.

Old age requires a more frequent recourse to food than the adult, though not in so large a quantity. "A little and often" is a maxim that enables many aged persons to continue their influence in the world, whilst an attempt to maintain the habits of youth and middle age has cost many declining ones their lives.

The mode of life influences the diet. The sedentary, the inactive, do not consume so much muscle and nerve in their existence as the active and laborious, and accordingly require less food. The tailor ought not to eat so much as the day-labourer; and the lady all day in her drawing-room or carriage cannot expect the appetite or the enjoyment of food which is bestowed by the laws of nature on her housemaid.

Other things being the same more food is required in winter than in summer, more in cold climates than in hot ones. This arises from the greater consumption of certain parts of the food in maintaining the animal heat in order to keep off the external cold. Hence, to bring the appetite of Christmas to the Midsummer meal is to run the hazard of a surfeit; whilst the traveller who carries the eating habits of the north to countries under the line frequently perishes of fevers brought on by repletion.

FORAMINIFERA (*Foramen, fero*), a group of minute Marine Animals of low organisation, consisting of a slimy transparent jelly, invested with a hard, usually calcareous shell; found in sea-sand and amongst marine refuse dredged up from deep water. Owing to many of their shells having a spiral form, these creatures were long thought to be highly organised *Mollusca*, allied to the living *Nautilus*—an error into which most naturalists fell until recently, when these animals became the subject of a more rigorous and searching investigation than they had previously undergone.

Though usually very minute, their elegant forms early attracted the attention of naturalists. They were noticed by Gualtieri, Planchus, and Ledermuller, prior to the appearance of the 'Systema Naturæ' of Linnæus. In the latter work they are included amongst the *Nautili*, the animal, as well as that of the recent *Nautilus pompilius* with which Linnæus associates them, being alike unknown to the Swedish naturalist. In the 12th edition are descriptions of 15 species. In 1780 Soldani, an Italian priest, published two elaborate works, abundantly illustrated, and largely devoted to the recent and fossil forms of Foraminiferous Shells. He divides them into groups (such as *Nautili*, *Hammoniæ*, and *Orthocerata*) in the most arbitrary manner; but the works are monuments of his labour and perseverance. In 1784 some of the British species were figured by Walker in his 'Testacea Minuta Rariora.' The 'British Conchology' of Montague, 1803 (and 'Supplement,' 1808), contained a still larger number of British forms, respecting the majority of which the' error of Linnæus was still followed; but some were shown to be so different from the true *Nautili* as to require removing from that genus. In 1803 Fichtel and Moll figured many of the spiral forms, which they included amongst the *Nautili*. In 1808 De Montfort attempted to subdivide the group into a number of separate genera, but still regarded them as *Cephalopoda*, in which view he was followed by Fleming and other more recent writers.

In 1826 the study of the *Foraminifera* received a fresh impulse from the labours of M. D'Orbigny, a French naturalist, who in that year presented his first memoir on the subject to the French Academy. This memoir embraced the classification of the whole of the Cephalopodous *Mollusca*, or animals allied to the Cuttle-Fish; with which group of organisms D'Orbigny, like his predecessors in the study, imagined the *Foraminifera* to have the closest affinities. He divided the latter into five great families, which were again subdivided into a number of genera, most of them new; the various forms being thus thrown into natural groups in a way that had not previously been attempted even by De Montfort. Though D'Orbigny retained the erroneous idea of his predecessors as to the zoological relation of the *Foraminifera*, this error did not affect the value of his subdivisions of the class, which constituted an important step in advance of all that had been done by others. Indeed the value of his classification is shown by its retention in the writings of all who have succeeded him in the study. He distributed the species into 55 genera, introducing into the catalogue an enormous number of new forms, which he discovered in sands brought to him from various parts of the globe. The views of D'Orbigny and his predecessors respecting the Molluscous character of these animals were sanctioned by Cuvier in an edition of the 'Animal Kingdom,' published in 1828.

In 1835 M. Dujardin presented a memoir to the 'Annales des Sciences Naturelles,' based upon an examination of the recent animals of the *Foraminifera*, in which he rejected the idea that they had any affinities with the *Mollusca*. He pointed out the fact that the animal which tenanted the calcareous shell was a mere animated slime, having no visible organisation, and consequently very different from the highly organised *Cephalopoda*, with which they had previously been associated. He considered their true zoological position to be near the *Amœba*, commonly known as the Proteus Animalcule, and that they constitute part of a larger group, to which he assigned the name of *Rhizopoda*. In 1834 and 1839 Professor Ehrenberg presented two memoirs to the Academy of Berlin, in which he advocated the opinion that the *Foraminifera* were polype-bearing animals, allied to the *Flustræ* and other Moss-Corals, by him termed *Bryozoa*, and of which they formed the first order, *Polythalamia*. He also assigned to them internal organs which no other observers have been able to discover: but notwithstanding these errors he did good service by the discovery that the White-Chalk Rocks were principally composed of the aggregated shells of *Foraminifera*, which by their gradual accumulation had thus produced widely-extended masses of calcareous strata, many hundreds of feet in thickness. The existence of numerous Fossil *Foraminifera* in the Chalk had been demonstrated by Mr. Lonsdale in 1835; and still later, the rich harvest of beautiful forms to be obtained from these Cretaceous strata was further demonstrated by M. D'Orbigny in his monograph 'On the Foraminifera of the White Chalk.'

In 1845 Professor Williamson published a memoir in the 'Transactions of the Literary and Philosophical Society of Manchester,' in which he further demonstrated the entire absence of any real resemblance between the *Foraminifera* and the *Cephalopoda*, and the consequent necessity of arranging the former in an inferior portion of the zoological scale. At first he adopted the idea of Ehrenberg, but in a subsequent memoir (1848), he came to the conclusion that they were not polypiferous, but that they approximated to the Sponges on the one hand, and, as had been asserted by M. Dujardin, to the *Amœba* on the other; their true position in any linear arrangement being immediately above the former of these classes of objects. In another memoir, read in 1851, describing the complicated structure of some forms of the genus *Orbiculina*, Professor Williamson says, "Looking at the structure of the shell of the *Orbiculina adunca*, and especially at the large orifices which communicate between its various cavities, we cannot fail to observe that it is a reticulated calcareous skeleton, whose proportionate relation to the size of the soft animal has differed but little from that of the siliceo-keratose network of many sponges to the slimy substance with which they are invested. The attempt to isolate the various portions of *O. adunca*, and raise each portion to the rank of an individual animal, even in the limited sense in which we should admit such a distinction in the polypes of a *Sertularia* or of a *Gorgonia*, appears to me wholly inadmissible. If the soft structures of *Orbiculina* are as devoid of visible organisation as those of our British *Foraminifera*, and I have very little doubt that such will prove to be the case, the whole animal will be very little raised above the *Polypifera*, only possessing a symmetrical calcareous skeleton, which is at once both external and internal." ('Transactions of the Microscopical Society of London.')

In 1846 M. D'Orbigny published his work 'On the Fossil Foraminifera of the Tertiary Basin of Vienna,' in which he abandoned the views advocated in his earlier writings. He now recognised the inferiority of these objects to the Cephalopods, with which he had previously arranged them. He rejected the idea that they were aggregated creatures, as held by Ehrenberg, as also the existence of the intestinal canal and organs of reproduction described by the illustrious Prussian; but he arrived at the conclusion that they held a position intermediate between the *Polypifera* and the *Echinodermata*.

M. D'Orbigny says, "After what has preceded upon the characteristica of the *Foraminifera*, the comparison demonstrates that they cannot be arranged in any of the known Zoological Classes. Much less complex than the *Echinodermata* or the *Polypifera* as to their internal organisation, they have through their filaments (pseudopodia) part of the mode of locomotion of the former, and are by their isolated, non-aggregated, free existence, more advanced in the scale than the latter. This individual existence of the *Foraminifera*, the liberty which they enjoy, and their mode of locomotion, are characters which deserve to be taken into consideration. Although less complex than many *Polypifera*, they have not a common aggregate life. A multitude does not unite to form a regular body as amongst the *Polypifera*. They are locomotive, which the others are not. Their means of locomotion are complex, and the great regularity of the testaceous envelope of their segments places them far above the *Polypifera*. On the other hand, much less perfect than the *Echinodermata*, they are very inferior to them in all respects. We believe also that, because of the radiation of their filaments the position of the *Foraminifera* is in the interval (embranchement) of the radiating animals of Cuvier, between the *Echinodermata* and the *Polypifera*, as an altogether independent class." ('Sur les Foraminifères Fossiles du Bassin Tertiaire de Vienne,' p. 19.)

There can be no doubt of their great inferiority to the *Echinodermata*, which possess a distinct alimentary canal, a nervous circulating and sexual system; and connecting with the defined digestive cavity of the polype recent discoveries respecting its reproduction by ova, through the agency of medusiform buds, we must conclude that these latter are equally removed from the structureless animals of the *Foraminifera*. In the preceding argument M. D'Orbigny forgets that the freedom, isolation, and independence, upon which he lays so much stress, are the characteristics of the fixed compound *Polypifera*, in their embryonic or larval states. Consequently this feature, which in the *Foraminifera* is normal and persistent, betokens inferiority rather than superiority to the *Polypifera*, in which aggregation and fixation indicate maturity and a higher development. The argument drawn from their symmetry is of no value. Nothing can be more symmetrical than many of the sponge spicula; and in the vegetable kingdom the symmetrical plants (*Desmideæ*) are amongst the lowest forms.

An additional memoir by Professor Williamson, in 1851 ('Quarterly Journal of Microscopical Science,' vol. i.), afforded other and still more striking evidence of the probable correctness of the views previously enunciated, as furnished by the structure of a species of *Faujasina*, and especially showed that the new growths which added to the thickness of the shell were all applied to its exterior and not to its interior, apparently indicating that the gelatinous animal had the power of extending itself over the exterior of the shell, or of retreating to its interior at will, reminding us of the movements of the gelatinous envelope in some of the less highly organised Fungiform Corals. (Rymer Jones, 'Animal Kingdom,' p. 19.) In 1845 Dr. Carpenter laid before the Geological Society of London an elaborate memoir on the structure of some interesting fossil forms belonging to the genera *Orbitoides* and *Nummulina*, which with the publication of M. D'Orbigny on the *Foraminifera* of Cuba, constitute the chief additional works that have appeared on this subject.

The following is the latest classification of the *Foraminifera* adopted by M. D'Orbigny, and though marked by some serious imperfections, it is the best that has been hitherto published. The five principal divisions are chiefly based on the variations in the arrangement of the successively added segments.

Order 1. *Monostega.*—Animal consisting of a single segment. Shell composed of a single chamber. Genera: *Gromia*, Dujardin; *Orbulina*, D'Orbigny; *Oolina*, D'Orbigny.

Order 2. *Stichostega.*—Animal consisting of segments arranged in a single line. Shell composed of chambers superimposed linearly on a single straight or curved axis. No spiral growths:—

Glandulina, D'Orbigny.
Nodosaria, Lamarck.
Orthocerina, D'Orb.
Dentalina, D'Orb.
Frondicularia, Defrance.
Lingulina, D'Orb.
Rimulina, D'Orb.
Vaginulina, D'Orb.
Marginulina, D'Orb.
Conulina, D'Orb.
Pavonina, D'Orb.
Webbina, D'Orb.

Order 3. *Helicostega.*—Animal consisting of segments arranged in a spiral. Chambers piled up or superimposed on one axis, forming a spiral volute:—

Cristellaria, D'Orb.
Flabellina, D'Orb.
Robulina, D'Orb.
Fusulina, Fischer.
Nonionina, D'Orb.
Nummulina, D'Orb.
Assilina, D'Orb.
Siderolina, Lamarck.
Hanerina, D'Orb.
Operculina, D'Orb.
Vertebralina, D'Orb.
Polystomella, Lamarck.
Peneroplis, Lamarck.
Dendritina, D'Orb.
Spirolina, Lamarck.
Cyclolina, D'Orb.
Lituola, Lamarck.
Orbiculina, Lamarck.
Alveolina, D'Orb.
Rotalina, Lamarck.
Globigerina, D'Orb.
Planorbulina, D'Orb.
Truncatulina, D'Orb.
Anomalina, D'Orb.
Rosalina, D'Orb.
Valvulina, D'Orb.
Verneuilina, D'Orb.
Bulimina, D'Orb.
Uvigerina, D'Orb.
Pyrulina, D'Orb.
Faujasina, D'Orb.
Cauderina, D'Orb.
Chrysalidina, D'Orb.
Clavulina, D'Orb.
Gaudryna, D'Orb.

Order 4. *Entomostega.*—Animal composed of alternating segments forming a spiral. Chambers piled up or superimposed upon two alternating axes, forming a spiral:—

Robertina, D'Orb.
Asterigerina, D'Orb.
Amphistegina, D'Orb.
Heterostegina, D'Orb.
Cassidulina, D'Orb.

Order 5. *Enallostega.*—Animal composed of alternately arranged segments without forming a spiral. Chambers disposed alternately along two or three distinct axes, not forming a spiral:—

Dimorphina, D'Orb.
Guttulina, D'Orb.
Polymorphina, D'Orb.
Virgulina, D'Orb.
Bigenerina, D'Orb.
Gemmulina, D'Orb.
Textilaria, Defrance.
Vulvulina, D'Orb.
Bolivina, D'Orb.
Sagrina, D'Orb.
Cuneolina, D'Orb.

Order 6. *Agathistega.*—Animal composed of segments wound round an axis. Chambers wound round a common axis, each one investing half the entire circumference:—

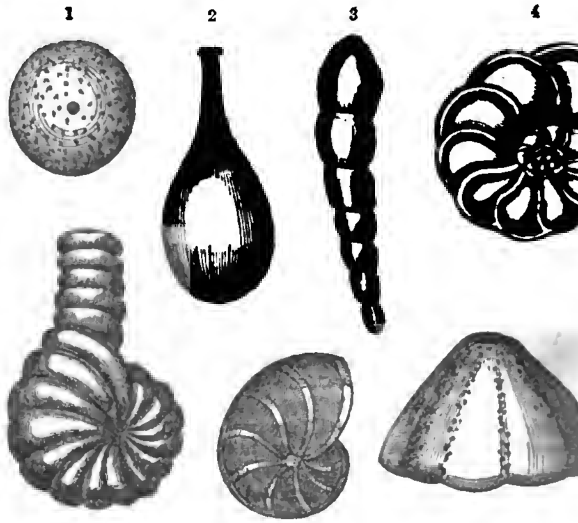
Uniloculina, D'Orb.
Biloculina, D'Orb.
Fabularia, D' Orb.
Spiroloculina, D'Orb.
Triloculina, D'Orb.
Cruciloculina, D'Orb.
Articulina, D'Orb.
Sphæroidina, D'Orb.
Quinqueloculina, D'Orb.
Adelosina, D'Orb.

The simplest type of the *Foraminifera* (*Monostega*), presents but a single segment, and is illustrated by the *Orbulina universa* (*fig.* 1), which is a small spherical shell with a lateral aperture, the interior of which has been occupied by the living jelly to which the shell owes its existence. The beautiful symmetrical *Lagenæ*, or Flask Animals (*fig.* 2), the British species of which have been figured by Professor Williamson in the 'Annals of Nat. Hist.,' also belong to this type.

In the order *Stichostega*, as for example the *Nodosaria*, *Dentalina* (*fig.* 3), the shell advances beyond the simple type of the *Monostega* by a process of linear budding. The first cell is usually spherical, as in *Orbulina*, but through the orifice in this primary cell there protrudes as a growth from the contained animal segment, a second segment, usually a little larger than the first, which speedily incases itself in a shelly covering. This new growth is successively followed by others developed in the same way, until the organism attains to its maturity, when it exhibits a series of cells arranged end to end in a straight or but slightly curved line.

In the *Helicostega*, a large and conspicuous group, the gemmation takes place with a spiral bias, producing the nautiloid form of shell which misled the earlier microscopists. Sometimes all the convolutions are visible. (*Operculina*, *fig.* 4.) In others the outer convolution embraces those previously formed, and conceals them. (*Cristellaria*, *fig.* 5.) In a third type all the spiral convolutions are visible on one truncated half of the shell, whilst they are embracing on the others (*Faujasina*, *fig.* 6), thus combining the other two types. Some genera, like the Stichostegous and Heliostegous orders, develop on the plan of the latter, up to a certain stage of their growth, when the arrangement of the cells ceases to be spiral and becomes straight (*Spirolina*, *fig.* 7), as in the *Nodosariæ*. The orifices penetrating the septa and connecting the contiguous segments are sometimes single, and at others more numerous.

1 2 3 4



7 5 6

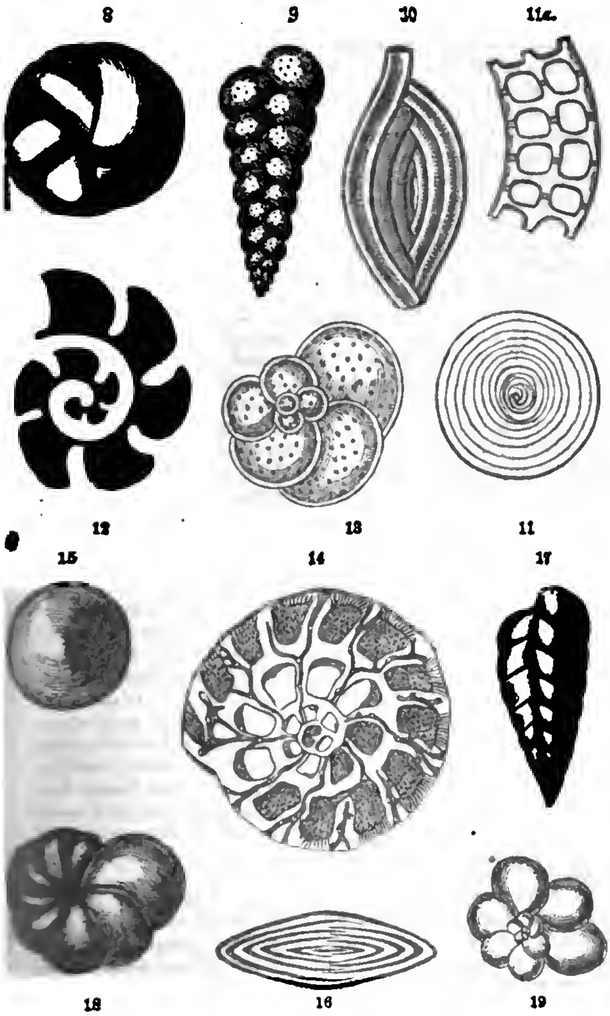
1. *Orbulina universa.* 2. *Lagena striata, var. perlucida.* 3. *Dentalina communis;* Chalk. 4. *Operculina.* 5. *Cristellaria Lyonsi;* Chalk. 6. *Faujasina.* 7. *Spirolina.*

In the *Entomostega* the shell is spiral as in the *Helicostega*, but instead of each chamber being equilateral, it has a larger and a smaller side, the position of which is alternately reversed as the segments are multiplied. (*Cassidulina*, *fig.* 8.)

In the *Enallostega* the new segments are arranged alternately on opposite sides of a central line, so as to form two parallel, non-spiral, alternating series (*Textilaria*, *fig.* 9), the segments being connected by a single orifice.

The *Agathistega* present an entirely different aspect, as well as structure, from the rest of the *Foraminifera*. They are much less transparent than the majority of the other orders, being composed of a material resembling white porcelain, and which presents a rich amber-brown hue when viewed by transmitted light. They are usually more or less oblong, and as each new segment is equal to the entire length of the shell, it follows that the terminal orifice presents itself alternately at its opposite extremities. Sometimes the new segments are spread out in one uniform plane (*Spiroloculina*, *fig.* 10), at other times each new segment instead of being exactly opposite its neighbour, is a little on one side of it; consequently the chain of segments is wound round the primary central one, as the thread is around a ball of worsted. (*Quinqueloculina*, *Triloculina*.)

In the great majority of the species the interior of each chamber is simple and undivided, but there are some forms, especially amongst the *Helicostega*, in which the newer and more external chambers are subdivided either by transverse pillars or by complete partitions perforated by one or more apertures, through which prolongations of the gelatinous substance unite the various segments of the soft animal. (*Orbiculina*, *fig.* 11.) Ordinarily but one such chain of communications exist (animal of *Rosalina*, *fig.* 12); but in the cases just referred to, there is a great increase in the number of such orifices, so that the septa become completely cribriform. The distribution of these apertures affects the gemmation or mode of growth, since it is through them that the new segments are successively formed, the gelatinous substance being extended by a process of budding or sprouting. An increase in the number of such orifices is most common where the consecutive segments present a rapid increase in their size. In the genus *Orbiculina*, this growth is sometimes so remarkable that the new segments soon form concentric circles, embracing all those previously formed. (*Orbiculina complanata*, *fig.* 11.) In such examples the connecting apertures are distributed round the entire periphery, and gemmation most probably takes place simultaneously through them all; so that the soft animal, if decalcified by an acid, would present a succession of rings, inclosing one another, and connected together by transverse radiating bars.



8. *Cassidulina*. 9. *Textilaria*. 10. *Spiroloculina*. 11. *Orbiculina complanata*. 11a. Part of two chambers of an *Orbiculina*. 12. Decalcified animal of a *Rosalina*. 13. *Rosalina globularis*, viewed as a transparent object showing the foramina. 14. Horizontal section of Fig. 6, showing the internal system of tubes. 15. Fossil *Nummulina*. 16. Vertical section of Fig. 15. 17. *Vernueuilina tricarinata*; from the Chalk. 18. *Rosalina Lornearia*; from the Chalk. 19. *Globigerina cretacea*; from the Chalk.

The memoirs of Professor Williamson have shown that the shell inclosing each new segment is at first very thin; but as additional calcareous chambers are formed, each such addition not only encases the new gemmation of the soft animal, but extends over all the exterior of the previously-formed shell. The exact way in which this is accomplished is doubtful; but it is probable that the soft animal has the power of diffusing itself over the shell, and depositing upon its surface additional layers of calcareous matter.

The foramina in the calcareous shell present various appearances. Sometimes they are large and conspicuous (*Rosalina globularis*, fig. 13); at others they are so small that their existence is only to be demonstrated by means of high magnifying powers. Through these foramina, long delicate processes of the soft animal, termed pseudopodia, are protruded. The exact use of these, whether for tactile, prehensile, and locomotive purposes, or for the imbibition of nutritive fluid, is not very clear; but they very probably fulfil in some degree each of these functions. They may be regarded as analogous to the prolongations which the Proteus Animalcule (*Amœba*) extends in various directions; only in the *Foraminifera* these organs are more delicate as well as more uniform in thickness than in the shell-less creature referred to.

Professor Williamson has also demonstrated the existence in several species of a curious system of interspaces and branching tubes, which ramify amongst the calcareous layers forming the walls of the shells. (Horizontal section of *Faujasina*, fig. 14.) These are especially obvious in the genera *Faujasina*, *Operculina*, and *Amphistegina*. The tubes open at the exterior of the shell, especially at the peripheral margins, either by a few large or by numerous small apertures. These canals are probably designed to admit water to the interior segments of the animal, with which they communicate through the minute foramina. In some cases the pseudopodia are protruded through such of these canals as are situated in the umbilical region; but these appear to be exceptional instances.

The relations of the *Foraminifera* to Palæontology render them interesting objects to the geologist. Many of the more recent calcareous strata chiefly owe their origin to the accumulation, through successive ages, of these minute atoms. The white chalk rocks are mainly composed of them; vast ranges of Tertiary strata present the same characteristic features; and though the older limestones have been so altered by pressure and chemical agents that their origin is less clear, there are many indications that they have primarily resembled the rocks of more recent age—an inference that is rendered probable by the great extent to which sediments now accumulating in the bottom of the sea are charged with these little organisms, and in some cases entirely composed of them.

The fossil *Foraminifera* are chiefly distinguishable from recent ones in the greater prevalence of specimens of comparatively large size. Though one recent species was brought from Borneo by Sir E. Belcher measuring more than two inches in diameter, the living forms usually range from the $\frac{1}{4}$th to the $\frac{1}{150}$th of an inch. But the Tertiary strata of the earth abound in examples of the fossil genus Nummulite (*Nummulina*, fig. 15), so called from their resemblance to coins, which vary from $\frac{1}{4}$th of an inch to the size of half-a-crown. These are often so abundant as to form mountain masses, extending through the Alps, Northern Italy, Greece, Syria, Egypt, and Northern India. The Mokkadam Mountains in Egypt, where the stone used in building the pyramids was obtained, chiefly consist of these Nummulites which are known to the natives by the name of Pharoah's Pence.

The structure of the Nummulites has been investigated by Messrs. Jolie and Leymerie, and especially by Dr. Carpenter, whilst the specific forms have been studied by M. D'Archiac. The genus belongs to the group of the order *Helicostega*, in which the outer convolutions completely embrace the earlier-formed ones; hence it is only by making microscopic sections, or thin slices, that their structure can be fully seen. When such a section is carried horizontally through the centre of the shell the segments present a spiral arrangement; they as well as the convolutions being remarkable for their small size and consequent great number. In other respects they present few or no essential differences distinguishing them from more recent forms. A still more curious genus, known by the name of *Orbitoides*, occurs in America, Switzerland, and India; in the former of which countries it appears largely to represent the Nummulites of the Old World. The labours of Dr. Carpenter have revealed a remarkable structure in this genus, but one that appears to have some recent representatives.

For *Fossil Foraminifera*, see FORAMINIFERA, FOSSIL, *S.* 1.

FORBES, EDWARD, a celebrated naturalist. He was born in 1815 in the Isle of Man, where his father was a banker. Without any one to direct his taste, he became a naturalist while yet a child. Nothing delighted him so much as to pick up the products of the shore of his native island, when as yet he could hardly read. By the time he was seven years of age he had collected a small museum. His first efforts at naming these objects were made through Turton's 'Translation of the Systema Naturæ of Linnæus.' Whilst yet a boy of twelve years old he had read Buckland's 'Reliquiæ Diluvianæ,' Parkinson's 'Organic Remains,' and Conybeare's 'Geology of England.' Such was the impression produced on his mind by the perusal of these works, that he ever afterwards attributed his taste for geological research to reading them. His first attempt at original work was the production of a 'Manual of British Natural History,' which, although it was never published, was the repository of many of his notes even to the close of his life. His habit of drawing the natural history objects which interested him, led him to think of painting as a profession, and with this object in view he studied for some time in the studio of the late Mr. Sass in Charlotte-street, London. This profession did not however comply with his restless desire to study the facts of natural history, and in 1832 he repaired to the University of Edinburgh with the object of studying medicine. Here under the teaching of Professors Jameson and Graham he first became acquainted with the true principles of natural science, and the views and objects of its cultivation. This fired his ambition to become himself an observer and add to the already accumulated stores of natural history facts. It was with this feeling that he started with a fellow-student on an excursion into Norway, where he made numerous observations on the rocks, plants, and *Mollusca* of the country, and afterwards published the result of his observations in a paper in the 'Magazine of Natural History,' entitled 'Notes of a Natural History Tour in Norway.'

At this early period of his natural history career he had recognised the importance of the dredge as an instrument of his research, and in his hands this simple instrument became as powerful a means of research as the telescope to the astronomer. With it he swept the bottom of the ocean, measured its depths by the character of its inhabitants, and discovered a law for the distribution of marine plants and animals in depth, as strict as the law which regulated their distribution on the altitude of mountains. His early papers, entitled 'Records of the Results of Dredging,' were published in the eighth and ninth volumes of the 'Magazine of Natural History.' Much of his student time was spent upon the sea in the neighbourhood of Edinburgh, and scarcely ever did he make a dredging excursion, so new was the operation to the naturalist, without adding some new form or species to his increasing collection of natural objects. His attention was not at all however exclusively confined to marine zoology. Plants were always favourite objects, and no student enjoyed more or profited more largely by the botanical excursions of the late Professor Graham. This habit of excursionising he held constituted a most important element in botanical study, at once invigorating the body, and giving the student a knowledge of the relation of plants to other objects which they could not otherwise obtain. Whilst he held the chair of botany at King's College, London, he never neglected periodical excursions with his students. He was mainly instrumental in 1836 in establishing the Botanical Society of Edinburgh, of which he became the foreign secretary. In 1837 he visited Paris, attended the lectures of the Professors there, and worked in the museum and collections in the Jardin des Plantes. In the same year he visited Algiers and the coasts of the Mediterranean. In 1838 he published an account of the 'Mollusca of the Isle of Man,' and in 1839 papers on the 'Land and Freshwater Mollusca of Algiers,' and on the 'Distribution of the Pulmonifera of Europe.' In these researches he was laying the foundation for the enlarged views, which he afterwards put forth, with regard to the distribution of the genera and species of animals and plants in time and space.

His papers from this time became very numerous. The materials he accumulated in his various excursions were truly astonishing, and he lived to publish but a comparatively small roportion of them.

In 1841 he published a 'History of British Star-Fishes,' containing accounts of several new species, with charming descriptions of the habits of these animals, and incidents connected with catching them, whilst the tail-pieces from his own pencil were worthy of a disciple of Bewick. In this year he accepted the appointment of naturalist to H.M.S. Beacon, commander Captain Graves, who was commissioned to bring from Lycia the marbles discovered by Sir Charles Fellows. Here new fields were opened up to him. For the first time the resources of a ship of war were placed at the disposal of a naturalist. The result of this voyage was the discovery of the great law, that among marine animals zones of depth corresponded to parallels of latitude. This law was announced at the meeting of the British Association held at Cork in 1843. The detailed results of this voyage were never given to the world, and Forbes always looked forward to the day when a little leisure would permit him to publish in detail his researches. But he had to work for his daily bread, and, to the disgrace of his country, no position was provided for him in which the necessary leisure could be found, till it was too late.

Other results came out of his Lycian excursions. In conjunction with Lieutenant, now Captain, Spratt, he published his travels in Lycia, with numerous illustrations made from his own drawings, and notes on the natural history of the Ægean.

It was in Lycia that he contracted the same form of remittent fever which killed one of his companions, the Rev. Mr. Daniell, and from the effects of which he suffered to the day of his death.

Whilst away in the Ægean, he was appointed to the Professorship of Botany in King's College, London, vacated by the death of Mr. David Don. Although he had resolved on a visit to Egypt and a dredging excursion to the Red Sea, the offer of a chair in London was too much in accordance with his tastes to refuse. He now deliberately gave up the medical profession, and became a naturalist for the rest of his life. He gave his first lecture in May 1844, and in the same year he was appointed assistant secretary to the Zoological Society. Both situations contributed to the development of his genius, for whilst the professorship compelled him to arrange and systematise his knowledge, and developed his power of communicating its results, the secretaryship afforded him a means of extending his acquaintance with fossils, and the relations of extinct with recent forms of both animals and plants. These offices however preceded one more important still, that of palæontologist to the Geological Society of Great Britain. When the Museum of Economic Geology was removed to Jermyn-street, and the School of Mines founded, he was appointed professor of natural history. Although prevented by these appointments from publishing all he had already stored up, he added here fresh stores to his stock of knowledge; and numerous memoirs and papers in the Natural History Journals, the Proceedings of the Zoological Society, and the Transactions of the Geological Society, attest his great observing powers and unwearied industry. One of the most important of these papers is entitled 'On the connection between the distribution of the existing Fauna and Flora of the British Isles, and the geological changes which have affected their area.' This paper attempts to explain the distribution of the plants and animals of the British Islands, on the hypothesis that they were all diffused from a common centre, and that consequently they must have been disseminated when these islands were continuous with those countries where the identical species are found. He then brings forward geological evidence to support his assertions, and even goes so far as to point out the fact, that at one time, and that recently, dry ground existed between the south-western portions of the British Islands and America.

In 1854 Professor Forbes was elected president of the Geological Society. In the same year he accepted the chair of Natural History in the University of Edinburgh. He was president of the geological section of the British Association which met at Liverpool in September. He died on the 18th of November in the same year. The Edinburgh chair was the object of his highest ambition. The increasing years of Professor Jameson rendered it not improbable even when he was a student that he might one day hope to fill this honourable post. He commenced the duties of his new position with his usual ardour, laid down a course of action which would have required years of development, but he had barely time to deliver a preliminary summer course before he was seized with a disease of the kidneys which proved fatal in a few days.

Besides the works to which reference is made above, he was the associate of Mr. Hanley in a great work on the 'History of British Mollusca,' which was published in parts, and completed in 1853. This work is one of the most complete and exhaustive on the subject of our native Mollusca, and all the descriptions were written by Forbes. He contributed several valuable papers and maps on the distribution of animals and plants to the last edition of Johnston's 'Physical Atlas.' He also indulged in general literature, and the world was somewhat surprised after his decease to find that for some years he had been a contributor to the review department of the 'Literary Gazette.' His papers were collected together by the editor, and published under the title of 'Literary Papers by the late Edward Forbes.' The third volume of the 'Bibliographia Geologia et Zoologia' of Agassiz and Strickland, published by the Ray Society in 1850, contains a list of eighty-nine papers and works supplied by the author himself, and arranged in chronological order. His contributions to natural history science were perhaps more numerous during the last four years of his life than during any former period of the same length. Few men have laboured more assiduously in the path of natural science, or produced a greater impression on the current thought of those who cultivated the same branches of knowledge as himself; and the time has not yet arrived when a clear estimate can be made of the influence he has exerted upon the time in which he lived.

FORDINGBRIDGE. [HAMPSHIRE.]

FORESTALLING. This offence, long obsolete, has at length, with others of the same character, ceased to exist. (7 & 8 Vict. c. 24.)

FORGET-ME-NOT. [MYOSOTIS, *S.* 1.]

FORMICA, a genus of Insects belonging to the family *Formicidæ*. It is distinguished by having the foot-stalk of the abdomen composed of a single joint, the mandibles triangular, and denticulated at the edge. The females are destitute of a sting. This genus comprises about a dozen British species, the largest of which is the Hill-Ant or Horse-Ant, *F. rufa*. The neuters in this species are about one-third of an inch long, of a black colour, with the thorax, abdominal scale, and a large part of the head, red. It makes its large conical nest in the open ground, in woods, &c., amassing together large quantities of sticks, straws, &c. For a description of these nests see ANT.

F. sanguinea is of a blood-red colour, with the eyes and abdomen black, and the wings dusky at the base. The neuter is similarly coloured, except that the head is darker. The male is black, with red legs. This species burrows in wood, and is one of those which steals the young of other species, rearing them to perform the duties of the nest. Two of the species subject to these marauders are *F. cunicularia* and *F. fusca*, both of which are inhabitants of this country. The latter species is of a shining black colour, with a slight ashy tinge; its form is rather long, and it is nearly smooth; the three or four basal joints of the antennæ are of a red colour, as are also the legs; the abdominal scale is large and triangular; and the ocelli are distinct. It establishes its nest under stones, moss, &c., and at the foot of trees, the nest being entirely under ground.

Among the exotic species of this genus are to be found many which are extremely injurious or annoying in their habits. Of these the Sugar-Ant of the West Indies is perhaps the most extensively prejudicial. *F. saccharivora*, as it is called, establishes its nest at the root of sugar-canes, lime-trees, and lemon-trees, where it loosens the earth so that the trees are either blown down by the violent gales, or so completely deprived of nourishment at the roots that they soon die. Some years ago the injuries committed by this insect were so great that a reward of 20,000*l.* was offered by the planters to any one who should discover an effectual mode of destroying them, yet nothing could be found to stay their ravages. The aid of fire was even resorted to in vain; the insects rushed into the flames in such myriads as to extinguish it. Heavy torrents of rain at last effected their destruction.

F. indefessa, another exotic species, is described by Colonel Sykes as being an extraordinary instance of the operations of instinct in so low a form of animal life. The fondness of these insects for sweet substances is very great, and their attacks on such things were resisted in every possible manner, yet although the table, on which the confectionary and sweets were, was placed with its legs in water and removed a short distance from the wall, they succeeded in reaching them, to the great astonishment of all, until the mode of access was discovered. Colonel Sykes says, "I observed an ant upon the wall about a foot above the level of the sweets; it fell, and instead of passing between the wall and the table and alighting upon the ground it fell upon the table." Others followed its example with similar success; and it was no longer a matter for doubt as to how they continued to swarm in such numbers about their favourite food, however carefully guarded.

FORMICIDÆ, an extensive family of Hymenopterous insects, belonging to the section *Aculeata*, and to the subsection *Heterogyna* of Latreille, comprising the Linnæan genus *Formica*, or the numerous tribes of Ants. The family is distinguished by the wingless state of their abortive females, by the great length of the basal joint of the antennæ in the females and the neuters, in which they are elbowed at the extremity of this joint, and by the first or the first and second joints of the abdomen being knotted; the upper lip of the neuters is large, horny, and perpendicular, falling between the jaws; the eyes are rounded, or oval and entire; the jaws are large in many of the species, the form of these organs varying greatly in many of the species. In their structural character the *Formicidæ* resemble the *Tiphiæ* and *Doryli* belonging to the section of the Sand-Wasps. The neuters are smaller than the males, and these are smaller than the females; the abdomen in the first and last of these sexes is composed of six segments, in the male of seven. The females and neuters are furnished with a sting in many of the species. Those species which have stings emit an irritating fluid into the wounds which they make, while the stingless species discharge a red transparent fluid on to the skin, causing painful blisters.

The various genera of this family, according to Latreille, are: — *Formica*, *Polyergus*, *Ponera*, *Myrmica*, and *Atta*. This last genus differs from *Myrmica* only in having very short palpi; the head of the workers is generally very thick. *Acephalota* is the Visiting Ant of the West Indies.

FORMYLE. [CHEMISTRY, *S.* 2.]

FORRES. [ELGINSHIRE.]

FORSTER, FRANK, civil engineer, was born in the year 1800, near Newcastle-upon-Tyne, and at an early age was put to learn the business of a colliery viewer, or mining agent. After some years, he was intrusted with the management of mining works near Swansea; and he was afterwards similarly engaged in Lancashire. Whilst thus occupied, about the year 1830, he became acquainted with Mr. Robert Stephenson, under whom he was ultimately employed in the superintendence of some of the most difficult works on the London and Birmingham railway, inclusive of the Kilsby Tunnel and the Blisworth Cutting, and somewhat later he was resident engineer of the portion of the Chester and Holyhead railway, from near Conway to Holyhead, including the masonry of the Britannia Bridge, and difficult works in sea-walls and tunnels along the line. On the formation of the Metropolitan Commission of Sewers, Mr. Forster was appointed chief engineer, and was instructed to furnish a general scheme of London sewerage, for which many plans had been sent in to an invitation some time previously. He very soon suffered from the effects of the arduous duties thrown upon him, and which were rendered more difficult by numerous contending opinions and interests. He himself was freely animadverted upon by the press, and he was at length compelled to resign his appointment, and died suddenly a few weeks afterwards, on the 13th of April 1852, in his fifty-second year. His reports and plans, with reference to the drainage of the north of London remain, and are understood to have formed the basis of the schemes now under consideration, and in which a partial commencement of work has been made.

FORTOUL, HIPPOLYTE, late Minister of Public Instruction in France, was born in 1811. He commenced active life as a literary man by contributions to the 'National,' 'L'Artiste,' and other periodicals. In the earlier part of his career he professed republicanism and St. Simonianism, and was befriended by Béranger the poet, of whom, in 1830, he published a biography. He was a contributor to the 'Revue de Paris,' and was an unsuccessful competitor for the editorship of the 'Revue des Deux Mondes.' Meantime, by laborious private study, he step by step attained to university honours. He was made Professor of Literature in the university of Toulouse, where he distinguished himself as a lecturer, and was afterwards recompensed for his services by being appointed Dean of the Faculty of Art. He was also admitted into the French Academy in the section of Belles

Lettres. After the revolution of 1848 he was elected a member of the French National Assembly, in which he spoke frequently, and obtained the favour of the Prince President. Immediately after the coup d'état he was appointed, December 3, 1851, Ministre d'Instruction Publique et des Cultes, and was one of the six ministers who signed the decree for the confiscation of the estates of the house of Orleans. He made himself extremely unpopular with the literary classes of France by the decision and energy with which he carried out the imperial system of restriction of the press. He had gone to Ems for the benefit of his health, when he died suddenly as he was conversing with his colleague M. Magne, on the 7th of July 1856. By a decree of the Emperor he was buried at the public expense, with the firing of guns, processions, and other honours, on the 12th of July, in the church of St. Thomas d'Acquin, Paris.

FORTROSE. [Ross and Cromarty.]

FOSSORES. [Hymenoptera.]

FOSTER, JOHN, architect, was born about the year 1786 or 1787, and was the son of a builder of the same name, who carried on a large business in Liverpool where he also acted as architect and surveyor to the corporation, and as engineer to the docks. Foster junior was the second of six sons. According to one account furnished to us, he became a pupil of James Wyatt; and from other information it would seem that he was also employed under Jeffry Wyatt, afterwards Sir Jeffry Wyattville. In 1809 he went abroad; was during some time with Mr. Cockerell at Ægina and Phigaleia; and was concerned in the excavation of the Æginetan and Phigaleian marbles. The portico at Ægina—that of the temple of Jupiter Panhellenius—became a favourite model with him in his later practice as an architect. He did not return to England till 1816 or 1817, having in the meanwhile, at Smyrna, married a Greek lady of that place. However, about the time mentioned, he settled at Liverpool; and for some years afterwards carried on the building business, in partnership with a brother, under the firm of John Foster and Co.—his father having withdrawn, but retaining his professional appointments with the corporation and dock trustees. It does not appear that the numerous buildings in which Foster, senior, was concerned, were erected from his own designs; Foster, junior, however, had received better education in art; and for some time, besides his building trade, had considerable practice as an architect. St. John's Market, in Liverpool, a covered area of little short of two acres, and one of the earliest works of its character, was commenced in 1820, "from the designs of Mr. John Foster, the corporation-surveyor of the day, and was completed and opened in 1823." ('The Architectural History of Liverpool,' paper by Mr. J. A. Picton, read at the Liverpool Architectural Society; see 'The Builder,' vol. xii. p. 231.) It is probable however that such architectural design as there is in the work was due to the younger Foster, who with his partner carried on the erection of the principal Liverpool buildings. But Foster, senior, having been compelled by ill-health to resign his several appointments, Foster junior was appointed in February 1824 corporation architect and surveyor, receiving a salary of 1000*l.* per annum, conditional upon withdrawal from the building business. When the Municipal Reform Bill came into operation in June 1835, much of the influence of the Foster family was brought to an end, and John Foster retired with a compensation of 500*l.* per annum, and did not afterwards follow his profession.

Few architects have had opportunities similar to those of John Foster. It may however be questioned whether he succeeded in turning these to proper account. That he had acquired a large stock of architectural knowledge cannot be doubted; but, like many of his contemporaries, he missed the special beauty of *art* in architecture in his manner of using the Greek models; and perhaps there is no town which now so well affords illustrations of two different systems of practice, as does Liverpool in some of the works of Foster and the great work of Elmes. [Elmes, Harvey Lonsdale, *S.* 2.]

Amongst Foster's works is the church of St. Michael, Pitt-street, commenced in 1816, though not completed till 1826; it is of exceptional character, having a portico and steeple obviously adapted from the church of St. Martin's-in-the-Fields in the metropolis, but is by many considered his best work. The church for the School of the Blind first erected in Hotham-street, and since removed and re-erected in Hardman-street, is described as originally presenting a somewhat imposing effect in its Grecian Doric columns. This has been impaired by alterations in the removal. The small chapel of St. James's cemetery in the same style, has a better effect from its site near the edge of the rock,—in that particular really adopting certain good Greek principles of art. The Custom House, though a very large building, is of little merit in point of art. It has a portico, as it has been pointedly remarked, advanced from each of its sides except that on which the sun shines. "There are no indications," says Mr. Picton, "such as are stamped on every line in St. George's Hall, of careful study and creative power." The screen of the Railway Station in Lime-street, built about the year 1835, is of more florid character. It has attached Corinthian columns, and is not without merit.

Foster died on the 21st of August 1846, after a long and painful illness. He was a Fellow of the Royal Society; was undoubtedly possessed of great architectural knowledge; holds an important place in the recent history of architecture, but perhaps deserves commendation for his general good qualities, rather than for high powers as an *artist*-architect.

FOULSHAM. [Norfolk.]

FOX-TAIL-GRASS. [Alopecurus.]

FRANCE. The 86 departments into which France is divided are subdivided into 363 arrondissements, 2847 cantons, and 36,835 communes, which, except that they have a corporate form of government, do not generally differ much in extent from parishes. Each department is administered by a prefect; each arrondissement by a sub-prefect; and each commune by a mayor (maire). In each department there are also several officers connected with the arrangement and receipt of taxes, an engineer of roads and bridges, a military sub-intendant, and a company of gensdarmes. In the chief towns of departments courts of assize are held; each arrondissement has its tribunal of first instance, and each canton a judge of the peace. The more important departmental capitals are seats of high courts of justice and appeal, and head quarters of Military Divisions.

In the following table the area and population of each of the 86 departments is given as returned in the official census of 1851:—

Department.	Area in Sq. Miles.	Population in 1851.
Ain	2,242·0	372,939
Aisne	2,843·0	558,989
Allier	2,821·8	336,758
Alpes (Basses-)	2,679·9	152,070
Alpes (Hautes-)	2,186·8	132,038
Ardèche	2,133·8	386,505

Yonne	2,868·0	381,133
Total	204,952·9	35,781,628

According to the census of 1851, the population of France was divided into—Roman Catholics, 34,931,032; Réformés, 280,507; Luthériens, 267,825; Jews, 73,995; other religions, 26,328. Of the rest the religion was unknown.

The population of France at the commencement of the 18th century was about 19,669,320, exclusive of Corsica and part of Lorraine, which were not then united to France. In the year 1762 the population had increased to 21,769,163, inclusive of Corsica and the whole of Lorraine. In 1784 it had further increased to 24,800,000.

The population, according to the different census returns of the present century, has been stated to be as follows:—

1801	27,349,003	1836	33,540,910
1811	29,092,734	1841	34,230,178
1821	30,461,875	1846	35,401,761
1831	32,569,223	1851	35,781,628

The population of the French colonies in 1851 was as follows:—

	Pop. 1851.
Asia.	
Pondichérie	96,712
Karikal	59,872
Yanaon	6,464
Maké	3,419
Chandernagore	31,396
Total	197,863
Africa.	
Algérie	2,880,383
(In 1857 the Europeans were 167,670.)	
Senegal and Dependencies (1857)	29,682
Gorée and Dependencies	3,197
Réunion (Ile de Bourbon)	10,826

Guyane	17,836
St. Pierre and Miquelon	2,226
Total	276,563
Australasia.	
Marquises	20,000
Nouvelle Calédonie	60,000
Total	80,000

According to the budget of 1858, the total receipts of the public revenue of France amounted to 1,717,156,190 francs (about 68,686,000*l.*); the expenditure to 1,737,115,171 francs, the expenditure thus exceeding the income by 19,958,881 francs.

In 1856, the entire army of France amounted to 577,536 men, of whom 310,347 were in France, 64,235 in Africa, 197,597 not then returned from the Russian war in the East, and 5357 in Italy.

In 1857, the total number of vessels comprising the navy of France amounted to 353, of which there were 10 of 120 guns, 10 of 100 guns, 15 of 90 guns, 5 of 80 guns, 17 of 60 guns, 17 of 50 guns, 16 of 40 guns, &c.

The constitutional monarchy and representative government which had prevailed in France under King Louis Philippe, the head of the younger branch of the Bourbons, were abolished by the republican revolution of 1848. A republic in form, governed by a president and a national assembly, the members of which were elected by ballot, with a suffrage all but universal, succeeded.

On December 2, 1851, Prince Louis Napoleon Bonaparte, President of the Republic, issued a decree dissolving the Legislative Assembly, establishing universal suffrage (the assembly had considerably restricted the suffrage), proposing a president for ten years, and a second chamber, or senate. On the 20th and 21st of December, the French people, by 7,439,216 affirmative votes against 640,737 negative ones, adopted a 'plebiscite,' or decree of the people, maintaining the authority of Louis Napoleon Bonaparte, and delegating to him the powers necessary for establishing a constitution on the bases proposed in the above proclamation. The power thus conferred upon the President resulted in the important state paper issued January 15, 1852, which contains the constitution under which France has since been governed.

According to this proclamation the President, while he retained that title, assumed more than royal authority. He is responsible to the people alone who had elected him, and not to a national assembly: the command of the land and sea forces, the exclusive initiation of new laws, the right to declare the state of siege, were among his leading attributes. A Senate was appointed, whose number was not to exceed 150, the members to be named for life by the President, who may also grant them salaries. A lower chamber, called the Legislative Body, consists of 261 members, one for every 35,000 electors, and chosen for ten years by universal suffrage, but without the ballot. The sittings of both chambers to be private; official reports only of the proceedings to be published. No member of either chamber has the power to originate any law; if amendments are adopted they must be sent to the council of state, and cannot be discussed if not also adopted by this body. The President convokes, adjourns, prorogues, and dissolves the Legislative Body. In case of a dissolution a new one is to be convoked within six months. The session of the chambers to last three months.

A council of state, composed of 40 or 50 salaried members, nominated and presided over by the President, draws up the projects of all laws. The Senate is not to be transformed into a court of justice. For crimes against the chief of the state and the public safety a high court (as above explained) is appointed. Ministers cannot be members of the legislature. Petitions may be addressed to the Senate, but none to the Legislative Body. The mayors of communes are appointed by the executive.

In this draught of the constitution the name of Republic was retained, and the title of President; but on December 2, 1852, in accordance with a decree of the Senate dated November 7, 1852, and a plebiscite carried by 7,839,552 votes against 254,401, the name of the government was changed, the Empire was re-established, and Louis Napoleon Bonaparte became Emperor of the French under the title of Napoleon III., the throne being hereditary to his legitimate male descendants, failing which, the succession rests in Prince Jerome Napoleon Bonaparte and his direct legitimate descendants in the male line by order of primogeniture. Since the establishment of the Empire some modifications have been made.

FRANKLIN, REAR-ADMIRAL SIR JOHN, was born in 1786 at Spilsby in Lincolnshire. His ancestors were substantial yeomen, and his father inherited an estate in that conuty, which though small was sufficient to give him local rank as a landlord. Unhappily, however, the property was so embarrassed that he was obliged to sell it, and he became entirely dependent on his commercial profits for the maintenance and education of twelve children, some of whom, besides the subject of this memoir, attained considerable rank and reputation. One, Sir Willingham Franklin, became judge at Madras; and another, Major James Franklin of the Bengal service, was highly distinguished for his scientific acquirements, which procured him the Fellowship of the Royal Society.

John, the youngest son, early evinced a great predilection for a sea-life. There is a story told of him which seems to rest on more than mere traditionary evidence. When a school-boy at Louth in Lincolnshire, he availed himself of a holiday to walk to the coast, a distance of twelve miles, in order to see the ocean, on which he gazed with wonder and delight for many hours. His father, who was extremely desirous that his son should follow any other profession than that of a sailor, conceived that by sending him in a small merchant ship to Lisbon, the discomforts of the voyage would effectually cure the lad of his love for the sea, but it had a totally different effect; and accordingly perceiving that he was bent on a naval profession, he was entered as midshipman on board the Polyphemus at the age of fourteen, and was in that ship in the celebrated battle of Copenhagen, from which he escaped without a wound, whilst a brother midshipman was killed at his side.

He next joined the Investigator, under the command of Captain Flinders, his cousin by marriage, with whom he sailed on a voyage of discovery to the coasts of Australia. During this expedition, which combined investigations into natural history with geographical discovery, young Franklin had abundant opportunities—which were not neglected—of acquiring much valuable knowledge. Besides sound practical seamanship he learned the more theoretical and difficult branches of nautical surveying, and was always one of the midshipmen selected to attend the Captain whenever he made excursions in boats, or visited the shore for scientific purposes. After some time the Investigator being unfit for further service, the officers were ordered home in the Porpoise. In this ship he was wrecked on a coral reef off the Australian coast, and with 94 persons spent nearly two months on a narrow sandbank only a few feet above the sea level, whilst Captain Flinders proceeded to Port Jackson for relief.

Having fortunately escaped the fate of his chief, who on his voyage home was unjustly detained as a prisoner in Mauritius, Franklin proceeded to Canton with Captain Fowler, who had charge of the Porpoise, and embarked on board the Earl Camden, commanded by Sir Nathaniel Dance, for the purpose of returning to England. This ship and other Indiamen were attacked by the French admiral, Linois, in the Straits of Malacca, but Sir Nathaniel Dance gallantly defeated his antagonist. During the engagement Franklin acted as signal midshipman, and was of considerable service in other ways.

Shortly after his arrival in England he was appointed to the Bellerophon, Captain Laing, and had the charge on board that ship of the signals during the memorable battle of Trafalgar. It is recorded that he performed this important duty with singular coolness and intrepidity, although many of his brother officers were shot around him. Indeed, out of forty companions, only seven, of whom he was one, came out of the battle unscathed. He now served for two years with the Channel fleet and Rochefort squadron, and then joined the Bedford, in which ship he was present at the blockade of Flushing,—off the coast of Portugal,—on the Brazil station, and at the attack of New Orleans in 1814. Here he greatly distinguished himself in a gun-boat action, in the course of which he received a slight wound. For his gallant conduct on this occasion he was promoted to the rank of lieutenant.

Peace having been established, the attention of Government was turned to Arctic discovery, which had been interrupted during the long war; and in 1818 commenced the brilliant and remarkable series of Arctic expeditions with which Franklin's name is so honourably associated. The scientific knowledge he had acquired when serving under Captain Flinders, was now of great benefit to him, and Sir Joseph Banks, who at that time presided over the Royal Society, and who took great interest in Arctic matters, recommended him to the Admiralty as a proper officer to be employed in Arctic exploration. Accordingly Franklin commenced his Arctic career by commanding the Trent, which ship, with the Dorothea, commanded by Captain Buchan, formed an expedition appointed to sail from Spitzbergen across the supposed Polar Sea.

Unhappily the Dorothea in lat. 80° 34′ N. became disabled, but Lieutenant Franklin, with a gallant disregard of danger, earnestly requested to be allowed to proceed alone in the execution of the service. The nature of Captain Buchan's instructions prevented this, and the ships returned to England.

Franklin's conduct and aptitude for the peculiar service of Arctic enterprise brought him into prominent notice, and he was intrusted in 1819 with the command of his first overland expedition for the purpose of tracing the coast-line of the North American continent, at that time very imperfectly known. Descending the Coppermine River the party surveyed a large portion of the coast east of the mouth of that river, during which they underwent frightful privations and trials, the history of which, as told in Franklin's own manly and unaffected language, is undoubtedly one of the noblest pictures of heroic exertion and patient endurance ever presented for our admiration. The results of the labours of Franklin and of his distinguished associate Sir John Richardson, in this memorable journey, deserve more full and fitting recognition than can be attempted on this occasion: the party travelled 5550 miles, mostly over ground previously unknown, and large acquisitions were gained for science by the careful study of the physical geography and natural productions of the North American continent.

For his services on this occasion he was promoted to the rank of captain, having while absent risen from lieutenant to commander. In 1823 he was elected a Fellow of the Royal Society, and served on the council of that body.

Undeterred by the appalling sufferings he had already undergone, Franklin, although lately united in marriage to the youngest daughter of William Porden, Esq., again volunteered his services for Arctic exploration. These were accepted, and in 1825 he left England on his second land exploration. Descending the Mackenzie River, he traced the North American coast from the mouth of the Coppermine River to the 150th meridian. For these fresh services he received the honour of knighthood, and had the degree of D.C.L. conferred on him by the University of Oxford. He also received the Gold Medal from the French Geographical Society, and was elected a Corresponding Member of the Institute of France.

Sir John Franklin now remained at home two years, when he was appointed to the Rainbow, and served in that ship in the Mediterranean for three years. He was chiefly employed in the Greek waters, and had the good fortune to be of considerable service in the delicate adjustment of complicated diplomatic relations. It is worthy of remark, as illustrative of the amiability of Franklin's character, that the sailors who then served under him named the ship the 'Celestial Rainbow' and 'Franklin's Paradise.' During this period, as indeed on all other occasions, he eagerly availed himself of every opportunity, not only to improve his knowledge of geology, to which science he was greatly attached, but also used every exertion to add to the museum of the Geological Society, and to the private collections of scientific men.

After a brief period of rest which followed his services in the Mediterranean, he applied to Lord Glenelg for employment under the Colonial department, and his lordship in a very complimentary manner offered him the important post of Governor of Van Diemen's Land, which he held for seven years. During this time that colony received convicts, New South Wales having ceased to be a penal settlement. This rendered Sir John Franklin's position most onerous and trying, but he acquitted himself so entirely to the satisfaction of the colonists, that in grateful remembrance of his government, which was marked by the establishment of a college and a philosophical society, they, unsolicited, subscribed 1600*l.* towards the expenses of a private expedition fitted out for his rescue.

It might be supposed that, after so long a period of laborious services, Sir John Franklin would have desired repose, particularly as he had now attained high renown;

but his wishes still pointed towards active employment, and consequently, when the Arctic expedition was contemplated, which has cost him his life, he was willing to take the command, when the Admiralty were of opinion that he was the officer best fitted to act as chief. That expedition was originated by the late Sir John Barrow, secretary to the Admiralty, who submitted a plan for the discovery of the North-West Passage to government, which, after having been referred to the council of the Royal Society was adopted.

The expedition, consisting of the Erebus and Terror, which had recently returned from a voyage of discovery in the Antarctic Sea, left England in May 1845. Unhappily its history and fate are still veiled in obscurity; this however, we know, that everything was done to render it efficient; that the officers under Sir John Franklin were men of experience and zeal, and that the last accounts received from them represent their commander animated by all the ardour and spirit which characterised his early Arctic exertions.

It would have been unjust to have expected less from such a man, and as his instructions contained the usual discretionary power given in these documents, there is too much reason to fear that he fell a victim to his daring attempts to achieve success. It will ever be a matter of regret, though it cannot be of surprise, that the discovery of traces of the Erebus and Terror at the entrance of Wellington Channel caused the search for our countrymen to be directed principally to the north and west of Barrow's Straits; because, although the information brought home by Dr. Rae in 1854, to the effect that Esquimaux had seen the bodies of forty white men in the spring of 1850 on what is supposed to be Montreal Island, at the mouth of the Fish River, cannot be regarded as trustworthy; yet the relics of the expedition procured by Mr. Anderson and Dr. Rae suffice to prove that Franklin's ships must have been beset within an area comprised within the 70th and 72nd parallels of latitude and the 97th and 100th meridians.

Another expedition, and doubtless the last, has been sent out by Lady Franklin, in order, if possible, to dissipate the mystery which still shrouds the fate of the Erebus and Terror, and their crews. The expedition left Aberdeen, July 1, 1857, in the Fox, a screw yacht, under the command of the distinguished arctic explorer, Captain M'Clintock.

FRANZEN, FRANS-MICHAEL, an eminent modern Swedish poet and prosaist, was born on the 9th of February, 1772, at Uleaborg, in Finland, at that time a province of the Swedish crown. Finland, both before and since its compulsory union with Russia, has been fruitful of poets to Sweden, though possessed of a language of its own of an entirely different character. Runeberg, at present the head of Swedish poetical literature, is a Finn, and the first effort of Franzén that attracted attention was his poetical eulogy on Creutz, also a Finn, who combined the unusual characters of a poet and a diplomatist, and passed much of his life as ambassador at Paris. The 'Atis and Camilla' of Creutz had introduced an ease and elegance, before unknown, into Swedish poetry, and the eulogy on its author by Franzén produced a commotion in the literary world of Stockholm, by the originality and vigour of its tone, which was in strong contrast to that of the school of Leopold, then dominant, who was an ingenious imitator of French models. The eulogy obtained, in spite of its originality, the great prize of the Swedish Academy. This was in 1794, at which time, and for nine years previous, Franzén had been a student at the Finnish university of Abo. In the following year he set out on a tour to Denmark, Germany, France, and England, and chanced to be a witness of the great fire of Copenhagen, which destroyed a third part of the city. In Paris he ventured on a piece of composition in French verse, which was printed in a French periodical, and which he reprinted thirty years afterwards in the introduction to his Swedish poem, founded on a tale of the revolution, 'Julie de St. Julien.' During his absence he was elected librarian to the University of Abo, and afterwards professor of literary history. After the transfer of Finland to Russia by the war of 1809, he resolved to remove to Sweden, where he remained for the rest of his life. At first he officiated as pastor of Kumla, in the diocese of Strengnäs, a parish remote from the capital, but he was afterwards minister of the church of Clara at Stockholm, where the poet Choræus had preceded him; and in 1834 he was chosen Bishop of Hernosand. While still a resident in Finland, he had been chosen one of the eighteen of the Swedish Academy; a distinction of the same importance for a literary man in Sweden, as to be a member of the Royal Academy here for an artist in England. In 1824 he became its secretary, and remained so for ten years, during which it was part of his duty to write a series of biographical notices, which were much admired for their literary merits. He appears to have resigned the secretaryship on his elevation to the bishopric, which he held till his death in October, 1847. Laing in his travels in Sweden gives an account of his meeting with Bishop Franzén on board of a steam-boat, when going on a visit to his northern diocese, and speaks of the general affection and veneration with which he was regarded.

Archbishop Wallin, Bishop Tegnér, and Bishop Franzén were three of the most distinguished poets of Sweden in the present century. They were all three associated in the new Swedish version of the Psalms, to produce which a commission was appointed in 1814, and respecting the excellence of which there is but one voice, it being generally regarded as the best in Europe. It is singular that so little reference has been made to this fact, in the frequent discussions that have taken place on the expediency of obtaining a new poetical version of the Psalms in English. The poetical works of Franzén were collected in five volumes, at Örebro in 1824 and subsequent years. The most successful are decidedly the songs and shorter pieces, many of the songs enjoying a high popularity both in Sweden and Finland. Their prevailing character is sweetness. The longer narrative poems, one of which 'Sten Sture,' extends to twenty cantos and fills an octavo volume, are of a somewhat dry simplicity, both of style and incident, approaching far too nearly to the level of prose. Franzén was regarded by Swedish writers as belonging to neither of the two rival schools of poetry in his time and country, the 'Academic' or Classical, and the 'Phosphoristic' or Romantic, but as standing at the head of a third or neutral party. His sermons, of which four volumes were published, are unusually animated; he was also the author of some controversial writings against the doctrines of the Rationalists, called forth by the controversy respecting Strauss's 'Life of Jesus.' The biographical sketches from his pen already mentioned, have been collected under the title of 'Minnesteckningar.' In the introductory speech before the Swedish Academy prefixed to them, the reader remarks a tone of courtly deference in speaking of Charles XIII., and even of the Russian government, to avoid living under which he left Finland, the absence of which would perhaps have inspired a higher notion of the dignity of Franzén's character.

FRASERBURGH. [ABERDEENSHIRE, S. 1.]

FRATERCULA. [AUK.]

FRINGILLA, a genus of Birds belonging to the order *Fringillidæ* and the division *Insessores*. The beak is straight, longer than deep, conic, and pointed; mandibles nearly equal, cutting edges entire, forming a straight commissure; nostrils basal, lateral, oval, partly hidden by the frontal plumes. Wings with the first quill-feather longer than the fifth, but a little shorter than the second or third, which are equal, and the longest in the wing. Legs with the tarsi of moderate length; toes divided, and adapted for hopping and perching; claws curved and sharp.

F. cœlebs, the Chaffinch. [CHAFFINCH.]

F. montifringilla, the Mountain Finch, Brambling, or Bramble Finch. This bird is a visiter to this country only in winter, coming to us from the north, but at different times, according to the temperature of the country from which it emigrates. They have not been known to breed in any part of this country; those kept in confinement under the most favourable circumstances have never done so. It is not an uncommon bird in Denmark. Mr. Hewitson saw them at one place in the southern part of Norway, where they were breeding. It is described as building in fir-trees; the nest formed of moss, and lined with wool and feathers; the eggs four or five in number, white, tinged with yellow, and spotted with dark red, like those of a chaffinch. The call-note of this bird is a single monotonous chirp.

FRUIT. In botanical language, that part of the plant which in the early stages of its growth is called the Pistil, and which contains the ovules or seed-buds, becomes the Fruit, when the ovules by the presence of the embryo, are changed into seeds. The Style and Stigma, when they still remain, retain their names, but the Germen is called the Pericarp. In this sense, there are of course some plants which have no fruit, because they are not provided with a Germen; these therefore have naked Seed-Buds, or Ovules, and also naked Seeds (Semina nuda); such as *Coniferæ*, *Cycadaceæ*, and *Loranthaceæ*. But there are some plants in which the germen is easily destroyed, so that the seed-bud is developed without an envelope to the seed: these, in order to distinguish them from the former, are termed Semina denudata, as in *Leontice* and *Peliosanthes*.

Fruits may be divided, according to the analogy of the flower, into Naked and Covered (Fructus nudus et Fructus tectus), according as the germen only appears to exist, as in *Lilium*, or as this is surrounded by other floral parts, as in *Nicandra*. When one pistil is developed into a fruit it is called a Simple Fruit (Fructus simplex), as in *Nigella;* when several, a compound or Multiple Fruit (Fructus multiplex), as in *Ranunculus*.

The parts of the Fruit are the Pericarp, the Spermophore, the Funiculus, and the Pulp.

The Pericarp is the transformed germen; sometimes it is united with the other persistent parts of the pistil, style, and stigma. The latter are seldom of particular importance; and all that need be said of them is that they are sometimes retained, as in *Papaver*, or they are more developed, as in *Pulsatilla*. The forms of the pericarp are exceedingly diversified, but admit of no general definition: they frequently exhibit hairs, prickles, protuberances, and membranous expansions (alæ), prominent ribs (costæ or juga), and pits in their interspaces (valleculæ), &c. The pericarp essentially determines the varied appearances of the fruit, by its diversity of structure. The parenchyma of the germen is developed in various ways. In the simplest cases, we find in the mature pericarp only the epidermis of both surfaces, and between these a uniform layer of parenchyma, without vascular bundles, as in the lower *Araceæ*, or traversed by a few simple bundles. In other cases only the epidermis of the external surface is perceptible, whilst the entire parenchyma, with the epidermis of the inner surface, is succulent or fleshy, as in *Atropa;* or it may be, that under the epidermis of the outer surface some layers of cellular tissue are woody, whilst the underlying are fleshy; in both cases very frequently passing without determined boundary into the pulp.

In many other cases four layers are distinctly discernible, and have been named, counting from without inward, Epicarp, Mesocarp (also Sarocarp, or Flesh, 'caro'); and the two inner undistinguished coats, the Endocarp. Those varieties of structure in the fruit are most important which cause the peculiar solutions of the continuity in the fully mature condition. Hence we obtain two comprehensive classes of fruits, according as their construction causes a separation into individual parts or not. The latter may be termed the berry-like, and the former the capsular. The capsular are again divided into two groups, according as the pericarp either opens and suffers the seed to escape—Capsules with their portions called valves; or separates into individual parts, which do not again open, but firmly inclose the seed—Splitting Fruits (Schizocarps), and their parts called Mericarps. The Berry-like Fruits are also subdivided into three groups, according as the inner leaves are the more tough and solid, and the outer the more fleshy and juicy—Stone Berries (Drupes); or the reverse—True Berries (Baccæ); or, lastly, all the layers appear thin and dry, or leathery (Achænia). All these forms may, with the germen from which they arise, be superior or inferior, one or many-celled, or one or many-seeded: which only require to be noticed when deviations in the structure of the germen have arisen through abortion, being otherwise self evident.

a. The Capsular Fruits occur in the most diverse families. The mode of bursting (Dehiscence) is especially to be observed. The simplest process is an apparent wholly irregular tearing open at any place, as in *Nicandra:* usually however the form of this dehiscence is very regular, even though it may be confined to a small part of the fruit, as in *Papaver*, *Antirrhinum*, &c.

The solution of continuity is either vertical or horizontal: in the latter case, the upper part forms a kind of cover upon the under, and the capsule is termed circumscissile. In the first case, the pericarp, &c., falls away in more or fewer separate pieces, which are termed valves. In many-celled fruits the valves may separate entirely from the persistent septa, as in *Cobæa scandens* (dehiscentia septifraga); or the septa may split into two lamellæ, and each valve may bear one of these lamellæ on each of its margins (dehiscentia septicida, valvulæ margine septiferæ); or the septa may remain undivided, adherent to the middle of the valves (dehiscentia loculicida, valvulæ medio septiferæ). If in any of these kinds of dehiscence a stalk-like mass of cellular tissue remains standing in the axis of the fruit, it is called the Columella.

From what has been said, it is sufficiently evident that these solutions in the continuity are not at all dependent upon the original composition. Such a relation has been assumed; and to the line in the external circumference of the pericarp, where the edges of real or pretended carpels have become blended, the term 'dorsal suture,' has been applied, while the term 'ventral suture' designates merely the line where the margins of one and the same carpel or similar part have become blended.

In the generality of capsular fruits, the above-mentioned four layers of the pericarp may be distinguished from the other; but they are usually very thin and membranous or leathery, or more rarely woody.

b. The Schizocarps, or Splitting Fruits, are usually distinguished chiefly according to the direction in which the cleft occurs. This is either parallel with the axis of the fruit, or perpendicular to it, that is, the solution of continuity is either vertical or transverse. In both, the separate parts are usually only one-seeded. In the first case the separate parts are sometimes named Cocci or Mericarps, in the last case Joints or Articulations; and they are distinguished, according to the texture of their layers, as dry, coriaceous, and succulent. The first (the mericarps) are proper to the families *Rubiaceæ*, *Euphorbiaceæ*, *Labiatæ*, *Boraginaceæ*, *Geraniaceæ*, *Tropæolaceæ*, *Malvaceæ*, *Umbelliferæ*, &c., &c.; the last (the joints) to some of the *Leguminosæ* and *Cruciferæ*. In the first a columella is not uncommon.

c. The Stone-Berries, characteristic of the *Amygdaleæ*, but also presented in other families, owe their peculiarity to the remarkable diversity in the structure of their layers, and indeed of the parenchyma layers, the inner of which are always hard, and often woody; whilst the outer are fleshy or coriaceous: both are developed in a greater thickness than usual.

d. The True Berries, predominating in the families of *Grossulariaceæ*, *Passifloraceæ*, *Cucurbitaceæ*, and the *Araceæ*, and occurring occasionally in many other families, depend essentially on the fleshy or juicy texture of the inner layers of the pericarp: this condition often exists to the extent of a dissolution into single cells, tumid with fluid, whilst the external layers are solid, and sometimes even woody, as in *Lagenaria*.

e. The Achænia, with always thin dry layers, not usually distinguishable, characterise the families of the Grasses, *Cyperaceæ*, *Cupuliferæ*, *Compositæ*, and *Dipsaceæ*, predominate in the *Dryaceæ* and *Ranunculaceæ*, and occur singly in other cases. They are one-celled and one-seeded, generally originally, but sometimes, as in the *Cupuliferæ*, through abortion of cells and seed-buds.

With regard to the Spermophore it may be remarked, that in the dehiscence of the fruit portions of cellular tissue are separated from the valves or septa, to which the seeds remain suspended, and which have been termed Spermophores. In these separations sometimes actually independent organs become solved from their union with others, as in *Cruciferæ*, and sometimes merely pieces of independent organs become detached, as in the *Asclepiadaceæ*.

The Pulp in the fruit assumes two conditions; on the one hand it passes into the loose cellular tissue of the pericarp in the true berries, as in *Solanum;* and on the other into the subsequent products of the funiculus; namely, into the aril in its widest sense, as in *Arum*, and probably into the true aril, as in *Ribes*.

The Funiculus exhibits manifold varieties, such as hairs, warty expansions among the seeds, membranous, continuous, or lobed envelopes of the seed (arils), and so forth.

There are often parts external to the germen, which are persistent till after the maturation of the seed [SEED], and they often undergo many changes; and when they become fleshy they assume the appearance of fruits. They are called Spurious Fruits. The most remarkable example of this is seen in the case of the fruit of the Fig (*Ficus*), in which the peduncle or receptacle swells up and incloses the true fruits. The pedicel in *Hovenia dulcis* also swells up and assumes the form of a fruit. In the Pine-Apples (*Ananassa*) the bracts enlarge and become the part eaten. In the Mulberry (*Morus*) the perianth is the fleshy part; in the Bladder-Campion (*Cucubalus baccifer*) the calyx enlarges; in *Mirabilis* it is the corolla; and the hips of the Rose (*Rosa*) are the dilated disc, whilst in the Strawberry (*Fragaria*) the sweet juicy part is the receptacle.

The terms applied to the fruits of plants by botanists are very numerous. The same kind of fruit has frequently several names, whilst the same name has been applied to several different kinds of fruits. The following enumeration of some of these terms is given by Schleiden in his 'Principles of Scientific Botany,' whose remarks on this subject deserve careful attention from those interested in the further development of this subject.

Enumeration of the Various Forms of Fruit.

I. Seed naked (*Semen nudum*).
 A. Seed solitary.
  1. *Bacca.* Seed inferior. Ex. *Viscum.*
  2. *Sphalerocarpium.* Seed with a fleshy aril. Ex. *Taxus.*
 B. Fructifications.
  3. *Strobilus.* Spikes with woody spermophores. Ex. *Pinus.*
  4. *Galbulus.* Capitula with confluent fleshy bracts. Ex. *Juniperus.*
II. Simple Fruits (*Fructus simplex*).
 A. Capsule (*Capsula*).
  † Superior.
  5. *Capsula circumscissa.*
  6. *Utriculus*, Gärtner, No. 5. One-celled, originating from a carpel; few-seeded. Ex. *Chenopodium.*
  7. *Pyxidium*, No. 5. One- or many-celled, formed of several carpels; many-seeded. Ex. *Hyoscyamus.*
  8. *Folliculus.* One-celled, or many-celled, one-valved. Seeds on the two margins of the valve. Ex. *Pæonia.*
  9. *Conceptacula.* Two disunited *folliculi* with one separating spermophore. Ex. *Asclepias.*
  10. *Legumen.* One-celled, one-seeded, or many-seeded, two-valved. Seeds on the two borders of one fissure. Ex. *Pisum.*
  11. *Siliqua.* Two-celled, two-valved, separating from the persistent spermophore, forming a Septum (*Replum*). Ex. *Matthiola.*
  12. *Silicula.* A very short *Siliqua.* Ex. *Thlapsi.*
  13. *Ceratium.* A *Siliqua* in some *Fumariaceæ* and *Papaveraceæ.*
  14. *Rhegma.* Elastically two-valved (?), dehiscing from a *Columella.* Ex. *Euphorbia.*
  15. *Capsula.* One-celled or many-celled, many-seeded, dehiscing by valves or pores, *Primula*, *Antirrhinum.*
  †† Inferior.
  16. *Diplotegia*, Desvaux. Inferior capsule, dehiscing by pores. Ex. *Campanula.*
 B. Splitting Fruits (*Schizocarpium*).
  17. *Cremocarpium* (?). In *Umbelliferæ*, *Rubiaceæ.*
   a. Mericarpia. The separate parts of the *Schizocarpium.*
  18. *Carcerulus.* In *Tropæolaceæ*, *Malvaceæ.*
  19. *Achænium.* In *Boraginaceæ*, *Lamiaceæ.*
 C. Stone Fruits (*Drupa*).
  20. *Drupa.* Originally one-celled, 1-seeded, 2-seeded. The *Mesocarpium* fleshy, the *Endocarpium* woody. Ex. *Amygdalus.*
  21. *Tryma*, (imagined to be) one-celled by suppression in *Juglans.*
 D. Berry (*Bacca*).
  22. *Bacca.* Many-celled, inferior. Ex. *Ribes.*
  23. *Nuculanium.* Many-celled, superior. Ex. *Vitis.*
  24. *Pepo.* One-celled, inferior. Ex. *Pepo.*
  25. *Hesperidium.* Coriaceous portion, strictly separated from the pulp. Ex. *Citrus.*
  26. *Amphisarca.* Woody towards the exterior. Ex. *Crescentia.*
 E. Closed Fruit (*Achænium*).
  27. *Achænium* (*Auctorum*), *Cypsela* (Lindley). One-celled, one-seeded, not blended with the seed. Ex. *Compositæ.*
  28. *Glans.* Through abortion one-celled, one-seeded. Ex. *Corylus.*
  29. *Caryopsis.* One-celled, one-seeded (imagined to be) blended with the seed. Ex. the Grasses.
  30. *Samara.* Two-celled, winged. Ex. *Acer.*
  31. *Carcerulus.* Many-celled, not winged. Ex. *Tilia.*
III. Multiple Fruits (*Fructus multiplex*).
 A. Several Achænia.
  32. *Etærio.* If wholly free. Ex. *Ranunculus.*
  33. *Syncarpium.* If connected. Ex. *Magnolia.*
 B. Several Berries.
  34. *Etærio.* Connected. Ex. *Rubus.*
IV. Fructifications (*Fructus compositus*).
 A. Capitula. With a flat or cup-shaped fleshy peduncle.
  35. *Syconus.* Ex. *Ficus*, *Dorstenia.*
 B. Spikes with fleshy bracts and perianths.
  36. *Sorosis.* Ex. *Ananassa*, *Morus.*
 C. a. Spikes with woody bracts.
  37. *Strobilus.* Ex. *Betula.*
  b. Spikes with woody bracts and perianths.
  38. *Strobilus.* Ex. *Casuarina.*
V. Spurious Fruits (*Fructus spurius*).
  39. *Cynarhodon.* Free one-seeded Achænia, surrounded by a fleshy disc. Ex. *Rosa.*
  40. *Pomum.* Many-seeded Achænia in one circle, blended with the fleshy disc. Ex *Malus.*
  41. *Balausta.* Many-seeded Achænia in two circles, blended with the fleshy disc. Ex. *Punica.*
  42. *Diclesium.* Achænia enclosed in a hardened perianth or corolla. Ex. *Spinacia*, *Mirabilis.*
  43. *Sphalerocarpium.* Achænia inclosed in a drupaceous perianth. Ex. *Hippophäe.*

FRY, MRS. ELIZABETH, was the third daughter of John Gurney, Esq., of Earlham Hall, near Norwich, an opulent merchant and banker, and a member of the Society of Friends. Elizabeth Gurney was born May 21, 1780, at Bramerton, four miles from Norwich, where her parents had then a summer residence; in winter they occupied a large and commodious house in Norwich. They were not 'plain Friends,' that is, they did not wear the plain dress of the Quakers, nor use 'thou' and 'thee' in place of the ordinary 'you,' nor abstain from the usual amusements of social life. They of course attended the Friends' meeting-house at Norwich, and the monthly and quarterly and yearly meetings; but in other respects there was little distinction between them and the gentry who belonged to the Church of England. Mrs. Gurney died when Elizabeth was only twelve years of age, leaving seven daughters and four sons. Mr. Gurney's business-pursuits led him into intercourse with persons of all denominations; and a warm heart, social disposition, and courteous manners introduced him to many acquaintances without as well as within the pale of the Society of Friends. The daughters, as they advanced in years, especially the three eldest, dressed gaily, and sang and danced — sometimes attending concerts and balls at Norwich, and sometimes pursuing their favourite amusements at Earlham Hall, which had then become their father's country residence.

Elizabeth Gurney, from the age of fourteen to seventeen, was, as she herself states in her 'Diary,' somewhat sceptical, and her doubts greatly distressed her. While she was in this fluctuating state of mind, William Savery, an American Quaker, paid a religious visit to England, and, on the 4th of February, 1798, preached in the Friends' meeting-house at Norwich. His discourse produced a very strong effect upon her feelings, and turned the balance of her judgment in favour of religion—a change which subsequent discourses and conversations tended strongly to confirm. She had made great progress towards becoming a 'plain Friend,' and instructed about seventy poor children in her father's house at Norwich, when Joseph Fry, who, with his brother, carried on an extensive business in London, paid a visit to Mr. Gurney at Earlham Hall. While there he made an offer of marriage to Elizabeth Gurney; and on the 19th of August 1800 they were married in the Friends' meeting-house in Norwich. Joseph Fry and his family belonged to the strict section of the Quakers, and Elizabeth Fry was now prepared to adopt their usages. She resided with her husband in his house of business, Mildred's-Court, in the City of London, till the spring of 1809, when, on the death of her husband's father, she removed to Plashet House, Essex. In 1810 she became a preacher among the Friends, and ever afterwards continued to perform with great zeal the duties of her sacred office.

In the month of February 1813 she visited the prison of Newgate in London, and saw about 300 women tried and untried, with numerous children, crowded together, without classification or employment, in rags and dirt, with no bedding, and nothing but the floor to sleep on. The season was inclement, and she supplied them with some necessary covering. After several other visits, and making much improvement in their manners as well as their condition, she in 1817 succeeded in establishing a Ladies' Committee for the reformation of the female prisoners in Newgate—the sheriffs of London and the governor of the prison granting their permission, but affording no assistance. A school and a manufactory were established in the prison; and riot, intoxication and filth, were succeeded by order, sobriety, and neatness. The improvements which she had been the means of introducing into Newgate, were gradually extended to other prisons. She had interviews with the most influential of the ministers, was examined before the House of Commons, obtained the assistance of clergymen, and visited different parts of the kingdom, including Scotland and Ireland, for the purpose of carrying out her benevolent plans. She next turned her attention to the female convicts sentenced to transportation, and introduced many improvements, tending not only to ameliorate their condition, but to reform their characters. From 1833 to 1836 she paid visits to Jersey and Guernsey; and about the same time procured the introduction of libraries in the coast-guard stations and the government packets. From 1837 to 1842 she visited the principal towns in France, Belgium, Germany, and Holland, chiefly for the purpose of extending her improvements in prison-discipline. She died on the 12th of October 1845 at Ramsgate, and was buried in the Friends' burying-ground at Barking in Essex,. She bore ten children, most of whom were living at the time of her death.

(*Memoir of Elizabeth Fry, with Extracts from her Journals; edited by Two of her Daughters*, 2 vols. 8vo, London, 1847.)

FUCACEÆ, a natural order of *Algæ*, or olive-coloured inarticulate Sea-Weeds, whose spores are contained in spherical centres, immersed in the substance of the frond. The root has almost always a conical disc, rarely branching or creeping. The fronds are of an olive-brown or olive-green colour, becoming darker in drying; of a tough leathery substance, and fibrous texture, tearing lengthwise with facility; dichotomous or pinnate; rarely irregularly branched, but very variable in habit. In the simpler kinds (*Splancnidium*) there is no distinction into parts (as stem, leaves, receptacle), but the fructification is equally dispersed through all parts of the plants; in others (*Durvillæa Sarcophycus*) there is a stem ending in a phyllo-caulon or leaf-like frond, through which the fructifications are scattered; in others (*Himanthalia*) there is a simple frond of small size, and a branching receptacle of fructification resembling a frond; in others (*Fucus Cystoseira*) there is a branching or imperfectly leafy frond, some portions of whose branches finally swell and are converted into receptacles of fruit; and, finally, in the most perfect kinds (*Sargassum Marginaria*) there is a branching frond, with well-formed mostly distinct and nerved leaves and receptacles, from their origin set apart as organs of fructification (not formed by swellings of the old branches), developed either in the axils or along the edges of the leaves or branches. Air-vessels are present in almost all, either in bladdery swellings of the stem and branches, as in *Fucus*, or as distinct organs, as in *Sargassum*, stalked, and mostly springing from the same part as the fructification. Receptacles of the fruit, mostly more or less distinguishable from the barren portion of the frond, swollen, succulent, often filled with slimy mucus, either formed from the metamorphosed ends of the branches, or evolved from the axils or sides of the branches or leaves. These receptacles are pierced by minute pores, which communicate with small spherical chambers formed by an introflexion of the walls of the receptacle at the points where they occur. The little chambers (called Conceptacles by some writers, Scaphidia by others) contain sometimes spores, or reproductive bodies, analagous to the seeds of more perfect plants; sometimes antheridia, supposed to be analogous with stamens; sometimes both organs in the same chamber. The spores spring from the sides of the chamber. One of the surface-cells being fertilised, gradually enlarges, projects from the wall of the chamber, becomes more or less obovate, and finally is converted into a perispore, or membranous transparent case, in which is contained the spore or spores. These last are formed from the matter contained within the enlarged cell. At first the contents are nearly fluid, of a pale olive colour; gradually they acquire density, become darker, and at length are consolidated into a single sporule, as in *Cystoseira, Halidrys*, &c., or formed into two, four, or eight sporules, as in *Fucus, Himanthalia*, &c. The antheridia are borne on branching jointed threads, called Paranemata, which rise, like the spores, from the walls of the conceptacle, and commonly fill the greater part of its cavity. Each antheridium is an oblong cell, forming the terminal articulation of the branches of the paranemata, and is filled with minute orange-coloured bodies called Sporidia (by J. Agardh), closely resembling the zoospores of the lower *Algæ*, and like the latter endowed with spontaneous movements. The motive organs are vibratory hairs, or cilia, with two of which each little body is furnished.

The *Fucaceæ* are easily known from all other Olivaceous Sea-Weeds, by a character at once natural and easily ascertained, namely, the position of their spores within little hollows sunk in the substance of the plant, and communicating with the surface by a pore. The order is represented in most climates, from high northern and southern latitudes to the equator. Very few species vegetate in the polar regions of either hemisphere. In the north the species of *Fucus* and *Himanthalia* alone reach to the Icy Sea; and in the Antarctic Ocean the order is limited to *Durvillæa* and to *Scytothalia Jaquinotii*, a fine *Alga* allied to sub-tropical forms. The British species, excluding three doubtful natives, are but fourteen; yet from the strictly social habits of several of them, they cover more surface of tidal rocks than all the other *Algæ* put together. It is these plants which impart the deep brown colour to the belts of rocks exposed on the recess of the tide.

The following is a synopsis of the British genera of these plants:—

Sargassum.—Branches bearing ribbed leaves. Air-vessels simple.

Halidrys.—Frond linear, pinnate, leafless. Air-vessels divided into several cells by transverse partitions.

Cystoseira.—Root scutate. Frond much branched, bushy. Receptacles cellular.

Pycnophycus.—Root branching. Frond cylindrical. Receptacles cellular.

Fucus.—Root scutate. Frond dichotomous. Receptacles filled with mucus, traversed by jointed threads.

Himanthalia.—Root scutate. Frond cup-shaped. Receptacles (frond-like) very long, strap-shaped, dichotomously branched.

I. SARGASSUM.—Frond furnished with distinct, stalked, nerved leaves, and simple axillary stalked air-vessels. Receptacles small, linear, tuberculated, mostly in axillary clusters or racemes. Seeds in distinct cells. The generic name is from Sargazo, the Spanish term for masses of sea-weed found floating in the ocean in some latitudes.

1. *S. vulgare;* and

2. *S. bacciferum*, though both of them have been found cast on our shores, have no just claim to a place in our British Flora, being natives of the tropics, occasionally driven, with other tropical productions, by the force of the western currents on our Atlantic coasts. The species of this genus are found over a wide extent of ocean, and have been generally called Gulf-Weed. They appear like floating meadows in the midst of the ocean, sometimes for miles in extent, and probably support a larger number of living creatures than the most productive pasturage in Great Britain. Myriads of Mollusks, *Radiata*, Fishes, and *Crustacea* may be seen playing about in these masses; and the abundance of Zoophytes which find shelter in such situations can hardly be estimated. The weed is eaten in China. In the East it is used as salads, and forms a pickle.

II. HALIDRYS has compressed linear fronds, pinnated with distichous branches. The air-vessels are lanceolate, stalked, divided into several cells by transverse partitions. The receptacles are terminal, stalked, cellular, pierced by numerous pores, which communicate with immersed spherical conceptacles.

H. siliquosa has linear very narrow branches, compressed linear lanceolate air-vessels, slightly constricted at the septa, mucronate. It is found on rocks and stones in the sea, at and below half-tide level.

III. CYSTOSEIRA has a frond furnished with branch-like leaves, becoming more filiform upwards. The air-vessels are simple, arranged within the substance of the branch-like leaves consecutively. The receptacles are cylindrical, more or less lanceolate, tuberculated, and terminal. The seeds in distinct cells. The name is derived from two Greek words, signifying a little sac, and a chain.

C. ericoides has a thick woody short stem, cylindrical, and beset with numerons slender filiform branches, variously divided, and densely clothed with small spine-like awl-shaped ramuli (or leaves). It is found on rocks in the sea, and has the property of being irridescent when nnder water in a growing state. In drying it becomes nearly black, and does not adhere to paper.

The other British species of the genns are—*C. granulata*, *C. fœniculacea*, *C. barbata*, and *C. fibrosa*.

IV. Pycnophycus has a root composed of branching fibres. The frond is cylindrical and dichotomons. The air-vessels, when present, innate and simple. The receptacles terminal, cellnlar, pierced hy nnmerons spores, which commnnicate with immersed spherical conceptacles, containing in the lower part of the receptacles parietal simple spores, and in the npper tnfted antheridia. The name is from two Greek words, signifying thick sea-weed.

P. tuberculatus is fonnd in rock-pools, on the recess of the tide, near low-water mark. It is better known hy the name of *Fucus tuberculatus*. It is very different in many respects from *Fucus* proper. When dry it becomes very brittle and black.

V. Fucus has a plane, compressed, or cylindrical frond, linear, dichotomous, coriaceons. The air-vessels, when present, are innate in the frond, simple and large. The receptacles terminal (except in *Fucus nodosus*), turgid, containing tnbercnles imbedded in mncus, and discharging their seeds by conspicnons pores.

F. vesiculosus is common on all onr sea-shores. It is the Sea-Ware, Bladder-Fncus, Kelp-Ware, Black-Tang of Scotland, and sometimes Lady-Wrack. In Gothland, according to Linnæus, it is Swine-Tang, becanse boiling it and mixing it with a little coarse flonr they give it to their hogs. In the Hebrides, cheeses are dried withont salt, being covered with the ashes of this plant, which abounds with salt. In Scania it is used as thatch and fnel. The root is a hard flat disc. The fronds are from 2 to 3 feet in length. The air-vessels, as large as nnts, are in pairs; the receptacles, in pairs, and often forked, terminate in branches. There is a variety of this which is often called *Fucus Balticus*. It is found among grass and moss in marshy gronnd occasionally overflowed by the tide. Lightfoot mentions that dnring the snow-storms in the Highlands, the red deer descend from the wild mountains to feed on this sea-weed. He mentions also that the saponaceous mncus of the vesicles has been recommended to remove glandnlar swellings, and the calcined powder of the plant is said to be valuahle as a dentifrice. The great use now made of this weed, as well as of others, is in the mannfactnre of kelp and iodine.

F. ceranoides is sometimes called the Horned Fncns. It resembles the preceding species, bnt is much thinner and more transparent, the midrih is more distinct, and the leafy part is narrower, although it is a more graceful plant than *F. vesiculosus*.

F. serratus, Serrated Sea-Weed, is very common on all onr sea-shores. It is perennial. The frond differs from the preceding by being serrated. In Scotland it is called Black-Wrack, or Prickly Tang. It is not so rich in kelp and iodine as the others. It is nseful as mannre. In Norway it is used as food for cattle, mixed with meal. The Dutch nse it to cover their crabs and lobsters, to keep them alive and moist, preferring it to any other because it is destitnte of that mncns which causes them to ferment and putrefy. It is a handsome species, the fronds on both sides heing dotted with pencil-like clnsters of whitish capillary fibres, and the fronds being often hroad.

F. nodosus, Knobbed-Wrack. The root is a large hard conical mass, from which spring several branches, from 2 to 4 or 6 feet in length. It is called in some places Yellow Wrack. In England it is often called Sea-Whistle, in conseqnence of the custom among children of converting the vesicles into whistles. The air-vessels are called crackers; for when thrown into the fire they make a slight explosion.

F. Mackaii is fonnd on muddy sea-shores, usually in land-locked hays and among honlders. The frond is from 6 to 10 inches long, densely tufted; branches crowded, spreading, compressed at the base, cylindrical upwards. The vesicles wider than the frond. In snbstance leathery; when dry somewhat horny.

F. canaliculatus, Channelled Fncus. This is abundant on rocks on the sea-shore near high-water mark. It is perennial. Cattle are exceedingly fond of it, and never fail to browse on it in winter as soon as the tide leaves it within their reach.

VI. Himanthalia has coriaceons orbicnlar top-shaped fronds. Very long strap-shaped receptacles, repeatedly forked, spring from the centre of the frond, filled with mncns, traversed by jointed fihres, and pierced by nnmerons pores, which commnnicate with immersed spherical conceptacles, containing either parietal spores or antheridia.

H. lorea is common on rocky sea-shores. It seems difficult to determine as to the dnration of this plant. Some regard it as annual, as the thongs are produced every year; bnt others say the long thongs are only receptacles, that the cnp-shaped disc is perennial, and that this part is truly the plant. The cup-shaped frond which adheres firmly to the rock is more than an inch in diameter. The branches or receptacles are in Scotland abont six feet long. In Cornwall they are sometimes twenty feet long. The name in English signifies Sea-Thongs. The fruit consists of tnbercles immersed in the fronds, and these tnbercles discharge their seeds by pores, which give the thongs a spotted appearance. This is remarkably the case when, after lying on the shore for some time, every pore is covered with a yellow dot, which is the mncus of the plant discharged in the death-struggle which goes on, when, torn from the rock and tossed ont by the waves, it lies withering in the open air. Dr. Neill mentions that in the north of Scotland a kind of sance for fish or fowl, resembling ketchnp, is made from the cnp-like or fungus-like fronds of this sea-weed.

(Harvey, *British Marine Algæ;* Landsborongh, *British Sea-Weeds.*)

FUCHSITE, a Green Mica from the Zillerthal, containing 4 per cent. of oxide of chrominm. From the crystallisation of mica, two additional species have been made ont of the old species so called. The common mica has an obliqne prism for its primary. Many micas when in perfect crystals have the form of a hexagonal prism, and but one axis of polarisation; this last fact proving the primary to be a regular hexagonal prism. This species is properly distinguished, and has been called Hexagonal Mica.

FULLER, SARAH MARGARET, MARCHIONESS OSSOLI, was born at Cambridge-Port, Massachnsetts, United States of North America, May 23, 1810. Her father, a solicitor and a member of the Congress, perceiving her early aptitude, had her so highly educated that he was accnstomed to speak of her while quite a child as "knowing more Greek and Latin than half the professors," while she herself says that she had nearly forgotten her native tongue from constantly reading other languages. The consequence was, that when she grew to womanhood she had an overwrought nervous system, was a somnambnlist, very near-sighted, and withal what is called a strong-minded, loud-voiced, excessively dogmatic, and nnquestionably clever, as well as cnltivated person. The sndden death of her father in September 1835, threw npon her domestic dnties and obligations to which she resolntely and without affectation addressed herself. She became a teacher at Boston of Latin, French, German, and Italian, then 'Lady Superior' of a school at Providence, Rhode Island, afterwards united herself for a while to that singular social or Fourieristic Society the 'Brook Farm Community,' and evontnally took up her pen as a means of support. She had already become well known as a writer in the periodicals when she in 1839 published a translation of 'Eckermann's Conversations with Goethe.' Having acquired great celebrity in the literary circles of Boston, especially among the transcendentalists of that learned city, for her conversational talents as well as her critical acumen, it was proposed to tnrn her powers that way to account, by forming under her guidance 'conversational classes' of the ladies of Boston. The scheme, odd as it may seem, met with acceptance. Five-and-twenty "of the most agreeable and intelligent women to be found in Boston and in its neighbourhood" met at stated seasons to converse—the 'conversation' heing of conrse mainly on the side of the learned president—on such suhjects as "the genealogy of heaven and earth; the will (Jupiter); the celestial inspiration of genins, perception, and transmission of divine law (Apollo)," and such other recondite themes as might be conveyed nnder the symbols of Venns, Bacchns, Cnpid and Psyche, and so forth; with poetry, music, the pictorial arts, the "thought that lies at the bottom of the different dances," aud other more sublunary topics.

When Mr. Emerson started his 'Dial' in 1840, Miss Fuller was one of the most prominent of his band of philosophical contributors; and she wrote for it many very clever articles on the 'Fine Arts,' &c., some of which were subsequently republished in her volume of 'Papers.' She also published at Boston in 1844, under the title of 'Summer on the Lakes,' an account of a summer tour. On the discontinuance of the 'Dial' she removed to New York, and was installed directress of the literary department of the 'New York Tribune.' Here she let her studies turn more directly on political and social philosophy; and she gave utterance to her impressions of the wrongs of her sex in 'Woman in the Nineteeth Century,' a work which excited some attention in England as well as in America. She also published here the collection of her 'Papers on Literature and Art,' already referred to: both of these works were, we believe, reprinted in London.

In the spring of 1846 she put in execution a cherished scheme of a prolonged European tour. She first visited England, where she stayed some time, and obtained introductions to many of the literary notabilities, whom she describes and criticises in her letters with a most amusing air of superiority. In Paris she also remained for some time, and formed the acquaintance of Madame Dudevant, &c. But Italy was the place she had most desired to visit, and thither she next proceeded—little dreaming to what a strange conclusion all her theories of woman's rights and claims and missions would there be brought. For a brief space she revelled in the enjoyment of the scenery, the climate, and the boundless treasures of art in that sunny region; and it must be added that a portion of her time was occupied in rendering herself conspicuous by her open and resolute, though somewhat imprudent avowal of extreme democratic opinions, and intercourse with persons obnoxious to the authorities on account of their suspected liberalism. But at length she became involved in an affair of a very different though not less exciting nature. She met by accident at vespers, in St. Peter's, Rome, while separated from her friends by the crowd, a young Italian gentleman; he behaved with a courtesy that charmed her; an intimacy ensued, and, though he was many years her junior, so utterly uneducated that he had scarce ever looked into a book, and without any kind of intellectual pretensions, the strong-minded worshipper of intellect with a very little wooing gave him her hand. But the young Marquis Ossoli, though of a noble family, had a very small patrimony, and that was in the hands of trustees. Moreover his family were devoted Roman Catholics, and his elder brothers held high appointments under the papal government; they would of course be bitterly incensed at his marrying a lady not of that faith, and especially one who was an avowed liberal. He therefore urged that the marriage should be strictly concealed: and to this she submitted. They were married in December 1847, and Madame Ossoli remained in Rome, ostensibly living alone as plain Margaret Fuller; indeed it was not till more than a year after the birth of a son that even her own mother was informed of the marriage. The sudden ascendancy of liberalism in Rome however altered matters. Miss Fuller had in London met Mazzini, and undertaken, as it would seem, to bear communications from him to various Italian liberals; and she had converted her husband to her own political creed. When the revolution broke out her husband threw himself heartily into the movement; and she shrank from none of the duties which her position and her opinions seemed to have devolved upon her. During the siege of Rome she was occupied as nurse, having charge of one of the hospitals opened by the Roman Commission for the succour of the wounded, and acted with a noble disregard of toil or danger, and with much judgment as well as the greatest kindness in her self-imposed task. The fall of the republic compelled her to leave Rome; and with her husband and her child, she, after staying the winter at Florence, embarked at Leghorn in May 1850, on board the Elizabeth, for America. From the first the voyage was unpropitious; the captain died soon after the ship sailed; the weather was throughout stormy; and though the vessel reached the American coast, it was only to be wrecked there, having struck on Fire Island Beach, Long Island, July 16th, 1850. A few of the passengers and crew were saved, but Margaret Fuller, her husband, and child were among the drowned. The body of her child came ashore, but her own tomb was the ocean.

The writings of Margaret Fuller will have no permanent value in themselves, either for their literary merits, their social opinions, or their estimates of character, of art, or of literature. But they will retain a certain value, in connection with the history of their author, as illustrative of a peculiar phase of society in America during the second quarter of the 19th century. Margaret Fuller herself was undoubtedly a woman of great ability as well as of considerable attainments, but she had thoroughly studied not a single subject, and her writings are all disfigured by dogmatism, assumption, and self-reference. In them you often come upon a striking and apparently original thought; but if the thought be dwelt on for a moment, it is recognised as owing its uncommonness mainly to peculiarity of expression: and sometimes these peculiarities degenerate into grotesqueness. Had her life been spared however there can be little doubt that what was strange, and almost repulsive in her earlier works, would have disappeared, and the better and lovelier part of her character and intellect have revealed itself. The severe mental discipline she had undergone in Rome had, as she said in one or more of her letters, subdued her pride; and with humility came in all the gentler virtues and intellectual graces. Nothing could be more noble and beautiful than her conduct as a woman, a wife, and a mother under her marriage trials, and during and after the siege of Rome; and the letters which she wrote then are more graceful and eloquent than perhaps anything else which has fallen from her pen. She wrote an account of the Roman revolution, the progress and suppression of which she had watched so eagerly, but the manuscript perished with her.

(*Memoirs of Margaret Fuller Ossoli*, compiled by her friends J. F. Clarke, R. W. Emerson, and W. H. Channing, 2 vols. 8vo, Boston, 1852, and 3 vols. 8vo, London, 1852.)

FUMARAMIDE. [CHEMISTRY, S. 2.]

FUNGI. There is frequently considerable difficulty in distinguishing *Fungi* from the other forms of Cryptogamic Plants. They are distinguished from Lichens by their more fugitive nature, their more succulent texture, their want of a thallus or expansion independent of the part that bears the reproductive matter, but more particularly in their never containing germs distinct from the fructifying bodies of a vegetable germ so constant in Lichens.

From some forms of *Algæ* they differ very little, but the most obvious distinction is their mode of growth. The *Algæ*, like the Lichens, do not derive their nutriment from the bodies on which they grow, which is the case with all the *Fungi*. There are however certain free forms of *Fungi* which it is difficult to distinguish from *Algæ* by this character; such are the moulds which are developed in ink, milk, and other liquids.

It has been stated that *Fungi* are distinguished from *Algæ* by the absence of spontaneous movements. It is no doubt true that the condition of the protein which is the motile agent in all plants is different in *Fungi* from what it is in *Algæ*, but this is no general distinction. In those *Fungi* which are developed in water, in one instance at least, the *Achlya prolifera*, or *Saprolegnia ferax*, the movements of the spores are as active as in any of the *Algæ*.

"In the simplest form *Fungi* are little articulated filaments composed of simple cellules placed end to end. Such is the mouldiness that is found upon various substances, the mildew of the rose-bush, and in short all the tribes of *Mucor* and *Mucedo*. In some of these the joints disarticulate, and appear to be capable of reproduction; in others spores collect in the terminal joints, and are finally dispersed by the rupture of the cellule that contained them. In a higher state of composition *Fungi* are masses of cellular tissue of a determinate figure, the whole centre of which consists of spores attached, often four together, to the cellular tissue, which at length dries up, leaving a dust-like mass intermixed more or less with flocci, as in the puff-balls, or sporidia, contained in membranous tubes or asci, like the thecæ of Lichens, as in the Sphærias. In their most complete state they consist of two surfaces, one of which is even and imperforate, like the cortical layer of Lichens; the other separated into plates or cells, and called the hymenium, to whose component cells, which form a stratum resembling the pile of velvet, the spores are attached by means of little processes, and generally in fours, though occasionally the number is either less or greater." (Lindley.)

The following is Schleiden's account of the development of the organs of reproduction in the *Fungi*:—

"The most simple (*Hyphomycetes*, filamentous *Fungi*) form, at the end of the thread-like cells, narrower protuberances, in each of which a spore is developed: this at length separates, having consequently a double membrane, the cell of the spore itself and the covering (sporangium) arising from the parent cell, as, for instance, in *Penicillium* and *Botrytis*. In others the thread-like cells form a spherical swelling at the extremity, from which project a number of such prolongations, each of which contains a spore, while the whole forms a divided sporangium, as, for instance, in *Mucor* and *Penicillium*.

"In others (*Gasteromycetes*, the ventricular *Fungi*) the thread-like cells combine into pointed, or non-pointed, variously shaped sporocarps; in or upon which are spores, of the development of which we know nothing. After the scattering of the spores, the thread-like cells often remain as tender wool, as in the *Trichiaceæ*, or as a delicate network (capillitium), as, for instance, in *Stemonitis cribraria;* and the external capsule (uterus peridium) generally composed of fine filamentous cells, is then dissolved, or bursts in different regular ways, as in *Arcyria* and *Geastrum*.

"In the most highly developed *Fungi* (*Hymenomycetes*, membraneous *Fungi*), elongated pouch-like cells (probably only the ends of the interwoven filiform fungus-cells, developed into the sporocarps, or cells formed at the ends of these cells) combine by arrangement side by side so closely as to form a membrane (hymenium). Some of the cells of this membrane enlarge considerably (sporangia), and send out from one to six points at their free extremity, in each of which a spore is developed. The filiform cells of the fungus then either form round masses, closed in all round (sporocarps), with cavities in their interior, the walls of which are clothed by the hymenium, or they form definitely arranged columns in *Merisma*, tubes in *Polyporus*, or lamellæ in *Dædalea* and *Agaricus*, which are clothed by the hymenium, as in the *Hymenomycetes*. Of the latter we only know, with any amount of accuracy, the law of development relating to the Toadstools, and more especially that of the *Agaricineæ*. In these latter there are formed, at definite parts of the flocculent mycelium, small hollow heads (volvæ), at the bottom of the cavity of which there grows a corpuscle, shortly pedunculated below, and enlarged into a spherical form at the top. In the lower part of this protuberance a horizontal circular cavity is formed, to the upper surface of which are attached the tubes, lamellæ, &c., which bear the hymenium. The bottom of the cavity is only formed by a membrane (indusium), which is either separated from the pedicel on its further development, or, loosening itself from it and the upper part at the same time, remains as a membranous ring (annulus) upon the stalk. The upper part, which supports the hymenium on its lower surface, dilates subsequently, and appears as an umbrella-like expansion, called the cap (pileus). The whole then breaks through the volva, which is very soon dissolved."

During their growth the same *Fungi* assume very different forms and appearances. It thus happens that the same species has not only been described under different specific names, but even referred to different genera. Fries states that he has traced no less than eight genera of different authors to mere degenerations or imperfect states of *Thelephora sulphurea*. Nees von Esenbeck also states that the same fungoid matter which produces *Sclerotium mycetospora* in the winter, developes *Agaricus volvaceus* in the summer. Professor Henslow has also shown that some of the supposed species of *Uredo* are forms of *Puccinia*, *Aregma*, &c. Kützing, in an essay on the 'Transformations of Plants,' carries his views on this subject very far, and maintains that according to different circumstances the same species will produce *Algæ*, *Fungi*, Lichens, or Mosses.

In the article Entophyta, *S.* 2, will be found an account of the plants growing on man and living animals. Many of these are *Fungi*. Professor Balfour, in his 'Class-Book of Botany,' gives the following account of diseases in plants produced by *Fungi*:—

"The attacks of Parasitic *Fungi* cause extensive injury and disease in plants. Some think that the spores of *Fungi* coming into contact with the plant act both as the predisposing and exciting cause of disease; others, perhaps more correctly, think that some change is first produced in the cells of the plant, which enables the spores to find a nidus, and then the disease goes on rapidly, assuming a peculiar type on account of the presence of the fungus: in the same way as vegetable organisms found in diseases of the skin are not to be looked upon as the origin of the disease, but as being developed in textures previously morbid, and as giving often a peculiar character to the disease. Many of the diseases of cultivated crops are attributed to *Fungi*. The spores of *Fungi* are very minute, and are constantly floating in the air. They can easily be applied to the surfaces of plants. When they find an appropriate soil they send out extensive filiform ramifications, which spread under the epidermis of plants, raise blisters, and finally burst forth in the form of orange, brown, and black spots, constituting the fructification. They attack the stem, leaves, flowers, and fruit. Different species are restricted to different plants, and even to different parts of the same plant. The forms which the same fungus assumes seem to vary sometimes according to the plant on which it grows. The disease called Bunt, Smut-Balls, or Pepper-Brand, is occasioned by the plant called *Uredo caries* by De Candolle, and *Uredo fœtida* by Bauer. It attacks the grains of wheat, and may be detected in them in their earliest state. It consists of extremely minute globules of a dark colour, at first attached to a thread-like matter or mycelium. Bauer estimates the diameter of each of the globules at 1-1600th of an inch, and consequently a grain of wheat (reckoned at less than 1-1000th of a cubic inch) would contain four millions such spores. The spores, or powdery matter, have a disgusting odour; hence the specific name given to it. The disease is propagated by contact. Steeping the grain is recommended by some as a means of prevention, and alkaline solutions have been suggested as a remedy. *Uredo linearis*, which is met with also in this disease, is considered as being a young state of the Mildew-plant. Another disease called Smut, or Dust-Brand, is caused by a fungus called *Uredo segetum*. It resembles the Bunt fungus in colour and shape, but its spores are not half so large, and it does not possess a fetid odour. This fungus destroys the ear of corn by first causing the innermost parts of the flower to become abortive, while the pedicels on which these are seated swell and become very fleshy. The fungus then consumes the whole of this fleshy mass, and at length appears between the chaff-scales in the form of a black soot-like powder. It is said also to attack the stem and leaves. When ripe the spores burst through the epidermis, and are dispersed in the form of a black powder like charcoal. The spore is 1-2800th of an inch in diameter. Smut is rare in wheat; it is common in barley, and more so in oats. It is also seen in many grasses, such as *Arrhenatherum avenaceum*. The disease denominated Rust, Red Rag, Red Robin, and Red Gum, is caused by a fungus called *Uredo rubigo*. It forms yellow and brown oval spots and blotches upon the stem, leaves, and chaff. The spores burst through the epidermis and are dispersed as very minute grains. The disease is common in corn and in grasses. Mildew is a disease caused by a fungus denominated *Puccinia graminis*. The ripe spore-cases of this plant are small dark-brown club-shaped bodies, their thicker end being divided into two chambers, each filled with minute spores, and their lower end tapering into a fine stalk. The sori, or clusters of spore-cases, burst through the epidermis sometimes in vast numbers. The minute spores seem to enter the plant by the stomata. Some think that they, as well as other minute spores, are absorbed by the roots. The disease attacks wheat. Spring wheat is less liable to this disease than winter wheat, and heavy soils are less subject to it than light ones. Many have supposed that the Barberry is in some way connected with the production of Mildew. This idea has been proved to be erroneous by the experiments of Standinger, near Hamburg, and of Hornemann at Copenhagen. Unger entertains the idea that blight, mildew, and smut are to be considered as exanthematous diseases of plants caused by the spores of *Fungi* entering the stomata.

"Henslow has shown by experiment that, if the diseased seeds of wheat be steeped in a solution of sulphate of copper, they will not produce diseased grain, and that the sulphate of copper does no injury to their germination. The solution used is one ounce of sulphate of copper to a gallon of water for every bushel of wheat. Grain also steeped in hot water does not reproduce these fungoid diseases. In East Lothian, with the view of preventing smut, seed-wheat is often steeped in stale urine, and afterwards some newly slaked lime is sifted on it. Sometimes a solution of salt is used as a pickle. Fourcroy and Vauquelin ascertained by analyses that blighted wheat contained an acrid oil, putrid gluten, charcoal, phosphoric acid, phosphate of ammonia and magnesia, phosphate of lime, and no traces of starch. As regards Bunt or Pepper-Brand, Henslow remarks, that upon simply immersing the grain in water the infected seeds float, and on the water being poured out, nothing but the sound ones remain in the vessel. This simple process of separation is not however perfectly effective, because in thrashing the wheat many of the infected grains are crushed, and the spores are dispersed in the form of fine powder which adheres obstinately to the sound grain, by means of an oily or greasy matter found in the *Fungi*. In order to detach them thoroughly, it has been considered useful to add some alkaline ley to the water in which they are washed. The alkali unites with the oil and forms a soapy matter. Lime has been used for this purpose, common potash, substances containing ammonia, and the liquid from stable dung have also been employed; other matters, as sulphate of copper, act by destroying the vegetating powers of the *Fungi*.

"Mr. Ellis, of Barning, Kent, says that the invariable prevention of smut in wheat is accomplished by scalding the blackest wheat in boiling water, and afterwards drying it with lime. The wheat placed in a colander or in a basket is immersed in boiling water for a few seconds, just long enough to wet it completely, it is then immediately dipped in cold water, afterwards dried with lime, mixed with other wheat, and sown. By this means the wheat was always found to be cured of smut, while the vegetating principle was uninjured, great care being taken that the water was boiling, and the wheat taken out of the water as soon as completely wetted. Mr. Ellis tried an experiment on a bushel of the blackest wheat he could procure, which he divided into sixteen equal parts, sowing them all the same day, but with different treatment. The result at harvest was that the wheat sown without preparation produced 33 black ears out of every 100, while that dipped in boiling water and limed had not a black ear in several thousands which were examined. Many other species of *Uredo* as well as *Ustilago* give rise to diseases. They receive their names from the plants on which they are parasitic, and it seems probable that the same species presents various forms according to the situation in which it grows. *Ustilago Maydis*, a maize smut, is a fungus which gives rise to protuberances on different parts of the maize. The stem, upper leaves, and especially the bracts become immensely swollen when attacked by this disease, and the ovaries, ovules, and male blossoms are not exempt. The parts affected are at first white tinged with red, smooth and juicy. The cellular tissue increases in volume, and is permeated by radiating lines consisting of mycelium and spores. The spores are twice as large in linear measure as those of the oat smut. At first the small balls contain a dark strong-smelling fluid, but ultimately the masses become dry, and present a quantity of dark dust mixed with irregular threads. *Ustilago vittata* causes disease in grasses in India. The spores of *Ustilago hypodytes* also cause disease in grasses. The spores are black and round, and the disease they occasion is denominated Grass-smut. The plant is described by Tulasne. According to Leveillé, the immense quantity of black dust resulting from it in the hay-fields of France, produces injurious effects on the haymakers. A species of *Depazea* or *Septoria* sometimes produces disease in the knots of wheat. Various species of *Erysiphe*, such as *E. guttata*, *E. penicillata*, *E. graminis*, *E. adunca*, and *E. bicornis* give rise to kinds of mildew. Erysiphes are often met with in common pea crops. Some say that Oidiums are merely particular states of Erysiphes. The plant producing mildew in the vine is *Oidium Tuckeri* of Berkeley. Other species of *Oidium* probably cause mildew in the peach, rose, hop, pea, and onion. For destroying the mildew in vines sulphur is recommended to be dusted on them. Some also use a solution of hydro-sulphate of lime, made by boiling sulphur and lime in water. A fungus called *Rhizoctoma Mali* is said to grow on the roots of apples, pears, and quinces, and to cause destruction to the trees. Ergot is a monstrous state of the grain, in which the enlarged and diseased ovary protrudes in a curved form resembling a cock's spur, hence the name from the French 'ergot,' meaning a spur. The ovary is black externally, spongy internally, and contains much oily matter. Some consider it as produced by the attack of a fungus, which induces a diseased condition in the ovarian cells. The disease is usually met with in rye, and the name of spurred rye is applied to it. It sometimes occurs in wheat and in barley, and it has also been noticed in *Lolium perenne*, *L. arvense*, *Festuca pratensis*, *Phleum pratense*, *Dactylis glomerata*, *Anthoxanthum odoratum*, *Phalaris arundinacea*, and *Alopecurus agrestis*. Ergot consists of a very dense tissue formed by polygonal cells, united intimately with one another, and filled with an oily fluid. It is developed in the unimpregnated ovule of rye, for although extremely dilated by the entophyte and rendered difficult of recognition, the integuments of the ovule increase without completely losing the form which they would have assumed, if they had grown into a true grain, imitating in this respect the ovaries of wheat, in which *Tilletia caries* (Bunt) has replaced the seed. The solid mass which has been called *Sclerotium clavus* by De Candolle, and the filamentous portion called *Sphacelia* by Leveillé and Fée, and *Eryotætia* by Quekett, are only, properly speaking, organs of vegetation. The fungus destined to grow from this apparatus is an elegant *Sphæria*, probably that called by Fries *Cordyliceps purpurea*. This plant has been seen by Schumacher in diseased cereal grains, and it has been detected by Roussel in *Sclerotium clavus*, growing on *Bromus sylvaticus* and *Arundo calamagrostis*, and by Dumeril in Ergot of Rye. Tulasne has shown that this *Cordyliceps* is produced from the Ergot when it is allowed to vegetate. Ergot of Grasses and Ergot of *Cyperaceæ*, according to Tulasne, do not belong to the same vegetable species. Rye affected with this disease, when used as bread, is very prejudicial. The Abbé Tessier showed that Ergot caused gangrene in animals that fed on it, and many instances are recorded of gangrene of the extremities occurring in persons who had lived on diseased rye. Ergot is said to prevail in rye grown on wet and stiff land.

"The disease which has recently attacked the Potato in various parts of the world is by many attributed to the attack of *Fungi*. This view has been strongly advocated by Berkeley, who describes the fungus as *Botrytis infestans*. The spores are supposed to enter the stomata and to cause disease in the leaves in the first instance, which afterwards extends to the tubers. The effects produced on the leaves resembled much those caused by poisonous gasses, such as hydrochloric, sulphuric, and nitric acids.

"Berkeley attributes the Potato disease entirely to *Fungi*. He states that the disease commenced in the leaves. They were attacked by the mould, which ran its course in a few hours; and from the rapidity of the action, the period for examination of the leaves has often passed over. The fungus generated does not live on decayed or decaying matter, but is one which produces decay, and renders the plants unhealthy. The fungus acts by feeding on the juices of plants, preventing the elaboration of the sap in the leaves, obstructing the admission of air and the emission of transpired fluids. The stem is thus overcharged with moisture, and ultimately rots, while every source of nutriment is cut off from the half-ripe tubers. The atmospheric conditions during the late disease made the fungus spread rapidly.

"While there is no doubt that the *Botrytis* is developed in the progress of the Potato disease, the question arises whether or not it is the originating cause. The view which seems to be most consonant with the phenomena is, that changes are induced in the cells of the potato by cultivation which render the leaves liable to disease. Atmospheric influences are thus enabled to act upon them, so as to cause alterations in their cells; and the attack of a fungus, such as the *Botrytis*, accelerates the morbid action, and causes it to assume a peculiar form. In this way high cultivation, atmospheric influences, and *Fungi*, all contribute to cause disease. In the Potato disease of 1845, Harting says that brown granular matter was deposited in the cells, first in those near the epidermis, then the cellular walls lost their transparency, and the cellules could no longer be isolated by boiling water; next the cell-wall was destroyed, and small cavities were formed in the midst of the tissue, in which were agglomerated grains of starch, and finally parasitic organisms appeared in the cavities. The vegetable parasites developed were *Polyactis alba*, *Fusisporium Solani*, *F. didymum*, *F. candidum*, and *Oidium violaceum*. When the disease had advanced insects were also present.

"Crum attributed the disease of the tubers of the Potato to rupture of the starch cells, and mixture of their contents with nitrogenous matter, thus causing fermentation, as in the apple and grape. Solly objects to the fungus theory of the Potato disease. He says that decaying organic matter is necessary for the growth of *Fungi*. He thinks that the disease is caused by the presence of putrefying azotised matter in the stem, just below the surface of the soil; that this is carried to all parts of the plant, causes a struggle between vital and chemical forces, and induces decomposition by a process of fermentation. The azotised matter, in a condition to act as ferment, is produced by the state of the season, by deficiency of light, and by other meteorological causes. Analyses show that the constituents of the diseased potato undergo a rapid and important change. Dr. Lyon Playfair and Mr. Phillips found that the amount of albumen and gluten decreased from 2·34 in the sound potato to ·32 in the diseased; and when the disease advanced they finally disappeared.

"Mitscherlich says that the change which cellulose undergoes by the action of a peculiar ferment is characteristic of the substance. This fermenting agent is obtained when half putrid potatoes cut up into pieces are placed in water with portions of fresh potatoes, and allowed to stand till the cells of the fresh portions begin to be easily separable. It is also formed, though more slowly, when fresh potatoes cut up are set aside covered with water; the liquid is filtered, and fresh potatoes, cut in slices, added to it; when these are decomposed, a portion of the liquid may be treated with water, and more slices of potato added, which soon become decomposed, and in this manner increase the activity of the liquid. Hence, just as in the fermentation of an infusion of malt, the yeast, the fermentative fungus, becomes augmented, so does the ferment increase. It only acts upon the cellulose, which forms the walls of the starch-cells of the Potato; first the cells separate from each other, so that it furnishes us with a convenient means of obtaining the cells with their contents in an isolated state, and facilitating their examination; the walls of the cells are subsequently also dissolved, and the starch-particles fall out: in this manner, in 24 hours, a slice of potato is rendered so soft to a depth of two lines, that this portion can be removed by a pair of forceps, the hard mass of the potato lying beneath the softened layer, so that this process takes place successively from the outside towards the interior, not by the whole of the potato being simultaneously permeated by the ferment to the innermost portion. Exactly the same process as that which we can produce spontaneously, he says, occurs in the Potato disease, which during late years has done so much mischief. In this also the cellulose, and not the starch, is decomposed; and the liquid, which the author had kept for a long time in contact with one of the diseased potatoes, immediately produced the decomposition of a sound one. This decomposition is, therefore, he says, not the disease itself, but merely the result of it. Its cause undoubtedly depends upon the dying or the previous death of the entire plant, and just as it is well known in the case of other plants that they die when the apices of their roots are too strongly cooled, so may a sudden cold rain following a long warm winter produce a similar condition of the potato plant. It is only after decay has commenced that *Fungi* and insects attack the plant.

"Liebig attributed the Potato disease to diminished or suppressed transpiration, depending upon the hygrometric state of the atmosphere. He refers to Hale's accurate researches in regard to the Hop blight, in which the disease is traced to the want of correspondence between absorption and transpiration, and a consequent stagnation and decomposition of the juices. The same thing, he thinks, takes place in the potato in consequence of cold and an atmosphere loaded with moisture; and he shows that in 1845 and 1846, when the disease overran Europe, damp, cold, and rainy weather followed heat and drought just at the period of the most luxuriant growth of the potato. The vessels and cells became charged with fluids; and, owing to the checked transpiration, there was stagnation of the sap and death.

"*Fungi* and putrefaction are, according to him, the consequences of the death of the plant. Klotzsch proposes to check the Potato disease by pinching off the extreme points of the branches and twigs to the extent of half an inch downwards when the plants have attained the height of six or nine inches above the soil, and to repeat this on every branch or twig on the tenth or the eleventh week. This check to the stem and branches, he thinks, will direct the nutrient matters in the direction of the increase and multiplication of subterranean as well as aërial branches. This leads to increased development of tuber, and strengthens the leaves and stalks. Tombelle Lomba, of Namur, says that he has saved potatoes from disease by cutting off the stems after flowering with a very sharp sickle, and then covering the ground with earth to the depth of not less than an inch and a half. The top dressing thus applied was not disturbed till the potatoes were ripe. The haulm was removed after being cut. It is said that the tubers acquired a good size and were of excellent quality. If these facts are true, it would appear that, while leaves are necessary to the development of tubers, the latter on acquiring a certain size can continue their growth by their own proper and unassisted vitality. The general conclusions to be drawn from all that has been said relative to the Potato disease are, that changes are induced in the cells and vessels of the potato by certain obscure meteorological and epidemic causes; that an alteration takes place in the cellulose and in the contents of the cells, which speedily leads to decay; that parasitic *Fungi* find a nidus in the decaying organic matter, so as to accelerate and give a character to the disease; and that, as yet, no remedy has been devised."

For an account of the *Fungi* supposed to produce Dry-Rot in timber see the article Dry-Rot.

In many parts of the world the *Fungi* afford a supply of food to the inhabitants, although not more than half a dozen species are to be found in the markets of London, and only the common Mushroom, Truffle, and Morel are eaten in Paris; in Italy and other parts of Europe, a large number of species are consumed. [Agaricus.]

Dr. Badham, in his work on the 'Esculent Funguses of England,' gives descriptions and drawings of the following species of British *Fungi* as those which may be used as food:—

Agaricus acris minor, *A. alutaceus*, *A. atramentarius*, *A. campestris*, *A. castaneus*, *A. caudicinus*, *A. comatus*, *A. deliciosus*, *A emeticus*, *A. exquisitus*, *A. fusipes*, *A. heterophyllus*, *A. melleus*, *A. nebularis*, *A. orcella*, *A. oreades*, *A. ostreatus*, *A. personatus*, *A. piperatus*, *A. procerus*, *A. prunulus*, *A. ruber*, *A. rubescens*, *A. sanguineus*, *A. vaginatus*, *A. violaceus*, *A virescens*, *A. virgineus*, *A. ulmarius*, *A. Cæsarea*, *Boletus edulis*, *B. luridus*, *B. scaber*, *Cantharellus cibarius*, *Clavaria coralloides*, *Fistulina hepatica*, *Helvella crispa*, *H. lacunosa*, *Hydnum repandum*, *Lycoperdon Bovista*, *L. plumbeum*, *Morchella semilibera*, *Peziza acetabula*, *Polyporus corylinus*, *P. frondosus*, *P. tuberaster*, *Verpa digitaliformis*.

Too great caution however cannot be employed in distinguishing the edible from the poisonous species. In the markets of Rome an inspector of Funguses is appointed, whose duty it is to examine all *Fungi* exposed for sale, and none are allowed to be sold but with his express sanction. But it would appear, from a case quoted in Lindley's 'Vegetable Kingdom,' that *Fungi* which are usually innocuous may, under certain circumstances, become poisonous. The fungus consumed in this instance by a family in Cambridgeshire was the *Agaricus personatus*, a species sold in Covent Garden under the name of Blewitts, and which all writers agree in regarding as perfectly free from danger.

The poisonous principles produced in the *Fungi* have sometimes been employed in medicine, an instance of which is given above in the Ergot. The action of a species of *Bovista* has been found similar to that of chloroform. [Bovista, *S.* 1.] The *Amanita muscaria* possesses an intoxicating property, and is employed by northern nations as an inebriant. The following is the account of Langsdorf, as given by Dr. Greville:—

"This variety of *Amanita muscaria* is used by the inhabitants of the north-eastern parts of Asia in the same manner as wine, brandy, arrack, opium, &c., are by other nations. Such *Fungi* are found most plentifully about Wischua, Kamtchatka, and Willowa Derecona, and are very abundant in some seasons and scarce in others. They are collected in the hottest months, and hung up by a string to dry in the air; some dry of themselves on the ground, and are said to be far more narcotic than those artificially preserved. Small deep-coloured specimens thickly covered with warts are also said to be more powerful than those of a larger size and paler colour. The usual mode of taking the fungus is to roll it up like a bolus and swallow it without chewing, which the Kamtchatkadales say would disorder the stomach. It is sometimes eaten fresh in soups and sauces, and then loses much of its intoxicating property. When steeped in the juice of the berries of *Vaccinum uliginosum* its effects are those of a strong wine. One large or two small *Fungi* are a common dose to produce a pleasant intoxication for a whole day, particularly if water be drunk after it, which augments the narcotic principle. The desired effect comes on from one to two hours after taking the fungus. Giddiness and drunkenness result in the same manner as from wine or spirits: cheerful emotions of the mind are first produced, the countenance becomes flushed, involuntary words and actions follow, and sometimes at last an entire loss of consciousness. It renders some remarkably active, and proves highly stimulating to muscular exertion. By too large a dose violent spasmodic effects are produced. So very exciting to the nervous system in many individuals is this fungus that the effects are often very ludicrous. If a person under its influence wishes to step over a straw or a small stick, he takes a stride or a jump sufficient to clear the trunk of a tree. A talkative person cannot keep silence or secrets, and one fond of music is perpetually singing. The most singular effect of the *Amanita* is the influence it possesses over the urine. It is said that from time immemorial the inhabitants have known that the fungus imparts an intoxicating quality to that secretion, which continues for a considerable time after taking it. For instance, a man moderately intoxicated to-day will by the next morning have slept himself sober, but (as is the custom) by taking a tea-cup of his urine he will be more powerfully intoxicated than he was the preceding day. It is therefore not uncommon for confirmed drunkards to preserve their urine as a precious liquor against a scarcity of the fungus. The intoxicating property of the urine is capable of being propagated, for every one who partakes of it, has his urine similarly effected. Thus, with a very few *Amanitæ* a party of drunkards may keep up their debauch for a week. Dr. Langsdorf mentions that, by means of the second person taking the urine of the first, the third of the second, and so on, the intoxication may be propagated through five individuals."

Fungi are often phosphorescent. The light given out by species of *Rhizomorpha* in the coal-mines of Dresden is described as giving them the appearance of an enchanted castle. *Agaricus Gardneri*, which grows on a sort of palm called Britada in Brazil, is highly luminous. The same phenomenon has been observed in *A. olearius* in the south of Europe, and in two species of *Fungi* at Swan River. Dr. Hooker describes a luminous fungus as growing upon decaying wood in the forests of the Sikkim Himalaya.

It is generally stated that *Fungi* differ from the rest of the vegetable kingdom, in the absorption of oxygen and the disengagement of carbonic acid gas. In experiments which have been performed, this has been the result; but it is well known that the tissues of *Fungi* are easily decomposable, and it is more probable that the absorption of oxygen, and the giving out of carbonic acid gas is the result of decay, rather than of the true growth of the plant. The following substances were found by Payen in his analysis of *Fungi*:—1. Water; 2. Cellulose; 3. Nitrogenised Substances; 4. Fatty Matters; 5. Sugar; 6. Volatile Matter; 7. Sulphur; 8. Salts, containing Silex and Potash. These substances are analogous to the ordinary products of the decomposition of water, ammonia, and carbonic acid gas by deoxidation, and must either be formed by that process in the fungus itself, or taken directly up from the substances on which they grow, by absorption.

A curious fact connected with the development of *Fungi* is the occurrence of vegetable cells, referred to this order, in liquids undergoing fermentation. During the conversion of malt into beer, plant-cells are constantly observed to be present, and these have been described as a plant, under the name of *Saccharomyces Cerevisiæ*. During the preparation of flax, as now carried on at Belfast, Professor Allman has observed present cells resembling those of *Saccharomyces*. Whether these are true plant-cells or not, is still a question; and it is still more a question as to whether they have anything to do with the changes going on in the solutions in which they occur. They are probably a result, and not the cause, of fermentation. These cells have not escaped the observation of Schleiden, and the following is his account of them:—

"In the last place, I must mention a highly interesting analogy, which, when more accurately examined, may perhaps one day lead to the most satisfactory explanation of the process of cell-formation—I mean vinous fermentation. We have here a fluid in which sugar and dextrin, and a nitrogenous matter, as a cytoblast, are present. At a certain temperature, which is perhaps necessary to the chemical activity of the mucus, there originates, without, as it appears, the influence of a living plant, a process of cell-formation (the origin of the so-called fermentation-fungus), and it appears that it is only the vegetation of these cells which produces the peculiar changes that occur in the fluid. Whether this organism is really a fungus, is a matter of indifference; but whether it alone, through the activity of its vital processes, determines the process of fermentation, deserves to be accurately determined.

"I will here add my own observations on these fermentation-cells. I bruised some currants with sugar, and having pressed the juice through a cloth diluted it with water and filtered through folded paper. The fluid was bright red, quite clear and transparent, and, under the microscope, showed no trace of granules, but presented a number of little drops of a pure clear oil. At the end of twenty-four hours the whole fluid was opalescent, and presented, under the microscope, a number of granules suspended in it. On the second day these granules had greatly increased, and there appeared amongst them perfectly-formed ferment-cells. There also appeared, now and then, vesicles of carbonic acid gas. On the fourth day fermentation was very active. At the bottom of the vessel and on the surface of the fluid, yeast had formed; but these yeasts consisted of single cells, or several attached one to another. In the solitary cells could be observed the way in which one cell was formed from another. The ferment-cells do not in this state permit of a distinction between the contents and the membrane of the cell. In the midst of the cell there is a transparent spot; but whether hollow, or a solid nucleus, I could not decide. The remaining parts appeared entirely homogeneous, yellowish like a nitrogenous substance, sometimes mixed with small solitary granules. In a similar way, a solution of sugar with elder-flowers was examined, and gave similar results. Other results were obtained in the following way:—Pure white protein (albumen) from the white of an egg, was dried, and rubbed down with sugar, and left to ferment: the fluid at first was perfectly clear. On the third day, the small portions of protein, which at the commencement exhibited a sharply angular aspect, assumed partly a granular aspect, and some a more or less rounded form. These globules showed an active molecular movement, and some appeared strung together. On the fourth day there was seen between these granules round or elongated cells, which were either solitary, or arranged together in a line with a tendency to the formation of branched fibres. These cells were not more than one-third of the diameter of ordinary ferment-cells. An active fermentation went on, and gas-bubbles were given out from the protein-granules and the linear cells. Proper ferment-cells did not make their appearance. Fluid albumen, mixed with sugar, and filtered, became thickened on the second day, and contained little granules of albumen (coagulated?). The further phenomena were similar to those exhibited by the preceding, except that there were developed a few true ferment-cells. Protein moistened with water displayed the same appearances as when mixed with sugar and water; ultimately putrefaction came on, and the development of *Infusoria*, but the vegetable formation preceded. There appears to be two very different types of ferment-cells, according as the fluid contains organic acids and essential oils or not. From the phenomena exhibited by the ferment-cells, one might be inclined to regard them as similar to animal-cells, which are formed through a cavity in the cytoblast, and which afford indications of the nucleoli in their highest development. But this analogy is not tenable, and the above observations must be regarded as imperfect. If we take fully developed ferment-cells, and treat them with ether, alcohol, or caustic alkalies, there will be found in the fluid a number of globular delicate cells, with thin but clearly distinguishable walls, which contain a clear fluid, with here and there very small granules, which, alone or in groups, are attached to the inner surface of the cell-wall, and (almost?) always a large round flat body (a cytoblast?)."

The following arrangement of the *Fungi* is given in Lindley's 'Vegetable Kingdom':—

Spores generally quaternate, on distinct Sporophores. Hymenium naked.	*Hymenomycetes*, or *Agaricaceæ*.
Spores generally quaternate, on distinct Sporophores. Hymenium inclosed in a Peridium.	*Gasteromycetes*, or *Lycoperdaceæ*.
Spores single, often septate, on more or less distinct Sporophores. Flocci of the fruit obsolete, or mere peduncles.	*Coniomycetes*, or *Uredinaceæ*.
Spores naked, often septate. Thallus floccose.	*Hyphomycetes*, or *Bothylaceæ*.
Sporidia contained (generally eight together) in Asci.	*Ascomycetes*, or *Helvellaceæ*.
Spores surrounded by a vesicular veil or Sporangium. Thallus floccose.	*Physomycetes*, or *Mucoraceæ*.

(Fries, *Systema Mycologicum*; Greville, *Cryptogamic Flora*; *Neues System der Pilze*; Corda, *Icones*; Endlicher, *Genera Plantarum*; Hooker, *British Flora*; Sowerby, *Fungi*; Bulliard, *Figures of Fungi*; Lindley, *Vegetable Kingdom*; Berkeley, *Papers in Annals of Natural History*.)

FUSEL OIL. [CHEMISTRY, *S.* 2.]

G

GADOLINITE. [YTTRIUM.]

GADWALL. [DUCKS.]

GAERTNER, or GÄRTNER, FRIEDRICH VON, architect, was born at Coblenz in 1792, and was the son of Johann Andreas Gaertner. Brought to Munich at an early age, he received a general scientific education, and in 1809 entered the Academy of Arts in order to devote himself specially to architecture. After three years he went to Paris, to enter the Academy there; and here he enlarged his knowledge under the guidance of Percier. France had been during many years regarded as the school of Germany in art—for German art was then only about to re-assert independent character, such as under Gärtner and other artists it soon acquired. In 1814 Gärtner went to Italy, where he remained four years. He visited Rome, Naples, and other places of general interest, but would appear to have devoted himself to the antique monuments as much as to later works, although it is the character of the Byzantine and early Italian styles to which the designs in his own buildings are nearest allied. He especially studied the ruins in Sicily, including those at Girgenti, Segesta, and Taormina, which he drew and published in lithography, in 1819, in a work entitled 'Views of the best-preserved Greek Monuments of Sicily, with Explanatory Text.' In 1819 also he came to England, and was induced to think of residing here; but in 1820, being made professor of architecture in the Munich Academy, he was from that time engaged in Bavaria. Well qualified by his studies and taste to co-operate in the grand revival fostered by the Crown Prince (afterwards Louis of Bavaria), Gärtner became connected with several important branches of manufacture. The superiority in forms and character attained in the works of the porcelain factory, of which he became director in 1822, was due to him, as also in great part was the revival of glass-painting. In 1829 the sphere of his influence was enlarged. King Louis, appreciating his talent, instructed him to design the Ludwigs-Kirche, which eventually was magnificently decorated internally with the aid of the painter Cornelius. Near the church is the great library and record-office, by the same architect. In 1833 he commenced the Blinden-Institut. Amongst his other buildings about the same time, or subsequently, were the University, the Erziehungs-Institut, the Damenstift, the Priester-Seminar, the Salzamt, the Ludwigs-thor, and the Feldhernnshalle, all at Munich. Besides these he built the palace at Wittelsbach, the pump-room at Kissingen, and the Befreiungshalle at Kelheim—a great monument in the form of a rotunda, designed to commemorate the liberation of Germany.

In 1836 Gärtner accompanied the king to Athens to study the Greek monuments, and there he was directed to design a new Residenz, or palace, for King Otho. At Athens he re-opened the quarries of Pentelic marble, said to have been forgotten since the time of Hadrian. On his return he was appointed oberbaurath, or architect to the court, and received the order of Civil Merit of the Crown of Bavaria; and on the departure of Cornelius for Berlin in 1841, he was made Director of the Academy of Arts. In addition to the works above mentioned, Gärtner was architect of the Pompeian House at Aschaffenburg—one of those efforts to collect a series of examples of *styles*, through which, in consequence of that aim, the value of King Louis's still great services to art is reduced. Gärtner also restored the Isar-thor, and portions of the cathedrals at Regensburg and Bamberg. He died on the 21st of April 1847, aged fifty-five years.

Gärtner's style, as described by Raczynski ('Histoire de l'Art Moderne en Allemagne'), is one which "recalls" the idea of the Byzantine; which, as a general statement, is correct. The University and the Bibliothek have however a marked Florentine character. The architect constantly uses the arch-headed window, divided into two lights by a centre-column, and avoids the characteristics of the late Italian styles,—whilst ornament of original character is freely introduced. Much of the fame of Munich for interior decoration in buildings, and the influence of which has spread even to this country, is due to Gärtner. A publication of his designs was commenced about 1844 or 1845.

GAGERN, HANS CHRISTOPH ERNST, FREIHERR (Baron) VON, was born January 25, 1766, at Klein-Neidesheim, near Worms, in the German duchy of Hesse-Darmstadt. He completed his studies at the universities of Leipzig and Göttingen. At an early age he entered the service of the Prince of Orange-Nassau, and was employed as a minister, and sent as an ambassador to Paris. When the Prince of Orange in 1814 became the sovereign of Holland, Baron von Gagern became his prime-minister, and in 1815 was his ambassador to the Congress of Vienna. The Prince of Orange having become king of the Netherlands, Baron von Gagern continued to be his principal minister, and was employed on important occasions as his ambassador. In 1820 the King of the Netherlands rewarded his services by a pension, and he then retired to reside upon his estate at Hornau in the duchy of Hesse-Darmstadt, where he died Oct. 22, 1852, at the age of 86. He was the author of several valuable works on subjects of history, politics, and national law.

When the German parliament was assembled at Frankfürt for the purpose of forming a confederation of the smaller states under a central government, Heinrich von Gagern (son of the above Baron) was appointed president, May 19, 1848; and on the 30th of June, when his first term of office expired, he was re-elected. On the 18th of December he resigned the presidency of the assembly, and Eduard Simson of Königsberg was elected as his successor, the Baron Von Gagern being nominated by the Regent of the Empire to the offices of Minister of Foreign Affairs and President of the Council of Ministers. After many discussions it was resolved, March 28, 1849, that the German states should be constituted an Empire, and that the imperial dignity should be offered to the King of Prussia. The offer was accordingly made, and negociations between the parliament and the king continued for some time; but the king ultimately refused to accept the dignity, under the conditions proposed, and the assembly was dissolved without producing any result.

GALEUS. [SQUALIDÆ.]

GALLAUDET, REV. THOMAS HOPKINS, to whom America is indebted for the introduction of instruction for the deaf and dumb, was born at Philadelphia, December 10, 1787. Having passed through Yale College, he commenced the study of the law; but being forced to abandon it, in consequence of ill-health, he engaged for a while in commercial pursuits; then, in 1814, he entered the theological seminary at Andover, and upon being licensed to preach, was chosen pastor of a congregational church at Portsmouth, New Hampshire. While thus occupied he became much interested in a little deaf and dumb girl, Alice Cogswell, the daughter of a friend, and he was induced to attempt to instruct her. In this he was by great patience very successful, and her father, Dr. Cogswell of Hartford, was incited by the great benefit which his child had derived, to earnest efforts to extend the blessings of education to other children suffering under similar deprivation. An association was formed, and funds being provided, a requisition was made to Mr. Gallaudet to resign his ministry, and proceed to Europe for the purpose of learning the system and organisation of the existing deaf and dumb institutions.

After some hesitation, caused by a reluctance to separate from his flock, he accepted the offer, and in May 1815 embarked on his mission. He first addressed himself to the London Deaf and Dumb Asylum, but after considerable correspondence he was refused admission to the asylum, except as ordinary junior assistant, and to perform the usual drudgery of that class of assistants. As this he found would have obliged him to spend at least three years in the school without any corresponding gain, he proceeded to Edinburgh, where there was an asylum in considerable reputation. But there, while the committee and master showed every sympathy with him, and would have been glad to assist him in his excellent object, there was an obstacle which it was found impossible to surmount. The teacher had learnt his system from the Messrs. Braidwood [BRAIDWOOD, THOMAS], and had been compelled by them to sign an engagement not to impart the method to any one person intending to become a teacher.

Thus baffled, Gallaudet was compelled to try Paris. Here he met from the Abbé Sicard a warm welcome. Everything was laid freely open to him, and every means that could be devised was used to accelerate his acquisition of the desired knowledge. He was able to return to America before the close of 1816, and the Abbé Sicard cheerfully consented to Lawrence le Clerc, himself a deaf-mute, who had been one of the pupils, and was then one of the most valued teachers of the institution (he had indeed already been designated its 'glory and support'), accompanying him to America. During his absence in Europe, the society had been incorporated; Mr. Gallaudet was now appointed its principal, Le Clerc being his head assistant, and on the 15th of April, 1817, 'The American Asylum for the Deaf and Dumb,' at Hartford, Connecticut, was formally opened.

Mr. Gallaudet remained the active head of the asylum until 1830, when he resigned from failing health. His devotion to his duties had been most exemplary, and his success as a teacher, we are told, was "uniform and pre-eminent." The system which he in conjunction with M. le Clerc ultimately established, and which has been adopted in the other asylums (of which there are now fourteen) in the United States, was founded on that of the Abbé Sicard, but with very considerable modifications. It is known as the American system. The main principle with Mr. Gallaudet was to call out the intelligence of the pupil as much as possible, by exercising him in describing things for himself, and to discourage the mere learning by rote; and the result was to stimulate the mind of the teacher, as well as of the pupil, in no ordinary degree.

Mr. Gallaudet's exertions were by no means confined to the deaf and dumb asylum. He took an ardent and active interest in the improvement and extension of common schools, and in the raising up of a superior body of teachers, and wrote several pamphlets on the subject. He also zealously advocated the adoption of means of imparting moral and religious training to prisoners; and he was an earnest promoter of the movement for improving the management of the insane. So strongly did he feel on this matter that, though in but feeble health, he accepted in 1838 the office of chaplain of the State 'Retreat for the Insane,' at Hartford; where it is stated, "the experience of each successive year furnished accumulating evidence of the usefulness of his labours, and the efficacy of kind moral treatment, and a wise religious influence in the melioration and care of the insane."

He died on the 10th of September, 1851. About twelve months before his death, the good old man, and his colleague M. le Clerc, had the gratification of receiving from the deaf-mutes in America, as a testimonial of their gratitude, a service of plate each; and on the death of Gallaudet, his fellow-citizens proposed to erect a monument to his memory, as a mark of their sense of his services; but as soon as their intention became known, the deaf and dumb urged their superior claim to the performance of that duty, and accordingly a handsome and costly monument was erected to his memory at Hartford, at the "sole expense of the deaf-mutes of the United States;" the designer and the architect of the monument being both deaf and dumb persons.

The publications of Mr. Gallaudet are numerous, but chiefly pamphlets on the education of the deaf and dumb, and on other educational matters; lesson books; and articles in educational journals. But he also published a volume of sermons, and some books for the young, one of which, 'The Child's Book of the Soul,' had an extended popularity both in America and in England, and was translated into French, Spanish, Italian, and German.

(Barnard, *Tribute to Gallaudet*, 8vo, Hartford, U. S., 1852.)

GALLE, POINT DE, a town, fort, and harbour on the south coast of the island of Ceylon, 72 miles S. by E. from Colombo, is situated in 6° 1′ N. lat., 80° 16′ E. long. The town and fort are built on a low rocky promontory named the Point de Galle. The harbour is formed between the point, which extends towards the east, and a piece of land slooping inwards from the west, thus forming a small bay. The entrance to the bay is about a mile wide, but as there are many rocks in it, a pilot is required to take the vessel to the anchorage, which is abreast the town in 5 fathoms depth of water. There is a pier; a jetty was constructed in 1847, and a new wharf in 1853. The increase in the number of steam-vessels calling at the port chiefly to take in coals has caused various proposals to be made for improving the harbour, but funds are wanting. The fort, built by the Dutch, is upwards of a mile in circumference, and contains several large and commodious houses inhabited by Europeans. The town, or pettah, inhabited by natives, is extensive, contains many neat houses, and has a large population. There are schools here maintained by the government for the education of the natives. An iron lighthouse, constructed in London, was erected in 1848; the total height of the light above the sea is 103 feet. The mail-steamers stop at Point de Galle, and the letters, &c., are forwarded immediately to Colombo, whence they are transmitted to all parts of Ceylon. Letters taken by steamers from Point de Galle reach Madras in three days and Calcutta in nine days. Bombay is reached by steam-vessel in six days.

GALLIONELLA. [Melosireæ, *S.* 2.]

GAMBIA COLONY, the British settlements on the Gambia, a river in Western Africa. The source of the Gambia has not been definitely ascertained. According to the most reliable accounts it rises in the country of the Fouta-Jalon, very near and a little to the south of the source of the Rio-Grande, in 10° 36′ N. lat., 11° 18′ W. long., in a valley surrounded by mountains. The river flows first east and then north till it reaches 13° 22′ N. lat., whence it turns and flows south to 11° 18′ N. lat., where, after having flowed upwards of 400 miles, it is less than 50 miles from its source. Its course is then generally north-west as far as 14° 30′ N. lat., 13° 15′ W. long., whence it flows westward with many bends to the sea, which it enters in 13° 30′ N. lat., 16° 40′ W. long. The Gambia has many affluents, especially in the upper part of its course. The most remarkable on the right bank are the Ba Creek, the Neolacaba, the Nyarico, the Nicolico, and the Nanijar. On the left bank it receives the Poré, the Jelata, and the Eropina, 45 miles below which the Gambia throws off a considerable branch named the Casamansa, which by numerous channels flows into the St. Domingo. The width between Cape Ste. Marie and the island of Sanguomar is about 20 miles. The width gradually diminishes. For nearly 400 miles the Gambia presents a fair water-road into the interior. Early in 1851 Governor Macdonnell, at the close of a tour of inspection on the river Gambia, proceeded up the river as far as about 160 miles above the Rock of Barraconda, which has generally been considered to be 450 miles above Bathurst. The governor's party included Mr. Bage, the colonial engineer, Staff-Surgeon Kehoe, and Lieutenant Mostyn; they proceeded in open boats, accompanied by a canoe. In their progress they observed few signs of cultivation or of inhabitants along the banks. Near the junction of the Nyarico the inhabitants of a town called Jallacoota waited upon the governor, soliciting the visits of traders to their district. The influence of the British has been beneficially exercised in abating the violence of intestine strife among the native tribes in the interior, and cultivating commercial intercourse, thereby promoting agricultural industry, and fostering conciliatory feelings amongst the tribes. By the exertions of Governor Macdonnell and Staff-Surgeon Kehoe vaccination has been brought into very extensive adoption among the native tribes on the Gambia.

The English have trading establishments at intervals along both banks of this river for many miles into the interior. The whole of the establishments are included under the title of the Gambia Colony. The colonial revenue for 1851 was 8414*l.* The exports from the Gambia are African teak, ship-timber, ground-nuts, ivory, hides, gold, palm-oil, gum-arabic, and bees'-wax. The value of the exports in 1851 amounted to 186,404*l.*, of the imports to 107,011*l.* In 1852 the exports amounted to 217,856*l.*, the imports to 110,174*l.* The number of vessels arriving at the colony during 1852 was 258, tonnage 29,274, of which 31 ships of 5307 tons were British. The number and tonnage of ships cleared outwards during 1852 were:—Ships 260, tonnage 30,188, of which 30 ships of 4994 tons were British. The number and tonnage of vessels registered as belonging to the port of Bathurst on December 31st 1853 were:—Under 50 tons 49 vessels, tonnage 923; above 50 tons 14 vessels, tonnage 1270. Of the amount of exports for 1851 (186,404*l.*) the article of ground-nuts alone furnished 133,133*l.* value. The quantity of ground-nuts raised by agricultural labour in the countries immediately bordering on the Gambia River and exported from Bathurst has risen from 47 tons in 1835, to 11,094 tons in 1851. The ground-nuts are chiefly exported to France. The increased demand for this produce has tended to encourage settled and industrious habits among the native African population, many of whom travel hundreds of miles from the interior, and hire from the chiefs whose lands lie on the banks of the Gambia, such small portions of ground as their circumstances allow them to cultivate. After the produce of two or three years has enabled them to purchase supplies of European goods, they usually make up parties of from 20 to 100 strong and return to their homes in the interior. These migratory labourers are called 'tilliebunkas,' or men from the east. The principal establishments of the Gambia Colony are at *Bathurst*, on the island of St. Mary, at the mouth of the river, whence the produce of the country is shipped for England, and at Mac Carthy's Island. A colonial steamer has been stationed at Bathurst for some years, and has been of considerable benefit in facilitating communication with Mac Carthy's Island, and with trading stations on the banks of the Gambia. The land and sea breezes blow regularly over St. Mary Island for a considerable part of the year. The surface is a low plain with a slight descent on the north and east towards the centre, which during the rainy season is much inundated. The soil is sandy, with a very small admixture of loam. In the shade the thermometer does not rise above 90°. Water is scarce and not of good qnality. Bathurst town does not stand more than 12 or 14 feet above high-water mark. Many good and snbstantial government and public buildings have been erected, as well as numerous handsome and convenient warehouses and dwellings; the remainder of the houses are rude African huts. The European residents average only about 50, but the number of European and American sailors and others visiting Bathurst every year is little short of 1200. There is a Roman Catholic chapel, capable of accommodating 600 persons, but no suitable place of worship for Protestants. The circumstances of the colony having been somewhat prosperous of late years, several improvements are being effected. Among these may be mentioned—the placing of a light-ship at the month of the river; the sinking of wells in Bathurst for the use of the shipping; the erection of a pnblic hospital, a market, a wharf, a chnrch, a court-house, and public-offices at Bathurst; and the construction of roads in the neighbourhood. About the close of 1850 a piece of ground in a very healthy spot, about 8 miles from Bathurst, was obtained from the King of Combo. The gronnd is about 2½ miles in length, and stretches along the shore of the Atlantic, with an elevation above the sea varying from 50 to 90 feet. It is situated near Cape St. Mary, and being intended to be built npon by merchantsand others, residents of Bathurst, it has been called Clifton.

The popnlation of Gambia Colony, according to the census taken March 31st 1851 was 5693, as follows, namely:—

	Whites.		Coloured population.	
	Males.	Females.	Males.	Females.
Island of St. Mary . .	167	13	2192	1890
Mac Carthy's Island .	8	0	637	526
Barra Point	1	0	131	74
Cape St. Mary . . .	1	1	36	16
Total . . .	177	14	2996	2506

Of the total population 82 were returned as engaged in agriculture, 330 in mannfactures, and 278 in commerce.

Mac Carthy's Island, the Janjan Bure of the natives, has an area of abont 3 square miles, and is 180 miles from the month of the river, following its windings, in a populous district, 60 miles below the falls of Barracunda, np to which spot the river is navigable for vessels of 50 tons burden. Fort George, on the island, is in 13° 33′ N. lat., 14° 45′ W. long. Like St. Mary Island, it is but little raised above the level of the sea, and both are in a great measure covered with water during the rainy season. Tropical remittent fever occurs at both places, but with most intensity at Mac Carthy's Island. Mac Carthy's Island has a rich alluvial soil, which in the dry season becomes a mass of burnt clay. The thermometer freqnently rises to 106° or 108° in the shade.

The Wesleyan Methodists have schools at Bathurst, at Mac Carthy's Island, and at Barra opposite Bathurst; the total number of scholars is about 600. The Roman Catholics have a school at Bathurst under the care of several Sisters of Charity.

GAME LAWS. *Hares* are no longer game, in the sense of its being necessary to take out a certificate to kill them (11 & 12 Vict. c. 29).

GAMING. The numerous alterations which have been made in the law relating to contracts by way of gaming, to gambling-houses, and to betting-offices, call for some repetition of what has been already stated on this subject. [GAMING.] Playing at cards, dice, or other games of chance, merely for recreation, and without any view to inordinate gain, is by the common law considered perfectly innocent. Not so the offence of *gaming;* which the law looks upon as "a tacit confession that the company engaged therein do, in general, exceed the bounds of their respective fortunes; and therefore they cast lots to determine upon whom the ruin shall at present fall, that the rest may be saved a little longer." In this light, "it is an offence of the most alarming nature; tending by necessary consequence to promote pnblic idleness, theft, and debauchery, among those of a lower class: and among persons of a superior rank, it has frequently been attended with the sudden ruin and desolation of ancient and opulent families, an abandoned prostitution of every principle of honour and virtue, and too often has ended in self-murder." To restrain this pernicious vice among the inferior sort of people, the statnte of 33 Hen. VIII. c. 9, was made; which prohibited to all but gentlemen the games of tennis, tables, cards, dice, bowls, and other unlawful diversions, snch as logetting in the fields, slide-thrift, or shove-groat, cloysh-cayls, half-bowl, and coyting, nnless in the time of Christmas, under pecuniary pains and imprisonment. By the statute 16 Car. II. c. 7, it was next enacted, that if any person by playing or betting lost more than 100*l.* at one time, he was not compelled to pay the same; and the winner forfeited treble the value, one moiety to the king, the other to tho informer. The statute 9 Anne, c. 14, further provided, that all bonds and other securities, given for money won at play, or money lent at the time to play withal, should be ntterly void; that all mortgages upon the same consideration, should enure to the use of the heir of the mortgagor; that, if any person at any time lost 10*l.* at play, he might sue the winner, and recover it back by action; and in case the loser did not, any other person might sue the winner for treble the sum so lost; and the plaintiff might by bill in equity examine the defendant himself npon oath; and that in any of these suits no privilege of parliament should be allowed. The statute further enacted, that if any person by cheating at play should win any money or valuable thing, or should at any one time win more than 10*l.*, he might be indicted thereupon, and shonld forfeit five times the value to any person who sued for it, and (in case of cheating) should be deemed infamous, and suffer snch corporal punishment as in case of wilful perjury.

The effect of these and of various other statutory provisions, which need not be enumerated, was that all gambling securities, even when transferred to purchasers for a valuable consideration, and without notice of their illegal origin, were altogether void; a result nnder such circumstances often attended with great hardship and injustice. The law was therefore altered by statute 5 & 6 Will. IV. c. 41, by which securities given for considerations arising out of illegal transactions are declared not to be void; but to be deemed as having been given for an illegal consideration only, the object and effect of this enactment being to protect innocent holders of such secnrities. Finally, by the statute 8 & 9 Vict. c. 109, repealing the Act of Hen. VIII. (so far as relates to the prohibition of the games of skill therein mentioned, together with the statutes of Charles II. and Anne, and several others), every person who by any fraud, unlawful device, or ill practice, in playing at or with cards, dice, tables, or other game, or in bearing a part in the stakes, wagers, or adventures, or in betting on the sides or hands of those that play, or in wagering on the event of any game, sport, pastime, or exercise, shall win from any other person any sum of money or valuable thing, is guilty of obtaining it by a false pretence, with intent to cheat or defraud; and being convicted thereof, is punishable accordingly. By the same statute all contracts or agreements, by way of gaming or wagering, are declared to be null and void, and no suit is to be maintainable for recovering any money or valuable thing alleged to have been won npon any wager, or deposited in the hands of a stakeholder. This provision, however, does not apply to any subscription, contribution, or agreement to subscribe or contribute for or toward any plate, prize, or sum of money to be awarded to the winner of any lawful game (snch as a *foot-race* or *dominoes*), sport, pastime, or exercise.

For the suppression of *gaming-houses*, many statutes have been passed from time to time. The Act 33 Hen. VIII. c. 9, first prohibited the keeping of any gaming-house for profit, under a penalty of 40*s.* a-day; and subjected any person haunting and using such gaming-houses to a penalty of 6s. 8d. The same statute, and also the statute 30 Geo. II. c. 24, inflicted penalties as well upon the master of a public-house, wherein servants were permitted to game, as upon the servants themselves, who were found to be gaming there. Special provisions for the prevention of this offence were afterwards made by the statute 3 Geo. IV. c. 79; and now, by the statute 9 Geo. IV. c. 61, the unlawfully and knowingly permitting of any unlawful game, or any gaming whatever, in a public-house, may involve a forfeiture of the licence as well as the imposition of a penalty. A licence is now also required, under a penalty, to be obtained annually, at the general annual licensing meeting of the justices of the peace, by such persons as keep public billiard-tables and bagatelle-boards, or instruments used in any game of a like kind.

By several statutes of the reign of King George II., all private *lotteries* by tickets, cards, or dice (and particularly the games of faro, basset, ace of hearts, hazard, passage, rolly-polly, and all other games with dice, except back-gammon), are prohibited under a penalty of 200*l.* for him that shall erect such lotteries, and 50*l.* a time for the players; and by the statute 42 Geo. III. c. 119, games called *little-goes* are declared to be common and public nuisances, and a penalty of 500*l.* is imposed on persons keeping any office or place for that game, or for any other lottery whatsoever, not authorised by parliament. *Public lotteries*, unless by authority of Parliament, and all manner of ingenious devices, under the denomination of sales or otherwise, which in the end were equivalent to lotteries, had been before prohibited by a great variety of statutes under heavy pecuniary penalties.

The effect of these statutes being to render all lotteries illegal, whatever might be the object, it was found necessary to pass a special Act for the protection of those laudable associations, generally called *Art-Unions*, having for their object the promotion of a taste for the fine arts; and accordingly, by the 9 & 10 Vict. c. 48, any voluntary association constituted for the distribution of works of art by lot, is to be deemed legal; provided it be incorporated by charter or that the deed constituting the association and its rules be submitted to and approved of by a committee of the Privy Council.

The statute 13 Geo. II. c. 19, to prevent the multiplicity of *horse-races*, another fund of gaming, directed that no plates or matches under 50*l.* value should be run, upon penalty of 200*l.* to be paid by the owner of each horse running, and 100*l.* by such as advertised the plate. But in consequence of a number of vexatious actions having been brought under this statute, it was, so far as it related to horse-racing, repealed by the statute 3 Vict. c. 5. The effect of the repeal of the provisions of the statutes 33 Hen. VIII. c. 9, and 13 Geo. II. c. 19, and of the exception before mentioned in the statutes 8 & 9 Vict. c. 109, is to place all bargains relating to horse-racing on the same footing as other contracts.

"But," as observed by Blackstone, "particular descriptions will ever be lame and deficient, unless all games of mere chance are at once prohibited; the inventions of sharpers being swifter than the punishment of the law, which only hunts them from one device to another." No sooner were contracts as to horse-racing legalised, than an immense number of petty gaming-houses sprung up, under the name of *betting-offices*. The demoralisation which was found to be the immediate result called for the interference of the legislature, and the statute 16 & 17 Vict. c. 119, was accordingly passed, expressly for the suppression of these haunts of vice. Under this Act, the owner or occupier, or any person using such places, may be summarily convicted, and either punished by a fine not exceeding 100*l.*, or by imprisonment with or without hard labour, for any period not exceeding six months. Persons receiving deposits on bets in such houses incur a penalty of 50*l.*, or three months' imprisonment with or without hard labour; the exhibition of placards or hand-bills, or the advertising of betting lists, is prohibited, under a penalty of 30*l.*, or two months' imprisonment; and summary powers are conferred on magistrates and constables to enter and search suspected houses.

It may be added here that a bankrupt is not entitled to a certificate, or the certificate if granted is void, if he has lost 20*l.* in one day or 200*l.* a-year by any sort of gaming or wagering.

Common gaming-houses are *public nuisances*, and the keeper thereof may be indicted at common law. To encourage the prosecution of such pernicious establishments, the statute 25 Geo. II. c. 36, as amended by 58 Geo. III. c. 70, imposes on the overseers of the parish, or the constable, the duty of prosecuting, whenever two rated inhabitants depose before a magistrate to their belief of the fact of the house being a gaming-house, and enter into recognizances to give material evidence thereof. The costs of the prosecution are, in this case, allowed out of the rates; and on conviction, the two inhabitants who originated the proceedings are entitled to 10*l.* each. To facilitate such prosecutions, it is expressly provided that the person appearing or acting as master, or as having the care and management of any gaming-house, shall be deemed the keeper thereof and liable as such. The offence is punishable by a fine, to which, by the statute 3 Geo. IV. c. 114, imprisonment and hard labour may be added.

The more recent enactments of the statute 8 & 9 Vict. c. 109, and 17 & 18 Vict. c. 38, have still farther facilitated the prosecution of this offence. The owner, occupier, or keeper, and every person in any manner conducting the business of any common gaming-house, or advancing or furnishing money for the purpose of gaming, may now be convicted on the oath of one witness, before two justices of the peace; and in addition to the penalties of the Act of Henry the Eighth, be fined in any sum not exceeding 500*l.*, or in the discretion of the justices, be committed to the house of correction, with or without hard labour, for any period not exceeding twelve months. No proceeding under these statutes is a bar to an indictment being preferred; but no person summarily convicted under them can afterwards be proceeded against by indictment for the same offence. To remove any difficulty in obtaining the necessary evidence, the first-mentioned statute expressly provides that any person examined as a witness, either before the justices or on the trial of any indictment or information touching any unlawful gaming, and who shall receive from the court a certificate of his having made true discovery thereof, shall be free from all criminal prosecutions, forfeitures, and disabilities in respect of such unlawful gaming, while the second statute expressly enables the justices to require persons apprehended in gaming-houses to give evidence.

Facilities are given by these statutes for entering forcibly houses and rooms suspected to be used as places for gaming; and for the arrest of persons found there; heavy penalties being imposed on persons obstructing the entry of constables, and the fact of such obstruction being itself made evidence of the house being a common gaming-house. To prevent persons evading punishment by pretending that the house was only open for the use of subscribers, it is sufficient to prove, in default of other evidence, that the house was used for playing at any unlawful game, and that a bank was kept there by one or more of the players, or that the chances of any game played in the house were not alike favourable to all the players. Thus careful has the legislature been to prevent this destructive vice; which may show that our laws against gaming are not so deficient, as ourselves and our magistrates in putting those laws in execution.

(Blackstone's 'Commentaries;' Mr. Kerr's edition, vol. iv. p. 188.)

GAMPSONYX. [FALCONIDÆ.]

GARAY, JA'NOS, a popular modern Hungarian poet, was born in 1812, at Szegszard, in the county of Tolna. He first attracted attention in 1834 by his heroic poem of 'Csatar,' written in imitation of Vörösmarty's epics; and continued rising in reputation for some years, during which he was one of the favourite contributors to three or four of the Hungarian annuals, and gained several prizes from the societies which offer premiums for successful contributions to the Magyar drama. He gained a scanty subsistence by literary labours of less ambition—by a 'Handbook of Hungarian and German Dialogues,' and by editing a sort of almanac, and at one time a newspaper. In his later years, when his health was bad and he had almost lost his eyesight, he and his family were preserved from positive want by his appointment to a subordinate place in the university library of Pesth, where he died after a long illness, on the 5th of November, 1853. He was a member of the Hungarian Academy. His last productions are 'Elizabeth Batori,' a play in 5 acts; 'Christina Frangepán,' a poetical tale; a series of historical legends entitled 'The Arpads;' a collection of poems called 'The Pearls of the Balaton Lake;' and 'Saint Ladislaus,' an historical poem. He was enthusiastically patriotic, and took a warm interest in the progress of Hungary during what is now almost looked back upon as its golden age, from 1840 to 1848. In his lyric poems he takes by preference national subjects, and those connected with modern improvement, such as the power of steam, and the wonders of railways.

GARNISHEE. Where the debts owing to a judgment debtor are attached to answer the claim of the judgment creditor [ATTACHMENT; ATTACHMENT OF DEBTS, *S.* 2], the judgment debtor is called the GARNISHEE, a designation derived from the process of foreign attachment peculiar to the Lord Mayor's Court of London, the Tolsey Court of Bristol, and the Borough Court of Exeter. The garnishee may be examined as to his indebtedness, he may dispute his liability, or he may pay the debts to the judgment creditor, who can effectually discharge him if he does so. ('Common Law Procedure Act,' 1854.)

GARSTANG. [LANCASHIRE.]

GASES, LIQUIFICATION OF. [CHEMISTRY, *S.* 1.]

GAULT. [CRETACEOUS GROUP.]

GAULTHERIA, a genus of Plants belonging to the natural order *Ericaceæ*. It has a 5-cleft or 5-toothed calyx, bibracteate at the base, after flowering becoming large and succulent, and covering the capsule with a baccate coating. The corolla is ovate, ventricose, with a 5-cleft revolute border, transparent at the base. There are 10 stamens, inclosed, with flat filaments; anthers bifid at the apex; lobes biaristate. The hypogynous scales 10, usually united at the base. The ovarium half inferior. The capsule 5-celled, with a loculicidal dehiscence.

G. procumbens, Partridge-Berry, Chequer-Berry, Boxberry, Mountain-Tea, is found on sterile sand and gravel in mountainous forests in the driest situations in North America. It has a horizontal woody rhizoma, often a quarter of an inch in thickness. The branches are ascending, but a few inches high, round and somewhat downy. The leaves are scattered near the extremities of the branches, evergreen, coriaceous, shining, oval, or obovate, acute at both ends, revolute at the edge, and furnished with a few small serratures, each terminating in a bristle. The flowers are axillary, drooping, on round downy stalks. There are two concave heart-shaped bracts. The calyx is white, cleft into 5 roundish acute segments. The corolla is white, urceolate, 5-angled, contracted at the mouth, the limb divided into 5 short reflexed segments. The filaments white, hairy, bent in a semicircular manner to accommodate themselves to the cavity between the corolla and ovary. The anthers oblong, orange-coloured, ending in two double horns, bursting outwardly for their whole length. Above the filaments the pollen white. The ovary is roundish, depressed, 5-angled, resting on a reddish 10-toothed glandular disc; the style erect, straight; the stigma simple. The fruit is a small 5-celled many-seeded capsule, invested with the calyx, which becomes large, round, and fleshy, having the appearance of a bright scarlet berry. The fruit contains an aromatic sweet highly pungent volatile oil, which is antispasmodic and diuretic. A tincture has been useful in diarrhœa. Cox states that the infusion is useful in asthma. It is used in North America as tea, and brandy in which the fruit has been steeped is taken in small quantities, in the same way as common bitters. The oil is known under the name of Oil of Wintergreen, and is used by druggists to flavour syrups, and also by perfumers.

G. Shallon is a native of North America on the falls of the Columbia, and near the Western Ocean. It has a procumbent hairy stem, ovate subcordate serrated leaves, glabrous on both surfaces, the racemes secund bracteate, clothed with rusty down. The corolla is white tinged with red, downy, urceolate, with a closed limb. The berries are globose, acute, fleshy, and purple. This plant grows in the shade of close pine-forests where hardly anything else will grow, which makes it a very desirable shrub for plantations. The berries are much esteemed by the natives on account of their agreeable flavour.

G. hispida, Wax-Cluster, is a native of Van Diemen's Land; it has long lanceolate serrulated leaves, pilose beneath as well as on the petioles; the branchlets hispid; racemes axillary and terminal, shorter than the leaves; the rachis and pedicels downy; the calyxes baccate, fruit and ovaries glabrous, the stem erect. It bears snow-white berries, with a flavour by no means unpleasant; in taste it is said to resemble the gooseberry, but is somewhat bitter. According to some *G. antipoda* is said to have more merit as a fruit.

The species are all ornamental, and grow best in a peat soil. (Lindley, *Flora Medica;* Lindley, *Vegetable Kingdom;* Don, *Dichlamydeous Plants.*)

GAUSS, CARL FRIEDRICH, one of the most celebrated mathematicians of his day, was born at Brunswick, April 23, 1777. He displayed early such marked talent for the abstract sciences, that the Duke of Brunswick, Charles Ferdinand, undertook the charges of his education. In the thesis which he maintained in 1799, before obtaining his degree of Doctor, he evinced his talent by analysing the previous methods for proving the truth of the fundamental axioms in algebra, giving one of his own still more exact. In the same year he published his 'Demonstratio nova theorematis omnem functionem algebraicam rationalem integram unius variabilis in factores reales primi vel secundi gradus resolvi posse:' and in 1801 this was followed by his 'Disquisitiones Arithmeticæ,' published at Leipzig, in 8vo. The last-mentioned work showed his rapid advance in the mathematical sciences. There was so much of novel speculation in this treatise as to excite some merriment among the French scientific men; but their ridicule failed to affect his reputation. In 1807 he was appointed Professor of Astronomy in the University of Göttingen; and in 1816 was named a privy-councillor. In the beginning of the present century the new planets were discovered, and he propounded a method for calculating their courses, in his 'Theoria motûs corporum cœlestium,' published at Hamburg, in 4to, in 1809; to which Professor Paucker added, in a separate pamphlet, a geometrical formula, more definitely proving the truth of the principle of the curvilinear triangulation upon which Gauss's comparisons depended. Gauss's work greatly contributed to the succeeding more exact and useful application of the astronomical observations to which, about this time, the attention of the scientific world began to be directed. His 'Theoria combinationis observationum erroribus minimis obnoxiæ,' published at Göttingen in 1823, in 4to, with the supplement, issued in 1828 from the same place, was a great addition to scientific knowledge.

On the completion of the Göttingen Observatory, Gauss devoted himself to astronomical observations. On the appointment of the government commission for extending the Danish admeasurement of an arc of the meridian to the kingdom of Hanover, he invented the means of making distant stations visible, by reflected sun-light, by an instrument known as the heliotrope. Afterwards he was zealously occupied with investigations as to terrestrial or telluric magnetism, for which purpose the government caused a building to be erected for his experiments, near the observatory. By the labours of himself and W. Weber, the science of telluric magnetism assumed a new and important phase. The theory was explained by them in conjunction in the Transactions of the Magnetic Union, under the title of 'Resultate aus dem Beobachtungen des Magnetischen Vereins in Jahre 1836, herausgegeben von C. F. Gauss und Wilhelm Weber,' published at Göttingen in 1837, with another volume for 1839, published at Leipzig in 1840, with an 'Atlas des Erdmagnetismus, nach den Elementen des Theorie entwarfen.' In 1841 he published at Göttingen his 'Dioptrische Untersuchungen' ('Dioptrical Investigations'). His latest labours were directed to the theory of geodesy, the first essay of a series upon which he published at Göttingen in 1844, under the title of 'Untersuchungen über Gegenstände der höhern Geodesie.' In this, with a modest pride, he speaks of the trigonometrical admeasurement as "partly executed by myself, and partly under my guidance." This was contributed to the 'Transactions' of the Royal Scientific Society at Göttingen, and appeared in the second volume. He died on February 23, 1855.

We do not attempt to give a complete list of Gauss's works: he contributed many papers to scientific publications, but the following are among the more interesting that have appeared separately, in addition to those already mentioned:—'Methodum peculiarem elevationem poli determinandi explicat,' Göttingen, 1808, 4to; 'Disquisitiones generales circa superficies curvus,' Göttingen, 1828, 4to; 'Theoria residuorum biquadraticorum Commentatio prima,' Göttingen, 1828, 4to; 'Intensitas vis magneticæ terrestris ad mensuram absolutam revocata,' Göttingen, 1833, 4to.

GAY-LUSSAC, NICOLAS-FRANÇOIS, was born at St. Leonard, in the department of Haute-Vienne, on December 6th, 1778. He was educated at the Polytechnic School, where his assiduity and talents gained him the friendship of Berthollet. On leaving the school he entered into the scientific department of Les Ponts et Chaussées. The expansibility of the gases was at that time a subject exciting much attention; and Gay-Lussac gave the law of dilatation, and showed its constant uniformity. His application to the subject led M. Charles, a scientific physician, to recommend him the use of the balloon, just previously invented, as an excellent means of testing some of his theories, of making fresh experiments, and of at least exciting public attention by his boldness and the novelty of the attempt. In conjunction with M. Biot, he made the proposal to the government; Laplace and Berthollet supported it; and M. Chaptal, then Minister of the Interior, gave them the balloon which had been constructed for the use of the war department, having had it refitted at the public expense. Furnished with chronometers, thermometers, barometers, hygrometers, electrometers, compasses, and papers and pencils, Messrs. Gay-Lussac and Biot ascended from the garden of the Conservatoire des Arts et Métiers, on August 23, 1804. Their highest elevation attained was 3977 metres (4335 yards) above the Seine. M. Biot was affected with giddiness; but Gay-Lussac, by his experiments, ascertained that the influence of terrestrial magnetism on the compass was nearly as great as on earth; that the atmospheric electricity increased as they rose, and was always negative; that the hygrometer showed increased dryness; and the thermometer, which marked 14° Réaumur (63½° Fahrenheit) on earth, sank to 8½ (51°). The bold adventurers at last descended safely about 54 miles from Paris. On September 5, in the same year, M. Gay-Lussac made a second ascent alone, when he reached a height of 4¼ miles; at which height he experienced a difficulty of breathing and an excessive cold, the thermometer being 6 degrees below 0 of Réaumur (20° Fahr.). He calculated that the air lost 1 degree of heat for each additional height of 174 metres (180 yards). On this occasion he brought down, in bottles carefully prepared for the purpose, some air from the highest point reached, which on analysis was found to be composed precisely the same as at the surface. After a voyage of six hours he descended at a village about 21 miles from Rouen.

M. Charles had been correct in supposing these experiments would draw attention to his friend. They introduced him to honour, titles, and illustrious friends. Of the society of Arcueil, instituted by Laplace and Berthollet in 1804, consisting at first of only nine members, Gay-Lussac was one. Here he met Alexander von Humboldt, with whom be joined in the investigation of the polarisation of light, several memoirs on which were furnished to the society. In conjunction also with Von Humboldt he endeavoured to determine the position of the magnetic equator, and its intersection with the terrestrial equator. Gay-Lussac's chief attention however was directed to the Voltaic pile, and the decomposition of acids and alkalies. Napoleon I. had instituted a magnificent prize for the most important discovery made by means of the pile, hoping that it would be gained by some one connected with the École Polytechnique, but Sir H. Davy, by his discovery of the metallic bases of soda and potassium, was the successful competitor in 1810. Bonaparte was dissatisfied; he inquired why the members of the institute had suffered the prize to be taken by a stranger, and he was told there was no pile in France powerful enough to obtain any grand results. He ordered a colossal one to be constructed immediately, and with it Gay-Lussac and M. Thénard commenced their experiments in 1808. The result was a work in 2 vols. published in 1811, 'Recherches physico-chimiques sur la pile, sur les alcalis, sur les acides, l'analyse végétale et animale,' &c. Their discoveries, and the improvements on methods of Davy, detailed in this work, were of great importance. In 1816 he was created Professor of Chemistry in the Polytechnic School.

Gay-Lussac's life was one of constant activity. Though he only published two works, and those little more than pamphlets, 'Mémoire sur l'Iode,' and 'Mémoire sur le Cyanogène,' both highly esteemed, he wrote more than a hundred papers on various subjects, and all of great ability. Besides the subjects already mentioned, he wrote on hygrometry, on capillary attraction, on the distinction between oxides and hydratides; and to him is due the discovery of the hydro-sulphuric and oxy-chloride acids. A course of chemical lectures delivered by him at the Sorbonne, taken down in short-hand, has been published in two volumes.

The merits of Gay-Lussac were not unrewarded by his country. After 1830, he was repeatedly chosen a member of the Chamber of Deputies; and in 1839 he was created a peer of France. He was a member of the Academy of Sciences, honorary professor of natural philosophy at the Sorbonne, professor of chemistry at the Jardin du Roi, verificator at the mint of works in gold and silver, editor (with M. Arago) of the 'Annales de Physique et de Chimie,' with several other official employments connected with the manufacturing industry of France. After a long life of useful labours, and in the enjoyment of excellent health till within a short period of his decease, he died May 9, 1850, at Paris, in the mansion provided for him in the Jardin du Roi.

GAYAL. [Ox.]

GEDRITE. [MINERALOGY, S. 1.]

GEIJER, ERIK GUSTAF, said by a Swedish critic to be equally eminent as a poet, a thinker, and an historian, was born at the iron-foundry of Ränsater, in Ränsater chapelry, province of Wermeland, Sweden, on the 12th of January, 1783. His father, the proprietor of the foundry, was the descendant of a family which had emigrated to Sweden from Austria in the time of Gustavus Adolphus, and by establishing foundries had peopled the district. Geijer, in his 'Minnen,' or 'Reminiscences,' has given a vivid description of the wild country of his birth and the hearty patriarchal manners which prevailed in it, to both of which he was strongly attached. At twelve years old he was sent to the school at Carlstad, five Swedish miles south of his birth-place, and at sixteen to the University at Upsal; during his residence at which, however, he enjoyed nothing so much as his frequent visits home, where he used to declare his conviction that the solemn academical disputations of Upsal would be the laughing-stock of future ages. At the age of twenty he was still without a degree, and when his friends, who were anxious to see some fruits of his studies, applied to a family of consideration to secure him the place of tutor, they received for answer that inquiries had been made at the university as to his character, and that he was found to be a "youth without steadiness." The rejection, and the motive assigned for it, stung Geijer to the soul. He resolved to do something to raise his reputation from so low a point, and without informing any one of his design, went to the parsonage, begged to look over a file of old newspapers, and ascertained that the subject of the great prize offered that year by the Swedish Academy was the 'Äreminnet,' or eulogy of Sten Sture, the administrator of the kingdom before the time of Gustavus Vasa. There was an imperfect copy of Dalin's 'History of Sweden,' at the foundry-house; this he studied in secret, found means to possess himself of some paper, which was scarce in those quarters, and as fast as he wrote his essay, concealed the sheets in the unsuspected hiding-place of an old clock-case. It needed some contrivance to get the essay sent off by post without taking any one into his confidence, but this too was done. Some months after his sister asked him what made him turn so red on a sudden as he was reading the newspaper. He had come on an advertisement requesting the author of the essay on Sture, with a certain motto—the same which he had selected—to make himself known to the Academy. He had won the prize, and from that day was looked on in a different light by his family and all his friends. In the next year, when he visited Stockholm, he was introduced to many of the leading literary men, and universally regarded as a youth of high promise. In the same year (1804), on a visit to his native Wermeland, he became acquainted, on a hunting excursion, with another young Wermelander, a student of the University of Lund, and they took a ramble together, sleeping occasionally in barns, and keeping up a continual disputation. This student, who became a friend for life, was Esaias Tegnér, afterwards Bishop of Wexio, now universally regarded as the greatest poet whom Sweden has produced. "We never talked together, then or afterwards," Geijer said in later life in his eulogy on Tegnér, "without disputing; and as we never came to agree, perhaps the solution may be, that we never understood one another. How this might be with Tegnér I know not, but I at least believed that I understood him."

In 1806 Geijer took his degree, and soon after obtained a post in the National Archives; but he was anxious to travel in foreign countries, and in 1809 obtained his wish by visiting England as travelling tutor to a youth of the name of Von Schinkel. He stayed about a twelvemonth in this country, two months of which were spent in studying English at Stoke Newington. Several of Geijer's letters from England were printed by himself in his 'Minnen,' in 1834; others have appeared since his death in the collected edition of his writings now publishing. In one of them, dated from Bath in 1810, and first printed in 1855, he says, "I came to England with strong prejudices against the people. It is a nation, I thought to myself, in which a love for gain and a narrow selfishness has quenched all that is beautiful and noble. Mine was a Swedish notion of selfishness, drawn from an imperfect state of society, where the connection between the public and private advantage is often far from obvious. Here every man knows that connection; and there is no honester man in the world than the selfish industrious Englishman, from the merchant to the day-labourer. This result may be owing to prudence as well as to principle, but such is the case. No foreigner can come here without admiring the honour and the mutual confidence that prevail in commerce and in life." On his return to Sweden, Geijer was soon engaged in the editorship of a magazine having the name of 'Iduna,' set up by a society of twelve, of whom he was one, and his brother another, who christened themselves 'the Goths.' The main idea of their union was that of reviving the manners and spirit of their Gothic ancestors, and some of their rules and ceremonies were sufficiently childish; but for these the founder, one of their friends, named Adlerbeth, was chiefly responsible. The 'Iduna' contained in its earliest numbers poems by Geijer—'The Viking,' 'The Last Champion,' &c.—which were full of vigour and spirit, which became immediately popular, were translated into Danish and German, and still retain their place in all selections of Swedish poetry. In subsequent numbers the early cantos of Tegnér's 'Frithiof' appeared for the first time. As in the case of many other Swedish periodicals, there seems to have been no intention of continuing the 'Iduna,' however successful, for an indefinite space of time: it was brought to an end after ten numbers, and the society of the Goths, which was painfully kept up by the exertions of Adlerbeth for many years after the other members had grown tired of it, was finally buried in his grave on his death in 1844. Geijer put forth, in 1813, a translation of 'Macbeth;' and between 1814 and 1816 was associated with Afzelius in the publication of a collection of Swedish popular ballads, 'Svenska Folkvisor,' in 3 vols., to which however Geijer contributed little more than introductory matter. He had held from 1810, when he was elected during his absence in England, a subordinate post in the University of Upsal, and for some years was in search of a position that would enable him to marry. In 1816 he was appointed adjunct or assistant to Fant, the professor of history at the University of Upsal, on his retirement; he then married a lady to whom he had been engaged before his journey to England, and in the next year, on the death of Fant, he succeeded to the full professorship. His first lectures had an unexampled popularity, and the lecture-room was crowded, not only with students, but with the best society of Upsal, including ladies. These early lectures were different both in matter and manner from those which his more matured knowledge and taste afterwards approved: as he grew more profound he became less popular, but he still continued the pride of the university and the favourite of the students. His success with the eulogy of Sten Sture had proved his genius, but had not proved the steadiness he was charged with wanting, and as a professor he was not remarkable for regularity in the discharge of his duties. His musical tastes interfered a good deal with his other pursuits, and it was remarked that when he had once got to a pianoforte, it was not easy to get him away from it. He had also frequent leave of absence for the purpose of prosecuting historical researches. One of the most prominent incidents in his academical life was an academical trial to which he was subjected on account of his theological opinions. In an edition which he published about 1820, of the works of Thorild, a Swedish philosophical speculator, some passages in the introduction by Geijer, which was entitled, 'A Philosophical or Unphilosophical Confession of Faith,' were regarded by some of his colleagues as hostile to the doctrine of the Trinity, and the author was denounced to the university authorities; but a long examination terminated in an acquittal, which was celebrated as an important triumph of liberty of thought and liberty of the press in Sweden. Geijer says, in a passage in one of his writings, "I am not a Church-Christian, I am not a Bible-Christian; I am, so to speak, a Christian on my own account;" and he concludes a statement of his way of thinking in theology with the declaration, "If this is Christianity, I am a Christian." The trial to which he had been subjected did not prevent his being twice offered a bishopric, that on the second occasion being in his native diocese of Carlstad, a distinction the more flattering that in Sweden a bishop must in the first instance be nominated by the clergy. He declined on both occasions. "Perhaps if I accepted," he wrote to a friend, "they might have a blameless middling bishop, but there would be an end to Erik Gustaf Geijer. It is not pride that speaks, but humility and conscience. I am afraid of this dignity, this new path, these new duties. Better keep on working in the circle where I am at home, and know that I work to some purpose. For the University of Upsal I am somebody. That would lose more than Wermeland gained." Geijer was in fact for many years in a distinguished position as the head of Swedish historical literature. He planned a great history of the country, to supersede that of Dalin and Lagerbring, who have been for Sweden what Hume and Smollett have been for England; and it was universally acknowledged that his introduction to the great work, the first volume of 'Svea Rikes Häfder,' or 'Records of Sweden,' promised a masterpiece. Unfortunately, the great work was never carried further. Before proceeding with it the author undertook another history of Sweden on a smaller scale, the 'Svenska Folkets Historia,' for the general collection of the histories of Europe, set on foot by Leo and Uckert; and this was carried before 1843, in three volumes, to the death of Queen Christina, but there it stopped. The professor, in place of continuing it, was occupied in examining the papers of Gustavus III., which the king had bequeathed to the University of Upsal, in a chest not to be opened till fifty years after his death. The work founded on these, 'Konung Gustaf III.'s efterlemnade Papper Öfversikt, Utdrag och Jemnförelse af E. G. Geijer' (2 vols., 8vo, Upsal, 1843), disappointed the public expectation, but more owing to the insignificance of the royal legacy than to any deficiency on the part of the editor.

Geijer was also occupied with speculations in politics and political economy. Twice be was the representative of the University of Upsal at the diet, and while on the first occasion he was a warm defender of monarchical power, in the second (in 1838) he saw cause to modify his views, and lost the approbation of several of his former supporters by a change of opinion in favour of progress and liberalism, which he avowed and defended in a periodical called 'Litteraturbladet,' written by himself. His views of pauperism were developed in 'The Poor Laws and their bearing on Society, a Series of Political and Historical Essays,' which were published in English (Stockholm, 1840) as well as Swedish, and of which the English version, as it bears no translator's name, and has marks of a foreign hand, may possibly be from his own pen. A dissertation on the history of Sweden during the 'Frihetstiden,' or 'Freedom-Time,' as it is called, which extended from the death of Charles XII. to the revolution in favor of regal power which was forcibly effected by Gustavus III., is the last of Geijer's works of much importance. His opinions of the superiority of regal to aristocratical government did not pass unquestioned, and were the subject of a controversy with Fryxell. During about thirty years Geijer continued one of the literary magnates of Sweden, in constant intercourse with all that was distinguished. He was the intimate friend of Tegnér and Atterbom, had a correspondence with Frederika Bremer, and wrote both verses and music for Jenny Lind. In 1846 his health began to break, he was obliged to pay a visit to the Schlangenbad of Nassau, and resigned his professorship. He died at Stockholm on the 23rd of April, 1847—a year which was fatal to many of the literary celebrities of Sweden.

A collected edition of Geijer's works was commenced soon after his death, but is still incomplete, though advanced (in 1856) to thirteen octavo volumes. A life by his son, Knut Geijer, is prefixed to the first volume, but before the second sheet had been printed the writer suddenly died. Most of the works of Geijer have been already mentioned. The most important is undoubtedly his 'Svenska Folkets Historia,' of which an English translation by J. H. Turner was published in London, and the first volume of a continuation of which by Carlson was issued in German, in Leo and Uckert's collection in 1855. Many of the volumes of his works are occupied with shorter pieces, articles in periodicals and papers read before the Swedish Academy, of which Geijer, became 'One of the Eighteen' in 1824, and was afterwards for some years President. The academical dissertations of which he was the author are as yet not reprinted, but several of them—one in particular on the Swedish colonies in America—are of considerable interest. His letters and his minutes of conversations with Bernadotte, with whom he seems to have been a favourite, were first printed in this collection, and embrace much that is worthy of notice and preservation, especially when taken in conjunction with his 'Minnen,' or 'Reminiscences,' perhaps his most attractive production, but one which like so many others was left unfinished. It should be observed that Geijer had not only a taste but a talent for music, and enjoyed some reputation as a musical composer, a volume of music having been published in conjunction by himself and Lindblad.

GELATIN. [TISSUES, ORGANIC, *S.* 1.]

GENERATIONS, ALTERNATION OF. During the course of the development of many of the lower animals from the ovum to their adult condition, they not only pass through various forms, as is seen in the Insect tribes [INSECTA], but at certain stages of their growth they possess the power of multiplying themselves. The individuals which exhibit this phenomenon have been called 'nurses,' and the whole series of phenomena connected with this mode of reproduction have been called by its first expounder, Professor Steenstrup, an 'alternation of generations.' This phenomenon has been particularly observed in the *Acalephæ*, *Entozoa*, *Polypiferæ*, *Salpæ*, and *Vorticellæ*. In the various articles on these families of animals, their mode of development is described. As however this subject is one of general interest, and very imperfectly understood, we take the opportunity of reproducing here Professor Steenstrup's general remarks on this subject, from a translation of his work published by the Ray Society:—

"The mode of development by means of 'nurses,' or intermediate generations, is thus seen to be no longer an isolated phenomenon in nature. The circumstance of an animal giving birth to a progeny permanently dissimilar to its parent, but which itself produces a new generation, which either itself or in its offspring returns to the form of the parent animal, is a phenomenon not confined to a single class or series of animals; the vertebrate class is the only one in which it has not been observed. It would consequently appear that there is something intrinsic in this mode of development, and that it occurs as it were with a certain necessity; on which account it will undoubtedly soon be recognised to a greater extent and more generally. It should no longer be considered as something paradoxical or anomalous (as we have hitherto been too much inclined to deem both it and the phenomena in which it is exhibited), it must be in harmony with the rest of development in nature, in which the fundamental principle of this course of development must also be elsewhere expressed, although it may be displayed in a form under which we shall less readily perceive and recognise it. This is seen when we trace the mode of development in question more widely through nature; and whilst contemplating it through the phenomena in which it is manifested, we comprehend it in its true light.

"If we collect and regard in one view the whole system of development by means of 'nursing' generations, as it is exhibited in the Bell-Shaped *Polypes* (*Campanularia*), the Claviform *Polypes* (*Coryne*), *Medusæ*, *Salpæ*, *Vorticellæ*, and *Entozoa*, it appears as a peculiar and consequently as an essential feature in this course of development, that the species (that is, the species in its development) is not wholly represented in the solitary, full-grown fertile individuals of both sexes, nor in their development; but that to complete this representation, supplementary individuals, as it were, of one or of several precedent generations are requisite. Thus, the distinction between this course of development and that which is generally recognised in nature, in which the species is represented by the individual (of both sexes) and its development, is the want on the part of the individuals of a complete individuality as representatives of the species, or of a specific individuality, if I may so express it. If now we agree to regard such an incompleteness in the individual as the essence of this development, we shall comprehend its significance in nature when we thoroughly consider this course of development in its various periods, throughout the above-mentioned families, how it begins and advances, so that at last we discover to what it tends. I believe, also, that we might trace even now this development by means of precedent preparatory generations of 'nurses' in its peculiar course and advance, notwithstanding the paucity of instances adduced in the foregoing pages, and the many gaps in the series of observations. Thus we see the greatest incompleteness and the highest degree of mutual dependence in the *Campanulariæ* and similar *Polypes*, in which the generations representing the unity of the species are very unlike each other, and in which all the individuals are fused, as it were, into an outward unity, or into a set of *Polypes*. They exist, organically connected with each other, and are normally free only in their first generation, and indeed only in their earliest stage of development, and only for a short time, since the free-swimming ciliated embryo swims about in the water at most for some hours, in order to find a suitable place for the foundation of a new polype stem. In the *Corynæ*, or claviform *Polypes*, the organic connection between the individuals and generations is rather more lax; the perfect gemmiparous or ovigerous individuals are usually quite free, often even at an early age (*Coryne fritillaria*,† *Corymorpha*), so that they do not attain their full development until after their separation from the 'nursing' generation. In the *Medusæ* and *Salpæ*, the generations which are connected together into one whole, become more like each other; the first generation of the *Medusæ* is still fixed but more active and mobile in its parts; the individuals of the perfect generation leave the 'nursing' animal while still very small, and undergo remarkable changes after they have become free and are swimming freely about; both generations of the *Salpæ*, finally, are free, and free swimmers, only the individuals of one of them are organically connected with each other; they have however no common organs (in the full-grown state), and if my explanation of the alternate generation of the compound Ascidians is correct, we have in that instance precisely the development of the *Salpæ* at a somewhat lower stage; the individuals of the one generation are organically connected, without having a common organ; but both generations are fixed.

"In the class of *Entozoa* a similar progressive attempt at becoming free and accomplishing a perfect growth appears evident to me.

"In the *Cestoidea* the generation of perfect individuals constitutes externally a unity; they are only successively detached from each other as the term of their existence approaches, and their whole existence is throughout connected with the 'nursing' animal. In some of the *Trematoda*, the later generations remain within the earlier until they have attained their full development; in others they forsake them in an earlier condition, are free, and free swimming, and undergo a complete metamorphosis; in some of these latter, the earlier generations are transformed into motionless, and, as it were, lifeless cysts, whilst in others they remain free and active (the 'nurses' and 'parent nurses' of *Cercaria ephemera* and *C. echinata*), but retain during their whole life a form which, at most, resembles the larvæ of the more perfect generation. In this way an advance in a certain direction may indisputably be observed. At first all the generations constitute a unity, not merely as regards the interior, but also with respect to the exterior: they form a stationary colony; after which the generations are detached more and more from each other, and become at the same time more free; and, finally, all the individuals constituting the generation are separate from each other, and acquire the power of free locomotion. In this latter stage, or that of freedom and perfection, we found the development of animals which are certainly no longer attached to inanimate objects at the bottom of the sea, but live buried in other animal organisms, and belong not to the sea but to fresh water. In a still higher and more free stage than this we observe the development of animals which do not belong to the water, but to the air, as in that which occurs in the *Aphides*. The propagation of these creatures through a series of generations has been already long known. In the spring, for instance, a generation is produced from the ova, which grows and is metamorphosed, and without previous fertilisation gives birth to a new generation, and this again to a third, and so on, for ten or twelve weeks; so that in certain species even as many as nine such preliminary generations will have been observed; but at last there always occurs a generation consisting of males and females, the former of which, after their metamorphosis, are usually winged; fertilisation and the depositing of eggs take place, and the long series of generations recommences in the next year, and in the same order. All the individuals are free, and enjoy the power of free locomotion, and undergo a metamorphosis. Here, however, we have before us aërial animals, and which are no longer parasites inhabiting other organisms; at most they are only externally parasitic, and on plants alone; the phenomena of this mode of development are no longer exhibited by *Entozoa*, but by *Epiphyta*. Nevertheless, the course of development is in itself similar; but in the external, more free, and nobler form in which it is now exhibited, the endeavour to attain something higher is manifest. Each link or generation certainly brings its offspring nearer to the perfection aimed at; but this approachment towards perfection is effected only by means of the 'nursing' by special animals, and is committed to the still and quiet activity of an organ, without the nursing animals themselves being conscious of it; it is a function merely, and not an expression of the will. In all parts of the animal kingdom we see the instances of the still, quiet, and unconscious activity of the animal being developed into voluntary actions, which are undertaken by it from an internal, obscure, and irresistible impulse (or artificial impulse), as is the case in this instance. The development and mode of feeding or nourishing the young, exhibited in its course, of Bees, Wasps, Ants, and *Termites*, affords a direct example of the mode in which the care of the young is provided for, by the voluntary action of numerous individuals devoted to that object. Those of the young which are to be developed into the more perfect fertile individuals are not protected in the body of the foster-parents, nor is their nourishment secreted by one of the organs; both protection and food are afforded them by means which are brought about by the conscious activity of the 'feeders.' The Wasp, for instance, or the Wild Humble-Bee, which has been impregnated in the autumn, and has afterwards sought a shelter to protect itself against the cold of winter, prepares a solitary habitation in which it builds cells and deposits its eggs. From the eggs proceed larvæ, but the insects into which these larvæ are metamorphosed, are not fertile; they are barren, and all their faculties are directed to the assisting of the parent animal in the better nourishing of the future brood, to which end some of their external organs are transformed, and to the erection of a better habitation and cells, into which they convey the eggs of the female, and the food of the larvæ to be developed from them. Other cells, which contain a better sort of food, are erected for a later and less numerous progeny of eggs; and again in others, which are more roomy and provided with the best kind of food, but of which there are only a few, is the last brood of the female deposited. From the first kind of cells proceed the barren individuals, from the second the males, and from the third the females; after undergoing a metamorphosis, the males and females fly away, impregnation takes place, and the males die; the females however return, and the whole multitude of barren individuals, which at the same time perform the duty of feeding the young, build cells for their various progeny of eggs, and nourish the three forms of larvæ which proceed from them. In this way the inhabitants of the colony become very numerous: nevertheless they all die off in the winter: the fertile females alone remain alive, and propagate the species the year following, under the same development of alternating broods, the earlier of which is always by far the most numerous, and assists in the development of the latter. In the colonies of Bees, Ants, and *Termites*, the same thing occurs; the many thousand individuals which constitute one of these colonies are principally 'feeders,' or individuals which have originated in the precedent divisions of the eggs of the females, and in these is exhibited, even with greater precision, a more marked division of labour in the feeding of the progeny; so that, out of the various precedent divisions, individuals apparently arise which assist in the development of the more perfect progeny in various ways. Thus there are in a hive of bees, individuals which are employed almost wholly in the feeding of the larvæ (foragers), whilst others do scarcely anything else than collect wax and build cells (workers). In ant-hills, one set of the feeders is constantly employed in conveying the larvæ from one place to another, according as they require a greater or less degree of warmth, &c., whilst others are engaged in building the passages or earth-cells, and in making excavations around the habitation. Among the *Termites* also we are acquainted with several forms of 'feeders,' constituting particular tribes or classes; the description of labour, however, which each of these classes performs, is unknown. It is known, however, that a form with a large head and strong jaws is always posted at the entrance of the artificially constructed dwelling, and keeps guard there as soon as any disturbance is remarked, and thus constitutes the safeguard not only of the young but of the whole community.

"Now in the cases in which the more perfect development of the progeny is promoted, either by means of 'nurses' or of 'feeders' (under which latter term we understand special individuals devoted to the actual care or nourishing of the young, which office they fulfil by a conscious activity), we see that nature always has in view the production of a multitude of individuals to whose life or care is then committed the perfecting of a later generation or progeny, consisting of less numerous individuals. This previous or preparatory multitude seems to consist invariably of females, the males being apparently excluded from any participation in the office, on which account the males of all the animals among which the system of 'nursing' or of 'feeding' obtains, constitute a very subordinate number. That the 'nursing' should be committed to females alone appears to us very natural, since we are acquainted with an organ in them whose natural function would be to perform that office. The generative organs are, indeed, in perfect (female) individuals divided, as it were, into two parts of very distinct natures; the ovarium for the preparation of the germ and the production of the egg, and the oviduct and uterus, in which the ova are, as it were, incubated, and the germ and embryo sufficiently developed to allow of its being born. Now, it is actually the case that no true ovary has been discovered in the 'nursing' generations; on the contrary, the germs, as soon as they are perceptible, are situated in organs which must be regarded as oviducts and uteri, as, for instance, in the most perfect 'nurses' we are acquainted with, the *Aphides*. In the 'nurses' of the the trematode larva, the *Cercaria echinata*, I have remarked that the germs in their earliest condition are collected into an organ at the root of the tail, which may probably be regarded as a uterus, and that they appear to distend this organ gradually to the size of the whole body. The accurate anatomical researches of Professor Eschricht on the *Salpæ* also show in the most precise way that the associated brood of the *Salpæ* does not originate from ova, but that, as germs which are arranged in a definite manner between the walls of a hollow organ, it is contained in what can in no case be an ovary, and which the author has termed a 'germ-tube.' This organ lies in a cavity which may probably be considered very nearly a uterus, which is however always, as it were, a secondary receptacle for the germs; but in the present instance it cannot be shown that they have occupied any previous receptacle or place of formation.

"From what we at present know, we may probably assume with some degree of certainty that the 'nursing' individuals are never themselves gemmiparous, but that they are born with germs in the organs in which the embryos are afterwards nourished; and from all this it appears as if the female generative organism were always divided in those cases in which development by means of 'nurses' occurs, so that as in the more perfect females an ovary especially is formed, so in the 'nursing' individuals a much-developed uterus is presented, in consequence of which, they, as individualised uteri, have assigned to them, as the object of their existence, the performance of the functions of a uterus, and their complete formation must thus necessarily precede that of the germs which are committed to their fostering care. We cannot readily perceive the reason, that because all 'nursing' individuals must be of the female sex, it should follow that all those individuals which feed the young should also be of that sex, and yet this seems to be the law. Anatomy shows us that the 'feeders' among bees, wasps, &c., and probably those of all insects living in regular societies, are females, whose sexual organs remain in an undeveloped state. They present scarcely the vestige of an ovary; the uterus is rudimentary, and all propagation consequently in the material way, so to say, is rendered impossible; the imperfection of the organ does not even allow of their acting as 'nurses,' and the propagative instinct in a physical corporeal sense passes into a will for the propagation of the species, into a *nisus* impelling to the feeding or nourishing of the young; and the fulfilment of these impulsive duties is favoured by the peculiar transformation which some of the organs undergo at the expense of those intended for propagation, in order that they may become adapted to the bringing up of the young. Whence it follows that the development of the species, in this case does not take place by means of several generations, but through several broods of the same generation. The reason of the great number of 'feeders,' and for the common good of 'workers,' so that they often constitute thousands, whilst the fertile individuals scarcely amount to hundreds, may be readily understood when we consider more closely the regular societies of bees and ants, and witness the labour required for the nourishment of the young. But, on the other hand, how the development of the species is promoted by the multitude of 'nursing' animals of which we often see thousands for each single fertile one, appears to us difficult of explanation, since, even all of them can only be regarded as animated organs, which do not appear to act for or with each other. It does not however seem to me improbable that even the *Aphides*, trematode nurses, and other parasites, which are so immediately injurious to the organisms upon which they live, are not destined merely to promote the extension of the species, but that they also induce in the organisms themselves conditions necessarily more and more favourable to a later generation; plants also and animals afford us many instances that to a certain abundance of parasites there usually succeeds a complete overflow of them.

"I conclude with the remark that, inasmuch as in the system of 'nursing' the whole advancement of the welfare of the young is effected only by a still and pesceful organic activity, is only a function of the vegetative life of the individual, so also all those forms of animals in whose development the 'nursing' system obtains, actually remind us of the propagation and vital cycle of plants. For it is peculiar to plants, and, as it were, their special characteristic, that the germ, the primordial individual in the vegetation or seed, is competent to produce individuals which are again capable of producing seeds or individuals of the primary form or that to which the plant owed its origin, only by the intervention of a whole series of generations. It is certainly the great triumph of Morphology, that it is able to show how the plant or tree (that colony of individuals arranged in accordance with a simple vegetative principle or fundamental law) unfolds itself, through a frequently long succession of generations, into individuals, becoming constantly more and more perfect, until, after the immediately precedent generation, it appears as calyx and corolla, with perfect male and female individuals, stamens, and pistils (so that even in the vegetable kingdom the grosser hermaphroditism does not obtain, which is still supposed to take place in the animal); and after, the fructification brings forth seed, which again goes through the same course. It is this great and significant resemblance to the vegetable kingdom, which in my opinion is presented by the *Entozoa* and all 'nurse' generations, and to which I have alluded in the preceding Essay: I might almost say that the condition of continued dependence incidental to the animal life, is to a certain extent one of less perfection than that which is presented in the progressive elevation in development effected by the agency of the vegetative life."

GENTIANINE. [CHEMISTRY, *S.* 2.]

GEOKRONITE. [MINERALOGY, *S.* 1.]

GERARD, MAURICE-ÉTIENNE, COMTE, Marshal of France, was a native of Danvilliers, in the department of the Meuse, and was born April 4, 1773. He entered the army as a volunteer in 1791, and first saw fire under Jourdan, at Fleurus. He was already a captain in 1793, and Bernadotte, who was for many years his steadfast friend, appointed him soon after one of his aides-de-camp. After the treaty of Campo Formio, he attended that general in his embassy to Vienna, and having saved his life during a riot stimulated by the Austrian police, a lasting friendship was established between them. In 1799 he became a chef-d'escadron; and at the battle of Austerlitz (Dec. 2, 1805) his good conduct was so conspicuous that he received the Cross of the Legion of Honour on the field.

In 1806 Gérard was appointed to a brigade; and in 1809, at the battle of Wagram, Bernadotte gave him the command of the Saxon cavalry. He next went to serve in Spain, where he continued until October 1811, having been present at the battle of Albuera and several others.

Called to take part in the expedition against Russia in 1812, he contributed to the capture of Smolensko; and during the disastrous retreat which followed the burning of Moscow he was placed as second in command, under Marshal Ney, in the rear of the army. General Gérard distinguished himself by many proofs of valour at the passage of the Bérésina, where, with a few regiments greatly reduced in numbers, and consisting of half-famished men, he repeatedly sustained the shock of an entire army. In 1813 he commanded one of the divisions of the 11th corps, under Marshal Macdonald: he was present at the battle of Bautzen, and his exertions, which were made on the impulse of the moment and without orders, accelerated the victory. He charged the enemy again without (or rather contrary to) orders at Goldsberg, and routed the Prussians with great slaughter, for which feat of arms the emperor gave him the command of the 11th corps. General Gérard was several times wounded, and very grievously at the battle of Leipzic, October 18, 1813. During the defence of the French territory in 1814, his zeal and intrepidity were frequently commended by Napoleon, especially at the victory of Montereau. After his return from Elba, in 1815, the Emperor gave him the command of the army of the Moselle. On the 18th of June he was under the orders of Marshal Grouchy at Wavres, and when the report of the cannon was heard proceeding from the forest of the Soignies, Gérard recommended an immediate advance of Grouchy's army of reserve in that direction.

On the return of Louis XVIII., Gérard retired to Belgium, where in 1816 he married the daughter of General Valence. The following year he was permitted to return to France. In 1830 Louis Philippe created him marshal of France, and appointed him minister of war, but his health compelled him to resign this office a few months later. In 1832 he was sent to besiege the fortress of Antwerp, defended by the Dutch general Chasse, when, having compelled the garrison to capitulate after a gallant defence, he returned to France and was made a peer. In 1834 the citizen king made him president of the council, or prime minister; but his declining health obliged him to resign this office on the 29th of October, after which he withdrew into private life. The provisional government of February 24, 1848, raised Marshal Gérard to the function of Grand Chancellor of the Legion of Honour. The Marshal lived to see the restoration of the Bonaparte dynasty. He died at Paris, August 17, 1852, and was interred in the chapel of the Invalides.

GERARD, JEAN-IGNACE-ISIDORE, but best known by his pseudonym, GRANDVILLE, one of the most eminent French caricaturists and designers of illustrations for books, was born at Nancy in 1803. He went to Paris young, an adventurer without money, and without friends; after a while got admission to the atelier of Lecomte; managed to subsist by designing costumes, &c.; then advanced to making lithographic drawings; and continued improving his artistic powers and increasing his stores of observation till 1828, when he brought out his 'Metamorphoses du Jour,' by Grandville, a series of genial, piquant, and mirthful crayon commentaries and criticisms on passing follies. These sketches had a prodigious success; Grandville's position was secured; and his pencil found abundant employment. The revolution of 1830 interfered for a time with his occupation; but when familiarity had brought its inseparable attendant, and the citizen king had come to be regarded by the citizens as a fair mark for the shafts of ridicule, Grandville made himself abundantly merry with the face and person of his sovereign and the royal advisers. Grandville was the very soul of 'La Caricature' as long as his pencil was permitted its free exercise; but on the promulgation of the law re-establishing the 'censure préalable' for designs, he abandoned politics, and threw all his energy into the making of drawings on wood for illustrated editions of classic authors, &c. Here he found a new field of triumph. His drawings were in their way almost the perfection of designs for engraving on wood. Not merely were they admirably conceived, and excellent as exemplifications of the passages they were intended to illustrate, but clear, correct, and vigorous in drawing, and brilliant in effect, they exhibited remarkable aptitude for that particular kind of engraving. As illustrations—full of fancy, ingenuity, quaint and genuine humour, and singularly suggestive—they not only pleased the eye, but really added a new charm to the text. Among the works he illustrated were 'Gulliver's Travels,' 'Robinson Crusoe,' 'La Fontaine's Fables,' 'Beranger,' 'Jerome Paturot,' &c. Indefatigable in labour, he produced an almost infinite number of designs, and yet his active fancy showed no symptoms of exhaustion or even fatigue.

But in the midst of his success, and in the prime of his powers, his labours were brought to a sad and sudden termination. A man of domestic habits, and devotedly fond of his family, he had already had the misfortune to lose two children within a brief space of time by some of the ordinary maladies of childhood, when his third child in attempting to swallow a piece of meat got it so firmly fixed in its throat that all attempts to remove it proved unavailing. An incision was proposed as the only remaining though dangerous remedy; and while Grandville hesitated whether to consent to the operation, the child died in his arms. The shock was more than the unhappy father could sustain: his intellect gave way, and he survived his child but a short period. He died on the 17th of March 1847, aged forty-three.

GEYSERS. This name is applied to a series of intermittent hot-springs, situated in the south-western division of Iceland, where nearly one hundred of them are said to break out within a circle of two miles. These springs are evidently connected with the volcanic phenomena which so remarkably characterise the whole district of Iceland. A recent investigator of the eruptive phenomena of Iceland thus describes its more prominent physical features:—

"The surface of Iceland slopes gradually from the coast towards the centre, where the general level is about 2000 feet above the surface of the sea. On this, as a pedestal, are planted the Jökull, or Icy Mountains of the region, which extend both ways in a north-easterly direction. Along this chain the active volcanoes of the island are encountered, and in the same general direction the thermal springs occur, thus suggesting a common origin for them and the volcanoes. From the ridges and chasms which diverge from the mountains mighty masses of steam are observed to issue at intervals, hissing and roaring, and where the escape takes place at the mouth of a cavern, and the resonance of the cave lends its aid, the sound is like that of thunder. Lower down in the more porous strata we have smoking mud pools, where a repulsive blue-black aluminous paste is boiled, rising at times into huge bladders, which on bursting scatter their slimy spray to a height of 15 or 20 feet. From the base of the hills upwards extend the glaciers, and on their shoulders are placed the immense snow-fields which crown the summits. From the arches and fissures of the glaciers vast masses of water issue, falling at times in cascades over walls of ice, and spreading for miles and miles over the country before they find definite outlet. Extensive morasses are thus formed, which lend their comfortless monotony to the dismal scene already before the traveller's eye. Intercepted by the cracks and fissures of the land a portion of these waters is conducted to the hot rocks underneath; here, meeting with the volcanic gases which traverse these underground regions, both travel together, to issue at the first convenient opportunity either as an eruption of steam or as a boiling spring.

"The origin of the water which feeds the springs is here hinted at. That origin is atmospheric. The summits of the Jökull arrest and mix the clouds, and thus cause an extraordinary deposition of snow and rain. This snow and rain constitute the source from which the springs are fed. The nitrogen and ammonia which occur without exception in every spring, exactly as we find them in rain water, furnish the proof of this; for the known deportment of these substances preclude them from being regarded as real volcanic products."

The springs which feed the Geysers, and which are poured out from them again boiling hot, probably take their rise in Mount Hecla, the summit of which is not more than 30 miles from the Geyser district. It is here that the rushing water is sometimes heard in chasms beneath the surface, and it has more than once happened that after earthquakes some of the boiling fountains have increased or diminished in violence and volume, or entirely ceased, or that new ones have made their appearance.

The phenomena of the Geysers of Iceland have for a length of time arrested the attention of naturalists, and many explanations of them have been given. No one has however so successfully investigated the subject as Professor Bunsen, of Giessen. A summary of these views, with experimental illustrations, were presented to the Royal Institution by Professor Tyndall in June 1853. After referring to the general eruptive phenomena of Iceland, he described the Great Geyser.

"We have here," he says, "a tube 10 feet wide and 70 feet deep; it expands at its summit into a basin, which from north to south measures 52 feet across, and in the perpendicular direction 60 feet. The interior of the tube and basin is coated with a beautiful smooth plaster, so hard as to resist the blows of a hammer. The first question that presents itself is, how was this wonderful tube constructed? How was this perfect plaster laid on? A glance at the constitution of the geyser water will perhaps furnish the first surmise. In 1000 parts of the water the following constituents are found:—

Silica	0.5097
Carbonate of Soda	0.1939
Carbonate of Ammonia	0.0083
Sulphate of Soda	0.1070
Sulphate of Potash	0.0475
Sulphate of Magnesia	0.0042
Chloride of Sodium	0.2521
Sulphide of Sodium	0.0088
Carbonic acid	0.0557

"The lining of the tube is silica, evidently derived from the water; and hence the conjecture may arise that the water deposited the substance against the sides of the tube and basin. But the water deposits no sediment, even when cooled down to the freezing point. It may be bottled up and kept for years as clear as crystal, and without the slightest precipitate. A specimen brought from Iceland and analysed in this institution was found perfectly free from sediment. Further, an attempt to answer the question in this way would imply that we took it for granted that the shaft was made by some foreign agency, and that the spring merely lined it. A painting of the Geyser, the property of Sir Henry Holland—himself an eye-witness of these wonderful phenomena—was exhibited. The painting, from a sketch taken on the spot, might be relied on. We find here that the basin rests on the summit of a mound; this mound is about 40 feet in height, and a glance at it is sufficient to show that it has been deposited by the Geyser. But in building the mound the spring must also have formed the tube which perforates the mound; and thus we learn that the Geyser is the architect of its own tube. If we place a quantity of the geyser water in an evaporating basin the following takes place:—In the centre the fluid deposits nothing, but at the edges where it is drawn up the sides of the basin by capillary attraction, and thus subjected to a quick evaporation, we find silica deposited; round the edge we find a ring of silica thus laid on, and not until the evaporation is continued for a considerable time do we find the slightest turbidity in the central portions of the water. This experiment is the microscopic representant, if the term be permitted, of nature's operations in Iceland. Imagine the case of a simple thermal spring whose waters trickle over its side down a gentle incline; the water thus exposed evaporates speedily, and silica is deposited. This deposit gradually elevates the side over which the water passes, until finally the latter has to choose another course; the same takes place here, the ground becomes elevated by the deposit as before, and the spring has to go forward—thus it is compelled to travel round and round, discharging its silica and deepening the shaft in which it dwells, until finally, in the course of centuries, the simple spring has produced that wonderful apparatus which has so long puzzled and astonished both the traveller and the philosopher.

"Before an eruption the water fills both the tube and basin, detonations are heard at intervals, and after the detonation a violent ebullition in the basin is observed; the column of water in the pipe appears to be lifted up, thus forming a conical eminence in the centre of the basin, and causing the water to flow over its rim. The detonations are evidently due to the production of steam in the subterranean depths, which, rising into the cooler water of the tube, becomes condensed and produces explosions similar to those produced on a small scale when a flask of water is heated to boiling. Between the interval of two eruptions the temperature of the water in the tube towards the centre and bottom gradually increases. Bunsen succeeded in determining its temperature a few minutes before a great eruption took place; and these observations furnished to his clear intellect the key of the entire enigma. A little below the centre the water was within two degrees of its boiling point, that is, within two degrees of the point at which water boils under a pressure equal to that of an atmosphere, plus the pressure of the superincumbent column of water. The actual temperature at 30 feet above the bottom was 122° centigrade, its boiling point here is 124°. We have just alluded to the detonations and the lifting of the geyser column by the entrance of steam from beneath. These detonations and the accompanying elevation of the column are, as before stated, heard and observed at various intervals before an eruption. During these intervals the temperature of the water is gradually rising. Let us see what must take place when its temperature is near the boiling point. Imagine the section of water at 30 feet above the bottom to be raised six feet by the generation of a mass of vapour below. The liquid spreads out in the basin, overflows its rim, and thus the elevated section has six feet less of water pressure upon it; its boiling point under this diminished pressure is 121°; hence in its new position its actual temperature (122°) is a degree above the boiling point. This excess is at once applied to the generation of steam; the column is lifted higher, and its pressure further lessened; more steam is developed underneath; and thus, after a few convulsive efforts, the water is ejected with immense velocity, and we have the geyser eruption in all its grandeur. By its contact with the atmosphere the water is cooled, falls back into the basin, sinks into the tube through which it gradually rises again, and finally fills the basin. The detonations are heard at intervals, and ebullitions are observed; but not until the temperature of the water in the tube has once more nearly attained its boiling point is the lifting of the column able to produce an eruption.

"In the regularly-formed tube the water nowhere quite attains the boiling point. In the canals which feed the tube, the steam which causes the detonation and lifting of the column must therefore be formed. These canals are in fact nothing more than the irregular continuation of the tube itself. The tube is therefore the sole and sufficient cause of the eruptions. Its sufficiency was experimentally shown during the lecture. A tube of galvanised iron six feet long was surmounted by a basin; a fire was placed underneath and one near its centre to imitate the lateral heating of the geyser tube. At intervals of five or six minutes throughout the lecture eruptions took place; the water was discharged into the atmosphere, fell back into the basin, filled the tube, became heated again, and was discharged as before.

"Sir George Mackenzie, it is well known, was the first to introduce the idea of a subterranean cavern to account for the phenomena of the Geyser. His hypothesis met with general acceptance, and was even adopted undoubtingly by some of those who accompanied Bunsen to Iceland. It is unnecessary to introduce the solid objections which might be urged against this hypothesis, for the tube being proved sufficient, the hypothetical cavern disappears with the necessity which gave it birth.

"From the central portions of the geyser tube downwards, the water has stored up an amount of heat capable, when liberated, of exerting an immense mechanical force. By an easy calculation it might be shown that the heat thus stored up could generate, under ordinary atmospheric pressure, a column of steam having a section equal to that of the tube and a height of nearly 1300 yards. This enormous force is brought into action by the lifting of the column and the lessening of the pressure described above.

"A moment's reflection will suggest to us that there must be a limit to the operations of the Geyser. When the tube has reached such an altitude that the water in the depths below, owing to the increased pressure, cannot attain its boiling point, the eruptions of necessity cease. The spring however continues to deposit its silica and forms a 'laug,' or cistern. Some of these in Iceland are of a depth of 30 or 40 feet. Their beauty is indescribable; over the surface a light vapour curls, in the depths the water is of the purest azure, and tints with its own hue the fantastic incrustations on the cistern walls; while at the bottom is observed the mouth of the once mighty Geyser. There are in Iceland traces of vast, but now extinct, geyser operations. Mounds are observed whose shafts are filled with rubbish, the water having forced a way underneath, and retired to other scenes of action. We have in fact the Geyser in its youth, manhood, old age, and death, here presented to us:—in its youth as a simple thermal spring, in its manhood as the eruptive spring, in its old age as the tranquil laug, while its death is recorded by the ruined shaft and mound, which testify the fact of its once active existence.

"Next to the Great Geyser the Strokkur is the most famous eruptive spring of Iceland. The depth of its tube is 44 feet. It is not however cylindrical like that of the Geyser, but funnel-shaped. At the mouth it is 8 feet in diameter, but it diminishes gradually, until near the centre the diameter is only 10 inches. By casting stones and peat into the tube and thus stopping it, eruptions can be forced which in point of height often exceed those of the Great Geyser. Its action was illustrated experimentally in the lecture, by stopping the galvanised iron tube before alluded to loosely with a cork. After some time the cork was forced up and the pent-up heat converting itself suddenly into steam, the water was ejected to a considerable height—thus demonstrating that in this case the tube alone is the sufficient cause of the phenomenon." ('Proceedings of Royal Institution.')

The results of the researches of Professor Bunsen on the Geysers of Iceland seem to throw great and unexpected light on the phenomena of volcanoes. Sir Charles Lyell closes his account of Bunsen's researches with the following remarks:—

"In speculating therefore on the mechanism of an ordinary volcanic eruption, we may suppose that large subterranean cavities exist at the depth of some miles below the surface of the earth, in which melted lava accumulates, and when water containing the usual mixture of air penetrates into these, the steam thus generated may press upon the lava and force it up the duct of a volcano, in the same manner as a column of water is driven up the pipe of a Geyser. In other cases we may suppose a continuous column of liquid lava, mixed with red-hot water (for water may exist in that state, as Professor Bunsen reminds us, under pressure), and this column may have a temperature regularly increasing downwards. A disturbance of equilibrium may first bring on an eruption near the surface, by the expansion and conversion into gas of entangled water and other constituents of what we call lava, so as to occasion a diminution of pressure. More steam would then be liberated, carrying up with it jets of melted rock, which being hurled up into the air may fall in showers of ashes on the surrounding country, and at length, by the arrival of lava and water more and more heated at the orifice of the duct or the crater of the volcano, expansive power may be acquired sufficient to expel a massive current of lava. After the eruption has ceased a period of tranquillity succeeds, during which fresh accessions of heat are communicated from below, and additional masses of rock fused by degrees, while at the same time atmospheric or sea-water is descending from the surface. At length the conditions required for a new outburst are obtained, and another cycle of similar changes is renewed." ('Principles of Geology,' p. 558.)

GIGANTHOLITE. [MINERALOGY, *S.* 1.]

GILBERTITE. [MINERALOGY, *S.* 1.]

GILT-HEAD. [CHRYSOPHRYS; CRENILABRUS.]

GIOBERTI, VINCENZO, was born on the 5th of April 1801, in the city of Torino (Turin), the capital of the kingdom of Sardinia. He studied with a view to the ecclesiastical profession, and having completed his education in the University of Turin, received the degree of Doctor of Theology, and became one of the teachers in the theological college. Soon after the accession, in 1831, of Charles-Albert to the throne of Sardinia, Gioberti was appointed chaplain to the court, and continued to perform the duties of this office till 1833, when, on some accusation or suspicion of being implicated in the political agitations then prevailing in various parts of Italy, he was suddenly seized in the apartments which he occupied in the palace, and imprisoned in the citadel. There he was detained some weeks, but was at length set at liberty on the condition that he quitted the country as an exile. He went to Paris, where he resided till the end of 1834, when he removed to Brussels, having accepted the offer of a situation as teacher in one of the public schools of that city.

Gioberti wrote at Brussels, during his long abode there as an exile, nearly all those works which not only extended his literary reputation throughout the whole of Europe, but produced that enthusiasm of admiration which was displayed by the Italians after his return to his native country. The first of these works was the 'Teorica del Sovranaturale, osia Discorso sulle Convenienze della Religione Rivelata colla Mente Umana e col Progresso Civile delle Nazioni,' 8vo, 1837. His next work was the 'Introduzione allo Studio della Filosofia,' 8vo, 1840, which was followed by the 'Lettere intorno agli Errori Filosofici di Antonio Rosmini,' 3 vols. 8vo, 1841-42; and the two treatises 'Del Bello,' 8vo, 1841, and 'Del Buono,' 8vo, 1843. His 'Primato Morale e Civile degli Italiani,' 8vo, 1843, was read with eagerness in every part of Italy, and excited expectations of the regeneration of that unfortunate country, which, with the sole exception of the Sardinian kingdom, have not hitherto been realised. There was to be a confederation of the Italian states, in which the kings and princes, the pope and the priests, the citizens, and even the monks and Jesuits, were all to bear a part. The states were to be reformed, and popular rights and privileges gradually established. The pope was to be the religious head of the confederation, and Rome the capital city; the King of Sardinia was to be the military chief, and Turin the grand citadel. The Jesuits alone were dissatisfied, and Gioberti attacked them in his 'Prolegomeni,' 8vo, 1845. Pius IX., on his accession to the papal chair in 1846, adopted the views of Gioberti, and began to carry ont the reforms recommended in 'Il Primato;' and as the opposition of the Jesuits still continued, Gioberti produced his great attack on their principles and practice, under the title of 'Il Gesuita Moderno,' 5 vols. 8vo, Lausanne, 1847.

When the French revolution of February 1848, occurred, Gioberti was at Paris occupied with his plans for the renovation of Italy. On the 25th of April he quitted Paris, after an exile of fifteen years, to return to his native city of Turin, where his arrival was welcomed by a display of banners by day, and illuminations and fireworks at night, accompanied with music and dancing and patriotic songs; and afterwards when he passed through Milan, Genoa, Florence, Rome, and other places, he was everywhere received with the greatest enthusiasm, so that his journey resembled a triumphal procession. On his return to Turin he was elected a member of the chamber of depnties, of which he was unanimously chosen president. He was opposed to all violent reforms, bnt the tide of political excitement in the year 1848 threw him into the ranks of the opposition, and on the 16th of December the king appointed him the prime minister of a democratic cabinet. He soon found himself to be in a false position, and the differences of opinion between himself and his colleagues led to a dissolution of the ministry on the 18th of February 1849. He was succeeded by Pinelli, and soon afterwards was sent to Paris to solicit aid from the French government in the approaching contest with Austria. His mission was of no avail. Milan was reconqnered by Radetsky, Charles-Albert defeated at Novara, and Victor-Emmannel II. has alone, of all the rulers of Italy, preserved for his snbjects a constitntional government, a free press, and a just administration of the laws. Gioberti remained in Paris, and the fruit of his renewed studies was his work 'Del Rinnovamento Civile d'Italia,' 2 vols. 8vo, 1851. He died October 26, 1852, in Paris.

GIRARDIN, MADAME DELPHINE DE, the wife of Emile Girardin, and daughter of Sophie Gay, a literary lady of considerable talents, was born in 1805, at Aix-la-Chapelle. She was what is called a precocious genins, and at the age of fourteen was noted for her remarkable beauty. In 1822 a poetical eulogy of hers, containing all the illustrious names of the day, was honourably mentioned by the French Academy. On the 26th of April 1827, she was received with great pomp in the Capitol of Rome by the Académie du Tibre, as one of their members. She received a more flattering ovation in Paris, on her return. The artist Legros, who had recently completed the new frescoes of the Pantheon, condncted Madlle. Delphine Gay to a place of honour beneath the dome, whence she recited some of her own poems in the presence of a brilliant assembly. As soon as she finished a shower of wreaths and bouquets were thrown at her feet. King Charles X. awarded her a pension of 1500 francs from his privy purse. Shortly after, she met with M. Émile de Girardin, to whom she was married in 1831.

Immediately after this union Madame de Girardin engaged in a variety of literary undertakings, producing novels, romances, and fugitive poems for the booksellers; tragedies, comedies, and vaudevilles for the theatres; and feuilletons for the newspapers. Her charming 'Lettres Parisiennes' appeared in the journal 'La Presse,' under the name of Vicomte C. de Launay. The small hotel she occupied with her husband at Chaillot was the resort of all the *célébrités* in art and literature, as well as of the *élite* of the Beau Monde. Every intelligent foreigner desirous of seeing the eminent and distinguished persons, whom he already knew by name, hastened to this house, built on the model of the Greek temples.

This clever authoress died on the 29th of June 1855, and on the 2nd of July she was followed to the grave by an immense crowd. The chief funeral oration was delivered by Jules Janin.

The catalogue of her works is very long; bnt the following are her most esteemed productions:—'La Pélérine,' published in 1828; 'Le Lorgnon,' a romance, 1832; 'Qu'on est heureux d'etre Curé,' a pastoral, 1833; 'Contes d'une Vieille Fille,' 1834; 'La Canne de M. de Balzac,' 1836; 'L'Ecole des Journalistes,' a five-act comedy, 1840; 'Judith,' a tragedy, 1843; 'Cléopatre,' a tragedy, 1847; 'Lady Tartuffe,' a comedy which produced much sensation, 1852; and 'La Joie fait Peur,' 1854.

GLADIOLUS, Corn-Flag (from 'gladius,' a sword, referring to the shape of the leaves), a genus of plants belonging to the natural order *Iridaceæ*. It has a tubnlar 2-lipped corolla; segments nndulate and uneqnal; stigma trifid; seeds with an arillus; root a coated bulb; leaves ensiform, sheathing. The species in the gardens are bulbous, and are chiefly brought from the Cape of Good Hope.

G. segetum has about 10 flowers in two rows. The npper division of the corolla is divaricate, the lower segment nearly equal and lanceolate; anthers longer than the filaments; capsules with 3 fnrrows. It has been supposed to be an aphrodisiac, a repntation obtained from its acrid qualities, which are however common to the whole of the order. The Hottentots eat the tubers or corms of several species of this genns, the starch they contain rendering them nntritious.

G. triphyllus has about 3 flowers in one row; the anthers much shorter than the filaments. It is found in the monntains of Carrara.

G. palustris has 3 or 4 flowers, secund; the tnbe twice as long as the seed-vessel; the claw of the middle division curved and remote; the lobes of the stigma papilloso-ciliate almost from the base; anthers shorter than the filaments; auricles at the base obtuse, parallel; capsules oblong, obovate, rounded at the top, marked with six equal furrows. It is found in Germany.

G. communis has secund flowers; the filaments half as long again as the anthers; auricles at the base obtuse and parallel; the tube half as long again as the germen; lobes of the stigma gradually broader npwards, papilloso-ciliate almost from the base; capsules 3-edged, obovate, impressed at the top; the seeds broadly winged. It is found near Stettin and Frankfurt-on-Oder.

G. Illyricus has secund flowers; the tnbe three times as long as the germen; division of stigma linear from the base to the middle, and with a smooth margin suddenly enlarged at the top with a papilloso-ciliate margin; the capsules obovate, 3-edged. A native of Illyria.

G. imbricatus has secund approximate flowers; the tnbe nearly three times as long as the germen; the division of stigma gradually broader npwards, papilloso-ciliate almost from the base; the capsules with 3 rounded angles. Found in Bohemia and Silesia.

G. infestus has a lax spike; flowers 4 to 14, obliquely alternate; division of corolla alternately pink and purple, nppermost very broad, covering the 2 lateral ones, the 3 lower unequal; anthers abont as long as the filaments; seeds globose, prolonged downwards. It is a native of Sicily.

G. Byzantinus has numerous flowers in two rows; the upper segment of the corolla covered by the lateral ones; the lower division lanceolate, the middle largest; the anthers longer than the filaments; seeds winged; leaves long, ensiform, and linear. Found in Sicily.

GLAND, a term applied to cells and collections of cells in the animal body, which have the power of absorbing or separating the various substances which pass into or are separated from the circulating fluid. In one sense all the cells of the animal act as glands, for they separate from the blood the peculiar substances of which they are composed. The term gland however is only strictly applied to special forms of tissue which separate peculiar matters. "A true gland," says Dr. Carpenter, "may be said to consist of a closely packed collection of follicles, all of which open into a common channel, by which the product of the glandular action is collected and delivered. The follicles contain the secreting cells in their cavities, whilst their exterior is in contact with a network of bloodvessels from which the cells draw the materials of their growth and development."

In a wider sense however the term gland has been applied to those parts of the body which are engaged in absorbing the food or carrying to the blood the materials of used-np tissues. [ABSORPTION.] In all cases the cell is an active agent whether of absorption or separation. The agency of the cell in absorption is seen in the way in which the chyle is taken from the intestines and carried into the lacteals.

For fnrther investigations on the structure of Glands, see TISSUES, ORGANIC, *S.* 1, pp. 642, 643, 644. After describing the development of glandular tissue, Professor Goodsir concludes his paper on this subject with the following remarks:—

"It appears to be highly probable therefore that a gland is originally a mass of nucleated cells, the progeny of one or more parent cells; that the membrane in connection with the embryo gland may or may not, according to the case, send a portion of the membrane in the form of a hollow cone into the mass; but whether this happens or not, the extremities of the ducts are formed as closed vesicles, and then nucleated cells are formed within them, and are the parents of the epithelium cells of the perfect organ. Dr. Allen Thomson has ascertained that the follicles of the stomach and large intestines are originally closed vesicles. This would appear to show that a nucleated cell is the original form of a follicle, and the source of the germinal spot, which plays so important a part in its future actions. The ducts of glands are therefore intercellular passages. This is an important consideration, inasmuch as it ranges them in the same category with the intercellular passages and secreting receptacles of vegetables.

"Since the publication of my paper on the secreting structures, in the 'Transactions of the Royal Society of Edinburgh,' in 1842, I have satisfied myself that I was in error in attributing to the cell-wall the important function of separating and preparing the secretion contained in the cell-cavity. The nucleus is the part which effects this. The secretion contained in the cavity of the cell appears to be the product of the solution of successive developments of the nucleus, which in some instances contains in its component vesicles the peculiar secretion, as in the bile-cells of certain *Mollusca;* and in others becomes developed into the secretion itself, as in seminal cells. In every instance the nucleus is directed towards the source of nutritive matter; the cell-wall is opposed to the cavity into which the secretion is cast. This accords with that most important observation of Dr. Martin Barry on the function of the nucleus in cellular development. I have also had an opportunity of verifying—and to an extent which I did not at the time fully anticipate—the remarkable vital properties of the third order of secretion referred to in the memoir to which I have just alluded. The distinctive character of secretions of the third order is, that when thrown into the cavity of the gland they consist of entire cells, instead of being the result of partial or entire dissolution of the secreting cells. It is the most remarkable peculiarity of this order of secretions, that, after the secreting cells have been separated from the gland and cast into the duct, or cavity, and therefore no longer a component part of the organism, they retain so much individuality of life as to proceed in their development to a greater or less extent in their course along the canal or duct before they arrive at their full extent of elimination. The most remarkable instance of this peculiarity of secretions of this order is that discovered by my brother. He has observed that the seminal secretion of the decapodous crustaceans undergoes successive developments in its progress down the duct of the testis, but that it only becomes developed into spermatozoa after coitus, and in the spermatheca of the female. He has also ascertained that, apparently for the nourishment of the component cells of a secretion of this kind, a quantity of albuminous matter floats among them, by absorbing which they derive materials for development after separation from the walls of the gland. This albuminous matter he compares to the substance which, according to Dr. Martin Barry's researches, results from the solution of certain cells of a brood, and affords nourishment to their survivors. It is one of other instances in which cells do not derive their nourishment from the blood but from parts in their neighbourhood which have undergone solution, and it involves a principle which serves to explain many processes in health and disease.

"I conclude therefore, from the observations which I have made, 1st, that all the true secretions are formed or secreted by a vital action of the nucleated cell, and that they are first contained in the cavity of that cell; 2nd, that growth and secretion are identical—the same vital process under different circumstances."

Having thus examined the nature of the process by which the cell secretes, we may now refer to some of the more prominent modifications of the organs called glands. The simplest condition of a Gland is the simple inversion of a secreting membrane called a follicle. These occur in the skin, as in the sebaceous follicles, and also in the mucous membrane of the stomach, where they are called gastric follicles. In these cases we have simply a pit in the membrane covered with secreting cells. In the early stages of the development of all glands we have this simple condition, and in the permanent condition of the more complicated glands, when occurring in the lower animals, we have the same simple development. Thus the liver in some of the Polypes and lower *Mollusca* consists merely of a series of separate follicles placed in the walls of the stomach. The chick whilst in the egg presents the same condition of this organ. The same simplicity is seen in the commencement of the development of a mammary gland in the *Mammalia.* In the *Ornithorhynchus* this organ consists of a mere cluster of blind sacs. In the same way in many fishes the pancreas begins its existence as a mere group of blind follicles. The next stage in the complexity of a gland is where a number of follicles open into a single tube. Such a condition of the gland is seen in what are called the Meibomian glands of the eye. The larger glands of the body, as the pancreas, liver, and parotid gland, are but mere complicated stages of this process. Innumerable follicles empty themselves into tubes which again empty themselves into other tubes until the whole contents of the gland are thrown out from some common outlet.

GLANFORD BRIGG. [LINCOLNSHIRE.]

GLAPHYRIA, a genus of plants belonging to the natural order *Myrtaceæ.* The limb of the calyx is 5-lobed, petals 5, berry 5-celled, many seeded; seeds fixed to the axis, 2 rows in each cell. The species are small Indian trees, with alternate minutely-stipitate leaves, and few-flowered axillary peduncles.

G. nitida is called by the Malays 'the Tree of Long Life,' probably from its maintaining itself at elevations where the other denizens of the forest have ceased to exist. It affords at Bencoolen a substitute for tea, and is known by the name of the Tea Plant. Various species of *Leptospermum* and *Melaleuca* bear the same name in the Australian colonies.

G. sericea has lanceolate acuminated leaves. It is a native of Pulo Penang and on the west coast of Sumatra. The calyx, peduncles, bracts, and young leaves are silky; the petals and cells of ovarium 5 or 6 in number.

GLAUCINE. [CHEMISTRY, *S.* 2.]

GLEAD (*Milvus*). [FALCONIDÆ.]

GLECHOMA. [NEPETA, *S.* 1.]

GLIADINE. [CHEMISTRY, *S.* 1.]

GLOBE-FISH. [TETRODON.]

GLOBE-FLOWER. [TROLLIUS.]

GLOBULIN. [TISSUES, ORGANIC, *S.* 1.]

GLOIOCLADIEÆ, a sub-order of Sea-Weeds belonging to the natural order *Cryptonemiaceæ.* The fronds are loosely gelatinous, the filaments of which they are composed lying apart from one another, surrounded by a copious gelatine. The favellidia are immersed among the filaments of the periphery. It embraces the following genera:—

Cruoria.—Frond crustaceous, skin-like.

Naccaria.—Frond filiform, solid, cellular; the ramuli only composed of radiating free filaments.

Gloiosiphonia.—Frond tubular, hollow, the walls of the tube composed of radiating filaments.

Nemaleon.—Frond filiform, solid, elastic, filamentous; the axis composed of closely packed filaments, the periphery of moniliform free filaments.

Dudresnaia.—Frond filiform, solid, gelatinous, filamentous, the axis composed of a net-work of anastomosing filaments; the periphery of moniliform free filaments.

Crouania.—Frond filiform, consisting of a pointed filament, whorled at the points, with minute multifid gelatinous ramuli.

(Harvey, *British Sea-Weeds.*)

GLOSSOP, Derbyshire, a manufacturing town and the seat of a Poor-Law Union in the parish of Glossop, is situated on elevated ground rising from a deep valley near the north-western boundary of the county, in 53° 26′ N. lat., 1° 55′ W. long.; distant 49 miles N.W. by N. from Derby, 176 miles N.W. by N. from London by road, and 193 miles by the Great Northern and Manchester Sheffield and Lincolnshire railways. The population of the township of Glossop in 1851 was 5467; that of the entire parish, which contains 49,960 acres, and is the most extensive in the county, and one of the most extensive in England, was 28,625. The living is a vicarage in the archdeaconry of Derby and diocese of Lichfield. Glossop Poor-Law Union contains 10 townships and hamlets, forming a part of Glossop parish, with an area of 20,807 acres and a population in 1851 of 19,580.

The cotton manufacture, which is carried on more extensively in Glossop than in any other Derbyshire town, gives employment to many of the inhabitants. About 50 cotton-mills are in the town and neighbourhood; there are also woollen-mills, paper-mills, iron-foundries, dye-works, and bleach-fields. Besides the parish church, there are chapels for Independents and other Dissenters. A charity for clothing 24 poor men and women was founded by Joseph Hague, Esq. There is a savings bank. Melandra Castle, situated on an eminence near the town, is the site of a Roman station; the works appear to have been nearly square, 366 feet by 336 feet; the ramparts, parts of the ditch, and other portions may be distinguished. A Roman road called the Doctor's Gate runs from Melandra Castle to Brough.

GLOSSOPORIS, a genus of Animals belonging to the order *Annelida*, and placed commonly near the Leeches. It has a posterior disc, hut it is not suctorial.

GLOTTALITE. [MINERALOGY, *S.* 1.]

GLYCERIN. [CHEMISTRY, *S.* 1; TISSUES, ORGANIC, *S.* 1.]

GLYCERIS, a genus of Dorsibranchiate Annelids. It is distinguished by the form of its head, which terminates in a conical fleshy horn-like point, which is divided at the top into four very small tentacles.

GLYCERYLE. [CHEMISTRY, *S.* 2.]

GLYCOEINE. [CHEMISTRY, *S.* 2.]

GLYPHISODON, a genus of Acanthopterygious Fishes belonging to the family *Sciænidæ*. The gill-covers are entire, and they have a single row of trenchant and sometimes notched teeth. The species are found in the Atlantic, but are more abundant in the Indian Seas.

GLYPTODON (Owen, so named from the fluted character of its teeth), a genus of extinct Fossil Animals belonging to the order *Edentata*, and allied in form and structure to the modern Armadillos. The first notice of the discovery of the remains of the skeleton of a large edentate animal, with fragments of a tesselated bony armour, similar to that of the Armadillo, appears in the note appended to the end of Cuvier's chapter on the *Megatherium*, in the 4th edition of the 'Ossemens Fossiles,' published in 1823. This notice occurs in an extract from a letter addressed by D. Daniasio Larranaga, curé of Monte Video, to M. Auguste St.-Hilaire. The facts stated in this letter are as follows:—A femur was discovered in the Rio del Lance, branche du Sanlis Grande, which weighed 7lbs.; it was short, but might be from 6 to 8 inches in width; it resembled in every respect the femur of an Armadillo; with it was found a portion of tesselated bony armour, of which the curé promises to send one of the component pieces to M. Auguste Geoffroi. The tail was very short and very stout; it had in like manner a bony armour, hut this was not verticillate or disposed in rings. These fossils were stated to have been met with near the surface of the earth, in alluvium or strata of transport, indicative of a very recent epoch. Similar fossils are said to occur in analogous strata near the Lake Nirum, on the frontier of the Portuguese colonies.

These remains were supposed to belong to the *Megatherium*, and Cuvier does not appear to suspect that they belonged to anything else, as he merely remarks that the *Megatherium* had pushed its analogies with the Armadillos so far as to be covered like them with a scaly cuirass.

Subsequently remains of this kind were sent to England, and in the meantime M. Laurillaud and Mr. Pentland, on comparing these with those originally sent to England, came to the conclusion that they belonged to the genus *Dasypus*. This however was doubted by Mr. Clift and Professor Owen, seeing that the conformation of the alveoli of the jaw indicated a dentition differing more widely from that of the existing sub-genera of Armadillos than their respective dental characters differ from one another. "It was at this conjuncture," says Professor Owen, "that Sir Woodbine Parish received the intelligence of the discovery of an entire skeleton, covered with its tesselated coat of mail, about 5 feet below the surface, in the bank of a rivulet near the Rio Matanza, about 20 miles south of the city of Buenos Ayres; and with the account of this remarkable discovery there was at the same time transmitted a drawing or sketch of the whole animal, which has since been lithographed, and one of the teeth of the fossil itself. This tooth Sir Woodbine Parish obligingly submitted to my examination. Its general structure proved it to belong to an animal referrible to the *Edentata* of Cuvier; hut its character was so peculiar that I had no hesitation in pronouncing it to differ from that of any known edentate animal, recent or fossil, and from its intimate texture, to be indicative of a new sub-genus of the Armadillo family, for which I proposed the name of *Glyptodon*, in reference to the plated or sculptured character of the tooth."

The *Glyptodon* differs from the *Megatherium* not only in the form and structure hut in the number of its teeth, which appear to be eight on each side of each jaw, as in the section of Armadillos called *Cabassous* by Cuvier. It differs from the Armadillos in the form of the lower jaw, and in the presence of a long process descending from the zygoma, in both which respects it resembles, and evidently indicates a transition to the *Megatherium*.

Numerous remains of this curious and interesting animal have been found in various parts of the country, and a very fine specimen, with the coat of mail almost entire, is to be seen in the museum of the College of Surgeons. Portions of this animal are also to be seen in the collection of the British Museum.

Although, when the remains of the *Glyptodon* were first brought to Europe, it was not thought improbable that the *Megatherium* also was enclosed in a gigantic suit of armour, no remains that could be regarded as the tesseræ of such a covering have yet been discovered. It is always difficult however to establish a negative, but the following arguments have been adduced by Professor Owen against this supposition, and will be probably regarded by most naturalists as conclusive:—

"1. The opinion of Cuvier and Weiss, in favour of the *Megatherium* being so armed, rests on no better ground than the mere fact of bony armour of some gigantic quadruped and the skeleton of the *Megatherium* having been discovered on the same continent.

"2. The skeleton, or its parts which have been actually associated with the bony armour above mentioned, belongs to a different and smaller quadruped.

"3. No part of the skeleton of the *Megatherium* presents those modifications which are related to the support of a bony dermal covering.

"4. The proportions of the component tesseræ of the bony armour in question to the skeleton of the *Glyptodon*, are the same as those between the dermal tesseræ and skeleton of existing Armadillos, but are vastly smaller as compared with the bones of the *Megatherium*.

"5. No bony armour composed of tesseræ, having the same relative size to the bones of the skeleton of the *Megatherium*, as in the *Glyptodon* and existing Armadillos, has yet heen discovered.

"6. The skeleton of the *Megatherium* has never been found associated with bony armour of any kind, neither have its parts been found associated."

(Owen, *Proceedings of Geological Society*, vol. vii., 2nd series.)

GMELIN, LEOPOLD, was born at Göttingen on the 2nd of August, 1788. This eminent chemist and contributor to the literature of the science of which he was an equally eminent academic teacher, belonged to a family which for four generations had been actively engaged in the pursuit of chemistry, the medical sciences, and several branches of natural history, and one member of which, if not more, is still so engaged. Three of his eminent relatives have already been noticed in the 'Penny Cyclopædia.'

Johann George Gmelin, apothecary at Tübingen, who was born in 1674, and died 1728, had three sons, all of whom devoted themselves to chemistry and the allied sciences. The eldest Johann Conrad Gmelin (born 1707) was a physician and apothecary at Tübingen; his grandson, Christian Gottlob Gmelin (born 1792) is now professor of chemistry in the same university. The second is the subject of the article GMELIN, JOHN GEORGE. The third son, Philip Friedrich Gmelin (born 1722), succeeded the last-mentioned in his professorship of chemistry and botany at Tübingen, and died there in 1768. His elder son was GMELIN, SAMUEL GOTTLIEB, and his younger son GMELIN, JOHN FREDERICK, who succeeded him in that chair, and afterwards became professor of chemistry at Göttingen, was the father of the distinguished man we have now to commemorate.

Leopold Gmelin, from 1799 to 1804 attended the Lyceum in that city, and in the summer of 1804, his father's lectures on mineralogy. In the autumn of the same year he went to Tübingen, where he practised chemical manipulation in the pharmaceutical laboratory of his near relation, Dr. Christian Gmelin (the son of Johann Conrad Gmelin and father of Christian Gottlob Gmelin, both already mentioned), and attended Killmeyer's lectures on chemistry. In the autumn of 1805 he returned to Göttingen, where he devoted himself with zeal to all branches of medical science, but especially to chemistry, for which he attended Stromeyer's lectures; he also studied mathematics. After passing a distinguished examination, he went, in the summer of 1809, to Würtemberg, and thence to Switzerland, which he traversed in all directions, hammer in hand. From the autumn of 1809 to Easter 1811 he remained in Tübingen, and then went to Vienna, where he visited the hospitals, and carried out, in Jacquin's laboratory, the greater part of the experiments, which form the basis of his Doctor-dissertation 'On the Black Pigment of the Eye,' published in 1812, and afterwards in the tenth volume of Schweigger's Journal. He left Vienna in the spring of that year, and went to Italy, where he remained till the spring of 1813, chiefly at Naples, but for some time also at Rome.

The observations and collections made in these journeys supplied the principal materials of the chemico-mineralogical investigations which formed the subject of his 'Habilitation-Schrift' or thesis at Heidelberg, 'On Hauyne, and minerals related to it, together with geognostic observations on the mountains of ancient Latium,' published in 1814. On his way back to Göttingen he stayed some time at Heidelberg, where the professor of chemistry, George Succow, being then recently dead, Gmelin was encouraged to give lectures on that science. Availing himself of the opportunity thus presented, he obtained the 'venia docendi' in Heidelberg, spent the remainder of the summer at Göttingen, making the necessary preparations for his new duties, and in the autumn of the same year began his career as an academic teacher in Heidelberg, which he subsequently pursued with zeal and success for nearly forty years. Twelve months afterwards he was appointed extraordinary professor of chemistry in the university. His celebrated 'Handbook of Chemistry' was then already begun. In the autumn of 1814 he went to Paris, and occupied himself chiefly with practical researches in Vauquelin's laboratory. Two years afterwards he married Luise Maurer, the daughter of a clergyman of Heidelberg, and settled there, declining the appointment of professor of chemistry at Berlin, whither he was invited in 1817, to succeed Klaproth [KLAPROTH, MARTIN HENRY], who died in that year. He was soon afterwards made ordinary professor of medicine and chemistry at Heidelberg. In 1835, he declined an invitation to fill the chair of chemistry at Göttingen, preferring to remain in his adopted home, although his emoluments there were much less than they would have been either at Göttingen or at Berlin. In the latter portion of his life he was so completely engrossed with the gigantic labour of preparing the fourth edition of his 'Handbook,' that he became quite neglectful of his health. In 1848, he had an attack of paralysis, which, though it only deprived him for a while of his power of action, destroyed the freshness and vigour of his manner, and elasticity of spirit. But he still worked at his 'Handbook' with untiring assiduity, as shown by the volumes which afterwards appeared. In 1850, he was again attacked by paralysis, which obliged him to resign his professorial functions. He still however remained active in the cause of science, and laboured earnestly at the second volume of the 'Organic Chemistry,' which he completed in May, 1852. But from that time his powers, both mental and bodily, rapidly declined; an insidious disease of the brain was steadily gaining ground. In the spring of 1853 it became evident that his end was approaching, and he died on the 13th of April, in the sixty-fifth year of his age.

Leopold Gmelin's original researches in chemistry are numerous; they are all of high character, and as complete as the means of investigation existing at the time when they were instituted would admit. In 1820 he undertook, in conjunction with Tiedemann, a series of experiments on digestion; and in 1826 and 1827 these two philosophers published their celebrated work, entitled 'Die Verdauung nach Versuchen.' But the greatest service which he rendered to science,—"a service in which," in the words of competent authority, "he surpassed all his predecessors and all his contemporaries"—consisted in the production of his 'Handbuch der Chemie,' the beginning and later progress of which have been mentioned above. The late Dr. Thomas Thomson, F.R.S., afterwards Regius Professor of Chemistry in the University of Glasgow, had published the earlier editions of his 'System of Chemistry,' in which he reduced to order, in a clear and exact manner, the facts of the science, scattered at the time he wrote over a thousand different publications, and had thus himself conferred an inestimable benefit, especially on British chemists; other writers also had arranged large quantities of materials in systematic order; but for completeness and fidelity of collation, and consecutiveness of arrangement, Gmelin's 'Handbook' is unrivalled. In it the known facts of the science are condensed into the smallest possible space, but nevertheless it presents a complete picture of them. Detached and long-forgotten observations of other chemists were often indebted to the author for first giving them their true value. In this great work, to use the words adopted, in 1854, by the President of the Chemical Society of London, of which Gmelin was a foreign member, he "sets the example of putting together, in a purely objective view, and on the authority of the several investigators, all that has been observed within the domain of chemistry, —not, indeed, withholding his own opinions, but placing them side by side with those of others, and never suppressing the latter."

The 'Handbook of Chemistry,' moreover, has often directed attention to deficiencies and contradictions in existing chemical knowledge, and has thus given rise to new investigations; it has also been widely influential in extending an accurate knowledge of chemistry, not only in Germany, but wherever the science is cultivated. The first edition, which appeared in the years 1817-1819, included in a comparatively small space the extent of chemical science then known; the fourth, which was the last prepared by Gmelin himself, was published from 1843 to 1852, and comprehends inorganic chemistry, but, unfortunately, only a small part of organic chemistry. From this the English edition, now in course of publication under the auspices of the Cavendish Society, is translated by Mr. Henry Watts, B.A., Fellow of the Chemical Society of London, of whose 'Quarterly Journal' he is also the editor. The additions made by him bring the 'Handbook' down to the existing state of chemical science at the time of publication of each volume. The desire to make this work generally available to British chemists, was one of the motives which originally contributed to the establishment of the Cavendish Society. The first volume was published at the end of the year 1848; the eleventh, being the fifth of organic chemistry, has recently appeared (November 1857). The translation is continued from a new German edition.

In the 'Annals of Philosophy' for August and September 1814, (Series I., vol. iv. pp. 115, 193,) a few months only after the appearance of Gmelin's Thesis in Germany, Dr. Thomson published satisfactory abstracts in English of the geological and mineralogical portions respectively. Of his dissertation on the black pigment of the eye, Dr. Thomson gave a short account in the same work for January 1816 (vol. vii. p. 54,) in which Gmelin's examination of the ink of the cuttle-fish, which he had found to possess very nearly the same properties with the black pigment, is compared with Dr. Prout's, then recently published.

GOGOL, NIKOLAY, a Russian author of great celebrity, whose career throws a light on several points of the moral and political state of his country. He was born apparently about 1810, in Malorussia, or Little Russia, the inhabitants of which are distinguished from those of Great Russia by vivacity of character and a comparatively strong feeling of self-respect and independence. They have a language or dialect of their own, about as distinct from that of Russia as the Lowland Scotch from the English, but of which no use is made in serious composition. Gogol was educated at Neghin, at the Besborodko Lyceum, a provincial high school founded and endowed by one of the Bezborodko family, and one of the few institutions of the kind in Russia which are not directly supported by the public money. On completing his education he repaired to St. Petersburgh in search of employment under government, and it is said that his claims were rejected by one of the government offices on the ground that he was insufficiently acquainted with the Russian language. Soon after he published his first work, a collection of short novels and sketches, entitled 'Evenings at a Farmhouse' ('Vechera na Khutorie'). The book became immediately popular, and the charm of the style was compared by Russian critics to that of Washington Irving. It consists of a series of delineations of country life in Malorussia, which are said to be remarkable for their fidelity. It was soon followed by 'Mirgorod,' a supplementary collection of the same character, which met with equal favour. One of the author's habits deserves remark; Gogol, like Dickens, was noted for the excellence with which he read aloud his own productions, and it is said that in composing a dialogue, it was his practice to recite all the different speeches in character before committing them to paper, by means of which he ascertained more satisfactorily if they were in complete consonance with what the character and situation required. He soon tried his powers in the drama, and his comedy of 'The Revisor' met with the most brilliant success. A revisor in Russia is the title of a high government officer despatched to a province to ascertain and report on the character of its administration. The plot and the moral of the play is, that an impostor who makes his appearance at a provincial capital, assuming this title, discovers such universal peculation and misconduct among all the government officials, that when he is at last discovered they are glad to let him off scot free and hush up the whole affair. The Emperor Nicolas, who saw the play acted more than once, gave it his marked applause. It was however chiefly popular among the Russian liberal party, who affixed to it a deeper significance than to a foreigner appears altogether just, and considered it an open and serious attack on the institutions of Russia in general. That it was not looked upon in this light by the government seems sufficiently proved by the appointment of Gogol as professor of history at the University of St. Petersburg, where it was his intention to devote himself to more serious studies. His next work however was another novel, the 'Adventures of Chichagov, or Dead Souls' ('Pokhozhdeniya Chichagova ila Mertvuiya Dushi'), published at Moscow in 1842. The English public has an opportunity of forming an estimate of this, the principal work of Gogol, as an English translation of it appeared in 1854, under the title of 'Home Life in Russia, by a Russian Noble,' falsely declared in the preface to be an unpublished novel, originally written by a Russian in the English language. The style of the English version is indeed remarkably bad, while that of the Russian original is remarkably good; but the main strength of a novel lies in the plot and characters. The hero of the 'Dead Souls,' like the hero of the 'Revisor,' is a daring impostor, who goes about to a number of country gentlemen to persuade them to sell to him the nominal property in their dead serfs, or, as they are technically called in Russia, their 'dead souls,' for the purpose of obtaining an advance from government as the proprietor of a certain number of serfs—the names of the dead not being for a certain period struck off the records. Some of the characters introduced in the tale are certainly sketched with vigour, but in no other production of Russian literature is the foreign reader so much at a loss to detect the charm which has excited the enthusiasm of the native critics. The praises which were lavished on the original may be suspected of having their origin partly in political feelings.

Soon after the appearance of the book which raised his fame to its highest point, the author, whose health was bad, obtained permission to travel abroad, and was still abroad at the time of the publication of 'Select Passages from N. Gogol's Correspondence with his Friends' ('Vuibrannuiya Miesta iz Perepiski s Druziami'), St. Petersburg, 1847, 8vo. From the height of popularity this publication sunk him at once to the lowest depths of contempt. His liberal friends found with surprise that the satirist of Russia, when at home, had become the panegyrist of Russia, autocracy and all, when beyond the frontier. Beilinsky, who was one of the principal, attacked him fiercely in the 'Sovremennik,' one of the leading reviews in St. Petersburg, in an article which could hardly have been expected to pass the censorship. Gogol addressed to him a letter of remonstrance, protesting that the change which had taken place in his opinions was the result of conviction produced by reflection and experience. Bielinsky, who dying of consumption, had himself obtained permission to leave Russia, addressed to him from his sick bed at Salzbrunn one of the most terribly crushing letters to be found in the whole annals of literature, and which was first printed, with the rest of the correspondence, in the 'Polyarnaya Zviezda,' or 'Polar Star,' a Russian periodical issued in London in 1855. "Yes," exclaims Bielinsky, "I loved you with all the passion with which a man warmly attached to his country, can love its hope, its honour, its glory, one of its great leaders in the path of self-consciousness, development, and progress. You had good cause indeed to be shaken out of your repose of soul, for a minute at least, when you lost the right to such love as this. I do not speak thus because I consider any feelings of mine an adequate recompense for such genius as yours, but because in this respect I do not stand alone, but represent a multitude of whom neither you nor I have ever seen the majority, and who have never seen you." "You," he afterwards bursts out, "you, the author of the Revisor and the Dead Souls,—can you, sincerely, and from your soul, raise a hymn of praise to the disgusting Russian clergy, placing it immeasurably above the clergy of the Roman Catholics. Let us suppose you do not know that the latter was sometimes something, while the former was never nothing but the lackey and slave of the secular power; but is it possible you do not know that our clergy stands in the lowest degree of contempt with Russian society and the Russian people. Is not a 'pope' throughout Russia for every Russian the representative of gluttony, meanness, servility, impudence? . . . . I will not dilate on your dithyrambic about the bond of affection between the Russian nation and its rulers. I will only say that this dithyrambic has met with no sympathy, and has lowered you even in the eyes of persons who in other respects are very close to you in the direction you are taking. I leave it to your conscience to intoxicate itself with the divine beauty of Autocracy; only continue to have the good sense to contemplate it from a reasonable distance,—when near, it is not so beautiful, and is apt to be dangerous. . . . . You placed yourself too high in the opinion of the Russian public for it to be able to believe in the sincerity of such convictions as this. What may seem natural enough in fools cannot seem natural in a man of genius." Bielinsky goes on to accuse him of views of personal emolument, and touches with bitterness on a passage in the 'Perepiski,' in which Gogol had appeared to speak with humility of his own works, and to intimate that he did not share the opinion of their admirers. "These persons," says Bielinsky, "may in their admiration of you have made more noise with their applause than the case required; but after all, their enthusiasm sprung from so pure and noble a source that it was altogether unbecoming in you to surrender them up in the face of their enemies and yours, and to accuse them into the bargain of attributing a wrong meaning to your productions." The reply of Gogol to this bitter diatribe is singular. "God knows," he writes, "there may be some truth in what you say.—One thing appears to me an established truth—that I do not know Russia—that much has been changed in it since I left, and that I must almost begin to study it anew to know it now. The inference I draw from this for myself is, that it behoves me not only not to print new sketches of life, but not even two lines on the subject till I have returned to Russia, have seen it with my own eyes, and touched it with my own hands." Neither Bielinsky nor Gogol ever returned. Bielinsky died in France soon after the Paris revolution of February 1848, which he hailed as the dawn of an era of liberty; and Gogol, whose last letter is dated from Ostend, in August 1847, soon followed him. His death is repeatedly alluded to in recent Russian publications, but we have not seen its real date stated.

GOLD, one of the precious metals. It differs remarkably from other metals, with a very few exceptions, in the fact that it is found in nature in its metallic state. It is occasionally found mineralised by tellurium. Native gold is Monometric, and occurs in cubes without cleavage, also in grains, thin laminæ, and masses, sometimes filiform or reticulated. The colour varies in shade, sometimes being a bright yellow, at others almost silvery-white, from the quantity of silver with which it is mixed. It is very ductile and malleable. Hardness 2·5 to 3. Specific gravity 12 to 20, varying according to the metals alloyed with the gold. Native gold usually contains silver, and in very various proportions. The finest native gold from Russia yielded—gold 98·96, silver 0·16, copper 0·35, iron 0·05; specific gravity 19·099. A gold from Marmato afforded only 73·45 per cent. of gold, with 26·48 per cent. of silver; specific gravity 12·666. This last is in the proportion of 3 of gold to 1 of silver. The following proportions have also been observed:—3½ to 1, 5 to 1, 6 to 1, 8 to 1; and this is the most common; 12 to 1 also is of frequent occurrence.

Copper is often found in alloy with gold, and also Palladium and Rhodium.

A Rhodium Gold from Mexico gave the specific gravity 15·5 to 16·8, and contained 34 to 43 per cent. of rhodium.

Iron and copper pyrites are often mistaken for gold by those inexperienced in ores. Gold is at once distinguished by being easily cut in slices and flattening under a hammer. The pyrites when pounded are reduced to powder: iron pyrites is too hard to yield at all to a knife, and copper pyrites affords a dull greenish powder. Moreover the pyrites give off sulphur when strongly heated, while gold melts without any such odour.

Native gold is to a large extent obtained from alluvial washings. It is also found disseminated through certain rocks, especially quartz and talcose rocks, and is often contained in pyrites, constituting the auriferous pyrites; the detritus affording gold-dust has proceeded from some gold-bearing rocks.

Gold is widely distributed over the globe. It occurs in Brazil (where formerly a great part of that used was obtained), along the chain of mountains which runs nearly parallel with the coast, especially near Villa Rica, and in the province of Minas Geraes; in New Granada, at Antioquia, Choco, and Grion; in Chili; sparingly in Peru and Mexico; in the southern of the United States. In Europe it is most abundant, in Hungary, at Königsberg, Schemnitz, and Felsobanya, and in Transylvania, at Kapnik, Vorospatak, and Offenbanya; it occurs also in the sands of the Rhine, the Reuss, and the Aar; on the southern slope of the Pennine Alps, from the Simplon and Monte Rosa to the valley of Aosta; in Piedmont; in Spain, formerly worked in Asturias; in the county of Wicklow in Ireland; and in Sweden at Edelfors. In the Ural Mountains there are valuable mines, also in the Cailles Mountains in Little Tibet. There are mines in Africa at Kordofan, between Dar-fur and Abyssinia; also south of Sahara, in the western part of Africa from Senegal to Cape Palmas; also along the coast opposite Madagascar, between 22° and 23° S. lat., supposed to have been the Ophir of the time of Solomon. Other regions in which gold is found are China, Japan, Formosa, Ceylon, Java, Sumatra, and the Philippines.

Until lately nearly all the gold of commerce came from Asiatic Russia and Mexico, but recent discoveries of gold in California and Australia have opened new and vast sources of supply.

From 1600 to 1700 the entire supply of gold for Europe was obtained from America, whose mines are estimated in the one hundred years to have produced 337,500,000*l*. worth of the precious metal. During the 18th century the supply of gold and silver was still mainly derived from the Americas, the great mine of Valenciana producing 125,000*l*. sterling per annum for 40 years, and the district of Zaccatecas adding largely to the amount, although these were rapidly failing towards the end of the century. A great increase of gold was produced from the mines of Russia, which are still very productive; they are principally alluvial washings, and these washings seldom yield more than 65 grains of gold for 4000lbs of soil, never more than 120 grains. The alluvium is generally most productive where the loose material is most ferruginous. The mines of Ekaterinburg are in the parent rock—a quartz constituting veins in a half-decomposed granite called Beresite, which is connected with talcose and chloritic schists. The shafts are sunk vertically in the beresite, seldom below 25 feet, and thence lateral galleries are run to the veins. These mines afforded between the years 1725 and 1841 679 poods of gold, or about 30,000 lbs. troy. The whole of the Russian mines yielded in 1842, 970 poods of gold, or 42,000 lbs. troy, half of which was from Siberia, east of the Urals. In 1843 the yield was nearly 60,000 lbs. troy; in 1845, 62,000 lbs. troy; and in 1846, 75,353 lbs.

In the five following years to 1851 nearly 296,932 lbs. troy weight of gold have been raised in Russia.

At the Transylvania mines the gold is obtained by mining, and these mines have been worked since the time of the Romans. The annual yield of Europe exclusive of Russia is not above 250,000*l*. The sands of the Rhone, Rhine, and Danube contain gold in small quantities. The sands of the richest quality contain only about 56 parts of gold in 100,000,000. Sands containing less than half this proportion are worked. Africa yields annually at least 4500 lbs. troy, and Southern Africa 1250 lbs. For an account of the gold-region and gold-produce of California, see CALIFORNIA, *S.* 2.

From November 1850 to June 1851 the Bank of England issued 9,500,000 sovereigns, being at the rate of 18,000,000 a year, and so great is the increasing demand for gold coins, that the rate of production can scarcely keep pace with it.

It may be interesting to know, that from the account kept at the Bank when the light coin was called in, in 1842, that 12,000,000*l*. were received light, and 36,000,000*l*. still circulated of full weight; 40,000,000*l*. may therefore be regarded as the quantity of gold coin in circulation, allowing from 3 to 4 per cent. for the natural wear of the coin.

In the year 1856 there were coined at the royal mint 4,806,160 sovereigns, and 2,391,909 half-sovereigns; total 6,001,114*l*. 10*s*.

A large quantity of gold is consumed every year in arts and manufactures, and thus regularly removed from the stock of our circulating wealth. In Birmingham not less than 1000 oz. of fine gold are used every week, and the weekly consumption of gold leaf is as follows:—

	Ounces.
London	400
Edinburgh	35
Birmingham	70
Manchester	40
Dublin	12
Liverpool	15
Leeds	6
Glasgow	6
Total	584 weekly,

of which not one-tenth can be recovered. For gilding metals by the electrotype and the water-gilding processes not less than 10,000 oz. of gold are required annually. One establishment in the Potteries employs 3500*l*. worth of gold per annum, and nearly 2000*l*. worth is used by another. The consumption of gold in the Potteries of Staffordshire for gilding porcelain and making crimson and rose-colour varies from 7000 to 10,000 oz. per annum.

The Indus and the Euphrates were the earliest spots whence man obtained the precious metal, gold—Nubia and Ethiopia on the south, and Siberia on the north next opened out their auriferous treasure to gratify human necessity and to indulge human luxury. Europe then began to unfold her golden stores, and Illyria and the Pyrenees, together with the land of the Hungarians and many parts of Germany to the Rhine, were sought successfully for gold. Our islands yielded something to the store, and then the New World of the Americans opened by Columbus a source from which the Old World was to supply its golden waste. On and on still westward rolled the golden ball, until at length it rested in California; Europe and Asia rush equally to that new El Dorado, and the man of China is found at the side of the English gold streamer. Then, as if to double the girdle, the islands of the Pacific and our own Australia open their exceeding stores.

Australia is undoubtedly the most important gold-bearing district in relation to Great Britain. Her shores are now being crowded with emigrants from the mother country seeking the precious metal, and in proportion to her population she is now undoubtedly, in this point of view, the richest country of the world. [AUSTRALIA, *S.* 2; EMIGRATION, *S.* 2.]

For the purpose of guiding those who are seeking Australia on account of its gold, the professors of Natural Science, in the Museum of Practical Geology, delivered a course of lectures in the summer of 1852. These lectures were as follows:—

1. 'The Geology of Australia, with Especial Reference to the Gold Regions,' by J. Beete Jukes, M.A. F.G.S., Local Director of the Geological Survey of Ireland; author of 'Sketch of the Physical Structure of Australia.'

2. 'On our knowledge of Australian Rocks as derived from their Organic Remains,' by Edward Forbes, F.R.S.

3. 'The Chemical Properties of Gold, and the Mode of Distinguishing it from other substances resembling it,' by Lyon Playfair, C.B. F.R.S.

4. 'The Dressing or Mechanical Preparation of Gold Ores,' by W.W. Smith, M.A. F.G.S.

5 'The Metallurgical Treatment and Assaying of Gold Ores,' by John Percy, M.D. F.R.S.

6. 'The History and Statistics of Gold,' by Robert Hunt, Keeper of Mining Records.

We subjoin an account of the auriferous rocks of Australia from the lecture of Mr. Jukes:—

"In Mr. Arrowsmith's map, appended to the Parliamentary Report just issued, all the auriferous spots are marked in yellow. They occur at intervals along the flanks of the Great Eastern Chain, or on its lateral spurs and subordinate ranges through an extent of country about 1000 miles in length, about as far as from London to Gibraltar or the confines of Turkey, or as from London to Iceland in a straight line. The principal localities marked on this map are Grafton Range and Burnet River, north of the Condamine; Stanley Creek and Canning Downs in the Moreton Bay district; several spots in the neighbourhood of Liverpool Plains; the Turon and Conobalas on the Macquarrie, below Bathurst; the Abercrombie River at the head of the Lachlan; some spots on each side of Breadalbane Plains; the Braidwood and Araluen diggings in the Shoalhaven district; Lake Eimeo in the Australian Alps; and Ballarat, and Mount Alexander and Mount Blackwood, north-west of Port Phillip.

"In every one of these localities granite and metamorphic rocks occur, and quartz veins are frequently spoken of. This is an important fact to bear in mind.

"In scarcely any of them do we find mention made of the gold being seen in the actual rock, but in the drift clay, sand, and gravel, or lying loose on the surface of the ground. The hundredweight of gold, indeed, found by Dr. Ker, north of Bathurst, is described as a block of highly auriferous quartz, lying among a lot of other loose blocks, evidently derived from a broad quartz vein running up the hill behind them. Such a mass, indeed, could hardly be transported far from its original site by any conceivable current of water.

"The superficial drift in which the diggings have been carried on varies in thickness from a few inches to 20 or 30 feet. The following is an extract from a lecture given by a Mr. Gibbon, in Melbourne, and reported in the 'Melbourne Argus,' giving an account of the Ballarat diggings:—'On the surface of the earth was turf in a layer of about a foot thick, below which was a layer of rich black alluvial soil, and below that gray clay; below that again was a description of red gravel, which was sometimes very good; then red or yellow clay, in which gold was found; and then a stratum, varying in thickness, of clay streaked with various colours, and scarcely worth working; and the next stratum was of hard white pipe-clay, which was a decided barrier. Immediately above it however was a thin layer of chocolate-coloured clay, tough and soapy. This was the celebrated blue clay, and was very rich.

"'The ground on which the diggings were situated was a sloping bank. The blue clay is found near the surface on the brow of the hill, that is, at the depth of about a foot; but it is sometimes necessary to dig 20 feet before arriving at it.'

"Mr. Latrobe, governor of Victoria, describes the Ballarat diggings as carried on through—

"'1. Red ferruginous earth and gravel.

"'2. Streaked yellowish and red clay.

"'3. Quartz gravels of moderate size.

"'4. Large quartz pebbles and boulders; masses of iron-stone set in very compact clay, hard to work.

"'5. Blue and white clay.

"'6. Pipe-clay.

"'In some workings the pipe-clay may be reached at the depth of 10 or 12 feet, in others not at 30 and upwards.'

"To enter farther into the details of the several diggings would be alike tedious and useless. I must refer you for them to the two Parliamentary Reports published, the one in February and the other in June, and to the many small publications with which the shops are now swarming.

"My object to-night has been to give you such a rough sketch of the geology of Australia, and of the geological facts and principles that ought to guide any one in his search after gold, as may be of use to those intending to emigrate there.

"In conclusion, I may perhaps be allowed to utter one word of advice.

"Gold-digging is very hard work—just such work as you see navigators at in a railway cutting, or brick-makers in a brick-pit. You must work hard all day, lie hard all night, with but little shelter, often with scanty food, and with nothing of what you have probably been accustomed to consider necessary comfort. If you find you have no luck at the diggings, or if your health, or strength, or resolution fail you, do not therefore give up or despond altogether. You go out to dig for gold; do not be ashamed to dig for anything else. I speak to those now who have been hitherto unaccustomed to manual labour. Recollect, it is the avowed object of your voyage, and the only thing you have to trust to. If you fail to dig up gold there are lands to be ploughed, sheep to be herded and sheared, cattle to be tended, corn to be sown and reaped—every one of these fully as honourable occupations as digging for gold. Go, then, with a bold and resolute heart, determined to get your living by the strength of your own arms and the sweat of your own brows; and be assured that industry and perseverance lead to fortune in Australia with fewer impediments and uncertainties in the way than in any part of the world."

Since the above was written, other districts in Australia have yielded the precious metal, and every day is adding to our knowledge of the wide extension of this metal on the surface of the earth.

GOLD COAST COLONY. The Gold Coast is part of Upper Guinea, but its boundary is not exactly determined. Geographers state that Cape Three Points (2° 30′ W. long.) constitutes its western boundary; but our navigators extend it farther west to the small river Assinnee (about 5° W. long.), nearly 70 miles E. from Cape Lahoo. On the east, the eastern mouth of the river Lagos (4° 20′ E. long.) is generally considered as constituting its boundary towards Benin, though the most eastern districts are often distinguished by the name of the Slave Coast. In the interior are the powerful kingdoms of the Ashantees and Dahomey, on which most of the small states along the coast are dependent. According to Governor Hill, in his despatch to the Secretary of State for the Colonies, transmitting the 'Blue Book' for 1851, the territory under British protection is estimated to include about 8000 square miles of country, with a population of about 400,000. In a despatch of April 15th, 1853, however, Governor Hill states that he considers his previous estimate of the population to be exaggerated, and that it is probably not more than 300,000. The revenue of the colony is derived from a government grant of 4000*l.* per annum, a duty of half per cent. ad valorem on all imports, and certain small fees. The income for 1853 amounted to 12,339*l.*, the expenditure to 12,045*l.* The value of the imports for the year 1853 amounted to 60,000*l.*; the value of the exports for the same year amounted to 115,000*l.* The imports for 1854 amounted to 107,200*l.*; the exports for the same year to 200,002*l.* The chief article of export is palm-oil.

Nearly in the centre of the coast is the fortress of Accra. The country west of Accra has an undulating surface, with a small proportion of level ground: the hills are covered with shrubs and timber of small growth. The coast, though rarely high, is rocky and bold. At Accra the low country begins, and extends a considerable way to the eastward. It is a fertile, open, and level plain, which contain extensive savannahs covered with high grass; but in some parts it is thickly wooded with fine trees. The shores here are flat and sandy. There are no harbours along the coast; and as the surf is very violent, the trading vessels are obliged to anchor four or five miles from the beach. This coast was formerly much resorted to by European and American vessels for slaves. At present it is visited by a few vessels for palm-oil, gold, and ivory: they give in exchange fire-arms, iron, and iron-ware, tobacco, rum, Manchester cottons, and some other articles.

The whole of this coast being near 5° N. lat., is considered one of the hottest countries on the globe; yet the mean temperature is only 78°, and in the cold season the thermometer sometimes falls to 73° or 74°. During the Hamattan season, from the middle of December to March, which is the driest and coolest part of the year, the wind blows from north-east. The great rainy season begins in March, and continues to the beginning of June. From June to the end of September is the warm season, which is the most unhealthy, especially the month of August, when the fogs are denser than at other times, and generate fevers. In October and November showers of rain are frequent. Except during the Hamattan season, the winds blow from the west in the middle of the day, from 11 to 3 o'clock, but in the evening from south-west, and in the morning from north-west. The climate is in general unhealthy, especially to Europeans on their arrival. Every person is attacked by a fever, which is called the seasoning. This fever in many instances proved fatal; but it is stated that of late years the administration of quinine has been found exceedingly useful in promoting the recovery of persons attacked by the fever.

Cape Coast Castle is the principal English fortress; it is situated in 5° 5′ N. lat., 1° 12′ W. long., and covers a considerable area. In it are apartments for the officers, and barracks for the private soldiers. There are some spacious warehouses. It is built on a rock close to the sea. Near it are the small outposts called Fort William and Fort Victoria. The town, which is behind the fortress, is of considerable extent; it has about 10,000 inhabitants, of whom about 20 are Europeans. The streets are regularly arranged, but the houses are of mud, and huddled together. Within Cape Coast Castle is a government-school, which in 1852 was attended by 153 boys.

The other forts are Accra, Annamaboe, and Dixcove. Fort St. James at *Accra* is occupied by a small garrison. The native population is stated to be about 3000. The fort is situated on the coast in 5° 32′ N. lat. 0° 12′ W. long, and the station is regarded as among the most healthy on the Gold

Coast. Two insurrections occurred at Accra in 1854. Severe measures were required to suppress the second insurrection. Near Accra is the Dutch fort of Crevecœur. About 3 miles E. from Accra is the fort of Christiansborg, and about 30 miles N.E. from Accra is the fort of Fredensborg, both recently purchased from the Danes by the British government. The purchase of the Danish forts on this coast has added considerably to the area of territory under British protection. ANNAMABOE has been noticed separately. The population is said to be about 4500. The exports include the articles usually sent from this coast, namely, palm-oil, gold-dust, ivory, and grains, and the imports include British manufactured goods of a useful description, besides arms, gunpowder, spirits, and wines. Annamaboe is an entrepôt of commerce for Ashantee and the interior. *Dixcove* is situated in 4° 48′ N. lat., 1° 57′ W. long. The bay affords accommodation for vessels of 100 tons to take in their cargoes. The native population inhabiting the town is about 1200.

The introduction of civilising influences to the native population of the Gold Coast, is chiefly owing to the labours of the Wesleyan missionaries. From the despatches of successive governors of the colony, addressed to the Secretary of State, it would appear that considerable progress has been made in communicating to the natives the benefits of an educational and industrial training. In the year 1852 the Wesleyan chapels were attended by upwards of 6000 persons, and about 1200 children were in attendance at the schools of the mission. Mr. Freeman, the missionary superintendent, established in 1851 an industrial school and garden at Beulah, about 8 miles from Cape Coast Castle. In February 1852 there were 28 native youths under training at this establishment. On December 31st 1852 Mr. Freeman, writing to Governor Hill, says, "We have now about 750 vines and 5000 coffee-plants. The lads in the establishment work willingly, and behave well." The Wesleyan Missionary Society expends about 5000*l.* a year on the Gold Coast Mission. Among other evidences of advancing civilisation may be noticed the erection by the natives of many neat cottages for the residence of their families, with some pretension to the conveniences and comforts of European dwellings, and the construction of several good roads to facilitate communication between the towns and villages in the interior. The roads have been constructed voluntarily by the natives under the direction of the missionaries. These encouraging features have been more particularly noticeable in the neighbourhood of Abrakrampa, the capital, and Domonasi, the second town of the Abrah tribe and district, in the Cape Coast territory. In some of the principal towns of the interior chapels for Christian worship have been built by the chiefs at their own expense.

Governor Hill has endeavoured to enlist the sympathies and co-operation of the native chiefs, by forming them into a kind of legislative body, including the council, with the executive at its head. Each chief has agreed to pay a poll-tax of 1*s.* yearly for each person belonging to his tribe: from the fund thus provided each chief is to receive a stipend to support the dignity of his position, and from it is to be defrayed the cost of such general measures of improvement as the legislative body may agree to undertake. Besides the school at Cape Coast Castle, already noticed, the Governor has recently established one in the interior, which in April 1853 had 24 scholars, and he proposes to establish schools at such places within the range of his government as have not been already supplied by the Wesleyan body. He has also employed the natives composing the Gold Coast corps, numbering 333 non-commissioned officers, rank and file, in executing works of public utility, giving them the opportunity of attending the regimental school when they can be spared from other service. In this way many members of the corps have made considerable progress in reading, writing, and a knowledge of the mechanical arts. By their labours 40 miles of a military road has been opened through the Assin country, directly into the interior towards the capital of Ashantee; and a fine carriage-road to Annamaboe was in process of construction in April 1853. On this road a handsome bridge had been constructed, at the entrance of the town, the granite for which had been first quarried by the soldiers from a deposit opened by them in the immediate neighbourhood.

(Robertson, *Notes on Africa;* Hutton, *Voyage to Africa;* Adams, *Remarks on the Countries extending from Cape Palmer to the River Congo;* Monrad, *Gemählde der Küste von Guinea; Parliamentary Papers.*)

GOODS. In actions for the non-delivery of goods, the plaintiff, if successful, may now have the same alternative judgment as in the action of DETINUE (*S.* 2); that is, either to have the goods themselves specifically delivered to him, or the value of them assessed by the jury. This most beneficial change in the law is made, and an appropriate writ of execution, to give effect to it, provided by the Mercantile Law Amendment Act, 1855, 19 & 20 Vict. c. 97.

GOOLE. [YORKSHIRE.]

GOOSE-GRASS. [GALIUM, *S.* I.]

GORGONIA, a genus of Animals belonging to the order *Polypifera*, and the type of the family *Gorgoniadæ*. It has the following generic characters:—Polype-mass rooted, arborescent, consisting of a central axis backed with a polypiferous crust; the axis horny, continuous, and flexible, branched in co-equality with the polype-mass; the crust when recent soft and fleshy, when dried porous and friable; the orifices of the polype-cells more or less protuberant. The species of *Gorgonia* thus defined are not numerous. Dr. Johnston enumerates four species as being found on the British coasts.

G. verrucosa, the Warted Sea-Fan, is somewhat fan-shaped, much and irregularly-branched, the branches cylindrical, flexuous, backed when dry with a white warted crust; segments of the cells unequal, obtuse. This polype is found abundantly on the whole of the south coast of England. It lives in deep water.

G. pinnata, branched and pinnated, the branches compressed; polype-cells in regular rows on each margin, mammillate, unarmed. This species was dredged by Professor E. Forbes and Mr. M'Andrew in the sound of Skye, where they found it attached to stones in 30 fathoms water.

G. placomus, irregularly branched, the branches disposed in a dichotomous order and a flattish form, cylindrical, warty; cells protuberant, conical, surrounded at top by little spines. This is the Warted Sea-Fan of Ellis, and is found on the Cornish coast, but is rare.

G. anceps, the Sea-Willow of Ellis. It is branched, subdichotomous; branches with the flesh fat on each side, with a row of little mouths along both the margins. This is a rare species. It was found originally by its describer Mr. Dale, near Margate. It is of a violet colour when fresh. It is a doubtful native of our seas.

G. flabellum has been found on British coasts, but it has been undoubtedly accidental.

(Johnston, *British Zoophytes.*)

GÖTHITE, a Mineral, to which also the name *Lepidokromite* is given. It is a hydrous peroxide of iron, differing from the brown iron-ore by containing half as much water. The crystals are of a brown colour, and blood-red by transmitted light when sub-transparent. It has a hardness of 5; and its specific gravity 4 to 4·2. It is found with hæmatite at Eiserfeld in Nassau, at Clifton in Cornwall, also in Siberia. *Turgite*, from the Ural, seems to be identical.

GRAINING. [LEUCISCUS.]

GRAMINACEÆ. [GRAMINACEÆ.] The following list of British genera is from Babington's 'Manual of British Botany:'—

Digitaria.	*Avena,*	*Phalaris.*	*Triodia.*
Setaria.	*Holcus.*	*Hierochloe.*	*Melica.*
Anthoxanthum.	*Kœleria.*	*Alopecurus.*	*Catabrosa.*
Phleum.	*Molinia.*	*Gastridium.*	*Glyceria.*
Knappia.	*Poa.*	*Milium.*	*Briza.*
Polypogon.	*Sclerochloa.*	*Apera.*	*Dactylis.*
Agrostis.	*Cynosurus.*	*Arundo.*	*Bromus.*
Stipa.	*Festuca.*	*Phragmites.*	*Brachypodium.*
Psamma.	*Serrafalcus.*	*Spartina.*	*Lolium.*
Cynodon.	*Triticum.*	*Sesleria.*	*Hordeum.*
Leersia.	*Elymus.*	*Aira.*	*Lepturus.*
Lagurus.	*Nardus.*	*Trisetum.*	
Corynephorus.	*Echinochloa.*	*Arrhenatherum.*	

"The family is very numerous. Persoon's 'Synopsis' contains 812 species, 1-26th part of all the plants therein enumerated. In the system of Roemer and Schultes there are 1800, and since this work, were it brought to a conclusion, would probably contain 40,000 in all, it may be assumed that the grasses form a 22nd part. It is more than probable however that in future the grasses will increase in a larger ratio than the other phanerogamic plants, and that perhaps the just proportion will be as 1 to 20 or as 1 to 16. Greater still will be their proportion to vegetation in general when the number of individuals is taken into account, for in this respect the greater number, nay perhaps the whole, of the other classes are inferior. With regard to locality in such a large family, very little can be advanced.

"Among the grasses there are both land and water, but no marine plants. They occur in every soil, in society of others and alone, the last in such a degree as entirely to occupy considerable districts. Sand appears to be less favourable to this class, but even this has species nearly peculiar to itself. The diffusion of this family has almost no other limits than those of the whole vegetable kingdom. Grasses occur under the equator, and *Agrostis algida* was one of the few plants which Phipps met with on Spitzbergen. On the mountains of the south of Europe *Poa disticha* and other grasses ascend almost to the snow line, and on the Andes this is also the case with *P. malulensis* and *P. dactyloides*, *Deyeuxia rigida*, and *Festuca dasyantha*. The greatest differences between tropical and extra-tropical grasses appear to be the following:—

"1. The tropical grasses acquire a much greater height, and occasionally assume the appearance of trees. Some species of *Bambusa* are from 50 to 60 feet high.

"2. The leaves of the tropical grasses are broader, and approach more in form to those of other families of plants. Of this the genus *Paspalus* affords many examples.

"3. Separate sexes are more frequent in the tropical grasses. *Zea*, *Sorghum*, *Andropogon*, *Olyra*, *Anthistiria*, *Ischæmum*, *Ægilops*, and many other genera which only occur in the torrid zone, and are there found in perfection, are monœcious or polygamous. *Holcus* is perhaps the only extra-tropical genus with separate sexes.

"4. The flowers are softer, more downy, and elegant.

"5. The extra-tropical grasses on the contrary far surpass the tropical in respect of the number of individuals.

"That compact grassy turf, which especially in the colder parts of the temperate zones in spring and summer composes the green meadows and pastures, is almost entirely wanting in the torrid zone. The grasses there do not grow crowded together, but like other plants, more dispersed. Even in the southern parts of Europe the assimilation to the warmer regions in this respect is by no means inconsiderable.

"*Arundo donax* by its height reminds us of the Bamboo, *Saccharum Ravennæ*, *S. Teneriffæ*, *Imperata arundinacea*, *Lagurus ovatus*, *Lygeum spartum*, and the species of *Andropogon*, *Ægilops*, &c., by separate sexes exhibit tropical qualities. The grasses are also less gregarious, and meadows seldomer occur in the south than in the north of Europe. The generality are social plants.

"The distribution of cultivated grasses is one of the most interesting of all subjects. It is determined not merely by climate but depends on the civilisation, industry, and traffic of the people, and often on historical events. Within the northern polar circle agriculture is found only in a few places. In Siberia grain reaches at the utmost only to 60°, in the eastern parts scarcely above 55°, and in Kamtchatka there is no agriculture even in the most southern parts (51°). The polar limit of agriculture on the north-west coast of America appears to be somewhat higher, for in the more southern Russian possessions (57° to 52°) barley and rye come to maturity. Only in Europe, namely in Lapland, does the polar limit reach an unusually high latitude. Beyond this dried fish, and here and there potatoes, supply the place of grain.

"The grains which extend farthest to the north in Europe are barley and oats. These, which in the milder climates are not used for bread, afford to the inhabitants of the northern parts of Norway and Sweden, of a part of Siberia and Scotland, their chief vegetable nourishment. Rye is the next which becomes associated with these. This is the prevailing grain in a great part of the northern temperate zone, namely in the south of Sweden and Norway, Denmark, and in all the lands bordering on the Baltic, the north of Germany, and part of Siberia. In the latter another very nutritious grain, buckwheat, is very frequently cultivated. In the zone where rye prevails wheat is generally to be found, barley being here chiefly cultivated for the manufacture of beer, and oats supplying food for the horses. To these there follows a zone in Europe and Western Asia where rye disappears, and wheat almost exclusively furnishes bread. The middle and the south of France, England, part of Scotland, a part of Germany, Hungary, the Crimea, and Caucasus, as also the lands of middle Asia, where agriculture is followed, belong to this zone. Here the vine is also found; wine supplants the use of beer, and barley is consequently less raised. Next comes a district where wheat still abounds, but no longer exclusively furnishes bread, rice and maize becoming frequent. To this zone belong Portugal, Spain, part of France on the Mediterranean, Italy and Greece, further, the countries of the East, Persia, Northern India, Arabia, Egypt, Nubia, Barbary, and the Canary Islands; in these latter countries however the culture of maize or rice towards the south is always more considerable, and in some of them several kinds of *Sorghum* (Donra) and *Poa Abyssinica* come to be added. In both these regions of wheat, rye only occurs at a considerable elevation, oats however more seldom, and at last entirely disappear, barley affording food for horses and mules. In the eastern parts of the temperate zone of the old continent, in China and Japan, our northern kinds of grain are very unfrequent, and rice is found to preponderate. The cause of this difference between the east and the west of the old continent appears to be in the manners and peculiarities of the people. In North America, wheat and rye grow as in Europe, but more sparingly. Maize is more reared in the western than in the old continent, and rice predominates in the southern provinces of the United States. In the torrid zone, maize predominates in America, rice in Asia; and both these grains in nearly equal quantity in Africa.

"The cause of this distribution is, without doubt, historical, for Asia is the native country of rice, and America of maize. In some situations, especially in the neighbourhood of the tropics, wheat is also met with, but always subordinate to these other kinds of grain. Besides rice and maize there are in the torrid zone several kinds of grain as well as other plants which supply the inhabitants with food, either used along with them or entirely occupying their place. Such are, in the new continent, Yams (*Dioscorea alata*), the Manihot (*Jatropha Manihot*), and the Batatas (*Convolvulus Batatas*), the root of which and the fruit of the Pisang (*Banana Musa*) furnish universal articles of food; in the same zone in Africa, Doura (*Sorghum*), Pisang, Manihot, Yams, and *Arachis hypogæa*; in the East Indies and on the Indian Islands, *Eleusine coracana*, *E. stricta*, *Panicum frumentaceum*, several Palms, and *Cycadaceæ* which produce the Sago, Pisang, Yams, Batatas, and the Bread-Fruit (*Artocarpus incisa*). In the islands of the South Sea, grain of every kind disappears, its place being supplied by the bread-fruit tree, the pisang, and *Tacca pinnatifida*. In the tropical parts of Australia there is no agriculture, the inhabitants living on the produce of the sago, of various palms, and some species of *Arum*.

"In the high lands of South America, there is a distribution similar to that of the degrees of latitude. Maize indeed grows to the height of 7200 feet above the level of the sea, but only predominates between 3000 and 6000 feet of elevation. Below 3000 feet it is associated with the pisang and the above mentioned vegetables, while from 6000 to 9260 feet the European grains abound: wheat in the lower regions, rye and barley in the higher, along with which *Chenopodium Quinoa* as a nutritious plant must also be enumerated. Potatoes alone are cultivated from 9260 to 12,300 feet. To the south of the tropic of Capricorn, wherever agriculture is practised, considerable resemblance with the northern temperate zone may be observed. In the southern parts of Brazil, in Buenos Ayres, in Chili, at the Cape of Good Hope, and in the temperate zone of Australia, wheat predominates; barley, however, and rye make their appearance in the southernmost parts of these countries, and in Van Diemen's Land. In New Zealand the culture of wheat is said to have been tried with success, but the inhabitants avail themselves of the *Acrostichum furcatum* as the main article of sustenance. Hence it appears that in respect of the predominating kinds of grain, the earth may be divided into five grand divisions, or kingdoms—the kingdom of rice, of maize, of wheat, of rye, and lastly of barley and oats. The first three are the most extensive; the maize has the greatest range of temperature, but rice may be said to support the greatest number of the human race." Schouw, in Jameson's 'Philosophical Journal.'

The uses of this most important tribe of plants for fodder, food, and clothing, require little illustration. The abundance of wholesome fæcula contained in their seeds renders them peculiarly well adapted for the sustenance of man; and if the Cereal Grasses only, such as Wheat, Barley, Rye, Oats, Maize, Rice, and Guinea corn, are the kinds commonly employed, it is because of the large size of their grain compared with that of other grasses; for none are unwholesome in their natural state, with the exception of *Lolium temulentum*, a common weed in many parts of England, the effects of which are undoubtedly injurious, *Bromus purgans* and *catharticus* are said to be emetic and purgative; *Bromus mollis* is also unwholesome, and *Festuca quadridentata* is said to be poisonous; *Molinia varia* is injurious to cattle; and some other species are supposed to affect the milk of cows which graze upon them.

Among corn-plants not generally known may be mentioned *Eleusine caracana*, called Natchnee on the Coromandel coast, and Nagla Ragee, or Mand, elsewhere in India; *Setaria Germanica*, yielding German millet; and *Panicum frumentaceum*. There are many other species.

The value of grasses as fodder for cattle is hardly less than that of corn for human food. The best fodder-grasses of Europe are usually dwarf species, or at least such as do not rise above four or five feet from the ground. The most esteemed are *Lolium perenne*, *Phleum*, and *Festuca pratensis; Cynosurus cristatus*, and various species of *Poa* and dwarf *Festuca*. The fodder-grasses of Brazil are of far more gigantic stature, and perfectly tender and delicate. In Australia the favourite is *Anthistiria australis*, or Kangaroo Grass; in India *A. ciliata* is also in request; but the most common Indian fodder-grass is Doorba, Doorwa, or Hurryalee (*Cynodon dactylon*). Gama grass (*Tripsacum dactyloides*) has a great reputation as fodder in Mexico; and attention has lately been directed to the Tussac Grass of the Falklands (*Festuca flabellata*), a species forming tufts five or six feet high, and said to be unrivalled for its excellence as food for cattle and horses.

The fragrance of our sweet Vernal Grass is by no means confined to it; other species possess the same quality, which is connected with the presence of aromatic secretions, which have in part recommended grasses to the notice of medical practitioners. Sugar is a general product of grasses. It exists in great quantities in the Sugar-Cane (*Saccharum officinarum*). Maize so abounds in it, that its cultivation has been proposed in lieu of the sugar-cane.

For economical purposes Grasses are often of much importance. The strong stems of the bamboo are employed instead of timber and cordage. The cuticle of some species contains silex, which occurs in large masses after the burning of a heap of corn, or a stack of hay, in the shape of a colourless glass mass.

9. Eubœa and North Sporades.	Chalcis	1,255	64,821
10. Cyclades	Hermopolis (Syra)		134,856
Total		15,235	990,373

GREEN IRON-EARTH. [MINERALOGY, *S.* 1.]

GREENOUGH, HORATIO, American sculptor, was born in Boston, United States, September 6, 1805. From his earliest childhood he showed a great facility in drawing and modelling, and his tastes were carefully cultured; but it was not till he had completed the ordinary collegiate training that he began seriously to contemplate the adoption of sculpture as a profession. Sculpture had then few practitioners in America, and none of any mark; Greenough therefore proceeded to Rome in order to study the art. Rome continued to be his residence for some years, and he derived much professional advantage from the friendly services of Thorwaldsen. His health however gave way, but it was speedily restored by a visit to his native land. There however he did not stay long. On his return to Europe he remained long enough in Paris to execute a clever bust of Lafayette, and then proceeded to Florence, where he fitted up a studio, and where during a residence of several years, his principal works were executed. Of these the most important perhaps are his colossal statue of Washington, which now stands in the grounds of the Capitol at Washington; and, the 'Rescue,' or, as it is sometimes termed, the 'Pioneer's Struggle,' now in the Capitol itself: both of these works were commissioned by Congress. The 'Rescue,' a work of considerable originality and power, is intended to typify the struggle between the native and European races, and consists of a group of a pioneer rescuing his wife and child from an Indian. Besides these he executed several portrait-statues and monumental groups, numerous busts, and some very pleasing and graceful poetic figures and busts. He returned to America in 1851 to superintend the erection of his group of the 'Rescue,' and eventually determined not again to return to Europe. But he had become inured to an Italian climate, and his constitution proved unable to withstand the variations of an American one. After a severe illness he died December 18, 1852.

Greenough will probably not ultimately rank among the foremost of modern sculptors, but he occupies, and will no doubt continue to occupy, a very respectable position; while he will always retain a prominent place in the history of American art as the first of his countrymen who obtained a European reputation as a sculptor. Greenough's attainments were not limited to sculpture: he painted with some skill, and he wrote well both in verse and prose. In private life, while thoroughly unassuming, few men have been more esteemed.

GREENOCKITE. [MINERALOGY, *S.* 1.]

GREENOVITE. [MINERALOGY, *S.* 1.]

GREGAN, JOHN EDGAR, architect, claims notice as one of those who have contributed by their works to the architectural improvement of the city of Manchester, where great progress in art has been manifested during the last twenty years. Gregan was born in 1813 in Scotland; it is believed at Dumfries. He received an excellent general education at Edinburgh, and acquired his first professional knowledge from Mr. Walter Newall, architect, at Dumfries. About the year 1836 or 1837 he went to Manchester, where he was for some time an assistant to Mr. T. W. Atkinson, an architect, who may be said to have commenced the improvement which has been referred to. Mr. Atkinson left Manchester in the year 1840, when Gregan commenced practice on his own account, and wholly by merit and exertion raised himself into a prominent position. His works include several churches and schools in the neighbourhoods of Manchester, Bolton, and Preston, and the chapel of the Diocesan Training School at Chester,—these being in the mediæval styles; the church of St. John at Miles-Platting, and the Presbyterian churches at Green-Heys and Ancoats, schools to the latter, and the Jews' school at Cheetham Hill—all in the style of Northern Italy; several private houses at Manchester and neighbouring towns; warehouses (the class of buildings through which the chief architectural character of Manchester is expressed); the lodges to the public parks of the same city, and other buildings. His best work however, and it is of great merit, is the bank of Sir Benjamin Heywood, Bart., and Co., of which an illustrated account may be found in the 'Builder' (vol. vii.), where also is a view, or an elevation, of one of his warehouses (vol viii.). The bank is designed in an adaptation of the Venetian Italian style,—with careful attention to beauty of detail. The new Mechanics' Institution at Manchester, from his designs, has been mainly carried out under Mr. Corson's superintendence, since the death of the original designer. Gregan died suddenly, after a short illness brought on by over-exertion, on the 29th of April 1855. He was a Fellow of the Institute of British Architects, Honorary Secretary to the Manchester Royal Institution, and took great interest in the local School of Design, the establishment of the Free Library, and other institutions. He possessed a cultivated taste in general art, was ready with pencil and brush, and was a skilful performer on one or two musical instruments.

GREGORY XVI., Mauro Capellari, was born September 18, 1765, at Belluno, in the Lombardo-Venetian kingdom. He entered at an early age into the Camaldoleusian order of monks, and having distinguished himself by his learning was elected their vicar-general. On the 21st of March 1825, Leo XII. created him a cardinal, and soon afterwards appointed him prefect of the college De Propaganda Fide. Under Pius

VIII. he conducted the negociation on mixed oaths with the kingdom of Prussia, and was the author of the celebrated papal brief of 1830. On the 2nd of February 1831, he was elected pope, and crowned on the 6th of February. In honour of the founder of the college De Propaganda Fide, Gregory XV., he assumed the name of Gregory XVI. He was a man of respectable character in private life, but his church administration was bigoted and exclusive, his temporal government harsh and despotic. In the early part of his reign he called in the Austrians to suppress the disturbances which had broken out in the Legations, and his pontificate of fifteen years was nothing less than a long oppression of his subjects. He died June 1, 1846, and was succeeded by the present pope, Pius IX.

GRETNA-GREEN. [DUMFRIESSHIRE.]

GRIFFON-VULTURE. [VULTURIDÆ.]

GRISTLE. [CARTILAGE.]

GROTEFEND, GEORG FRIEDRICH, a distinguished philologist and antiquarian, was born at Münden in Hanover on June 9, 1775. He was educated in his native town and at Ilfeld till 1795, when he proceeded to Göttingen, where he became intimate with Heyne, Tychsen, and Heeren. On the recommendation of Heyne he was appointed in 1797 assistant teacher in the Göttingen town school; and after he had made himself known by his work 'De Pasigraphia sive Scriptura Universali,' published in 1799, he was chosen prorector of the Gymnasium of Frankfort-on-the-Main in 1803, and shortly afterwards con-rector. Besides many learned contributions to the 'Allgemeinen Cyclopädie' of Ersch and Gruber, and to other periodical works, he published in 1815, 'Anfangsgründe der deutschen Poesie' (Elements of German Poetry), and founded in 1817 a society for the investigation of the German language. In 1821 he was called to be director of the Lyceum at Hanover, which thenceforth became his residence. In 1823–24 he published an entirely remodelled edition of Wenck's Latin Grammar in 2 vols. 4to, and a smaller one for the use of schools in 1826. His most noticeable works however are those relating to the deciphering of the eastern cuneiform inscriptions, on which he expended much and successfully directed labour; and those devoted to an investigation of the old Italian languages and geography. Among these works are his 'Neuen Beiträge zur Erläuterung der Persepolitanische Keilschrift' (New Contributions towards the Explanations of the Persepolitan Cuneiform Inscriptions), 1837; and 'Neue Beiträge zur Erläuterung der Babylonische Keilschrift,' 1840. For early attempts these works possessed considerable merit, but their value has been lowered by the indefatigable labours of more recent investigators. On the Italian antiquities he published, in eight parts, between 1835 and 1838, 'Rudimenta Linguæ Umbricæ ex inscriptionibus antiquisenodata;' in 1839 'Rudimenta Linguæ Oscæ;' 'Die Münzen der griechischen, parthischen und indoskythischen Könige von Bactrien und den Ländern am Indus,' (The Coins of the Greek, Parthian, and Indo-Scythian kings of Bactria and of the Countries on the Indus; and in 1840-42, in five parts, his investigation 'Zur Geographie und Geschichte von Altitalien,' a work remarkable for the copiousness of its materials and the bold felicity of many of its theories. The part he took in the controversy respecting the genuineness of Sanchuniathon's 'History of the Phœnicians,' has been already mentioned. [SANCHUNIATHON.] Grotefend has also published a history of the Lyceum at Hanover. He died December 15, 1853.

GROUCHY, EMMANUEL, COMTE DE, Marshal and Peer of France, was born in Paris, October 23rd 1766. He entered the artillery branch of the army in 1780. He was already a captain of horse in 1784, and in the course of the ensuing year, became one of the gardes-du-corps of Louis XVI. However, no sooner did the first dawn of the revolution appear than he quitted the gardes-du-corps and ardently embraced revolutionary principles. In 1792, he was made colonel of the 2nd regiment of dragoons, a few months later he became major-general, and was appointed to head the cavalry attached to the army of the Alps. In that campaign Savoy was conquered by Montesquien and annexed to France, General Grouchy having mainly contributed to its reduction.

Though scarcely in his 27th year, he began already to be esteemed the first cavalry officer in the French armies. In 1793 he was ordered to join the army of the Côtes de Brest in La Vendée, relieved Nantes, besieged by Charette, and by his skilful manœuvres at the head of the vanguard in the left wing he arrested the progress of the insurrection, preventing at one time, and rendering abortive at another, the repeated attempts of the royalists to open a communication with the English. At the battle of Sarrinieres, in a critical moment, seeing the republican infantry waver, Grouchy leapt from his horse, placed himself at the head of a few hundred grenadiers, charged the Vendeans, and in spite of a wound he received, wrested the victory from them. In December 1793, on account of his noblesse, he was removed from his command; but his soldiers having heard of his intended departure, flocked to his quarters to prevent it, and Grouchy had to rebuke their attachment, and recall them to obedience. Shortly afterwards the army of the insurgents having crossed the Loire, and approached the district in which he was residing, Grouchy mingled in the ranks of the national guards as a private soldier, and assisted in repulsing the enemy. His retirement lasted but eight months. In September 1794, Carnot gladly restored him to his dragoons; and on the 11th of June 1795, confirmed him in his post of general of division, to which the soldiers themselves had raised him. Carnot, shortly after, offered him the command of the army of the Côtes de Brest. The republic had, at this juncture, three armies operating against the royalists, and Grouchy feeling that a divided command would injure the service, declined the offer, and recommended that General Hoche should be placed at the head of the three armies. This was done. Grouchy took service under Hoche, and defeated Charette in his intrenchment at Saint-Cyr; and soon after the Vendean chiefs, Charette and Stafflet, were taken prisoners. At the beginning of 1797 Grouchy was appointed second in command of the army under Hoche, intended to invade Ireland, but the French fleet having been dispersed by a tempest, was compelled to regain the coasts of France. Early in 1798 he was ordered to Italy to join Joubert's army, shortly after commanded by Moreau, under whom, and at the head of a few troops, he took part in that celebrated campaign of Piedmont, where during six weeks 25,000 French soldiers held their ground and manœuvred in presence of the Austro-Russian army of 80,000 men. Grouchy afterwards distinguished himself at the battles of Valence and San Juliano; and on the 14th of June 1799, he defeated General Bellegarde on the banks of the Bormida. At the battle of Novi, in which Joubert was killed, Grouchy shared with Pérignon the command of the left wing, took 1200 Austrian prisoners, and charged the enemy eleven times at the head of his dragoons; but being placed between two fires, he fell from his horse, with fourteen wounds, and was taken by the Austrians. The Grand-Duke Constantine sent his own surgeon to attend him, ordered his servants to wait upon him, and offered him a liberal sum of money. After his recovery and exchange, Moreau anxious to mark his sense of Grouchy's services, put him at the head of his grand division, consisting of 18,000 troops. At the battle of Hohenlinden, in 1800, he took fourteen pieces of artillery, and greatly assisted in obtaining the victory.

During the trial of Moreau, in 1804, Grouchy stood by the side of his leader, and gave him continual proofs of esteem and friendship. At the battle of Zedenick, Grouchy, at the head of his dragoons, routed the Prussian horse, pursued the fugitives for nine miles, and utterly destroyed the famous regiment of the Queen of Prussia. After the combat of Prenzlan, October 27, 1805, he pursued the enemy into the town, and compelled several battalions to ground their arms. The dismay produced by this exploit, obliged the prince of Hohenlohe to sign a capitulation, by which 16,000 men, 64 pieces of artillery, and great stores of ammunition were given up to the French. General Grouchy shortly after, meeting the Prussians near Lubeck, drove them through the town, and well nigh captured Blucher. In the heat of the battle of Friedland, June 14, 1807, he was again grievously wounded, on which occasion his conduct was observed by the emperor, who gave him the grand cordon of the legion of honour. Throughout the Russian campaign, in 1812, his courage and intrepidity were conspicuous, and when Napoleon formed his sacred battalion, consisting of none but officers, whose duty was to watch over him, the command of this chosen band was given to General Grouchy. This was, perhaps, the greatest act of real confidence ever shown by Napoleon to a general officer; yet, in 1813, the Emperor refused Grouchy's application for the command of a corps, and for a time he abandoned the service. But the following year, when France was invaded, he offered his services, and Napoleon gave him the command of his cavalry. His name now appeared in almost every battle, at Brienne, January

26, 1814, at La Rothière, February 1, and at Vauchamps, February 14. His bravery and skill, at this last battle, rang throughout all France; the anger of Napoleon, which had lasted ten years, gave way before it, and Grouchy was created a Marshal.

After the battle of Ligny, June 16, 1815, Marshal Grouchy was commissioned to pursue the retreating army of Blucher with a force of 34,000 cavalry, and 100 pieces of cannon. In consequence of these orders, he found himself posted at Wavre, and was engaged in action against the Prussian general Thielemann, whilst Napoleon was fighting at Waterloo, on the 18th. The marshal heard the report of artillery, and was strongly urged by his lieutenant-generals to march towards the point whence it proceeded; but he declared himself bound to obey the orders he had received from the emperor on the 17th. Fatal as the battle of Waterloo proved to the French arms, nothing was publicly said at that period against Grouchy's conduct, nor for three years after. After the second abdication of Napoleon, the provisional government appointed the marshal to the united command of all the corps of the grand army; but the entire muster only amounted to 45,000 men.

Banished from France, after the return of Louis XVIII., he withdrew to the United States, where he was living in 1818, when the narrative of the battle of Waterloo, dictated to General Gourgaud, at St. Helena, was published. In this account a charge of treachery was made for the first time against him. Grouchy returned to France, in 1819. He was reinstated in all his titles and honours in 1831, by Louis Philippe, and died at Saint-Etienne, May 29, 1847, having been sixty-seven years in the French armies.

GROUND-IVY. [NEPETA, *S.* 1.]

GUALEGUAY. [ENTRE RIOS, *S.* 2.]

GUANINE. [CHEMISTRY, *S.* 2.]

GUATEMALA, Republic of, Central America, occupies the table-land of Guatemala, with the hilly country between it and the Gulf of Honduras, and a portion of the table-land of Yucatan. It lies between 13° 40′ and 18° 10′ N. lat., 81° 15′ and 93° 20′ W. long. On the S.E. it is bounded by the Republic of Salvador; E. by Honduras; N.E. by the Gulf of Honduras and the British settlement of Belize, or British Honduras; N. by the Mexican state of Yucatan; W. by Chiapa; and S. by the Pacific Ocean. The area is about 50,000 square miles; the population about 500,000.

Coast-line Surface, &c.—The general bearing of the Pacific coast from the Salvador boundary of the State to the Barra de Guacalate is W. by N., and thence to the Rio Sintalapa, the boundary between Guatemala and Chiapa, it is N.W. The shore is for the most part low, the descent from the table-land being steep, and a strip of lowland, from 20 to 30 miles across, being left between its base and the sea; but in many places the shore is high and rocky, and several rocky barriers lie off it. The only port at present frequented on the coast is that of Ystapa, at the mouth of the Rio Michetoyat; but though it is a port of entry, the harbour is little better than a roadstead, affording no protection for shipping. Ocos, further north, formed by the Barra de Ocos, is also an available port, but, owing to the absence of inhabitants, is not resorted to. The low tracts along the coast are very thinly peopled. On the northern coast Santo Tomas, in Honduras Bay, is a good and well-sheltered port; and somewhat inland, in the lake known as Golfo Dolce, is the port of Yzabal, in some respects the principal port of Central America; most of the European goods designed for that market being brought to it by vessels, and thence transported to the interior by mules: owing to a bar at the mouth of the Rio Dolce, Yzabal is inaccessible to vessels drawing over 7 feet of water.

The table-land of Guatemala occupies all the countries between the isthmus of Chiquimula and that of Tehuantepec in Mexico; the island in the interior of the peninsula of Yucatan, usually called the table-land of Yucatan, forms its north-eastern projection. Near its southern borders, about the town of Guatemala, it is nearly 5000 feet above the sea; and this may be considered as the mean height of that portion which is south of the Rio Motagua. But north of this river the country rises higher. The most elevated part of it appears to lie between the towns of Totonicapán and Gueguetenango (15° 30′ N. lat.). From this point it begins to lower gradually, and its north-western edges, which belong to the Mexican state of Chiapa, are indented by deep and sometimes wide valleys. No continuous range of any considerable elevation traverses this plain, the surface of which is slightly undulating, like the central parts of England; but here and there it is traversed by a range of hills, rising a few hundred feet above the plain. The descent from this plain to the low shores of the Pacific is extremely steep, and consequently when seen from that side it has the appearance of a mountain range, an illusion which is confirmed by a few lofty volcanoes standing near the edge of this descent. The most remarkable are the active volcano of Atitlan, near Gueguetenango, and the two volcanoes situated S. and N.W. of the town of New Guatemala, of which the Volcano de Agua (or Water Volcano), according to Colonel Galindo, is 12,620 feet, but according to other authorities 13,578 feet high; and the Volcano de Fuego (the Fire Volcano), appears to be somewhat higher, but which has not been ascended. All the volcanoes, whether active or extinct, are situated near the Pacific, and are in line with those of Salvador and Nicaragua. The eastern border of the table-land, by which it descends to the Gulf of Honduras, is cut by deep valleys, between which the high land takes the shape of ridges, which extend to a great distance, and in some places, as between the Rio Motagua and the Golfo Dolce, advances to the very shores of the sea. The country between the table-land and the Gulf of Honduras, may therefore be considered as a succession of valleys and ridges, except the part to the west and north-west of the Golfo Dolce, which is a low plain.

The state is well watered by a large number of rivers, but very few of them are navigable: the principal are the Dolce, Polochic, and Motagua. The Rio Dolce, though short, is the most important river of Central America, being the channel by which the Golfo Dolce discharges its waters into the Gulf of Honduras, 15° 35′ N. lat. The Golfo Dolce is a fresh-water lake, about 50 miles in circuit, having on its southern bank the small port-town of Yzabal. The Rio Dolce, issuing from the eastern portion of the lake, turns to the north, and expands into a small lake, called the Golfetta (the Small Gulf), about 10 miles in width. This river is about 20 miles long, and of considerable depth, except on its bar, where there are only 6 or 7 feet water.

The Rio Polochic rises near the village of Taçtiç, on the table-land of Guatemala, but soon descending into a wide and deep valley, it becomes navigable at the Embarcadero de Teleman, a considerable distance above the Golfo Dolce, into which it falls. It is a rapid river, and deep enough for vessels drawing several feet of water, but on the bar at its mouth there are only 3 or 4 feet of water.

The Motagua rises near the town of Solola on the table-land of Guatemala, through which it runs in an eastern direction till it descends from it some distance west of Zacapa. At Gualán, some miles further down, the river becomes navigable, but, owing to its numerous rapids and shoals, it can only be navigated by boats not drawing more than a foot and a half water. Towards its mouth the river turns to the north-east, and falls into the Gulf of Honduras about 15 miles west of Omoa. By means of this river a considerable quantity of European goods, especially the heavier kind, is sent into the interior of Guatemala; they are transported from Gualán to the places of consumption on mules.

The Lacantun, which rises in this state, and separates it for a considerable distance from Yucatan, becomes an important river after its entry into the state of Yucatan. The rivers which enter the Pacific are numerous, but have all a short course. One of the most important is the Michetoyat, which at its mouth forms the harbour of Ystapa, the port of the city of Guatemala.

There are four rather considerable lakes in the state. Of these, that called Golfo Dolce, noticed above, is the most important, as by means of it most of the foreign trade of the republic is carried on. The lake of Peten, situated in the most northern district of Vera Pas, on the table-land of Yucatan, is of an oval form and about 70 miles in circuit. It contains several islands, on the largest of which is a small fortress and a collection of houses forming the village of Flores. The lake of Atitlan is 80 miles north-west of the city of Guatemala, and near the western edge of the table-land. It is about 18 miles long and 9 miles broad, environed by lofty heights, including the volcano of Atitlan, and remarkable for its extraordinary depth, and for having no outlet, though several small rivers fall into it. The lake of Amatitan, 18 miles south-east from the city of Guatemala, is 9 miles long and 3 miles wide, and of great depth. It is much resorted to as a bathing-place by the inhabitants of the city during the season from February to April; and near the lake are several hot and mineral springs. The Rio Michetoyat flows from this lake.

Climate, Soil, Productions.—The climate of the table-land is that of a perennial spring; the thermometer scarcely varying throughout the year. The average heat in the middle of the year is from 68° to 70° Fahr.; but during the north winds, which prevail in the dry season, from October to May, it sometimes though rarely descends 20 degrees within a few hours. The rainy season usually sets in in May and lasts till October; but rain seldom falls except between 3 o'clock in the afternoon and 6 o'clock in the morning. In June thunder is frequent; in August and September the Pacific coast is subject to violent storms from the south-west. The table-land is considered to be very healthy, but goitre is prevalent, especially among the mixed races, and is often accompanied by idiotcy. Earthquakes are painfully frequent.

The soil is generally very fertile. The table-land is nearly without trees, and even bushes, except on the declivities of the hilly ranges, which traverse it in every direction. On the lower lands by the Pacific trees of very large size form extensive forests, and are a source of great natural wealth; but, owing to the thinness of the population and the want of roads, are at present of little profit. Among the trees are mahogany, cedar, Brazil, Santa Maria, guaiacum, pimento, &c. Various medicinal plants are also abundant. On the low tract by the Gulf of Honduras there is a luxuriant and vigorous vegetation.

On the table-land wheat and maize of excellent quality are largely grown. Most European fruits and vegetables produce well; and tropical fruits and vegetables abound. In the lower tracts excellent rice is raised. Tobacco, cotton, sugar, cacao, vanilla, and indigo are raised for exportation. Most of the cochineal, which forms so important an article in the commerce of Central America, is obtained in Guatemala. The agricultural resources of Guatemala remain however but slightly developed. The country is thinly peopled, and owing to its unsettled state, and the inert character of the major part of the people, little has been done towards improving the rude systems of cultivation or introducing superior implements; and a considerable portion of the country lies almost waste. Of this uncultivated land a large part is used as grazing ground, and a rather large number of cattle is kept. Sheep are reared in considerable numbers, the wool, which is somewhat coarse, being used for the native manufactures. The horses are small, but hardy and handsome. Mules are numerous, being largely used for carrying goods. Hogs abound, and are of good quality. A good deal of poultry is raised.

Several metals are believed to exist in sufficient quantities to be profitably worked, under favourable circumstances. Gold, silver, lead, copper and iron are said to have been found. Lead mines are worked by the Indians in Totonicapán. Jasper and marble are obtained. Brimstone of good quality is procured in the vicinity of some of the volcanoes. Salt is made along the Pacific coast.

The manufactures are chiefly confined to articles of domestic consumption. The cotton manufacture, once of considerable importance, has greatly declined. It is now chiefly carried on in the corregimientos of Guatemala and Sacatepeques. The manufacture of woollen cloth has retained more of its former consequence: the making of the ordinary coarse cloths, and of a kind of black cloak much worn in the country employs a large number of looms. Hats, jewellery, furniture, earthenware, and the ordinary articles of domestic use are largely made in several of the towns.

The exports are confined to few articles. Of these the most important is that of cochineal, which was introduced into Guatemala as late as 1811, and did not for several years produce more than sufficient for home consumption. In 1811 about 15,000 lbs. were exported: in 1849 the quantity had increased to 1,469,100 lbs. The other articles of export are chiefly mahogany and other woods employed in cabinet work; vanilla, sarsaparilla, and other medicinal roots and plants; indigo; and hides. Sugar, coffee, and cotton are also exported in small quantities. The imports are British cotton and dry goods, linen and silk fabrics; cutlery and hardware; porcelain and fine earthenware; fancy goods; wines, &c. In 1851 the exports amounted to 994,488 dollars; the imports to 1,354,430 dollars.

Divisions, towns, &c.—Guatemala is divided into seven departments (corregimientos), which, with their chief towns, are as follows:—

1. Guatemala occupies the south-eastern portion of the territory, has an area of nearly 5000 square miles, and a population of about 90,000. The surface of the country is considerably diversified, the climate equable and genial, and the soil remarkably fertile. This and the following department form the great cochineal district. The nopal (*Cactus opuntia*), the plant on which the cochineal insect is produced, grows freely and luxuriantly, especially around the town of Amatitan, where are the chief plantations: the insects come to maturity in April, and the collecting of them continues for about a month. The other productions of this department are maize and wheat, sugar and coffee, most of which however is required for home consumption. The principal towns are Guatemala, the capital of the state, Amatitan, Escuintla (population 3000), and Jalpatagua. *Amatitan*, at the foot of the lake of the same name, which formerly depended on the persons who annually resorted to it for bathing, is now, in consequence of the great increase in the rearing of cochineal, a rich and flourishing place, having a population including the suburbs of upwards of 9000.

2. Sacatepeques lies to the west of the corregimiento of Guatemala; it contains above 1900 square miles, and a population of about 56,000, who are chiefly settled in its southern part. The country around the city of Old Guatemala is one of the most picturesque in the world, and the soil is extremely fertile. Maize and other grains, and vegetables and fruit in great variety, are largely grown. Cotton, coffee, tobacco, and sugar flourish here, though they are not yet grown to any great extent. Poultry and hogs are raised in considerable quantities for the supply of the capital. The olive and vine grow well here, but are not cultivated to any extent. The chief town is Old Guatemala, but there are several other populous places around it notwithstanding the proximity of the two volcanoes Agua and Fuego, and the frequency and severity of the earthquakes with which it is visited. The larger of these towns are Chimaltenango, population 4000, and Patsun.

3. Sololá, lies to the west of the former corregimientos, and contains about 4000 square miles. The surface is very much broken, and the soil, especially in the valleys, very fertile. The climate is colder than in some other parts of the state. Wheat, maize, and fruits are the chief products. Sheep are bred in large numbers. Jerga and other coarse woollens are manufactured. At least three-fourths of the inhabitants are Indians, who are mostly engaged in agriculture or weaving: twelve or fourteen of their villages are placed around the shores of the lake Atitlan, which is nearly in the centre of Sololá. From the midst of this lake rises the volcano of San Pedro. The chief towns of this department are Sololá, population 5000, Atitlan, and Masatenango, but neither of them is of any importance.

4. Quesaltenango lies to the north-west of Sololá; it contains above 4500 square miles, and 70,310 inhabitants; and is one of the most important of the departments in an industrial point of view. It has a tolerably level surface, a temperate climate, and a very fertile soil. The products are maize and wheat, sugar, cacao, and various fruits and vegetables, which are largely exported to the city of Guatemala, to Salvador, and Chiapa. Large herds of cattle and mules, and great flocks of sheep are maintained. The capital *Quesaltenango*, population 20,000, a large portion of whom are Indians, is the next town in importance to Guatemala. It stands on the little river Samala, and is a large, well, and regularly-built place. It contains a spacious church, and six churches of smaller size, a large town-hall, a plaza, or great square, with a fountain in the centre, has a daily market, and is a place of considerable trade. In its vicinity is a hot spring, which ejects the water to a height of above 20 feet. The other towns are San Marcos, Tapachula, and Tejutla.

5. Totonicapán, is an inland department, lying north-east of Quesaltenango; it contains 5600 square miles, but is very thinly peopled; the larger part of the inhabitants are Indians. The surface is much broken; the climate is temperate but considerably varied; the soil in the valleys, which are well watered, is fertile. Maize and wheat, sugar, fruit, and vegetables are the chief products of the soil. Sheep and cattle are largely bred. Lead-mines are wrought by the Indians in the neighbourhood of Chiantla. Salt is made from springs near Yxtatan. The only town of any importance is Totonicapán, which is said to contain 12,000 inhabitants, nearly all Indians, who make considerable quantities of

woollen cloth, earthenware, and wooden utensils. The other towns are Momostenango, Gueguetenango, and Jacaltenango.

6. Chiquimula, occupies the north-eastern extremity of the state, bordering on the republic of Honduras: its area is nearly 5000 square miles; its population about 80,000. The surface is considerably diversified, and in parts very fertile; the valleys and low tracts by the Golfo Dolce and the Bay of Honduras are hot, moist, and unhealthy. Tobacco, cotton, rice, and sugar are raised largely, with maize, frixoles, &c. The sugar is grown chiefly for distillation or for making chicha, a favourite intoxicating drink of the Indians. Horses, mules, and cattle are reared in large numbers. The chief towns are Chiquimula, population 4500; Acasaguastlan, 3600; Jalapa, 3500; Jilokepeque, 3200; Mita, 3300; Quesaltepeque, 4000; Zacapa, 3000; and the little port town of Yzabal on the Golfo Dolce. Near this last place are the remarkable ancient remains of Quirigua, consisting of seven lofty columns, and various sculptured slabs.

7. Vera Paz, the largest of the seven corregimientos, comprehends the projecting tract of country which forms the most northern part of the republic; the area is about 11,000 square miles: the population is estimated at 65,000, of whom nine-tenths are Indians. The country is very varied in surface and character of soil: but comparatively very little of it is cultivated. Mahogany, rosewood, and other valuable timber-trees abound; the coffee, cacao, indigo, and nopal plants are said to be indigenous in the forests. In the northern part of Vera Paz is the lake of Peten. The most populous town is Coban, situated in a remarkably fertile valley of the same name, with a population of above 10,000, nearly all Indians, who are industrious and wealthy, possessing fine plantations of sugar-cane, bananas, pimentos and various kinds of fruit; the other towns are Salamá, population, 4500, Cajabon, 4000; and Rabinal, 6000; but none of them call for specific notice.

Government, &c.—According to the constitution of the 19th of October, 1851, the executive is confided to a president elected by a general assembly, composed of the legislative chamber, the archbishop of Guatemala, the members of the supreme court of justice, and the members of the council of state having a deliberative voice. The president is elected for four years, but is eligible to be re-elected. The legislative assembly consists of 59 members. The council of state is composed of the ministers, eight councillors chosen by the legislative assembly, and of others appointed by the president. The revenue and expenditure average somewhat over 400,000 dollars. The debt amounts to 1,200,000 dollars. The army consists of 1000 men, with a patriotic corps and a militia of 5000 men.

The population consists of aboriginal tribes, some of whom live in a state of almost perfect independence, but the main body have obtained all the rights of free citizens of the republic, and form the bulk of the population; of the descendants of Europeans, and of the mixed offspring of Europeans and Indians, who are known as 'ladinos.' The Roman Catholic is the established religion, and there are few if any open dissenters. The church is presided over by the Archbishop of Guatemala.

During the Spanish occupancy Central America was termed the kingdom of Guatemala, the city of Guatemala being the capital and seat of Government. During the struggle for independence it remained quiet and subject to Spain; but on the declaration of independence in 1821 it was for awhile united to the Mexican empire of Iturbe. On the publication of the new constitution, July 2nd, 1823, by which the federal union of Central America was formed, Guatemala became one of the united states. This union was however after a short time dissolved, and Guatemala then became an independent republic, and has so continued to the present time.

GURNEY, JOSEPH JOHN, was born August 2, 1788, at Earlham Hall, near Norwich, the country residence of his father, John Gurney, who was a member of the Society of Friends, and one of the partners of the Norwich bank. He was the tenth child of eleven children left by Mrs. Gurney at her death, Elizabeth Gurney being the third. [FRY, MRS. ELIZABETH, *S.* 2.] Joseph Gurney completed his education at Oxford under a private tutor, without becoming a member of the university, of which however he enjoyed many of the advantages. He acquired the Hebrew and Syriac languages, as well as Greek and Latin, mathematics, and a large amount of general knowledge. After the death of his brother John in 1814, he assumed his brother's Christian name in addition to his own. Joseph John Gurney in 1818 became a recognised Minister of the Society of Friends, and his preaching is described as having been very impressive. He accompanied Mrs. Fry in her journey to Scotland in 1818, and to Ireland in 1827, to inquire into the state of the prisons, and of the results of this last journey he wrote a Report addressed to the Marquis Wellesley, lord-lieutenant of Ireland, which was afterwards published. In 1837 he visited the United States of America and the Canadas, and was absent about three years. The journal of his travels was printed, but only for private circulation. In 1841 he made a journey to Holland, Belgium, and Germany, accompanied by Mrs. Fry, and in 1842-43-44, another journey to France and Switzerland, in the earlier part of which he was again accompanied by Mrs. Fry. The object of these journeys was to introduce improvements in prison-discipline, and also to induce the French government to abolish slavery in the French colonies, for which purposes he had an interview with Louis-Philippe, and much communication with M. Guizot.

Joseph John Gurney was the author of several works, religious and moral. His 'Observations on the Distinguishing Views and Practices of the Society of Friends' has been several times reprinted, as have also his 'Essays on the Evidences, Doctrines, and Practical Operation of Christianity,' a work intended for Christians generally. All his works are ably and judiciously written. He took an active part in many benevolent societies, such as those for the abolition of slavery, for the repeal of the laws inflicting capital punishments, in peace-societies, temperance-societies, the British and Foreign Bible society, and others. His donations to charitable institutions and for the relief of public distress were numerous and princely. His private gifts were only bounded by his judgment as to what was appropriate in each particular case. He died on the 4th of January 1847, at Earlham Hall.

(*Memoirs of Joseph John Gurney, with Selections from his Journal and Correspondence, edited by Joseph Bevan Braithwaite*, 2 vols. 8vo.)

GURWOOD, JOHN, an officer whose name will always be honourably associated with that of the Duke of Wellington, must have been born in 1791, as it is incidentally mentioned that he ceased to be a ward of chancery and came of age in 1812. He entered the army as an ensign in the 52nd regiment in 1808, and served during the war in the Peninsula, where he was distinguished for his accurate knowledge of the French and Spanish languages. He first emerged into notice as Lieutenant Gurwood, by volunteering to lead the forlorn hope at the storming of Ciudad Rodrigo, on the 19th of January 1812. Circumstances afterwards led him to print a minute account of all the transactions in which he was personally concerned on that night in a pamphlet, which is one of the most curious and instructive contributions in existence to the history of the Peninsular War, containing a number of details which are eminently characteristic and suggestive. When he knew that his offer had been accepted, "I kept on eating," he tells us, "principally bread, but I carefully controlled my thirst, knowing how insatiable it becomes under nervous excitement. On the concerted signal for the assault—three guns from the batteries—my heart beat double quick, and I applied my mouth to the calabash of Jack Jones, from which I swallowed a gulp of 'aguardiente.' On arriving at the top of the breach, I saw a musket levelled not far from my head, and a Frenchman in the act of pulling the trigger. I bobbed my head in time, but was wounded and stunned by the fire. I found myself at the bottom of the breach; I cannot tell how long I was there, but on putting my hand to the back of my head, where I felt that I had been wounded, I found that the skull was not fractured." Recovering from his trance, "we again set up a shout, scrambled up the breach, and gained the rampart of the bastion." Here his attention was attracted by seeing one of his men, Pat Lowe, in the act of bayonetting a French officer who resisted being plundered, and he saved the Frenchman by knocking down the Irishman. His prisoner guided him to a tower, where he found the French governor of the place, and some other officers, who had shut themselves up from the now victorious English soldiers. He summoned them to surrender, and the door was unbarred; but Pat Lowe, who had rejoined him, called out, "Dear Mr. Gurwood, they will murder you!" and as he entered he was seized round the neck, and fully expected a sword in his body; but his alarm ceased on finding himself kissed by the person who had seized him, who added that he was the governor, General Barrié, and that he yielded himself his prisoner. Gurwood conducted him to Lord Wellington, whom he found on the ramparts, who said to him, "Did you take him?" and, on his replying in the affirmative, handed to him the governor's sword, which had just been surrendered, with the observation, "Take it, you are the proper person to wear it." He wore it ever afterwards, and by special privilege when every other officer in the English army wore a regulation sword. From this time he became a noted officer; but though he served with distinction during the rest of the Peninsular war, and at Waterloo, where he received a severe wound, the rank of colonel was the highest that he attained, and he did not become full colonel till 1841. In 1830 he was placed on the unattached list, and shortly afterwards became private secretary to the Duke of Wellington. This appointment led to a very remarkable publication. In 1834 he commenced the issue of 'The Despatches of Field-Marshal the Duke of Wellington, K.G., during his various campaigns in India, Denmark, Portugal, Spain, the Low Countries, and France, from 1799 to 1818, compiled from official and authentic documents, by Lieutenant-Colonel Gurwood.' The work extended, with a volume of index, to thirteen volumes; the publication of it occupied the colonel for a series of years, and its popularity was unexpected and unexampled. No collection of official documents of any length has ever found its way into so many libraries and so many hands. A second edition was called for, and an abridgement into one volume was issued to satisfy the curiosity of those who could not purchase the complete edition. The reputation of the Duke of Wellington appears to have been materially raised by the publication, and most of his popularity in later life was based on the 'Despatches.'

Colonel Gurwood urged him to give his consent to other publications bearing on his military career, but did not always succeed. The Colonel was in the habit of showing his friends a paper by the Duke on the battle of Waterloo, in answer to the observations on the subject by the Prussian general Clausewitz, and was much surprised at finding that one of those to whom he showed it was guilty of a breach of confidence. The whole appeared in print in 'Fraser's Magazine,' as a portion of a review of Captain Siborne's 'History of the Battle.' The reader who is curious to see what Wellington had to say on Waterloo may be assured that he will find it word for word in that magazine for July 1844, without the slightest intimation from whose pen it proceeds—a fact which would indeed never be conjectured by any one perusing the article without previous information as to its authorship. The Duke also supplied to the late Earl of Ellesmere some observations on the battle which are interwoven with his article on Alison's 'History of the War' in the 'Quarterly Review.' In return for the Colonel's services the Duke appointed him Deputy-Governor of the Tower of London. He again visited Spain in company with Lord Eliot, the present Earl of St. Germans, to endeavour to mitigate the cruelties of the civil war between the Carlists and Christinos, in which neither party gave quarter; and their mission was partially successful.

From the time of the publication of some portions of Napier's 'History of the Peninsular War' in 1840, Colonel Gurwood was involved in a disagreeable controversy respecting the circumstances of the capture of the governor of Ciudad Rodrigo. An officer of the rank of Major, who had commanded one of the storming parties, made a statement in October 1838 to the effect that he (the major) had accepted the surrender of the governor; that a sword, afterwards found to be that of an aide-de-camp, had been presented to him in token of surrender; and that while he was engaged with two officers who laid hold of him for protection, one on each arm, Lieutenant Gurwood came up and obtained the sword of the governor; on seeing him present which on the ramparts, the major, according to his own account, "turned on his heel and left the spot." The major died in 1839, and this statement was made public in the following year in a second edition of that portion of Napier's history relating to the events of Ciudad Rodrigo, the first having stated that "Mr. Gurwood, who though wounded had been amongst the foremost at the lesser breach, received the governor's sword." Colonel Gurwood had been in garrison with the major in 1834 at Portsmouth, and always wore the sword when in uniform; but this circumstance had not produced any remark from that officer. A long and vexatious discussion ensued on the point, which was brought to a close by a very singular incident. Gurwood did not know the name of the French officer whom he had rescued from Pat Lowe, and whose evidence would of course be most important to show the justice of his claims, as the Frenchman had guided the Englishman to the tower where the governor was found, and witnessed what then took place. In turning over the Duke's papers in 1844, the Colonel found a letter addressed to Lord Wellington in 1812 by a captive French officer named Bonfilh, who might, he inferred, be the person he was in search of. He made inquiries in Paris to ascertain if M. Bonfilh was still alive, found that he was, wrote off to him, and received a letter dated the 1st of May 1844, in which M. Bonfilh informed him that he was indeed the officer whose life he had saved, and gave a statement of all that he remembered of the night of the storm, which differed in some few unessential particulars from the recollections of the Colonel, but in all essential ones confirmed his statement, and was irreconcileable with that of the major. The Colonel read it with feelings which he declared it impossible to describe. He visited M. Bonfilh at his residence in France, and embodied the history of the whole affair in a pamphlet, of which he printed only fifty copies for private circulation, from one of which these particulars are taken. The preface is dated on the 14th of June 1845, and it was his last literary effort. On the 25th of December in the same year, in a fit of temporary insanity, which was attributed at the inquest to the effects of the wound he had received so many years before at Ciudad Rodrigo, he terminated his life by his own hand at Brighton, leaving a widow, a French lady, and three daughters.

GUTTA PERCHA. [Isonandria, *S.* 2.]

GUYON, GENERAL RICHARD DEBAUFRE, was born March 31, 1813, at Walcot, near Bath, Somersetshire, in which city he received his early education. His grandfather was a captain in the Dragoon Guards; his father, John Guyon, of Richmond, Surrey, was a commander in the royal navy, and died in 1844. Richard Guyon was intended for the army, and at an early age held a commission in the Surrey militia. At the age of eighteen he obtained a commission in the Hungarian Hussars of the Austrian army, and after some years' service attained the rank of lieutenant, and was appointed aide-de-camp to Field-Marshal Baron Splenyi, commander of the Hungarian life-guards. In November, 1838, he married the daughter of Baron Splenyi, and soon afterwards retired to the neighbourhood of Pesth, where his wife's relations resided, and where he spent his time in country occupations and field-sports.

In September, 1848, when Jellachich, the Ban of Croatia, invaded Hungary, Guyon offered his services to the Hungarian diet, and received the appointment of Major of the Honveds, or national guards. On the 29th of September he contributed materially to the defeat of Jellachich at Sukoro. In the battle of Schwechet, near Vienna, on October 30th, Major Guyon with his raw troops achieved at Mannswörth the only successes of that disastrous day, when, his horse having been shot under him, he led his men to the charge on foot, and armed them with the muskets of the slain Austrians, in place of the scythes with which many of them had fought. He was rewarded by being raised to the rank of Colonel on the field of battle. He was afterwards raised to the rank of General at Debreczin. He commanded the rear of Görgei's army on the march from Pesth to Upper Hungary; and at Ipolysag (January 10, 1849), by a daring and skilful effort saved the baggage from the pursuing Austrians. On the 5th of February, with 10,000 Hungarians, he stormed the defiles and heights of Branyiszko, defended by 25,000 Austrian troops under General Schlick, took prisoners and baggage to a large amount, and cleared the way for the van of the army to pass, Görgei having vainly attempted to turn the defiles by a flank movement. At the battle of Kapolna (February 26) he commanded a division of Dembinski's army. On the 21st of April he entered the fortress of Komorn with a small body of troops, though it was then closely besieged by the Austrian troops, and announced to the despairing garrison the approach of Görgei with a relieving army. When Görgei was appointed minister of war, General Guyon for a time performed the duties of the office, in order to enable Görgei to retain his command-in-chief. On the 9th of August the Austrian and Hungarian armies met near Temesvar, where the impetuous bravery of Guyon and his Hussars could not save the Hungarian army from a defeat. On the 11th of August Kossuth resigned his office of governor, and named Görgei dictator, who on the 17th of August put an end to the war by an unconditional surrender.

Guyon, Bem, Dembinski, Kmety, and other officers who had not been included in the surrender, made their escape with much difficulty to Turkey, where, in defiance of the conjoint demand of Austria and Russia, they were protected by the sultan. After some time Guyon was joined at Constantinople by his wife, whose property in Hungary had been confiscated by the Austrian government. He was offered and accepted service under the Turkish government; and though he decidedly refused to become a Mohammedan, was sent to Damascus with the rank of lieutenant-general on the staff, and with the title of Kourschid Pasha. In November 1853 he was directed to proceed from Damascus to the army in Asia Minor, and reached Kars by a series of rapid journeys. There he had the appointment of chief of the staff and president of the military council, but without any real command over an army of 15,000 undisciplined troops under twenty-one pashas, each with the rank of a general. He was allowed, however, to organise the army and to construct defences. That organisation and those defences, though doubtless much improved afterwards by General Williams and his officers, became a basis for the heroic defence of Kars. He died of cholera, October 14th, 1856, at Constantinople, and was interred with Turkish military honours at Scutari.

(*The Patriot and the Hero; General Guyon on the Battle-Fields of Hungary and Asia*, by Arthur Kinglake.)

GWILT, GEORGE, architect, was well known as an antiquary, and for his restoration of the choir and tower, and the Lady Chapel, of St. Mary Overy's church, in the parish of St. Saviour's, Southwark. George Gwilt and Joseph Gwilt were the sons of George Gwilt, an architect, resident in the parish, who was surveyor for the county of Surrey, and who erected amongst other buildings, Horsemonger Lane Gaol and Newington Sessions House. He died on the 9th of December 1807. George Gwilt, the elder of the sons, was born on the 8th of February 1775. He was sent to a school at Hammersmith, but was indebted for his general education mainly to his own exertions. His professional knowledge was acquired in the office of his father, whom he succeeded in practice. Prior to this, however, Gwilt junior had commenced his own professional course with the building, about the year 1801, of the warehouses of the West India Docks. He soon acquired a marked taste for objects of antiquarian art, of which he at length got together, at his house in Union Street, an important collection, many of the remains being found in St. Saviour's. In 1815 he was elected a Fellow of the Society of Antiquaries. In March and June of that year two valuable communications by him, on the remains of Winchester Palace, Southwark, appeared in the 'Gentleman's Magazine'; and he contributed occasionally at other times to the same journal. In 1818 he was engaged upon the restoration of the steeple of Bow Church, a work which required much professional skill, and which he performed with strict regard to the preservation of Wren's design. The peristyle of columns and the obelisk had to be removed and rebuilt, and the whole was completed on the 11th of July 1820, when the copper vane (in the form of a dragon) eight feet 10 inches long, was fixed. Very soon afterwards, the foundations of the same church being found defective, some important works for their maintenance were carried out under Gwilt's supervision; and during these works the interesting Norman remains of the original building were identified, and were described by him to the Society of Antiquaries in June 1828, in a paper under the title of 'Observations on the Church of St. Mary-le-Bow, chiefly relating to its Original Structure,' and which paper was afterwards published, with six plates, in the 'Vetusta Monumenta,' vol. 5. The restoration of the choir and tower of St. Mary Overy's church was commenced about the year 1822, and was completed in about two years, with great fidelity and practical skill. In 1824 Gwilt visited Italy, and we find little to say of him till the year 1832, when the Lady Chapel of the church last mentioned being rescued from destruction, he undertook the direction of the restoration without remuneration, and completed it in 1833, with the skill which he had exhibited in the other part of the church. George Gwilt lived to the advanced age of eighty-one, occupied in his favourite pursuits till within a few days before his death. He had however suffered long from a painful complaint, and the loss of his wife who died a few weeks before him, was severely felt. He died on the 27th of June 1856, and was buried in the family vault, next the choir of St. Mary Overy's Church.

Joseph Gwilt, the younger brother of George Gwilt, is also an architect, and the author of several valuable works on architecture.

GYMNARCHUS, a genus of Malacopterygious Apodal Fishes. The body is long and scaly; the gill opening before the pectoral fins; dorsal fin running the whole length of the back; tail ending in a point; head naked and conical; mouth small, with a single row of cutting teeth. *G. Niloticus* is the only species; it inhabits the Nile.

GYMNEMA, a genus of plants belonging to the natural order *Asclepiadaceæ*. It has a sub-urceolate 5-cleft corolla, the throat usually crowned by five scales or teeth inserted in the recesses between the segments of the corolla. The stamineous corona is wanting. The anthers terminate by a membrane, the pollen masses are erect, fixed by the base. The follicles smooth. Seeds comose, generally marginate. The species are usually twining shrubs, natives of the East Indies, the tropical parts of Australia, and Equinoctial Africa. The leaves are opposite, membranous, and flat. The umbels interpetiolar and cymose. In the greater number of species the stamens are not usually naked, but are furnished with a gland-like body or fleshy tuft at the base of each filament.

G. lactiferum, Cow-Plant, or Milk-Bearing Gymnema, has an erect stem, or rather twining; the leaves are on short petioles, ovate, bluntly acuminated, usually unequal-sided; the umbels many-flowered, shorter than the petioles; the throat of the corolla crowned by five fleshy tubercles; the tube furnished with double pilose lines running from the tubercles. It is a native of Ceylon, where the milk of the plant is sometimes substituted for cow's milk, and the leaves are boiled with food.

G. tingens is a native of Pegu. It has a twining glabrous stem, cordate leaves, acuminated to oval; the umbels or corymbs often twin, at first shorter than the petioles, and at length spirally elongated; the glands of the filaments one-half shorter than the stamens; follicles cylindrical, spoon-shaped; stigma simple, oval, mutic, crowning the tube of the corolla, and therefore exceeding the stamens. The flowers are largish, numerous, and of a pale-yellow colour. The calyx 5-cleft to the base. From the leaves of this plant a green dye is prepared by the Burmese. Seventeen species of this genus are enumerated, none of them of any particular interest.

(Lindley, *Vegetable Kingdom;* Don, *Dichlamydeous Plants.*)

GYMNETRUS, a genus of Fishes belonging to the group of Riband-Shaped *Acanthopterygii*. It has the following characters:—Body elongated, compressed; a single dorsal fin extending the whole length of the back; ventrals consisting each of a single ray, only sometimes very long and dilated at the end; no anal fin; teeth pointed, small. The species of this genus have very rarely been obtained entire. They have generally been taken dead, and consequently have been crushed and mutilated. Of the species of this genus, Mr. Yarrell says, "three probably belong to the Mediterranean, two to the seas of the North of Europe, and two to India. One northern species, besides one of those apparently belonging to India, has been taken on the shores of this country. That of the north has occurred more than once in Scotland; that of India, once on the coast of Cornwall."

G. Hawkenii (Bloch), Hawken's Gymnetrus, the Oared Gymnetrus, the Ceil Conin of Cornwall. This species has been taken in Cornwall. The following description has been drawn up by Mr. Couch from a drawing and notes of a specimen taken in a net at Mount's Bay in 1791:—"The length without the extremity of the tail, which was wanting, was 8½ feet; the depth, 10½ inches; thickness, 2¾ inches; weight, 40 lbs. In the drawing the head ends in a short and elated front; eye large; pectoral fin round; no anal fin; the dorsal fin reaches from above the eye to the tail. The ventrals are formed of four long red processes, proceeding from the thorax, and ending in a fan-shaped appendage, of which the base is purple, the expansion, crimson. The back and belly are dusky-green; the sides whitish; the whole varied with clouds and spots of a darker green; the fins crimson." A very fine specimen of this fish caught off the coast of Northumberland, was exhibited in London at the time the discovery of the Great Sea-Serpent was announced, and was supposed to explain the nature of this discovery.

The *Gymnetrus arcticus* of Cuvier, the Vaagnaer, or Deal-Fish, has been referred to the genus *Trachypterus*. [TRACHYPTERUS, *S.* 2.]

GYRINIDÆ, a family of Coleopterous Insects belonging to the section *Pentamera*, and the sub-section *Hydrodephaga* or Water-Beetles, and distinguished by the minute size of the antennæ, which are clubbed and shorter than the head, the second joint being dilated into a kind of ear externally; the two fore legs are long and advanced in front like arms, but the four posterior legs are very short and compressed, but broad, forming two pair of short strong oars. The eyes are four in number, two being placed above and two below; the palpi are very small; the thorax short and transverse; and the elytra oval, depressed, and obtuse at the extremity, leaving the tip of the abdomen exposed.

This family corresponds with the genus *Gyrinus* of Linnæus, and unlike the *Dyticidæ* to which they are nearly allied, these insects are distinguished by the metallic brilliancy of their covering; living for the most part on the surface of the water, they receive the impressions of the light in a more direct manner than the *Dyticidæ*, and are accordingly ornamented with tints of a brassy or bronzed metallic hue, which glitter in the sun in the greatest degree. The velocity with which they execute their evolutions upon the surface of the water is really surprising, and has obtained for them the name of Tourniquets by the French, and Whirlgigs and Waterflies by the English. Sometimes indeed they remain stationary for a time, so that it seems easy to secure them, but on the least motion they are instantly alert, escaping with surprising agility and diving to the bottom of the water. The situation of their eyes adds greatly to their defence, enabling them to see objects both above and below them. In the 'Journal of a Naturalist' we find the following account of their proceedings:—"Water quiet, still water affords a place of action to a very amusing little fellow (*Gyrinus natator*), which about the month of April, if the weather be tolerably mild, we see gamboling upon the surface of the sheltered pool; and every school-boy who has angled for minnows in the brook is well acquainted with this merry little swimmer in his shining black jacket. Retiring in the autumn, and reposing all the winter in the mud at the bottom of the pond, it awakens in the spring, rises to the surface, and commences its summer sports. They associate in small parties of ten or a dozen near the bank, where some little projection forms a bay or renders the water perfectly tranquil; and here they will circle round each other without contention, each in his sphere, and with no apparent object from morning until night with great sprightliness and animation, and so lightly do they move on the fluid, as to form only some faint and transient circles on its surface. Very fond of society; we seldom see them alone, or if parted by accident they soon rejoin their busy companions. One pool commonly affords space for the amusement of several parties; yet they do not unite or contend, but perform their circlings in separate family associations. If we interfere with their merriment they seem greatly alarmed, disperse or dive to the bottom, where their fears shortly subside, as we soon again see our merry little friends gamboling as before. When they dive to the bottom of the water in the manner above described, they carry with them a little bubble of air affixed to the extremity of their bodies. Also they are sometimes to be found flying, their well-formed wings permitting such an operation, while the high polish of the body protects them from the action of the water." With the exception of a few exotic species, the insects of this family are of a small size, seldom exceeding a quarter of an inch in length; and the largest ones do not reach one inch. Some of the species are found on the margins of the ocean. They emit when touched a disagreeable scent, arising from a milky fluid which exudes from the different parts of the body, and which is not readily dispelled. The structure of the fore legs indicates their mode of life, serving as arms to convey the food, which they find floating upon the surface of the water, and which consists of small dead insects, &c., to the mouth. The number of species of this family does not exceed 50 or 60, and of these not more than eight or nine are found in this country; of these the *Gyrinus natator* is the most common. It is of a brilliant bronzy black colour, with the sides of the body and antennæ metallic; the margins of the elytra and legs reddish. The elytra are ornamented with lines of impressed spots. It is about a quarter of an inch in length.

H

HADLEIGH. [SUFFOLK.]

HÆMATIN. [TISSUES, ORGANIC, *S.* 1.]

HÆMATITE, a name given to certain forms of the native Peroxide of Iron. When of a red colour it is called Red Hæmatite; and when brown, Brown Hæmatite. [IRON.]

HAILSHAM. [SUSSEX.]

HAIR. [TISSUES, ORGANIC, *S.* 1.]

HALDANE, JAMES ALEXANDER, son of Captain James Haldane of Gleneagles, Perthshire, was born at Dundee, on the 14th of July, 1768, within a fortnight after his father's death. In many respects his career was a counterpart of that of his elder brother Robert. In 1777 he accompanied his brother to the High School of Edinburgh, and subsequently pursued his studies at the university. Declining a partnership which was offered him in connection with Messrs. Coutts's Bank, London, he entered in 1785 the East India Company's naval service. In 1793 he obtained the command of the Melville Castle, East Indiaman. In September of that year he married the only daughter of Major Joass, of Culleonard, in the county of Banff. At the close of this year he succeeded by his courage and presence of mind in quelling a mutiny which broke out in a ship which lay near the Melville Castle, in Portsmouth Harbour, and which was beginning to assume an alarming appearance. His views on religious matters becoming more decided, he at length resolved on retiring from the sea. Early in 1794 he rejoined his wife in Scotland. Soon afterwards he took up his residence in Edinburgh, and manifested a deep interest in various efforts for the religious instruction of the people. He took a leading part in the preaching tours which were undertaken through various parts of Scotland, in the establishment of Sunday Schools, and other Christian efforts. In December 1797, the Society for propagating the Gospel at Home was instituted. In February 1799, Mr. James Haldane became the first pastor of the Tabernacle or Circus Church. In May 1801 the congregation removed to a new Tabernacle, built at the head of Leith Walk, at the entire cost of Mr. Robert Haldane. In 1808 Mr. James Haldane having changed his views with respect to Infant Baptism, although he left the communion open to parties who might differ in their views of this question, many of the members of his church left. Mr. Haldane continued minister here till his death, which took place on the 8th of February 1851. Mr. Haldane published numerous pamphlets on subjects which at the time excited attention in the religious world. Among his larger treatises may be named his works on 'The Doctrine of the Atonement;' 'On Christian Union;' his 'Exposition of the Epistle to the Galatians;' and 'Views of Social Worship.' Some of his pamphlets were directed against the opinions of the Irvingites.

HALES OWEN, Worcestershire, a market-town and borough, in the parish of Hales Owen, is situated in 52° 32' N. lat., 2° 5' W. long., distant 36 miles S.E. by E. from Shrewsbury, and 117 miles N.W. from London by road. The population of the borough of Hales Owen in 1851 was 2412. The living is a vicarage in the archdeaconry and diocese of Worcester.

The town of Hales Owen is pleasantly situated in a valley, and contains many good houses. The parish church is a fine building, with a handsome spire, supported by four arches. The Independents, Baptists, and Wesleyan Methodists have chapels. In Hales Owen are a Free School, founded about 1652, which has an income of above 100*l.* a-year, and had 60 scholars in 1853; National Schools, and an Infant School. Nails and hardware are extensively made. The market-day is Monday; fairs are held on Easter Monday and Whit-Monday. Some remains exist of an abbey of Præmonstratensian canons, built in the reign of King John. Near Hales Owen is the Leasowes, the birth-place and residence of the poet Shenstone, and the grounds of which were arranged by him. Shenstone was buried in Hales Owen churchyard, and the church contains a monument to his memory.

HALESWORTH. [SUFFOLK.]

HALIBUT, OR HOLIBUT. [HIPPOGLOSSUS.]

HALOSCIAS (Fries), a genus of Plants belonging to the natural order *Umbelliferæ*, and the tribe *Seselineæ*. It has a calyx of 5 small persistent teeth; the petals ovate, with an inflexed lobe and short claw; the fruit elliptical, terete, or slightly dorsally compressed; carpels with five sharp somewhat winged ridges; interstices and commissure with many vittæ; seed not cohering to the carpel, without vittæ. One species of this genus is a native of Great Britain.

H. Scoticum, Scottish Lovage, is found on rocks on the sea-coast of Scotland and Northumberland. It has an herbaceous stem, tinged with red, from 12 to 18 inches high.

HALTICA. [TURNIP-FLY.]

HALTWHISTLE. [NORTHUMBERLAND.]

HAMILTON. [CANADA, *S.* 2.]

HAMILTON, SIR WILLIAM, as head of the old family of the Hamiltons of Preston, in Haddingtonshire, inherited a baronetcy created in 1673, but for a time dormant. He was born on the 8th of March, 1788, in Glasgow, where his father, Dr. Hamilton, was a professor in the university; and there he received the earlier part of his academical education. The Snell foundation of exhibitions in Balliol College has long been a prize for the more distinguished among the Glasgow students: Adam Smith, among others, owed his English education to it. As a Snell exhibitioner Hamilton went to Oxford; and he took his degree with honours as a first-class man, proceeding afterwards to A.M.

In 1813 he was admitted a member of the Scottish bar. But law, except the Roman, did not receive much of his attention; and the only practice he ever had was the very little which became incumbent on him, when, after a time, he was appointed Crown solicitor of teinds or tithes. Even while a very young man, he had acquired no small part of his singular and varied stock of knowledge; and mental philosophy began early to be his favourite pursuit. On the death of Thomas Brown, in 1820 he stood for the professorship of Moral Philosophy in the University of Edinburgh: but Mr. Wilson was the successful candidate. Next year, on the nomination of the bar, he became Professor of Universal History in the same university. This appointment, little more than nominal in respect of emoluments, was hardly better as to the performance of duty. The department is not in any way imperative on students: and it never commanded pupils, unless for a while under the elder Tytler. Sir William, being, though not rich, yet independent of professional drudgery, was left undisturbed and undiverted, to the prosecution of his studies and speculations. It was long before these bore fruits visible to any but his immediate friends. For the digesting of his thoughts he was nearly as independent of the necessity of writing, as his iron memory made him to be for the preservation of his knowledge; and he seems to have long shrunk from the toil of endeavouring to expound ideas, for which he did not hope to find an apt or sympathising audience. It was only, as he himself has declared, on the pressing request of the editor of the 'Edinburgh Review,' that he was induced, in 1829, to give to that periodical the first of a series of contributions, which closed in 1839, and which unfortunately constitutes as yet by much the larger proportion of his published writings. Those papers exhibit the variety of his learning not less than its depth; and the philosophical essays which were among them speedily found readers, who, if few, were competent to do them justice.

In 1836 he found his right place: he was appointed by the town council of Edinburgh, though not without a contest, to be Professor of Logic and Metaphysics in the University. He was, what very few of the Scottish professors holding offices thus designated have been, at home in both of the spheres indicated by the official title. The vague term which stands second, opened up to him in his teaching any walk he might choose to tread in the vast field of mental philosophy, of which he had probably in his studies traversed more than any other man then or now alive. The first title pointed his way to one special mental science, which he had studied in all its existing shapes, and which he now set about systematising in harmony with new lights that had dawned on his own mind. Instead of following the usual professional practice, of combining the whole matter of his instructions into one course of lectures, to be delivered in one and the same session (a term of six months in each year), he lectured alternately in the one named section and in the other—in Logic one year, in Metaphysics the next; and he had the gratification of defeating, after a whimsical squabble, an attempt of the town council, who are the legal administrators of that university, to force him into the common practice. His reputation and his influence now extended rapidly. Long before 1836, he had become celebrated in the learned circles of Germany, and had begun to be known and estimated by many at home: the most eminent foreign thinkers had concurred with not a few of our own, in pressing earnestly the pre-eminence of his claim to the Logic chair; and in England, as well as in Scotland, philosophical speculators discovered more and more plainly that, in those fragmentary treatises of his, there had been opened veins of thought which thinking men durst not leave untested. His teaching, again, now worked energetically on many young and ardent spirits gathered round him in his lecture-room. There is not evidence indeed that his logical lectures have as yet had much effect on his personal pupils. But the metaphysical lectures excited a keen interest in philosophy among all of his students who were qualified for severe abstract thinking; while they guided the thinking of not a few into channels in which it long or always continued to flow. He was, too, not less anxious in encouraging and directing for the young men wide philosophical reading, than in prompting them to active philosophical reflection and reasoning.

Sir William's studies seem to have been conducted, thenceforth, with a steadier view than before to systematic exposition and publication. Still the labour proceeded slowly. Academic business, and other temporary occasions of controversy, were somewhat too apt to interrupt the progress of one who was armed for warfare less ignoble. Among other things, he, himself a Presbyterian, published a pamphlet on the schism which split the Church of Scotland in 1843. Very soon, likewise, after that year, his health began to fail; and paralysis struck the right side of his body from head to foot. He was for a time utterly disabled from teaching, and was afterwards able to lecture only with frequent assistance. But the vigour, both of intellect and of will, was as unimpaired as it had been with Dugald Stewart under a similar calamity. His reading and thinking were still carried on; even his writing was so, not without very much aid from others. That more of his large designs were not executed, is a fact for which there were thus, in his latest years, but too sorrowful reasons. He had long worked at intervals on that which he had set himself as his first task, the annotating of the works of Thomas Reid. He aimed at showing the relations of Reid's system, both to older philosophical opinions on the one hand, and on the other to newer ones, especially to Hamilton's own metaphysical doctrines—doctrines which he himself always regarded, and firmly and thankfully represented, as having their essential germ and foundation in Reid, and as being merely a development of the 'common sense' philosophy to results made possible by a combination of scholastic and German methods. Sir William Hamilton's annotated edition of 'The Works of Dr. Thomas Reid' appeared in 1846, much of it having been printed long before. But all that has been published down to this date (1858) leaves it lamentably incomplete. On not a few problems of deep interest—on not a few also bearing closely on our comprehension of Hamilton's own system of thought, we are left with references, in foot-notes, to supplementary dissertations, of which not a word is yet given us; and a dissertation asserting his own peculiar theory of the Association of Ideas is broken off abruptly at the end of the volume. In 1852 appeared the first edition of a reprint, with large additions, of his periodical articles—'Discussions on Philosophy and Literature, Education and University Reform—chiefly from the Edinburgh Review.' Translations of several of the essays had previously been made into French, Italian, and German; Peisse's French translation and notes are particularly valuable. Sir William's regard for the Scottish school in philosophy next showed itself, not (unluckily) in the completion of his 'Reid,' and those further developments of his own doctrines which he had there promised, but in a tribute to the memory to another of its celebrated masters, from whom he had neither derived, nor professed to derive, much if anything in his own opinions. He undertook to edite, with notes, the collected works of Dugald Stewart. The publication, begun in 1854, is still uncompleted; and nothing has appeared of the biography which was to introduce it. In 1855, when in country-quarters, Sir William suffered fracture of a limb; and he died in Edinburgh on the 6th of May, 1856. He has left a widow and family. The manuscripts of his lectures, in both divisions, are said to be in such a state, that they may easily be prepared for the press.

As those who knew Sir William Hamilton through his writings only, cannot do full justice to the multifariousness of his knowledge; so likewise such as look chiefly to those of his writings which had personal bearings, will do positive injustice to the real likeableness of his personal character. He was undoubtedly a stern, and keen, and often eager controversialist, occasionally even a haughty one; in debate he never beat about for smooth words; and, absorbed in his love for science and learning, he sometimes forgot to be gentle towards those whom he thought to be erring or knew to be comparatively ignorant. He was watchfully jealous also (and once or twice, as in his controversy with Mr. De Morgan, needlessly and unjustly so), of anything that looked like interference with his claims to originality in points he had thought out for himself. But even in controversy, if he did hit hard, he never struck a man from behind; and the same chivalrous openness marked all his dealings. Under the combative tendency, moreover, there lay great generosity, great kindliness and warmth of heart: he was invariably amiable when occasion did not force on polemics: he was an active and steady friend, beloved as well as esteemed by those who were admitted to his friendship.

About his erudition there cannot well be two opinions among those who have had opportunities and competency for judging. Its mere mass was a thing extraordinary: it was minutely exact in all those points which raise the question of accurate scholarship: it spread over tracts of reading the most obscure and neglected; and it was, everywhere, the real knowledge of a thinking man, not the word-cramming of a pedant. His range embraced all the great divisions of knowledge, except mathematics and physical science; while here, too, it did not exclude anatomy, with physiology and some other branches of medicine. He was a thorough linguist in the classical tongues, and in German. With as little as possible of the poetical temperament, he was well read in the great poets; and his historical information was unusually extensive. In philosophy he was familiar with the Greek writers one and all: Aristotle and his commentators he had probably studied more extensively and profoundly than any even of our Teutonic neighbours. He knew the whole course of the scholastic philosophy, as no man else has ever known it since the middle ages departed. With British systems it is needless to say that he was familiar in all directions; and he was the only man among us who came near to having studied—and nowhere either carelessly or at second-hand—all the German systems that have emerged or diverged from that of Kant.

As to his originality, this question may be put: not whether Hamilton was the most original of philosophers; but whether there has ever been any philosopher who, to learning even half as great as his, united so much of real and active originality as a thinker. In his treatment of details he has a favourite manner, which often disguises his independence. He likes the position of an interpreter: he is wont to speak as if the best way of discovering philosophical truths were by deciphering them in some mediæval text through the dust of centuries. He takes a pride in quietly fathering on some schoolman or other a doctrine or an argument which many men would have been too glad to take credit for as their own; and sometimes, half-hidden in a brief note, there is given, as an obvious and matter-of-course comment on a scholastic brocard or term, some assertion which proves on close inspection to presuppose a wide process of new inference. The outlines, however, of those sections in his own philosophical creed which he has taken the trouble to expound, are laid down broadly enough to let their character be seen clearly. Be his leading doctrines held true or false, valuable or worthless, they are at least his own,—as much his own as very many systems which all of us rightly admit to be essentially novel,—as much his own, it may be said, as any system of philosophical opinions can be, unless it ignores everything that great thinkers have ever thought before.

What may be the correctness, and what the value, of his peculiar opinions, is a question on which, if it were to be adjudged at present, contradictory verdicts would be given. Probably no one will be competent to decide it justly, till there has taken place a long and intelligent sifting of speculations, which travel in a track, not only at several points new in itself, but likewise, everywhere, little familiar to most thinkers in this country. Hamilton's writings are Germanic rather than British; and that not merely in the freedom with which he has taken German doctrines and methods (with a large admixture of Scholasticism) as materials to be distilled in his own alembic. The exotic character is observable, both in his highly speculative aims, and in his severe exactness of technical expression. The former of these characteristics is distinctively alien to the broadly practical English mind; and the latter is one which has never, before him at at least, been made to take root in the philosophic mind of Scotland. Nor can his writings be mastered without pains. He never cares for doing more than saying what he thinks to be worth saying—saying it unequivocally, and saying it in the smallest number of words that is consistent with safety. He will not turn aside to amuse us; he will not hurry or rise to excite us. He is a hard thinker, and a hard, vigorous, precise, dry, writer. But for such as will take the trouble to follow his course of thought, and reflect on its contents, there are perhaps no philosophical discussions, certainly none of our times, that are so suggestive of processes of thought—processes wide in range, definite in direction, and lofty in design and in possible result.

Of Hamilton's Psychological and Metaphysical doctrines, nothing special requires to be said. They are before us, in certain parts, in his own exposition; and that they have already been much discussed, and have in some quarters excited a powerful influence on speculation, is a good omen for philosophy. We have, especially, his treatment of three great problems in philosophy. First, there is his theory of the two kinds of human knowledge, Immediate and Mediate. Secondly, there is a special application of this theory to the construction of a theory of External Perception. Thirdly, there is an exhaustive system of Metaphysics Proper, or Ontology, in his 'Philosophy of the Conditioned,' or 'Conditions of the Thinkable'—a vast and noble idea, traced out for us, as yet, in nothing but a tantalising fragment.

Regarding his Logical system, our public information is still very unsatisfactory. It is to be gathered from an appendix to his 'Discussions,' and an authorised but meagre publication from lectures, Baynes's 'New Analytic.' These materials will probably convey no distinct notion of the system, unless to readers who are familiar with the German methods of logical analysis since Kant. The leading points may be four; and it is perhaps possible to make these intelligible, very briefly, to persons acquainted with the outlines of the science in its received forms. 1. Hamilton insists on having, in all propositions through common terms which are set forth for logical scrutiny, a sign of quantity prefixed to predicate as well as to subject. The point, though merely one of form, is curiously suggestive of difficulties, and hence of solutions. 2. Instead of recognising only four forms of propositions, the A, E, I, O, of the old logicians, he insists on admitting all the eight forms which are possible. (See Thomson and Solley.) 3. He widens the range of the syllogism, by admitting all moods which can validly be constructed by any combination of any of his eight kinds of propositions. 4. The Port-Royal doctrine, of the inverse ratio of the extension and comprehension of terms, is worked out by him in its reference to the syllogism. This application of the doctrine has certainly not been anticipated by any logician; and, when elaborated to its results, it throws many new lights on the character and mutual relations of the syllogistic figures.

HAMMER-PURGSTALL, JOSEPH, BARON VON, was born in 1774 at Grätz in Styria, where his father held a respectable post under the Austrian government. He was educated at Vienna, and 1788 removed to the Oriental academy established by Prince Kaunitz. After having taken a part in the compilation of Meninski's Arabian, Persian, and Turkish Lexicon, he was appointed in 1796 secretary to the Baron von Jenisch, the reporter to the Oriental section in the ministry for foreign affairs. While in this employment he translated a Turkish poem on the Last Judgment, and supplied several other poems to Wieland's 'Deutschen Mercur.' In

1799 he was attached to the embassy of the learned Baron von Herbert at Constantinople, who sent him with one of the imperial consuls on an important errand to Egypt, where he procured for the imperial library some mummies of the ibis, hieroglyphic stones from the catacombs at Sakkara, several Arabian manuscripts, and other rarities. As interpreter and secretary he made the campaign in Egypt under Hutchinson, Sir Sidney Smith, and Jussuf Pacha, against Menou, and in the autumn of 1801 proceeded by Malta and Gibraltar to England. After his return to Vienna in April 1802, he accompanied, in August, the Austrian ambassador, the Baron von Stürmer, as secretary of legation to Constantinople. In 1806 he was appointed consular-agent in Moldavia. In 1807 he returned to Vienna; in 1811 he was made a state counsellor, and appointed court and state interpreter; in 1817 promoted to be imperial privy counsellor; and in 1845 created a baron, after having succeeded to the estates of the Countess von Purgstall. In 1815 he had occupied himself earnestly in procuring the restoration of the Oriental manuscripts and other treasures which had been removed from the Vienna library to Paris by Denon, during the occupation of Vienna by the French in 1809. In 1847, continuing to be in the active service of the department of foreign affairs as counsellor extraordinary, he was chosen president of the newly instituted academy, which he resigned after holding the office for two years. His intervals of leisure from business were spent at his castle of Hainfeld in Styria, where he laboured on his very numerous literary works, and where he died on November 21, 1856.

His works are extremely numerous, and those of a historical character highly valuable. His publications of Turkish, Arabian, and Persian poems are in many instances interesting to the general reader, but his philological knowledge was not sufficiently exact to enable him to render them satisfactory to the student. Among the more noticeable of his historical works are 'The Trumpet of the Holy War,' 1806; 'The Constitution and Government of the Ottoman State,' 1816; 'Glances upon a Journey in 1804, from Constantinople to Broussa and Olympus, and thence back by Nicæa and Nicomedia,' 1818; 'History of the Assassins, from Eastern Sources,' 1818, a work which has been translated into English by Mr. Wood; 'Constantinople and the Bosphorus, topographically and historically described,' 1821; 'Codices arab., pers., turk., bibliothecæ caes.,' 1822; 'History of the Ottoman Empire,' in ten volumes, 1827-1834, an excellent work, of which several editions have been published; 'The Government under the Khalifats,' 1835; 'Picture Gallery of the great Mussulman Commanders, with Memoirs,' in six volumes, 1837-39; 'History of the Golden Horde of Kiptschak, that is, of the Mongols in Russia,' 1840; 'History of the Ilkhane, that is, of the Mongols in Persia,' 1842-44. All these contain a vast collection of materials relating to the history and present state of the East. Of his other productions we may mention, 'Schirin,' a Persian poem, 1800; his translation of the 'Divan,' of Hafiz, from the Persian, 1813; his 'History of the Literature of Persia, with Specimens from 700 Poets,' 1818; 'The Eastern Trefoil,' from Persian, Arabian, and Turkish sources, 1818; 'The String of Jewels,' from Abul-Maanis, 1823; a translation of the Arabian lyrical poet Motenebbi, 1823; a translation from the lyrical poems of Baki, 1825; a 'History of Turkish Poetry,' with selections from 2200 poets; Fasli's allegorical Turkish Epic of the Rose and Nightingale, 1834; Samaschari's Arabian poem of the 'Golden Necklace,' 1835; Mahmud Schebisterei's didactic poem on Suffism, entitled the 'Rose-Bloom of Secrets,' 1838; 'The Falconer,' an old Turkish didactic poem on falconry, 1840; and a 'History of Arabian Literature,' in three vols. 1850-52. He has also written a volume 'Memnon's Driekklang,' (Memnon's Triad), containing an Indian pastoral, a Persian opera, and a Turkish comedy. For his translations of the 'Contemplations of Marcus Aurelius' into Persian, published in 1831, he was rewarded by the Shah with the order of the Sun and Lion. In 1810 he established a periodical work 'Mines of the Orient,' to which he contributed much, and in which he was assisted by Count Wenzel Rzewuski, which was continued till 1819; and he was a frequent contributor to the 'Jahrbüchern für Literatur' (Year-Books for Literature), and to other periodical works.

HANDSWORTH. [STAFFORDSHIRE.]

HARAR. [HURRAR, *S.* 1.]

HARBURG, a sea-port town in the kingdom of Hanover, province of Lüneburg, is situated on the left bank of the southern arm of the Elbe, opposite Hamburg, 106 miles by railway N. from the city of Hanover, and has about 8000 inhabitants. It is surrounded by walls, and defended by a citadel, which also commands the passage of the Elbe. There are two churches, an hospital, a gunpowder factory, sugar refineries, tanyards; manufactories of woollen stuffs, linen, and hosiery; and an active transit trade with Hamburg and the countries south of the Elbe. The timber trade of Harburg also is extensive. A steam-ferry affords frequent and rapid communication with Hamburg. As sea-going vessels could not formerly be brought alongside the quays, goods were usually trans-shipped at Hamburg or Altona and brought thence to Harburg, in lighters; but simultaneously with the construction of the railway from Hanover to Harburg (which, it may be added, connects the port with all the principal commercial towns of Germany) the harbour was deepened and enlarged so as to afford accommodation for 500 vessels, which may now land their cargoes on the wharfs. The depth of the channel between Harburg and Altona is 10 feet at low and 15 feet at high water. The port extends to the railway goods-station, and merchandise is lifted by a crane out of the hold of vessels and placed on the train. The improvement of the harbour, the completion of the railway, and the declaration of the freedom of the harbour in 1850 gave a great impetus to the commerce of Harburg, which still continues to improve, although the freedom of the port was suppressed in 1853 by the commercial treaty with Austria and Prussia. The distance to Hamburg across the Elbe is four miles and a half.

HARDINGE, HENRY, VISCOUNT, third son of the late Rev. Henry Hardinge, rector of Stanhope, in the county of Durham, by Frances, daughter of James Best, Esq., of Chatham, was born at Wrotham, Kent, on the 30th of March, 1785. He was a member of a family which has long been located at King's Newton Hall, Derbyshire, and is said to have originally come from Denmark.

Having spent a short time at Eton, Henry Hardinge was gazetted ensign in a regiment of foot, October 8, 1798, obtained his lieutenancy in 1802, and captaincy in 1804. It was his good fortune early to attract the notice of the Duke of Wellington, then Sir Arthur Wellesley, under whom he served throughout the whole of the Peninsular War, and for a considerable time was upon the staff of the commander-in-chief; he was also for nearly the entire period deputy-quartermaster-general of the Portuguese army. He was present at the battles of Roleia and Vimiera, where he was severely wounded; at the battle of Corunna he was by the side of the gallant Sir John Moore when he received his fatal wound. After having lost his friend at Corunna, he was present at the passage of the Douro, the battle of Busaco, the lines of Torres Vedras, and the battle of Albuera. In this engagement he displayed the greatest skill, courage, and self-command; it was a hard-fought field; and to the change in the fortunes of that day, effected as it was by the persevering valour of the British infantry, Lord Hardinge often pointed back in after life as having encouraged him as a general to persevere through every obstacle, and to place perfect confidence in the enduring valour of British troops. After this we find him side by side with Lord Wellington in almost every engagement of the war. He took part in the first and second sieges of Badajoz, at Salamanca, and at Vittoria, where he was again severely wounded, and also at Pampeluna, at the battles of the Pyrenees, and at Nivelle, Nive, and Orthes. When he returned to England after the close of the Peninsular War, he was justly regarded as one of the most gallant officers in the service. Upon the renewal of hostilities he was again in arms, and took an active part in the campaign of 1815 under the Duke of Wellington, upon whose staff he then was serving. Two days before the battle of Waterloo he was employed as a brigadier-general with the Prussian army at Ligny, where, in a skirmish with the enemy, he was wounded in the left arm, which had to be immediately amputated, and prevented him from taking a personal part in that glorious victory. He was however rewarded with the dignity of K.C.B. on the enlargement of the order of the Bath in the same year, and with a pension of 300*l.* a year for the loss of his arm.

When upon the resignation of Lord Goderich, in 1828, the Duke of Wellington undertook the construction of a ministry, he chose Sir Henry Hardinge (who had been returned as member for Durham in 1820 and again in 1826), to succeed Lord Palmerston as secretary at war. He was sworn a member of the privy council, and two years later exchanged this position for that of the chief secretaryship for Ireland, under the late Duke of Northumberland as lord lieutenant. Here however he did not remain long: the Duke's ministry retired from office in the autumn of the same year, and Sir Henry Hardinge returned to England. He resumed his high post however under the short-lived ministry of the late Sir Robert Peel, which lasted from November 1834 to April 1835. From this time till the return of Sir Robert Peel to power in September 1841, Sir Henry Hardinge remained in opposition. At the latter date he returned to Ireland as chief secretary under Earl de Grey, where he remained until 1844.

Towards the close of the year 1843 events arose in India to which we need not allude further than to say, that the directors of the East India Company thought that the time had come when it was necessary for them to recall Lord Ellenborough from the high post of governor-general of India. It was stated by Sir Robert Peel in his place in the House of Commons, that whilst the East India House and the Home Government were at issue as to the propriety of this step, they were quite of one mind as to the selection of his successor; and that when the premier recommended Sir Henry for the vacant post, on the ground of his great experience of civil matters, his high personal character, and his military eminence, the chairman of the company answered that his own choice had already fixed upon the same individual.

In April 1844 he accordingly undertook the government of India, and was sworn into office on landing at Calcutta in the July following. On his arrival he found the vast territories under British rule enjoying the most profound peace. The disasters of the Afghan campaign had been avenged; Sir Charles Napier had reduced the ameers of Scinde at Meeanee and Hyderabad; Scinde itself had been annexed to our dominions; and the Mahratta war had been terminated by the submission of the Durbar at Gwalior. The governor-general had therefore ample time to make himself master of very many details of government, in which he was not slow to perceive that considerable reforms were needed. Able and indefatigable in his efforts, he did his best to bring about a better feeling and a more friendly footing than had hitherto prevailed between the services; he admitted the claims of the natives to many privileges; he promoted a stricter discipline among the troops in general; he lent his powerful aid to the organisation of those Indian railways which have since been carried out with such marked success under his successor Lord Dalhousie; and in short, he did all that was in his power to promote the welfare of the community at large.

But the course of Indian events was not long destined to flow on in peace. A storm of war and bloodshed was gathering in the north; and Sir Henry Hardinge, with all his precaution, could not have foreseen or avoided the events which awaited him. The death of Runjeet Sing, 'the Lion of Lahore,' had paved the way for an infinity of plottings and intrigues in the capital of the Punjab. With the death of the Lion, it seemed that the controlling power had left Lahore; the young maharajah, Dhuleep Sing, a child of four years old, was, together with his mother, in the hands of the Sikh soldiery, who were wearied with domestic faction, and clamoured to be led out against their English neighbours. Active preparations were made by the Sikhs for crossing the Sutlej; but long before the public had any idea of what was going on, Sir Henry Hardinge was on the alert, and had quietly concentrated a force of 32,000 men and 68 guns round Ferozepore, Loodianah, and Umballa. The governor-general reached the latter place about the middle of December, and, proceeding to Loodianah, inspected the various cantonments, and made himself acquainted with the actual position of affairs. He at once moved up the whole of his force from Umballa; and on the 13th, learning that a large Sikh force had crossed the Sutlej River, he issued a proclamation against the hostile invasion. On the 17th the Sikhs advanced, and partly entrenched themselves within strong earthworks at Ferozeshah, while the other part encamped near Moodkee, opposite Ferozepore. The combined operations of the British cavalry under Brigadiers Gough, White, and Mactier, and the infantry under Sir Harry Smith, Sir J. M'Caskill, and General Gilbert, drove back the Sikhs from their well-contested position, and won the glorious victory of Moodkee—a victory too dearly purchased by the death of Sir Robert Sale. On the 22nd the attack was renewed at Ferozeshah; but night came on before the victory could be completed, and some Sikh guns were being brought to bear with deadly aim upon the British columns, when the governor-general mounted his horse, and at the head of the 80th regiment, and a portion of the Bengal 1st Europeans, carried the guns at a charge, and spiked them. The next day the Sikh entrenchments were carried by the bayonet, the enemy's guns were captured, and the invaders recrossed the Sutlej. The want of cavalry alone prevented Sir Hugh Gough from following the enemy into their country, and marching on Lahore. There is something truly touching in the fact that, in this important battle, Sir Henry Hardinge, though he held the supreme civil authority in India, offered his services to Sir Hugh Gough as second in command, and took an active part in the eventful scenes of this and the following day, directing the left wing of the army throughout. The Sikhs, again defeated at Sobraon and Aliwal, were forced to sue for terms; and the treaty of Lahore, concluded by Sir Henry Hardinge, exhibits him in the light of a moderate and magnanimous conqueror. He exacted from the Sikhs the whole expense of the war, and left a British garrison, under the late Sir John Littler, in Lahore, the capital of the Punjab, for the protection of the maharajah's authority. This country—a healthy, well watered, and fertile region—was subsequently annexed to our dominions by the Marquis of Dalhousie. On the ratification of this treaty, Sir Henry Hardinge received the thanks of both Houses of Parliament, together with a pension of 3000*l.* a-year, and was also advanced to the peerage as Viscount Hardinge of Lahore. The East India Company also conferred on him a further pension of 5000*l.* a-year; and the city of London voted him their freedom. In January 1848 he was superseded in his Indian government by Lord Dalhousie. Though originally of Tory principles, after his elevation to the peerage Lord Hardinge rarely spoke or busied himself in the House of Lords on any measures except those of military interest. On Lord Derby's advent to power in February, 1852, Lord Hardinge again took office as master-general of the ordnance, and succeeded to the post of commander-in-chief, on the death of the Duke of Wellington, in the September following. He obtained the colonelcy of the 57th Foot in 1843, and was promoted to the dignity of G.C.B. in 1844. Among foreign orders, he received those of the Red Eagle of Prussia, Wilhelm of the Netherlands, the Tower and Sword of Portugal, and that of San Fernando of Spain. He also received a cross and five clasps for his Peninsular services, and was present in no less than sixteen general actions for which medals were granted. He was promoted to the rank of Field-Marshal on the 2nd of October, 1855. He resigned the office of commander-in-chief in consequence of a paralytic seizure, in July 1856. In the administration of the Horse Guards, as a veteran disciple of the Duke of Wellington, Lord Hardinge trode most carefully and religiously in his Grace's steps. In 1821 he married the Lady Emily Jane Stewart, daughter of Robert, first marquis of Londonderry, and widow of John James, Esq., by whom he had an only daughter and two sons. The younger son, Arthur, now captain and lieutenant in the Coldstream Guards, was aide-de-camp to his father in the battles on the Sutlej, and was also present at the Alma. His lordship died September 24, 1856, and was succeeded by his eldest son, Charles Stewart, born in 1822, who had been private secretary to his father while governor-general of India.

HARE. [LEPORINÆ.]

HARE, JULIUS CHARLES, a distinguished English divine and controversialist, was born in 1796, and was one of the sons of the Rev. Robert Hare, rector of Hurstmonceaux and vicar of Ninfield in Sussex, who was the son of Dr. Francis Hare, bishop of Chichester. He was educated at Trinity College, Cambridge; was a fellow of the College; and graduated B.A. 1816, and M.A. 1819. In 1832 he was instituted to the rectory of Hurstmonceaux (a living belonging to his family); in 1840 he was appointed Archdeacon of Lewes; in 1851 he became one of the prebendaries of Chichester; and in 1853 he was nominated one of her Majesty's chaplains. He died at Hurstmonceaux on the 23rd of January, 1855. Such are the principal external facts in the life of a man whose personal influence in his day was very great, and who has besides left some contributions to our literature. His first literary appearance of any note was in 1827 when, in conjunction with a younger brother (the Rev. Augustus William Hare, M.A., of New College, Oxford, and rector of Alton Barnes, Wiltshire, who died in 1834), he published a volume of miscellaneous thoughts and observations entitled 'Guesses at Truth, by Two Brothers.' (Subsequent and enlarged editions of this work have been published; and also a 'Second Series' under the same title). In 1828, in conjunction with the Rev. C. Thirlwall, afterwards bishop of St. David's, Mr. Hare appeared as translator of the first two volumes of 'Niebuhr's History of Rome,' from the German. Of his subsequent publications, the following are the most important:—'The Children of Light: a Sermon,' 1828; 'A Vindication of Niebuhr's History of Rome from the charges of the Quarterly Review,' 1829; 'Sermons preached before the University of Cambridge,' 1839; 'The Victory of Faith, and other Sermons,' 1840; 'The Better Prospects of the Church: a Charge to the Clergy of the Archdeaconry of Lewes,' 1840; 'The Unity of the Church: a Sermon,' 1845; 'The Mission of the Comforter, and other Sermons,' 2 vols., 1846; 'The Means of Unity: a Charge,' 1847; 'A Letter to the Dean of Chichester on the Agitation excited by the appointment of Dr. Hampden to the See of Hereford,' 1848; 'The Duty of the Church in Times of Trial; a Charge,' 1848; 'The True Remedy for the Evils of the Age: a Charge,' 1849; 'Education the necessity of Mankind: a Sermon,' 1851; 'The Contest with Rome: a Charge,' 1852; 'Vindication of Luther against his recent English assailants (H. Hallam, Esq., J. H. Newman, W. G. Ward, and Sir William Hamilton),' 1854. From this list it will be seen that Archdeacon Hare's chief activity was in theological literature and ecclesiastical controversy. In the church he was regarded, alone with his friend Mr. Maurice, as being at the head of what has been called 'the broad party,' as distinct from either the 'high' or 'low.' The liberality of his opinions in philosophy and his tolerance of religious differences may be inferred from the fact of his having been the intimate friend of the late John Sterling, whose 'Remains' he edited, with a long and affectionate Memoir, in 1848. It was Mr. Carlyle's dissatisfaction with his memoir, as an account of his friend, that led him to write his 'Life of Sterling.' Mr. Hare's memory is held in high veneration, not only by those who regarded him as an ecclesiastical leader, but also by many who had learnt to respect him as an earnest thinker on social and philosophic subjects.

HASSELTIA, a genus of Plants belonging to the natural order *Apocynaceæ*. It has a 5-parted permanent calyx: a corolla with the tube contracted in the middle; the throat naked; the limb campanulate, 5-parted and contorted. The stamens are inserted in the throat. Anthers large, cuspidate, callous at the back, adhering to the stigma; the ovary double, surrounded by a fleshy ring; styles 2; stigma clavate; follicles 2, distinct, and long; seeds with a stipitate coma at the lower end.

H. arborea is found in Java, near Tjampiam. It is a handsome tree, with oval leaves, rather acute at each end, smooth above, paler and a little downy on the under side. The flowers are large, yellowish-white, in axillary fascicles. In Java the milk obtained from the trunk by incision, mixed with honey and reduced with boiling water, is employed as a powerful drastic for destroying the tape-worm; it is however apt to produce inflammation of the intestines, and in some cases has proved fatal.

HATCHETINE. [CHEMISTRY, *S.* 2.]

HAVELOCK, MAJOR-GENERAL, SIR HENRY, K.C.B., was born April 5, 1795, at Bishopwearmouth, near Sunderland, at which latter town his father carried on an extensive business as a ship-builder and merchant. His father retired from business in 1799, and purchased Ingress Park, Dartford, Kent. Young Havelock was placed in the Charterhouse School, where he distinguished himself by his application and success, and where he had for contemporaries the Greek historians Thirlwall and Grote, Archdeacon Julius Hare, Sir C. L. Eastlake, and several others who have attained eminence in various walks of life. The bar being the profession selected for him, he in 1813 was entered of the Middle Temple, and in 1814 became a pupil of Chitty. His own inclination was however for a military life. His elder brother, Colonel William Havelock, had attracted favourable official notice by his gallant conduct on more than one occasion in the Peninsula—honourable testimony is borne to his merits in Napier's 'History of the Peninsular War'—and through him Henry applied for a commission. In July 1815 he was made second lieutenant in the Rifle Brigade, and he served with his regiment in England till 1823, when having exchanged into the 13th Light Infantry, he embarked for India, and from this time his career of active duty may be dated, he being engaged in almost every subsequent Indian campaign. The Birmese having made various inroads upon the British territory, and collected large armies with the avowed determination of driving the English out of Bengal, Lord Amherst, in March, 1824, issued a formal declaration of war against the king of Ava. Havelock was appointed Deputy-Assistant-Adjutant-General, and in that capacity took part in the chief operations of the war. When the court of Ava was constrained to sue for peace, Havelock was named one of a commission to obtain the royal signature to the treaty which was concluded in February 1826.

Lord Combermere having formed a military depôt at Chinsurah, Havelock was appointed adjutant of it in 1827. On Feb. 9th, 1829, he married Hannah the third daughter of Dr. Marshman, the learned Baptist missionary at Serampore, with whose theological opinions his in a great measure coincided: and it is noteworthy, as an illustration of the extent to which deference to Hindoo notions has been carried in India, that it was long after made a matter of serious complaint against Havelock, that he was accustomed to hold meetings in his quarters for religious worship, and the charge was gravely investigated by the higher authorities. On the breaking up of the Chinsurah depôt Havelock returned for a while to his regiment; afterwards proceeded to Calcutta, passed an examination in the native languages, and in 1835 was appointed regimental adjutant. On the breaking out of the first Afghan war in 1838, Captain Havelock (for he had in this year, after twenty-three years' service, been promoted to a company), was placed on the staff of Sir Willoughby Cotton, and accompanied the army throughout the campaign, being present at the storming of Ghuznee, the capture of Cabul, &c. He published an account of this campaign, 'A Narrative of the War in Afghanistan in 1838, 1839,' 2 vols. 8vo., Lond., 1840.

Captain Havelock was now sent to the Panjab with a detachment, and placed as Persian interpreter on the staff of Major-General Elphinstone. On the recurrence of difficulties in Afghanistan in 1841, he joined the force of General Sale, and shared in the desperate fighting through the Khoord Cabul Pass and the difficult country beyond it to Jellalabad; in the protracted and noble defence of which fortress, as well as in the final defeat of Akbar Khan in the open field, April 7, 1842, the name of Havelock was one of the most distinguished, and he received the well merited reward of a brevet majority and the companionship of the Bath. As Persian interpreter he accompanied General Pollock in his march, and took part in the several encounters in which the army engaged. In 1843 he was appointed Persian interpreter on the staff of General Sir Hugh (now Viscount) Gough, and fought in the battle of Maharajpoor in which the Mahrattas, 18,000 strong, were defeated with a loss of about 3,400 men. In 1844 he was made lieutenant-colonel by brevet. The following year was marked by the commencement of the Sikh war. He was present at the battles of Moodkee, December 18, 1845 (where two horses were killed under him), Ferozeshah, December 21, 22, and Sobraon (where he lost another horse) February 10, 1846. When peace was restored he was appointed Deputy-Adjutant-General of the Queen's troops, at Bombay. In 1849 he came to England on leave of absence for two years on account of ill-health. On his return to India, Lord Hardinge, who had witnessed his gallantry and skill in the battles near the Sutlej, made him first Quarter-Master-General, and then Adjutant-General of the Queen's troops in India.

When the Indian government declared war against Persia, Colonel Havelock was despatched with the expeditionary force under General Sir James Outram, in command of the second division of the army, and took part in the brilliant affair of Bushire, and was present at the capture of Mohammerah. The war ended, he embarked in the Erin for Calcutta with the gallant 78th. The vessel was wrecked, April 1857, off Ceylon; but happily Havelock and his brave comrades were spared to do memorable service in the rescue of their countrymen and countrywomen subjected to far more fearful peril than that of shipwreck, and in inflicting retribution on their brutal assailants.

Immediately on reaching Calcutta he was despatched with the rank of Brigadier-General to Allahabad. He left that city on the 7th of July at the head of a column of about 1200 Europeans and Sikhs to retake Cawnpore, where the garrison had been treacherously massacred after surrendering on terms, and where some of the women and children were still in the enemy's hands. He had to force his way against terrible odds, but he made good his ground, and on the 16th of July he defeated Nana Sahib at the head of about 5,000 mutinous sepoys—his own force being 1000 Europeans and about 300 Sikhs. On the 17th he entered Cawnpore, too late notwithstanding all that he and his noble army had done to save their unhappy countrymen, yet he had in the last eight days marched 126 miles, and won four actions against overwhelming odds. Hardly waiting to give rest to his men, or to pay the last rites of sepulture to the mangled corpses of those who had been foully murdered in Cawnpore, Havelock prepared to push on for Lucknow. On the 19th of July he again inflicted a severe defeat on the mutineers, and finding that Nana Sahib had evacuated his stronghold of Bitboor, renewed his march. But he had to fight at every step, stout fortresses had to be captured, and at length after, on the 16th of August, achieving his ninth victory over six times his own numbers, he found his men so reduced by death, wounds, and sickness, as to render it imperative on him, after almost coming within sight of the besieged citadel to fall back upon Cawnpore—not however without being able to communicate cheering words to the besieged. Being strengthened by the arrival of General Neill with a small additional force, and joined by his old commander, General Sir James Outram, Havelock at the head of 2800 men crossed the Ganges from Cawnpore on the 19th of September. Sir James Outram—one of the best and bravest of the many officers who have achieved eminence in India—would of course, as the superior in rank, in the usual order of things, supersede Havelock as commander, but with the genuine chivalry of a true-hearted soldier, he in an order of the day announced to the army that "in gratitude for and admiration of the brilliant deeds in arms achieved by General Havelock and his gallant troops," he would "cheerfully waive his rank on the occasion, and accompany the force to Lucknow in his civil capacity as chief commissioner of Oude, tendering his military services to General Havelock as a volunteer." On the 21st of September the fortified position at Meengarsour was forced; on the 25th Lucknow was reached, and the garrison, which had been blockaded for nearly four months, relieved, just as it had been mined and was ready to be blown up by the besiegers. The following day the intrenchments of the enemy were stormed, though with great loss, including that of the gallant General Neill.

On the 17th of November, Sir Colin Campbell, after four days' operations and some very severe fighting, forced his way into the residency at Lucknow, and the garrison was relieved. General Havelock died of dysentery in the fortress of Alumbagh, near Lucknow, on the 24th of November, 1857.

We need hardly add that the splendid march of Havelock on Cawnpore and the relief of Lucknow have not merely rendered him the popular hero of the Indian war, but added new glories to the British arms. As a reward for his eminent services he was created (Sept. 1857) a Major-General in the army, his promotion bearing date July 30, 1857, made a Baronet, and raised to be a Knight-Commander of the Bath; and, in accordance with a royal message to both Houses of Parliament, voted a pension of 1000*l.* a-year for life, which is continued to his eldest son, who, when Captain Havelock, served on his father's staff as Deputy-Assistant Adjutant-General, and who is now Sir Henry Marshman Havelock, the second Baronet. He was born in 1830.

HAVERSIAN CANALS. [TISSUES, ORGANIC, *S.* 1.]

HAWK-MOTH. [SPHINGIDÆ.]

HAYDON, BENJAMIN ROBERT, was born January 25th 1786 at Plymouth, where his father was a bookseller. Haydon was educated first at the Plymouth grammar-school and afterwards at the Plympton grammar-school, where Sir Joshua Reynolds had received his education. Haydon's father drew a little himself, and had a taste for art, and was delighted with his son's skill in drawing; but he wished him, as there was no other son, to adopt his business, and Benjamin was accordingly apprenticed. But the youth hated the business, and expressed his resolution to become a painter so determinedly, that after much opposition his father consented, and in May 1804 he started for London. Through Prince Hoare, a friend of the family, he got introductions to Northcote and Opie, and afterwards to Fuseli, keeper of the Royal Academy, by whom he was readily admitted as a student at the Royal Academy; and thus at the age of eighteen, an enthusiast for Raffaelle, Michel Angelo, and high art, Benjamin Haydon commenced his career. Here he drew with great earnestness, and soon acquired great readiness of hand. He also spent much time in dissecting and the study of anatomy generally, of which he obtained a very fair amount of knowledge. But his studies were too desultory and interrupted, and there can be little doubt that the weakness of his sight—he had while a youth been for a short time quite blind—was a great hindrance to successful study in both form and colour. At the academy, Wilkie, Jackson, and others subsequently famous, were his fellow-pupils, yet he seems to have been generally regarded as one of the most promising students in the institution, while he was a great favourite with his companions there.

Haydon exhibited his first picture at the Royal Academy in 1807. The title alone will show the daring of the young painter, 'Joseph and Mary resting with our Saviour after a day's journey on the road to Egypt.' Mr. Hope, author of 'Anastasius,' became the purchaser of this picture. The reputation which the artist gained by it gave him increased energy and ambition. 'Dentatus' was the subject chosen by him next year; and from this period Haydon dates the commencement of a quarrel with the Royal Academy, whom he accused of illiberality or mismanagement in hanging his 'Dentatus' where it could not be seen, and of a fear of historical painting as the cause of their refusal to admit him as an associate, while they admitted less skilful artists. The 'Dentatus' was purchased by Lord Mulgrave, and in the following year was exhibited in the British Institution, where it received the praises of the public, and the prize of the committee. About this time the Elgin Marbles were first exhibited in London, and Haydon's enthusiasm about them was boundless. For a time he did scarce anything but draw, write, and talk about them; and to the last he was glad to believe that to his earnest pleas with men in power the purchase of them for the nation was partly due.

Haydon now got diverted from steady application to painting by his fondness for controversy; and the attacks he published on the Royal Academy, by estranging from him some personal friends among artists and the patrons of art, greatly exasperated his temper, and there can be little doubt produced a lasting ill effect on his fortunes. From this time his life was to a great extent one of strife, and of constant struggle with pecuniary difficulties. Still he was at no time without friends. Sir G. Beaumont gave him a commission for a subject from Macbeth, and his 'Judgment of Solomon' was bought by Mr. Elford and Mr. Tingcomb for 700 guineas; his 'Alexander returning in triumph, after vanquishing Bucephalus,' found a purchaser at 500 guineas in the Earl of Egremont; and his 'Venus and Anchises' was purchased for 200 guineas by Lord de Tabley. Another application for admission to the Academy resulted again in disappointment.

His next great work was 'Christ's Entry into Jerusalem,' begun in 1814, but not exhibited till 1820, when it formed part of an exhibition of his own in Bond Street. The picture did not sell, but this did not prevent him from painting 'Christ in the Garden,' and 'Christ Rejected.' In May 1821 he married. His 'Raising of Lazarus' was painted in 1823. About 1815 he began to receive pupils, his first being the Landseers—Edwin, Charles, and Thomas—and his purpose being "to form a school, and to establish a better and more regular system of instruction than even the Academy offered." With many drawbacks he made a good teacher, and some of our best living painters are numbered among his pupils, but he was ill fitted to carry on such an institution with the necessary regularity. He also became connected with Mr. Elmes in the conduct of the 'Annals of the Fine Arts,' and that publication became a vehicle for constant attacks by him on the Royal Academy, and eulogies (probably by Mr. Elmes) on Haydon and his pupils. But the school could not so prosper, the writing brought in no money, and his painting, when not neglected, was not of a kind to find ready patronage. He got deeper and deeper into debt, and became an inmate of the King's Bench prison. Here he found a subject for a successful picture in the 'Mock Election,' which took place within those walls in July 1827. George IV. purchased this work for 500 guineas. Haydon followed up the subject in his 'Chairing the Members,' which was sold for 300 guineas to Mr. Francis of Exeter. He had previously regained his liberty with the assistance of friends. Another picture of the same period was his 'Pharaoh dismissing Moses after the Passover,' for which he obtained 500 guineas from Mr. Hunter, an East India merchant.

Haydon's next subjects, after making an unsuccessful attempt to obtain employment as a portrait painter, were 'The Great Banquet at Guildhall' at the passing of the Reform Bill, and 'Napoleon musing at St. Helena:' the former was considered a failure, but the other met with great success. 'The Duke on the Field of Waterloo' fell far short of this, both in merit and public estimation. Again in 1836 he became a prisoner for debt in the King's Bench, but after a time he was able to effect a settlement with his creditors. He now engaged with great zeal in lecturing on painting at various literary institutions in London and the provinces, and his lectures were everywhere attended with signal success.

The determination of the government to decorate the interior of the new houses of parliament with pictures opened a new and grand field before the imagination of Haydon. He had petitioned, written, and lectured in favour of so adorning our public buildings, and impressed with a very high notion of his own capacity for executing such works, his sanguine temperament never permitted him for a moment to doubt that he would be one of the painters selected for the task. Accordingly, finding that fresco was the vehicle in favor with the authorities, he set himself to acquire mastery over the use of that material, and when the cartoon competition was summoned, he addressed himself eagerly to the preparation of a cartoon. The judges gave in their award, however, and his name was not among the successful competitors, even of the third class. It was a death blow to all his hopes; and though he struggled bravely against the disappointment, he never really recovered the shock. His last works were 'Uriel and Satan;' 'Curtius leaping into the Gulf;' 'Alfred and the Trial by Jury;' 'The Burning of Rome,' and numerous repetitions of his 'Napoleon.' 'Alfred,' and 'The Burning of Rome,' were exhibited in 1846 at the Egyptian Hall. The exhibition failed, and added to the embarrassment of his pecuniary affairs. Haydon's mind now entirely gave way under his misery. He died by his own hand, June 22, 1846. It should be added that a post mortem examination showed that there had been long standing disease of the brain. He left a wife and family, for whom a public subscription was immediately got up. It is not a little to the honour of Sir R. Peel, that, at what was perhaps the most busy and exciting period of his parliamentary career, he had found time just five days before the painter's unhappy death, to think of the artist, to whom he inclosed a cheque for 50*l.* Haydon's 'Lectures' are almost his only contributions to literature. Considerable difference of opinion exists as to his merits as a painter. The exaggeration and hardness, which it must be admitted disfigured his general style, are ascribed to his early intimacy with and imitation of Fuseli, but unjustly; they are Haydon's own, the result partly of insufficient study, partly of incomplete artistic education, more of his peculiar physical temperament, and habit of working. But he had many merits, and he did much to raise the character of English art, and to extend an interest in and a love of it.. For a fair and far from partial review of the character of Haydon as a man and an artist, the reader is referred to the concluding pages of the third volume of Taylor's 'Life of Benjamin Robert Haydon,' 2nd ed., 3 vols., 1853.

HAYESINE. [MINERALOGY, *S.* 1.]

HEAD, SIR GEORGE, Knight, was born in 1722, at the Hermitage, a few miles north from Rochester, in Kent. James Roper Head, father of Sir George Head and Sir Francis Bond Head, was descended from Fernando Mendez, a Jew, who came from Portugal to England, and was physician to King Charles II. The father of James Roper Head, married a daughter of the Rev. Sir Francis Head, Bart., and assumed the name of his wife's father.

George Head spent his early years at his father's residence, the Hermitage, and was afterwards educated at the Charter House School, London. Early in 1808 he obtained a captain's commission in the West Kent Militia, and having obtained leave of absence, in the spring of 1809 went to Portugal, where he accepted the humble situation of a commissariat clerk, and joined the British army under Lord Wellington at Badajoz. He was afterwards appointed to the commissariat charge of a brigade. After Massena had retreated from the lines of Torres Vedras, and the battle of Fuentes d'Onor had been fought, May 5, 1811, he was appointed deputy assistant commissary general, and attached to Sir Brent Spencer's division of the army. In May 1813 he was directed to proceed to Momento da Beira to undertake the commissariat department of the third division under Sir Thomas Picton. He was present at most of the great battles in the Peninsula, as well as the concluding victories in France, after which he returned to England. Of this active period of his life he wrote an interesting narrative, which is attached to his second 'Home Tour.'

In the autumn of 1814 George Head received orders to proceed to Canada, and having landed at Quebec, was sent to Lake Huron to superintend the commissariat department of a naval establishment intended to be formed on the Canadian lakes. Peace however was soon afterwards made with America, and in ten months he was again in England. In 1816 he was sent to Halifax, in Nova Scotia, and remained there five years on the peace establishment. After his return to England he described his experiences and adventures in America in his 'Forest Scenes and Incidents in the Wilds of North America, being a Diary of a Winter's Route from Halifax to the Canadas, and during Four Months' Residence in the Woods on the Borders of Lakes Huron and Simcoe, by George Head, Esq.,' 12mo, London, 1829. In 1831 he received the honour of knighthood. Encouraged by the favourable reception of his 'Forest Scenes,' he published 'A Home Tour through the Manufacturing Districts of England in the Summer of 1835, by Sir George Head,' 12mo, 1836, which was followed by another volume, 'A Home Tour through various parts of the United Kingdom; being a continuation of the Home Tour through the Manufacturing Districts: also Memoirs of an Assistant-Commissary General, by Sir George Head,' 12mo, 1837. The first Tour includes most of the large manufacturing towns of the northern part of England; the second, the Isle of Man, part of Scotland, the Channel Islands, and part of Ireland. They contain a large amount of information carefully collected and clearly stated concerning the places visited and the manufactures carried on in them. Both Tours were reprinted in one volume in 1840. In 1849 he published 'Rome, a Tour of Many Days.' He was also the author of several articles in the 'Quarterly Review,' and translated from the Italian the 'Historical Memoirs of Cardinal Pacca,' 12mo, 1850, and from the Latin, 'The Metamorphoses of Apuleius,' 8vo, 1851. He died in London, May 2, 1855, unmarried.

HEADINGTON. [OXFORDSHIRE.]

HEALTH, PUBLIC. [PUBLIC HEALTH, *S.* 2.]

HEART. One of the most interesting inquiries in connection with the heart is its development, on which considerable light has been thrown by modern research. The circulating system is not perfected until the moment of birth; and in its several transitory stages of growth it resembles permanent forms of the circulating apparatus amongst the lower animals. As the egg of the bird affords the best means of studying these changes, we give an outline of them from Dr. Carpenter's 'Physiology:'—

"At an early period of incubation the yolk is found to be enveloped by a germinal membrane, composed of distinct cells, which is divisible into three layers; and a thickened portion of this is easily distinguishable, at which the embryo will be subsequently evolved.

"The middle layer gives origin to the circulating system, and is therefore termed the 'vascular layer.' The thickened portion of this that surrounds the germ soon becomes studded with numerous irregular points and marks of a dark yellow colour; and as incubation proceeds these points become more apparent, and are gradually elongated into small lines, which are united together, first in small groups, and then into one net-work, so as to form what is called the 'vascular area.' A large dark spot of a similar kind is seen in the situation to be subsequently occupied by the heart. These dark points and lines are formed by collections of blood-corpuscles, which originate in the transformation of the cells of the embryo and of the germinal membrane; and the rows and masses of blood-discs seem at first to lie in mere channels, the walls of the heart and blood-vessels that subsequently inclose them being of later formation.

"From the first however a definite plan is perceptible; the network of capillaries that is formed over the vascular area being supplied with blood by the ramifications of a pair of arterial trunks, whilst the blood is collected from them by the circular venous sinus which bounds the area, and is returned to the embryo by the venous trunk. In the blood-vessels which are first observed in the body of the embryo, as well as in the vascular area, no difference is at first perceived between the characters of the arteries and those of the veins, and these are only to be distinguished by the direction of the currents of blood circulating through them.

"But at about the fourth or fifth day of incubation the coats of the arteries begin to appear thicker than those of the veins, and the distinction between them soon becomes evident. After the principal vessels are formed, the development of new ones appears to take place in two modes, according as they are to occupy the interspaces existing among those previously formed, or are to extend themselves into out-growing parts. In the first of these cases the new capillaries appear to be formed, like the original ones, from stellate cells, whose prolongations meet the vessels in which the blood is already circulating, coalesce with them, and thus receive the current into their own cavities, to transmit it to some other vessel. But in the second, the new vessels are formed entirely by extension from those already existing. This takes place in the following mode:—Suppose a line, or arch, of capillary vessels passing below the edge, or surface, of a part to which new material has been superadded; the vessel will at first present a slight dilatation in one, and coincidently, or shortly after, in another point, as if its walls yielded a little near the edge or surface. The slight pouches thus formed gradually extend, as blind canals, or verticula, from the original vessels still directing their course towards the edge or surface of the new material, and crowded with blood corpuscles, which are pushed into them from the main stream. Still extending, they converge, and meet; the partition wall that is at first formed by the meeting of their closed ends clears away, and a perfect arched tube is formed, through which the blood, diverging from the main or former stream, and then rejoining it, may be continuously propelled. This last process may be seen in the growing parts of the tail of the tadpole, in the development of the filamentous gills and legs of the water-newt, in the first evolution of the extremities of the embryos of higher animals, and in the formation of new structures in the fully-developed organism, either for the repair of injuries or as the result of morbid processes. In some instances it would appear that the wall of the newly-forming vessel gives way, and that the blood-corpuscles escape from it into the parenchyma, at first collecting in an undefined mass, but soon manifesting a definite direction, and coming into connection with another portion of the arch, or with some adjacent vessel. Thus, then, a channel, and not a vessel is formed; and it is probably in this way that those passages are excavated, which take the place of distinct vessels in many of the lower tribes of animals, and also, according to Mr. Paget, in some of the softer and least organised growths in man.

"The first rudiment of the heart appears about the 27th hour, and is a mass of cells, of which the innermost soon break down, so as to form a tubular cavity; for some time it is simple and undivided, extending however through nearly the whole length of the embryo; but the posterior part may be regarded as corresponding with the future auricle, since prolongations may be perceived extending from that part into the transparent area, which indicate the place where the veins subsequently enter. Although the development has proceeded thus far at about the 35th hour, no motion of fluid is seen in the heart or vessels until the 38th or 40th hour. When the heart, which may be considered as analogous at this period to the dorsal vessel of the *Annelida*, first begins to pulsate, it contains only colourless fluid mixed with a few globules. A movement of the dark blood in the circumference of the vascular area is at the same time perceived; but this is independent of the contractions of the heart, and it is not until a subsequent period that such a communication is established between the heart and the distant vessels, that the dark fluid contained in them arrives at the central cavity, and is propelled by its pulsations. This fact which we have just seen to possess a very important bearing on the theory of the circulation, and which has been denied by some observers, appears to have been positively established by the latest researches of M. von Baer.

"The contraction of this dorsal vessel (for so it may be termed) begins, as in the *Annelida*, at its posterior extremity, and gradually extends itself to the anterior; but between the 40th and 50th hours a separation in its parts may be observed, which is effected by a constriction round the middle of the tube; and the dilatation of the posterior portion becomes an auricular sac, and that of the anterior a ventricular cavity. Between the 50th and 60th hours the circulation of the blood in the vascular area becomes more vigorous, and the action of the ventricle is no longer continuous with that of the auricle, but seems to succeed it at a separate period. At the same time the tube of the heart becomes more and more bent together until it is doubled, so that this organ now becomes much shorter relatively to the dimensions of the body, and is more confined to the portion of the trunk to which it is subsequently restricted. The convex side of the curve which the tube presents is that which subsequently becomes the apex or point of the heart, and between the 60th and 70th hours this is seen to project forward from the breast of the embryo, much in the situation it subsequently occupies. About the same time the texture of the auricle differs considerably from that of the ventricle, the auricle containing the thin and membranous walls which it at first possessed; while the ventricle has become stronger and thicker, both its internal and external surfaces being marked by the interlacement of muscular fibres, as in the higher *Mollusca*. About the 65th hour the grade of development of the heart may be regarded as corresponding with that of the fish, the auricle and ventricle being quite distinct, but their cavities are as yet quite single. The heart of the dog at the 21st day bears a great resemblance to that of the chick at the 55th or 60th hour; it consists of a membranous tube twisted on itself, and partially divided into two principal cavities, besides the bulb or dilatation which at this period is found at the commencement of the aorta, and which corresponds with the bulbus arteriosus of fishes.

"Having thus traced the evolution of the heart of the chick up to the grade which it presents in fishes, we may now inquire what is the condition of the other parts of the vascular system at the same time. At the end of the second day the primitive arterial trunk is seen to have divided into two canals, which separate from one another to inclose the pharynx, and then unite again to form the aortic trunk, which passes down the spine. During the first half hour of the third day a second pair of arches is formed, which encompasses the pharynx in the same manner; and towards the end of the third day two other pairs of vascular arches are formed, so that the pharynx is now encompassed by four pairs of vessels, which unite again to supply the general circulation. These evidently correspond with the branchial arteries of fishes, although no respiratory apparatus is connected with them; and in fact the distribution of the vascular system of the bird on the fourth and fifth days exactly resembles that presented by many cartilaginous fishes, as well as by the tadpoles of the *Batrachia*. The first pair of arches is obliterated about the end of the fourth day, but a pair of vessels which is sent from it to the head and neighbouring parts, and which afterwards remains as the carotid arteries, continues to be supplied through a communicating vessel from the second arch. While the first pair is being obliterated a fifth is formed behind the four which had previously existed, and proceeds in the same manner as the fourth from the ascending to the descending aorta. On the fourth day the second arch also becomes less, and on the fifth day is wholly obliterated, whilst the third and fourth become stronger. From the third arch, now the most anterior of those remaining, the arteries are given off which supply the upper extremities: and the vessels of the head are now brought into connection with it by means of the communicating branches, which previously joined the third with the second arch. When these vessels are fully developed, the branches by which these arches formerly sent their blood into the aorta shrink and gradually disappear; so that about the thirteenth or fourteenth day the whole of the blood sent through the two anterior arches is carried to the head and upper extremities, instead of being transmitted to the descending aorta as before. There now only remain the fourth and fifth pair of branchial arches, the development of which into the aorta and pulmonary arteries will be described in connection with the changes which are at the same time going on in the heart. During the fourth day the cavities of the heart begin to be divided for the separation of the right and left auricles and ventricles. About the 80th hour the commencement of the division of the auricle is indicated externally by the appearance of a dark line on the upper part of its wall, and this after a few hours is perceived to be due to a contraction which, increasing downwards across the cavity, divides it into two nearly spherical sacs. Of these the right is at first much the larger, and receives the great systemic veins; the left has then the aspect of a mere appendage to the right, but it subsequently receives the veins from the lungs when these organs are developed, and attains an increased size. The septum between the auricles is by no means completed at once: a large aperture (which subsequently becomes the foramen ovale) exists for some time at its lower part, so that the ventricle continues to communicate freely with both auricles. This passage is often closed by the prolongation of a valvular fold, which meets it in the opposite direction; it remains pervious however until the animal begins to respire by the lungs, and sometimes is not completely obliterated even then. The division of the ventricle commences some time before that of the auricle, and is effected by a sort of duplicature of its wall, forming a fissure on its exterior and a projection on its interior; and thus a septum is gradually developed within the cavity, which progressively acquires firmness, and rises higher up, until it reaches the entrance to the bulb of the aorta, where some communication exists for a day or two longer. At last however the division is complete, and the inter-ventricular septum becomes continuous with the inter-auricular, so that the heart may be regarded as completely a double organ. The progressive stages presented in the development of this septum are evidently analogous to its permanent conditions in the various species of reptiles; but it must not be lost sight of that in all reptiles the inter-auricular septum is first developed, and that it is completely formed in many instances in which the inter-ventricular septum is absent or imperfect. The changes which occur in the heart of the *Mammalia* are of a precisely similar character, and as they take place more slowly they may be watched with greater precision. Soon after the septum of the ventricles begins to be formed in the interior a corresponding notch appears on the exterior, which as it gradually deepens renders the apex of the heart double. This notch between the right and left ventricles continues to become deeper until about the eighth week in the human embryo, when the two ventricles are quite separated from one another except at their bases; this fact is very interesting from its relation with the similar permanent form of the Dugong. At this period the internal septum is still imperfect, so that the ventricular cavities communicate with each other, as in the chick on the fourth day. After the eighth week however the septum is complete, so that the cavities are entirely insulated; whilst at the same time their external walls become more connected towards their bases, and the notch between them is diminished; and at the end of the third month the ventricles are very little separated from one another, though the place where the notch previously existed is still strongly marked."

We may now finally trace the distribution of the arterial trunks to their final modifications, by which the creature is enabled to become an air-breathing animal. The first, second, and third branchial arches are replaced by the brachial and carotid arteries, and lose all communication with the primitive arterial trunk except at its commencement, when the third pair of arches arises with the other trunks from its dilated bulb. This remains as a single cavity even after the ventricles have been separated. About the fifth or sixth day the bulb in the chick becomes flattened, and its opposite sides adhere together, so as to form two tubes running side by side; one of which unites with the left, the other with the right ventricle. The one on the left becomes the ascending aorta, that on the right the pulmonary artery.

A knowledge of the changes which go on in the development of the heart enables us to explain some of the malformations to which it is subject.

(Carpenter, *Principles of Physiology, General and Comparative.*)

HEATHER. [Erica.]

HEIMIA, a genus of Plants belonging to the natural order *Lythraceæ*. It has a hemispherical campanulate calyx, bracteolated at the base, with six erect lobes and as many alternating horn-shaped patent angles; petals 6, alternate with erect lobes; stamens 12, somewhat equal; ovary sessile, nearly globose, 4-celled; capsule included within the calyx; seeds numerous, minute, and wingless. Glabrous herbaceous plants. Peduncles 1-flowered, shorter than the calyx.

H. salicifolia is found in New Spain on the volcano of Jorullo. It has ternate or opposite leaves, the upper often alternate, on very short stalks, lanceolate, acute, narrowed to the base. The petals are obovate. It is a powerful sudorific and diuretic. The Mexicans consider it a valuable medicine, and call it Hanchinol.

HEINE, HEINRICH, was born on the 1st of January, 1800, at Düsseldorf, in the Prussian Rhine-Province, of Jewish parents. His father was a merchant. He was educated at the Lyceum at Düsseldorf, and as he was intended for the mercantile profession, he was sent in 1816 to Hamburg, to receive the necessary instruction and training. He remained there till 1819, when his father, as well as his uncle, Salomon Heine, a banker in Hamburg, acquiesced in his wish to be educated for a literary profession, and in the summer of that year he was sent to the university of Bonn, in order to study jurisprudence. In 1820 he went to Göttingen, but soon left it, and in 1821 removed to Berlin, where, in 1822, he published the first collection of his poems, 'Gedichte, von Heinrich Heine,' 12mo. Some of the earliest of these productions date as far back as 1816, and several of them had previously appeared in the periodical called 'Der Wachter' at Hamburg. He travelled in Poland in 1822, and after his return to Berlin published his remarks in the 'Gesellschafter.' In 1823 he published his tragedy of 'Almansor,' together with a one-act tragedy named 'William Radcliff,' and a 'Lyrisches Intermezzo.' While he remained at Berlin he also published in 'Der Sprecher' a series of letters under the head of 'Briefe aus Berlin,' which attracted much attention. In 1823 he returned to Göttingen, and resumed his studies in jurisprudence. On the 30th of July, 1825, he took a degree in law, and then proceeded to Hamburg, for the purpose of establishing himself there as an advocate. The practice of the law however seems to have been as little suited to the character of his mind, now developing itself, as the pursuits of trade. He appears about this time to have renounced the religion of his ancestors for that of the New Testament, in the Lutheran form, but afterwards became an unbeliever. While at Göttingen, in 1824, he had made a tour in the Harz Mountains, of which he published an account at Hamburg, 'Die Harzreise,' 1826. He afterwards made tours to the islands of the Baltic, to England, to South Germany, and to Italy, and wrote a descriptive account of each. The whole of these, including the 'Harzreise,' were published at Hamburg under the title of 'Reisebilder,' vols. 1-2 in 1826-27, and vols. 3-4 in 1830-31. These works he himself many years afterwards translated into French under the title of 'Impressions de Voyages.' In 1827 he published at Hamburg another volume of short poems, the 'Buch der Lieder,' and about the same period his poem of 'Alta Troll, ein Sommernachtstraum.' After his return from England he was employed at Stuttgart as the editor of the 'Neue Politischen Annalen.' He also wrote for the 'Morgenblatt,' and the 'Augsburger Zeitung,' and of the latter he became afterwards the Paris correspondent.

In 1831 Heine removed to Paris, where he continued to reside during the remainder of his life. In this year he published his series of letters 'On Nobility' ('Ueber den Adel'), Hamburg, 1831. In 1833 appeared his essays on modern literature in Germany, 'Zur Geschichte der Neueren Schönen Literatur in Deutschland,' 12mo, Paris and Leipzig, and his remarks on the state of France, 'Französische Zustände,' 12mo, Hamburg, which is a collection of articles previously published in the 'Augsburg Gazette.' 'Der Salon,' one of the most important of his prose works, was published at Hamburg, in 4 vols. 8vo, 1834-40. About this period he married a Frenchwoman, who was a Roman Catholic, and married her according to the Roman Catholic ritual. His observations on the 'Romantic School' ('Die Romantische Schule') appeared in 1836 at Hamburg. In 1840 he published his bitter personal attack on Börne, with whom he had become acquainted when he went to Paris in 1831, 'Ueber Ludwig Börne,' 8vo, Hamburg.

In the winter of 1843-44, Heine visited Germany for the last time. After his return to Paris he published his 'Deutschland, ein Wintermärchen' ('Winter's Tale'), which is a description of his journey. In 1847 he experienced an attack of paralysis, which deprived him of the sight of one eye; in other respects he recovered, but another attack in 1848 deprived him of the sight of the other eye also, and subjected him likewise to extreme bodily suffering, without at all injuring his mental faculties. He never afterwards left his chamber, but continued his literary labours by the aid of an amanuensis, with a cheerful resignation which was only interrupted occasionally by the severity of his sufferings. His latest poetical productions were the 'Romancero,' written in 1850-51; 'Das Buch des Lazarus,' written in 1854, and 'Neuer Frühling' ('New Spring'), written in 1855. In July 1855 he published at Paris, in the 'Bibliothèque Contemporaine,' a translation of his poems into French prose, under the title of 'Poëmes et Legendes, par Henri Heine.' The translations were made under his own supervision by his friend, the late Gérard de Nerval. A similar translation of the 'Neuer Frühling' appeared in the 'Révue des Deux Mondes,' vol. xi., 1855. His state of bodily suffering, during which he was dutifully attended by Madame Heine, was terminated by his death, on the 17th of February, 1856.

Soon after Heine's death, his brother, Dr. Gustav Heine, of Vienna, communicated to the 'Fremdenblatt' of that city some particulars of his last moments, together with the seventh clause of his will, in which he says, "Though I belong to the Lutheran confession, I do not desire to be followed to the grave by any clergyman of that denomination, and I wish to dispense with any other sacred solemnity at my burial. This is not the weak fancy of a freethinker. For the last four years I have cast aside all philosophical pride, and have again felt the power of religious truth." He regrets having so often spoken of sacred subjects in a disrespectful manner, and implores "forgiveness for any offence which in his ignorance he may have given to good manners and morals, which are the true emanations of all faith."

Heine wrote French with apparently as much facility as his native language, and was a contributor to the periodicals of Paris as well as to those of Germany. His prose-works are distinguished by great brilliancy of style and vividness of imagination, but are too often pervaded by a spirit of sarcasm which has no respect for persons, and are frequently traversed by veins of mockery which touch the most sacred subjects. His poems are distinguished by originality, freshness of feeling, fine fancy, and extraordinary beauty of versification, and will probably endure long after his prose, from its want of sincerity, has fallen into comparative neglect. The best as well as the most recent translation of his smaller poems is 'Heinrich Heine's Book of Songs, a Translation by John E. Wallis,' 12mo, London, 1856.

HEISTERIA. [PARTRIDGE-WOOD.]

HELICINE. [CHEMISTRY, *S.* 2.]

HELIGOLAND. [HELGOLAND.]

HELIOTROPE. [BLOODSTONE. *S.* 2.]

HELLENINE. [CHEMISTRY, *S.* 2.]

HELMINTHIA, a genus of plants belonging to the natural order *Compositæ*, to the sub-order *Cichoraceæ*, and the section *Scorzonereæ*. It has the phyllaries in one row, equal, with equal subulate adpressed ones at the base, and surrounded by 3-5 leaf-like loose bracts; the receptacle dotted; the fruit compressed, transversely rugose, rounded at the end, and with a slender beak longer than itself; pappus in several rows, feathery. There is but one species inhabiting Great Britain, *H. echioides*, the Ox-Tongue. It is a plant from 2 to 3 feet in height; the branches, stem, leaves, and involucre are covered with strong prickles springing from white tubercles, and with 3 minute hooks at the apex. It is found on dry banks; and blossoms in July, August, and September.

HELVELLACEÆ (Lindley), a natural order of Plants belonging to the *Fungales*, and equivalent to Berkeley's order *Ascomycetes*. The genera included in it are embraced in Fries' cohort *Hymenomycetes*.

HELWINGIACEÆ, *Helwingiads*, an order of Diclinous Exogenous Plants, represented by one species, *Helwingia Rusciflora*. This plant is a native of Japan, where its young leaves are eaten. It is a shrub with alternate stipulate leaves, and fascicled flowers. Decaisne, who first constituted the order, regarded it as allied to *Hamamelidaceæ*. But its minute embryo and unisexual flowers remove it far from this order, whilst its inferior fruit and seed bring it near to *Garryaceæ*. It has an indirect affinity also with *Santalaceæ*.

HEMATOSIN. [CHEMISTRY, *S.* 1.]

HEMEROCALLIS, a genus of Plants belonging to the natural order *Liliaceæ*. It has a campanulate corolla, seated on a cylindrical tube; the stamens are bent down; the capsule is 3-edged; the root is composed of thick fibres; the leaves are scattered, linear; the flowers are large, yellow, or yellow-brown. The species are called Day-Lilies. *H. flava* is a native of Germany, and *H. fulva* of Italy. Several species are cultivated in our gardens, as *H. disticha* from China, *H. Sieboldii* from Japan, *H. speciosa*, and *H. graminea*.

HEMIPINIC ACID. [CHEMISTRY, *S.* 1.]

HEMIRAMPHUS. [ESOX, *S.* 1.]

HENIOCHUS. [CHÆTODON.]

HERAT. [PERSIA.]

HERBARIUM, the name given to specimens of Plants when they have been collected and dried. The possession of an herbarium is almost essential to the study of systematic Botany, as it is impossible to cultivate at once the larger proportion of the species of plants which inhabit the earth's surface. The use also of an herbarium will be found constantly to supply the place of recent plants. Hence all persons who study botany possess themselves of an herbarium more or less extensive according to the range and nature of their studies. The following hints for forming an herbarium are chiefly derived from Professor Balfour's valuable 'Class-Book of Botany:'—

The specimens to be dried and kept in the herbarium should, if possible, be gathered in fine weather, and free from external moisture. In selecting them care should be taken to have the plants in a perfect state of growth, with all the parts from which the characters of the order, genus, or species, are taken. The entire plant, where practicable, should be preserved. Of course this is impossible with trees, but the completer the specimens the better for study. In trees, portions of the branches, with the leaves, flowers, and fruit, should be taken, and, where possible, sections or small portions of the stem, roots, &c. In the case of tall and slender grasses and sedges, they may be folded once or twice backwards and forwards, to make room for them on a single sheet. Thick branches, roots, stems, &c., may be split to allow of pressure. In plants with diœcious flowers, both the staminiferous and pistiliferous flowers should be obtained. Some plants, as species of the genus *Rubus* and *Salix*, demand that both flowering and leafing shoots should be gathered. In glueing the plants on to the paper, care must be taken to expose both sides, so that all parts of the structure may be seen. Careful dissections of plants may be dried and fastened on to paper, and these will facilitate subsequent examination very much. All bad, doubtful, injured, or imperfect specimens should be rejected.

In collecting plants a trowel will be found useful, and when gathered they should be placed in a tin box or vasculum till they are transferred to paper. Some plants require drying or pressure immediately. Under these circumstances, Dr. Balfour recommends a field-book, consisting of some bibulous paper strapped between two pieces of board, into which the plants needing drying may be thrust at once.

The paper employed may be ordinary blotting-paper, but the paper-makers have made a paper for botanical use which may be more advantageously employed. In London, Bentall's drying-paper is used; there is also another paper used in Scotland, called the 'Edinburgh botanical drying-paper.' It is made in sheets 18 inches long and 11 inches broad. This paper is included between boards. These should be exactly the size of the drying-paper. Several sets of boards of varying thicknesses should be employed, and pressure may be applied by means of a weight or straps. The latter is the most easy process whilst travelling. In order that the plants may dry freely, various suggestions have been made for making holes in the boards or forming them of a kind of framework, by which the air would pass through.

In putting down the plants the following plan should be pursued:—"A parcel of not less than four sheets of paper is put on one of the outside boards, then one or more specimens are laid on this sheet according to their size. The specimens should be spread out carefully, their natural habit being preserved as far as possible. When plants require to be folded, the slips of paper already mentioned are passed over the bent portions so as to retain them in their position. Having placed one specimen or set of specimens on the sheet, another parcel of not less than four sheets is laid over them; and in doing this the leaves and other parts are arranged with the hand or the forceps. The same process is repeated until a dozen or more such parcels have been arranged one over the other. Then a thin board is inserted, and other parcels of paper and specimens are arranged above it, until they are exhausted, or until the bundle is of sufficient size. Another such board is then laid on the top, and the whole is subjected to pressure. The paper is changed after twelve hours' pressure, the plants being lifted by means of the forceps and placed in dry parcels of paper, while that which is moist is hung up to dry. The intervals between the changing of the paper may be increased or diminished according to circumstances." Very succulent and wet plants require frequent changing and much drying. Most specimens will dry in eight or ten days. Succulent plants need to be killed first by immersion in boiling water. Aquatic plants and wet plants should be placed in a napkin and pressed before they are put into the paper. The moist paper will dry in ten or twelve hours. Along with the plant a label should be inserted, with all particulars known about the specimen, as where gathered, what elevation, &c.

When the specimens are thoroughly dry a selection is made for the herbarium. These should be fastened by means of thin fine glue on thick wide paper, 17 inches long and 10½ inches broad. The name of the plant, its locality, or any other particulars, may be then written on the paper. In order to preserve the specimens from the attacks of insects, &c., they should be touched with a strong solution of corrosive sublimate in camphorated spirit, or in a solution of naphtha (half a drachm to the ounce). The sheets may then be arranged in a case, according to their genera or natural orders.

Fruits, specimens of wood and bark, large roots, lichens and algæ on rocks and stones, may be arranged in drawers, glazed cases, or glass jars. Succulent fruits and roots are best preserved in a strong solution of salt and water, or in pyroligneous acid, diluted with 3-5 parts of water, or in alcohol. In some instances a solution of 4 ounces of bay salt, 2 ounces of burnt alum, and 5 grains of corrosive sublimate, in 2 quarts of boiling water, has been used with advantage. These jars are best covered with a stout piece of caoutchouc tied round the neck.

HERMASIA, a genus of Plants belonging to the natural order *Paronychiaceæ*. It has 5 sepals; 5 filiform petals inserted with the 5 stamens on a perigynous ring; 2 stigmas nearly sessile; fruit 1-seeded, indehiscent, membranaceous; leaves opposite. These species are insignificant plants. Three have been recorded as natives of Great Britain. One, *H. hirsuta*, is a doubtful native; the other two are very rare.

H. glabra has a prostrate herbaceous stem, with clusters of sessile flowers coalescing on the lateral branches into a slightly leafy spike. It has been found in Suffolk and Lincolnshire in England, and in West Kerry, Ireland.

H. ciliata. The sepals are tipped with a large bristle; the clusters of flowers are distinct, sessile, and axillary. It has been found at Lizard Point, Cornwall.

HERMINIUM, a genus of Plants belonging to the natural order *Orchidaceæ* and the tribe *Ophrydineæ*. The perianth is bell-shaped, segments all erect; lip 3-lobed, tumid beneath at the base, without a spur; glands of the stalks of the pollen-masses exserted, naked. *H. monorchis*, the Musk-Orchis, is a British species. The stem is about six inches high, and the spike of flowers is dense and slender; the sepals are ovate and greenish.

HERNE BAY. [Kent.]

HERNSHAW, or HERONSHAW, a name for the Common Heron. [Herons.]

HERON'S BILL. [Erodium, *S.* 1.]

HERRERITE. [Mineralogy, *S.* 1.]

HERSCHEL, CAROLINE LUCRETIA, the sister of the great astronomer Sir William Herschel, was born at Hanover on the 16th of March, 1750. Till her twenty-second year she lived with her parents in her native place; after which she came over to England to reside with her brother, then established as an organist at Bath. When Sir William exchanged his profession as a musician for those astronomical labours which were to immortalise his name, his sister became his constant and most valuable helpmate. "From the first commencement of his astronomical pursuits," says an authority who writes from intimate knowledge, "her attendance on both his daily labours and nightly watches was put in requisition, and was found so useful that, on his removal to Datchet and subsequently to Slough, she performed the whole of the arduous and important duties of his astronomical assistant—not only reading the clocks and noting down all the observations from dictation, as an amanuensis, but subsequently executing the whole of the extensive and laborious numerical calculations necessary to render them available for the purposes of science, as well as a multitude of others relative to the various objects of theoretical and experimental inquiry in which, during his long and active career, he was at any time engaged." For these important services she was in receipt of a moderate salary allowed her by George III. But, in addition to these labours performed expressly as her brother's assistant and amanuensis, she found time to perform others of a similar character on her own account. Though sitting up frequently all night till day-break, more especially in winter, while her brother required her help, she was able, by snatching such intervals of time as her brother's occasional absences permitted, to conduct a series of observations of her own with a small Newtonian telescope, which he had constructed for her. Her special employment with this instrument was to sweep the heavens for comets; and so successful was she in this employment that she discovered seven comets, of at least five of which she was entitled to claim a clear priority of discovery. The dates of the discoveries of the seven comets were as follows:—August 1, 1786; December 21, 1788; January 9, 1790; December 15, 1791; October 7, 1793; November 7, 1795; August 6, 1797. Besides the discovery of these comets, she had the merit of having made original observations of several remarkable nebulæ and clusters of stars, included in her brother's catalogues. In 1798 she published, with an introduction by her brother, an astronomical work of great value, entitled 'Catalogue of Stars taken from Mr. Flamsteed's Observations, contained in the second volume of the Historia Cœlestis, and not inserted in the British Catalogue, with an Index to point out every observation in that volume belonging to the stars of the British Catalogue: to which is added a collection of Errata that should be noticed in the same volume.' In this work, which was published at the expense of the Royal Society, no fewer than 561 stars observed by Flamsteed, but which had escaped the notice of the framers of the 'British Catalogue,' were pointed out. During the whole of her brother's career Miss Herschell remained by his side, aiding him and modestly sharing the reflection of his fame. After his death, in 1822, she returned to her native Hanover to spend the remainder of her days. They were unusually protracted; for, though she was seventy-two years of age when she left England, she lived for twenty-six years longer. Even these venerable years were not spent idly. In 1828 she completed a catalogue of the nebulæ and clusters of stars observed by her brother, for which labour the Astronomical Society of London voted her their gold medal. She was also chosen an honorary member of that Society—an honour very unusual in such a case. Living in dignity and tranquillity, retaining her memory and the full use of her faculties almost to the last, and receiving from time to time marks of the highest respect from the king and crown-prince of Hanover and from other German sovereigns, she survived till the 9th of January, 1848, when she died in her ninety-eighth year. Among the female examples of the pursuit of knowledge, very few names deserve so high a place as that of Caroline Herschel.

HILL, ROWLAND, VISCOUNT, was born on the 11th of August, 1772, at the village of Prees in Shropshire, where his father, John Hill, Esq., resided till the death of his brother, Sir Richard Hill, Bart., when he succeeded to the title, and removed to the family mansion and estate at Hawkstone in Shropshire. Sir John Hill had sixteen sons and daughters, of whom Rowland Hill was the second son and fourth child, and was a nephew of the Rev. Rowland Hill, the celebrated preacher. He was educated in his native county, where he remained till 1790, when he entered the army as an ensign in the 38th regiment of foot. Having obtained leave of absence, he went to a military academy at Strasbourg, where he remained till January 24, 1791, when he was appointed lieutenant in an independent company under Captain Broughton. On the 16th of March, in the same year, he was appointed lieutenant in the 53rd, or Shropshire regiment of foot. He went again to pursue his military studies at Strasbourg, but returned to England at the end of the summer, joined his regiment at Edinburgh January 18, 1792, and remained in Scotland till the end of that year. In the early part of the year 1793 he raised an independent company, for which service he received his commission as captain on the 23rd of March. He took his company to Ireland, delivered the men over to the 38th regiment, and returned to Shropshire in June. Lord Hood having taken Toulon from the French in August 1793, Captain Hill, before he was attached to any particular corps, was employed there as aide-de-camp to three successive generals, Lord Mulgrave, General O'Hara, and Sir David Dundas. On the 13th of December, 1793, Lord Hood and Sir David Dundas appointed him the bearer of despatches to England, where he arrived on the 14th of January, 1794. In the early part of that year Mr. Graham (afterwards Sir Thomas Graham, and subsequently Lord Lynedoch) having raised a regiment of infantry, offered Captain Hill the rank of major in it, on the condition of his supplying a certain quota of men, which he did. This regiment was the 90th, with which he was destined to win so many honours. It was afterwards augmented to 1000 men, and he was promoted to the rank of lieutenant-colonel. On the 1st of January, 1800, he was advanced to the rank of colonel.

Colonel Hill went through arduous duties with his regiment at Gibraltar and elsewhere, till, on the 8th of March 1801, he landed with his regiment at Alexandria in Egypt, as part of the army under Sir Ralph Abercromby. He received a wound on the temple in the action of March 13, 1801. After the defeat of the French he returned to England, where he arrived on the 1st of April 1802. He performed regimental duty in England and Ireland till 1805, when he accompanied the expedition to the river Weser in Germany, but was again in England at the end of January 1806, in which year he was promoted to the rank of major-general, and appointed on the staff.

In 1808, when he was on duty in Ireland, he received an order to join the army of Sir Arthur Wellesley in Portugal. He landed his troops successfully in Montego Bay, August 1st to 5th, and served under Sir Arthur Wellesley till the French evacuated Portugal, according to the terms of the so-called convention of Cintra. He afterwards served with his regiment under Sir John Moore in the latter part of 1808, till the battle of Coruña, January 16, 1809, when he returned with the shattered remains of the army to England.

After a short stay in England, Major-General Hill, in 1809, re-embarked for Portugal, in command of the troops ordered from Ireland for the next expedition, and was promoted to the rank of lieutenant-general. He served under Sir Arthur Wellesley till the 6th of February 1811, when he was compelled by illness to come to England. In May 1811 he was again in Portugal. In March 1812 he was invested by Lord Wellington with the insignia of the Order of the Bath, which had been sent over for that purpose by the Secretary of State. He received a slight wound on the head at the battle of Talavera, and received the thanks of both houses of parliament for his services in that action, as he did on other occasions afterwards. He continued to serve in the Peninsular War till it terminated with the battle of Toulouse. After his return to England Sir Rowland Hill was created, in May 1814, Baron of Almarez and of Hawkstone, with 2000*l.* a-year to himself and his heirs male. The honour was regranted to him in 1816, as Baron of Almarez and Hardwicke, with remainder, in default of male issue, to the issue male of his deceased elder brother.

On the return of Napoleon I. from Elba, in March 1815, Lord Hill was appointed to a command in the Netherlands and was engaged at the battle of Waterloo. On the restoration of Louis XVIII., he was appointed second in command of the army of occupation in France, and remained there till the evacution of the country by the allied armies.

In the year 1828 Lord Hill was appointed the General Commanding in Chief of the Army—an office which he filled with universal approbation till the declining state of his health compelled him to send in his resignation. He was then raised to the dignity of Viscount, September 3, 1842, with remainder to his nephew, Sir Rowland Hill, Bart., who is now the second Viscount Hill. He died December 10, 1842, at his residence, Hardwicke Grange, near Shrewsbury.

A column in honour of Lord Hill, erected by subscription after the termination of the Peninsular War, forms a conspicuous ornament of the town of Shrewsbury.

HINCKLEY. [LEICESTERSHIRE.]

HINDON. [WILTSHIRE.]

HINDUSTAN, [INDIAN EMPIRE, *S.* 2.]

HIPPOBOSCIDÆ, a family of Dipterous Insects belonging to the section *Pupipara* or order *Homaloptera*, containing the Forest-Flies, which exhibit such remarkable variations in their typical structure that they have been regarded by some authors as forming a distinct order. The head is received into a cavity in front of the thorax; it is divided transversely into two parts, the anterior or smaller of which supports the mouth and two small tubercles, almost imbedded at the lateral angles, being rudimental antennæ. The mouth is composed of two curved setæ, inclosed in a tubular canal, covered by two narrow elongated coriaceous plates, regarded by Latreille as palpi. The ocelli are wanting. The body is short, flat, and very coriaceous; the wings are either large or entirely wanting; the nervures of the anterior margin are very strong but they are effaced behind. In the winged species a pair of balancers are also present. The legs are very strong, and terminated by robust curved claws, which are toothed beneath. The abdomen is composed of a continuous leathery-like membrane, capable of very great distension, which peculiarity is owing to the remarkable circumstance that the young of these insects are singly nourished within the body of the parent, where they not only acquire their full size, but actually assume the pupa state, under which form, like very large eggs, they are deposited by the female. This egg-like cocoon is at first soft and white, nearly as large as the abdomen of the parent fly; but by degrees it hardens, becomes brown, of a rounded form, and often notched at one end, which is covered by a shining kind of cap, which is detached on the insect's assuming the perfect state. This cocoon is moreover entirely destitute of annular incisions, in which respect it differs from those of other Dipterous Insects. It is composed of the uncast skin of the larva, beneath which the insect becomes a real inactive pupa, with the limbs of the perfect insect laid along the breast, as in other species which undergo the strict coarctate species of transformation. M. Réaumur was the first to discover these curious particulars and he was so anxious to observe the development of the insect from these singular eggs, that he carried them in his pocket by day and took them to bed with him at night, in order that they might have a uniform degree of warmth; great was his surprise therefore when, instead of grubs as he expected, perfect flies were produced.

These insects are interesting in their habits. They live exclusively upon quadrupeds and birds; the horse is especially subject to the attacks of one of these species, hence called *Hippobosca equina*. This species is the type of the genus *Hippobosca*, in which the eyes are large and distinct, being placed at the sides of the head; the antennæ are in the shape of tubercles with three dorsal setæ: the wings are large. Mr. Curtis observes that these flies move swiftly, and like a crab, sideways or backwards; they are very tenacious of life, and live principally on horses, attaching themselves to the belly between the hind thighs and under the tail, where they are less protected by hair. It is remarked by Latreille that the ass fears them most, and that horses suffer very little from them. In the New Forest they abound in a most astonishing degree. Mr. Samonelle says, "From the flanks of one horse I have obtained six handsful, which consisted of upwards of a hundred specimens. They abound most on white and light-coloured horses."

The other genera are:—*Ornithomyia*, *Craterina*, *Oxypterum*, *Hæmobora*, *Melophagus*, *Feronia*, *Lipotepna*, and probably *Braula*. Of these the first three are British, and are found upon various birds, the *Craterina hirundinis* depositing its eggs like a cocoon in the nest of the swallow, where it receives all the necessary warmth; for which it repays the poor swallow by sucking its blood. The wings in this genus are very long and narrow. The genus *Melophagus* comprises a single species, *M. ovinus*, which is destitute of wings, and attacks the sheep. It is of a dark reddish colour, with the abdomen whitish. It is commonly called the Sheep-Louse, and is so tenacious of life that Ray states that it will exist in a fleece twelve months after it is shorn, its excrements even giving a tinge to the wool, which is very difficult to be discharged.

HIPPURIC ACID. [CHEMISTRY, *S.* 2.]

HIRCUS. [GOAT.]

HISTOLOGY (ἱστος and λογὁς), that department of science which embraces the facts relating to the ultimate structure of the parts of plants and animals. These facts have been usually comprehended under the term General Anatomy. But more recently it has been found convenient to use the term Histology. It is only recently that this word could be needed, for the observations upon which the science is founded have only been made since the extensive employment of the microscope. It may be said to have originated with Marcellus Malpighi (1628-94) and Anton von Leeuwenhoek (1622-1723) at the time when magnifying glasses were first constructed of such a kind as to be useful in observing the structure of plants and animals. The ultimate composition of organised bodies was unknown to ancient observers, as well as those who lived in the middle ages. It is true that Aristotle and Galen speak of homogeneous and heterogeneous parts of the body; and Fallopius, at the beginning of the 16th century, defined still more accurately the idea of what are now called the tissues of the body, yet the more minute structure of these parts was entirely hidden from these observers. Even after the time of Malpighi and Leeuwenhoek little was done towards unravelling the intimate structure of the tissues till the beginning of the present century. We can only poiut to such men as Fontana, Muys, Lieberkühn, Hewson, and Prochaska, as having engaged in isolated observations npon the structure of various parts of the body. It was not till the year 1801 that a connected view of the tissues of the human hody was given to the world, iu such a form as to lay the foundations of what is now called the science of Histology. The 'Anatomie Generale' (Paris 1801) of Bichat was in fact the first attempt to treat the suhject of Histology scientifically. It was not so much that Bichat contrihuted new observations on this suhject, as that he systematically arranged what had hitherto been done, and called attention to the importance of the suhject, and to the fact that it lay at the foundation of all physiological and pathological inquiries.

In the direction of botany, the present century witnessed the observations of Robert Brown, who was the first to draw the attention of hotanists to the importance of minute observations on the tissues of plants. One of the earliest attempts at a systematic arrangement of the tissnes of plants was made hy Slack, in the 39th volume of the 'Transactions of the Society of Arts,' in a paper on the Elementary Tissues of Plants and on Vegetable Circnlation. Observations upon the cellular and vascular structure of plants multiplied, and a greater valne and interest was given to these than they had before possessed by the observations of Schleiden on the origin and development of the cells of plants in his paper on Phytogenesis, pnhlished in Müller's 'Archiv fur Anatomie und Physiologie,' Part ii. 1838. He here pointed out, that in the formation of vegetahle cells, small sharply-defined granules are first generated in a granulous substance, and around them the cell-nuclei (cytoblasts) are fonnd, which appear like granulons coagulations around the granules.

The results of these observations were communicated in 1837 to Schwann, who, struck with the resemblance between the cells of animals and those of plants, conceived the idea that the same history of development would he found true of the parts of animals that had heen discovered hy Schleiden in the parts of plants. From this time the science of Histology made rapid progress, and we cannot more appropriately present its present condition than in the language of Professor Kölliker, in his introdnction to his 'Manual of Human Histology:'—

"In the year 1838 in fact the demonstration by Dr. Th. Schwann of the originally perfectly identical cellular composition of all animal organisms, and of the origin of their higher structures from these elements, afforded the appropriate conception which nnited all previous ohservations, and afforded a clue for further investigations. If Bichat founded Histology more theoretically by constructing a system and carrying it out logically, Schwann has hy his investigations afforded a basis of facts, and has thus won the second laurels in this field. What has been done in this science since Schwann has heen indeed of great importance to physiology and medicine, and in fact of great valne in a purely scientific point of view, inasmuch as a great deal which Schwann only indicated or shortly adverted to, as the genesis of the cell, the import of the nnclens, the development of the higher tissues, their chemical relations, &c., has received a further development, but all this has not amounted to a step so greatly in advance as to constitnte a new epoch. If, withont pretensions to prescience, it be permitted to speak of the future, this condition of Histology will last as long as no essential advance is made towards penetrating more deeply into organic structnre, and becoming acquainted with those elements of which that which we at present hold to he simple is composed. If it be possible that the molecnles which constitute cell-memhranes, muscular fihrils, axile fibre of nerves, &c., should he discovered, and the laws of their apposition and of the alterations which th-y undergo in the course of the origin, the growth and the activity of the present so-called elementary parts, shonld he made out, then a new era will commence for Histology, and the discoverer of the law of cell-genesis, or of a molecular theory, will be as mnch or more celebrated than the originator of the doctrine of the composition of all animal tissues out of cells.

"In characterising the present position of Histology and of its objects, we must by no means forget that, properly speaking, it considers only one of the three aspects which the elementary parts present to observation, namely, their form.

"Microscopical anatomy is concerned with the understanding of the microscopic forms, and with the laws of their structure and development, not with any general doctrine of the elementary parts.

"Composition and function are only involved so far as they relate to the origin of forms and to their variety.

"Whatever else respecting the activity of the perfect elements and their chemical relations is to be found in Histology, is there either on practical grounds, in order to give some nseful application of the morphological conditions, or to complete them, as, from its intimate alliance with the suhject, it is added only hecause physiology proper does not afford a dne place for the functions of the elementary parts.

"If Histology is to attain the rank of a science, its first need is to have as hroad and certain an objective basis as possihle. To this end the minuter structural characters of animal organisms are to be examined on all sides, and not only in fully-formed structures, but in all the earlier periods from their first development.

"Wheu the morphological elements have heen perfectly made out, the next ohject is to discover the laws according to which they arise, wherein one must not fail to have regard also to their relations of composition and function. In discovering these laws, here as in the experimental sciences generally, continual ohservation separates more and more, among the collective mass of scattered facts and observations, the occasional from the constant, the accidental from the essential, till at last a series of more and more general expressions of the facts arises, from which in the end mathematical expressions or formulæ proceed, and thus the laws are ennmerated.

"If we inquire how far Histology has satisfied these requirements, and what are its prospects in the immediate future, the answer must be a modest one. Not only does it not possess a single law, hut the materials at hand from which such should be deduced are as yet relatively so scanty, that not even any considerable number of general propositions appear well founded. Not to speak of a complete knowledge of the minuter structure of animals in general, we are not acquainted with the structure of a single creature throughout, not even of man, although he has been so frequently the ohject of investigation; and therefore it has hitherto been impossihle to hring the science essentially nearer its goal. It would however be unjust to overlook and depreciate what we do possess; and it may at any rate be said that we have acqnired a rich store of facts, and a few more trustworthy propositions. To indicate only the more important of the former, it may be mentioned that we have a very snfficient acquaintance with the perfect elementary parts of the higher animals; and that we also understand their development, with the exception of the elastic tissue, and of the elements of the teeth and bones. The mode in which these are united into organs has been less examined; yet on this head also much has been added of late, especially in man, whose individual organs, with the exception of the nervous system, the higher organs of sense, and a few glands (the liver, blood-vascular glands), have been almost exhaustively investigated. If the like progress continue to be made, the structure of the hnman body will in a few years be so clearly made out that, except perhaps in the nervous system, nothing more of importance will remain to he done with our present modes of investigation. With Comparative Histology it is otherwise: hardly commenced, not years but decades will be needed to carry ont the necessary investigations. Whoever will do good work in this field must, by monographs of typical forms emhracing their whole structnre from the earliest periods of development, ohtain a general view of all the divisions of the animal kingdom, and then by the methods above described strive to develop their laws.

"As regards the general propositions of Histology, the science has made no important progress since Schwann; however, mnch has been attained hy the confirmation of the hroad ontlines of his doctrines. The position, that all the higher animals at one time consist wholly of cells, and develop from these their higher elementary parts, stands firm; though it must not be understood as if cells, or their derivatives, were the sole possible or existing elements of animals. In the same way, Schwann's conception of the genesis of cells, though considerably modified and extended, has not been essentially changed, since the cell-nucleus still remains as the principal factor of cell-development and of cell-multiplication. Least advance has been made in the laws which regulate the origin of cells and of the higher elements; and our acquaintance with the elementary processes which take place during the formation of organs must be regarded as very slight. Yet the right track in clearing up these points has been entered upon; and a logical investigation of the chemical relations of the elementary parts and of their molecular forces, after the manner of Donders, Dubois, Ludwig, and others, combined with a more profound microscopical examination of them, such as has already taken place with regard to the muscles and nerves, and further, a histological treatment of embryology, such as has been attempted by Reichert, Vogt, and myself, will assuredly raise the veil, and bring us step by step nearer to the desired though perhaps never-to-be-reached end."

We refer here to some of the more important works and papers to be consulted on this subject.

HITCHIN. [HERTFORDSHIRE.]

HOLIBUT, or HALIBUT. [PLEURONECTIDÆ.]

HOLLYHOCK. [ALTHÆA.]

HOLMAN, JAMES, known as 'The Blind Traveller,' was born in or about the year 1787. He entered the royal navy in December 1798, and was appointed lieutenant in April 1807. At the age of twenty-five an illness which resulted from his professional duties deprived him entirely of his sight. On the 29th of September 1812, he was appointed one of the Naval Knights of Windsor, of whom there are six, with a governor. By degrees, when he had become accustomed to his condition, in 1819, partly the state of his health and partly a desire for change induced him to set out on a journey to the Continent, of which he published an account in 'The Narrative of a Journey undertaken in the Years 1819, 1820, 1821, through France, Italy, Savoy, Switzerland, parts of Germany bordering on the Rhine, Holland, and the Netherlands; comprising Incidents that occurred to the Author, who has long suffered under a total Deprivation of Sight; by James Holman, R.N. and K.W.,' 8vo. 1822. On the 19th of July 1822, he embarked on a voyage to St. Petersburg, whence he proceeded to Moscow, Novgorod, and finally to Irkutsk, the capital of Eastern Siberia. His intention was, when the ice on Lake Baïkal became sufficiently firm, to have crossed over, and travelled through Mongolia and China. At Irkutsk however an order was received by the Russian authorities from the Emperor Alexander, prohibiting him from proceeding any farther, and he was compelled to return. He was accompanied by a Russian officer to the frontiers of Germany, and was treated with external politeness combined with much harshness and severity. After his return to England he published 'Travels through Russia, Siberia, Poland, Austria, Saxony, Prussia, Hanover, &c., during the years 1822, 1823, and 1824, while suffering from total Blindness, and comprising an Account of the Author being conducted a State Prisoner from the Eastern Parts of Siberia,' 2 vols. 8vo, 1825.

Mr. Holman's 'Travels through Russia' were intended, as he states, to have been the commencement of a series of travels and voyages round the world, which he afterwards accomplished, and which occupied about five years. After his return he published 'A Voyage round the World, including Travels in Africa, Asia, Australasia, America, &c., from 1827 to 1832,' 4 vols. 8vo, 1834. In this 'Voyage' he visited first the islands of Madeira, Teneriffe, and the western coast of Africa; thence he crossed the Atlantic to Rio Janeiro, and went to the gold-mines. After travelling some time in Brazil, he recrossed the Atlantic to the Cape of Good Hope, and visited Caffirland, Madagascar, Mauritius, and Ceylon, whence he passed to Hindustan. He next passed by the Straits of Malacca to New South Wales, Van Diemen's Land, and New Zealand, and returned round Cape Horn to England. In 1843 he visited Dalmatia, Montenegro, Bosnia, and Servia, and passed in 1844 by Moldavia into Transylvania. Lieutenant Holman's series of voyages and travels excited much interest when they were published, chiefly from the extraordinary circumstance of their having been accomplished by a man who was totally blind, but they are, as might be expected, of little value for any information which they contain. He died July 28, 1857.

HOLOCANTHUS. [CHÆTODON.]

HOLSWORTHY. [DEVONSHIRE.]

HONDURAS, Republic of, Central America, occupies the elevated country between the table-land of Guatemala and the plains of Mosquitos and Nicaragua. It lies between 14° 5′ and 16° N. lat., and about 85° 30′ and 88° 40′ W. long.; but a narrow tract extends southward between Salvador and Nicaragua as far as the Gulf of Conchagua on the Pacific, 13° 30′ N. lat. Honduras is bounded E. by the Mosquito territory, but the boundary line on this side remains undefined; S. by the republics of Nicaragua and Salvador, except where the narrow tract of land reaches down to the Gulf of Conchagua; W. by Guatemala; and N. by the Caribbean Sea. The area is about 30,000 square miles; the population is about 230,000, of whom three-fourths are ladinos or mulattoes.

Surface, &c.—The Caribbean coast from Cape Cameron to Cape Honduras bears, with a general concave sweep, due west; and thence to Caballo Point, and to the mouth of the Rio Motagna, a short distance east of which is the boundary of the republic, it bears W. S.W. Between Capes Cameron and Honduras the coast is low; thence westward it is for the most part high and rocky. The only available ports are Truxillo at the mouth of the river of the same name, which is merely an open roadstead in a bay formed by Cape Honduras; and Omoa, a small but good harbour near the western extremity of the republic. The whole of this coast is extremely unhealthy, and consequently very thinly peopled. The small tract owned by Honduras bordering on the Gulf of Conchagua, in the Pacific Ocean, is also low, subject to be inundated by spring tides, and very unhealthy; but in neither case does the miasmatic influence extend far inland.

The surface of the country is greatly broken. It may be described as a table-land traversed by several ridges of hills running from north-west to south-east with secondary ridges branching obliquely from them. The general level of the table-land is perhaps about 4000 feet; the highest part is the southern side, where it borders on Salvador. Close upon the shores of the Caribbean Sea a ridge of mountains, the Sierra Omoa, extends from Cape Honduras to Caballo Point, near which is Mount Omoa, 7000 feet high, which gives its name to the ridge. The culminating point of this ridge is the peak of Congrehoy, 87° W. long., which is 7500 feet above the level of the sea. The ridges which traverse the interior of Honduras do not attain any great altitude above the general level. Between the ridges are long, wide, open and fertile valleys, which mostly descend gently to the great plain on the east. Near the western end of the state are the broad valleys of the Chamalicon and the Ulua, which are overgrown by thick forests of mahogany, cedar, and fustic trees. Along the southern side of the territory runs a ridge which divides the waters which flow into the Pacific from those which fall into the Atlantic; but only a few peaks attain any considerable elevation. From this ridge, and from the transverse ridges north-west of it, a series of high and steep hills rise from a broad-backed tract of high ground and connect the table-land of Honduras with that of Guatemala. The valleys between these ridges are of comparatively moderate width.

The principal rivers flow into the Caribbean Sea. Beginning on the west we have the Chamalicon, which rises on the Merendon Mountains near 14° N. lat. and flows in a generally northern direction into the Bay of Honduras a little east of Punta de Caballos. For a large part of its upper course it flows through a wild and uninhabited country; but as it approaches the sea the valley opens out to a great width, its slopes being covered with vast forests of valuable timber trees. Like most of the rivers of the state the navigation of the Chamalicon is impeded by a bar at its mouth. East of the Chamalicon is the Ulua, a much longer and more important stream. It is formed by the union near Santiago of several branches, the longest of which rises not far from the borders of Salvador; it falls into the sea a short distance west of Punta de Sal after a course of about 300 miles; only a few miles of the lower part are navigable. The next river of any size is the Truxillo, the mouth of which forms the harbour of the same name. East of this is the Aguan, which after a course of about 100 miles discharges itself by two branches into the Caribbean Sea, about 20 miles east of Cape Honduras. None of these are navigable for more than a short distance, and then only by piraguas (a sort of river barges), except the Ulua and Chamalicon, which admit small schooners. The Choluteca, which falls into the Pacific at the Bay of Conchagua, a small stream draining a narrow valley, is the only river of the state which does not enter the Caribbean Sea. The roads throughout the republic are mere tracks worn by continual use.

Climate, Soil, Productions.—The climate, except along the coast, is on the whole salubrious, though the temperature is somewhat high. Goître is common in the elevated districts. The valleys opening to the sea are very fertile, but moist and unwholesome. Those from which the air of the sea is intercepted by ranges of hills are less humid and more habitable, but their fertility is not so great. On the table-land, and in the districts not contiguous to the Caribbean Sea, the dry season begins about the close of October, and lasts until the end of May; during which time only a few showers occasionally refresh the air. In the beginning of June thunder is frequent, and is followed by long and heavy rains. But even during this time it rains only in the evening and night: from six o'clock in the morning till three or four o'clock in the afternoon, no cloud passes over the sky, and the air is dry and pleasant. Towards the middle of October the north winds set in with frequent thunderstorms, and after them the dry season begins.

The most important natural productions are the vast forests of mahogany, cedar, fustic, pimento, and numerous other valuable trees; but owing to the badness of the roads, the scarcity of labour, and other local causes, they are turned to comparatively little account. From the same causes, and from the indisposition of the inhabitants to steady labour in the fields, agriculture is in a very backward state; not only are immense tracts of fertile land wholly neglected, but the land which is under cultivation is very far from being rendered as productive as it easily might be. Maize, rice, some wheat and barley, frixoles, plantains, and various fruits and vegetables are the principal articles grown, but scarcely in sufficient quantities for the requirements of the inhabitants. In the western districts of Gracias tobacco of very fine quality is raised, but not enough for exportation. The chief dependence of the husbandman is on the cattle, of which vast herds are reared on the plains in the interior. Yet though such large numbers are maintained, they form but a limited article of export, and tallow and hides are only exported to a comparatively small amount. Sheep are not so numerous as in some of the other countries of Central America. Horses are not much attended to, nor are they of superior kinds. Mules are numerous, they being generally used in the country for the transport of goods.

The manufactures are confined to the coarser articles of home consumption. The commerce is but small; the foreign trade is chiefly carried on through Belize. As already indicated the exports are principally of mahogany, cedar, Brazil, and other cabinet and dye-woods; sarsaparilla, hides, and the products of the mines. The imports are British cottons, woollens, and hardwares, with various French, German, and American goods. Honduras is the principal mining country of Central America. The chief mining districts are the southern and western portions of the republic, but some mines occur in every department. Gold is found in veins in quartzose rocks; and in grains in alluvial deposits in the ravines, and in the sands of several of the rivers. Silver mines occur in several places in the department of Tegucigalpa, and also more or less frequently in all the other departments. Copper is found of good quality in Choluteca and elsewhere. Lead and iron-ore are found in several places. Of the present annual products of the mines we have however no reliable statement. In Gracias occur veins of remarkably fine opals, as well as some yielding emeralds. Jasper, asbestos, and cinnabar are likewise obtained. Excellent marble is wrought.

Divisions, Towns, &c.—Honduras is divided into seven departments—Comayagua, which occupies nearly the centre, and contains the capital of the republic: Gracias to the south-west, and Santa Barbara to the north-west of Comayagua, both of which extend to Guatemala, and Santa Barbara includes the coast as far east as Punta de Sal: Yoro, north of Comayagua, extends along the coast from Punta de Sal eastward to Cape Honduras, and contains the port-town of Truxillo: Tegucigalpa lies east of Comayagua, and is the chief mining district and most thickly inhabited department of the republic: on the north-east of it is the department of Juticalpa, which extends to the Mosquito territory: south of Comayagua is Choluteca, which stretches down to the Gulf of Conchagua, where is the little port-town of San Lorenzo, established a few years back in order to give the republic a port of entry on the Pacific. In the interior are few considerable towns; on the coast are only the small port-towns of Omoa and Truxillo.

Comayagua (*Valladolid de*), the capital, is situated in a fine but unhealthy valley, at nearly an equal distance from the ports of Omoa and Truxillo, in 14° 30′ N. lat., 87° 30′ W. long., and contains 3000 inhabitants. The public buildings are a cathedral, several churches, a college, an hospital, &c.

Tegucigalpa contains from 8000 to 10,000 inhabitants, and is the most populous place in Honduras, being the chief town of the great mining district. In its neighbourhood are mines of gold, silver, copper, and iron. It is at a considerable elevation above the sea.

Omoa, on the Bay of Honduras, 15° 38′ N. lat., 88° 5′ W. long., 12 or 15 miles from the mouth of the river Motagua, is a small place inhabited by a few ladinos, but is a good deal frequented; the harbour, which is formed by a small bay, is very good. The goods imported from Europe or America, are sent by barges to Gualán, on the banks of the Motagua. The town is very unhealthy.

Truxillo, farther to the east, formerly carried on an active trade with Havanna, but it now exports only mahogany and a few hides, with a small quantity of sarsaparilla and tortoise-shell to Belize. The town with its suburbs contains about 4000 inhabitants.

Government, &c.—The government is vested in a president and two chambers. The president is elected by the chambers, and assisted by a council of state consisting of the ministers and some other members. The chambers consist of a legislative assembly of 14 deputies, and a senate of 14 members. The republic has a debt of about 300,000 dollars. We have not a recent return of the revenue. The chief court of justice is the supreme court at Comayagua, which is presided over by three judges. The president is the commander-in-chief of the militia. The established religion is the Roman Catholic, but other forms of worship are permitted. Education is in a very neglected state.

The coast of Honduras was discovered by Columbus in 1502. The Spaniards effected the subjugation of the country a few years later; from which time it remained a part of the Spanish kingdom of Guatemala until the declaration of independence by South America in 1820. Honduras was then comprised in the Mexican empire of Iturbide, on the dissolution of which in 1823, Honduras formed one of the federal states of Central America; but this union was also of short duration, and Honduras then became and has since continued to be an independent republic.

(Juarros, *History of Guatemala*; Haefkins, ***Centraal Amerika***; Baily, *Central America*, &c.)

HONDURAS, BRITISH, or *Belize*, a British settlement on the east coast of Central America, is bounded N. by Yucatan, W. by Vera Paz, S. by Guatemala, and E. by the Bay of Honduras and the Caribbean Sea. The settlement extends from 15° 54′ to 18° 30′ N. lat., and from 88° to 89° 30′ W. long. The area is about 10,370 square miles, and the population, which consists chiefly of Caribs and negroes, is about 12,000.

The surface is very irregular. In the interior it is greatly elevated, while the coast is for the most part low, and fringed with reefs and small islands, termed keys, which render the navigation very hazardous. The country is watered by numerous rivers, the chief being the Belize, which is navigable for 150 miles from its mouth. The rocks are principally primary and calcareous. The easterly or sea-breezes which prevail during nine months of the year, temper the heat, which however is scarcely ever excessive; the thermometer seldom rises above 88° Fahr. even in the hottest time, and during the wet season it sinks to 60°. In June, July, August, and September heavy and frequent rains fall, and these are the most unhealthy months of the year, disease being engendered by the marsh miasmata arising from the lowlands and swamps. The soil by the coasts and rivers is a rich alluvial deposit, and very fertile. On the higher grounds are extensive forests of mahogany-trees of magnificent growth, and the logwood-tree abounds in the swamps. Cedar and other valuable timber-trees are among the natural products. The plantain is extensively cultivated. Maize, rice, cassava, arrow-root, yams, &c. are grown. Cotton, sugar, and coffee, though little cultivated, succeed well. In the woods the red tiger, the black tiger, the tiger-cat, the leopard, and other wild animals, and game, are found. Turtle abound on the keys.

British Honduras is governed by a Superintendent, and a Public Meeting, consisting of seven magistrates appointed by the inhabitants. The superintendent is immediately subordinate to the Governor of Jamaica, from whom he holds a commission. He is assisted in the administration of government by an Executive Council, consisting of the chief justice, the attorney-general, the officer commanding the land forces, and the public treasurer. An Act of the local legislature has however been passed by which the constitution of the council and assembly is proposed to be altogether remodelled. British Honduras is in the diocese of Jamaica. About 1000*l.* is voted annually by the legislature for the purposes of education.

The principal products of the country are mahogany and logwood, but cochineal, sarsaparilla, indigo, cigars, &c., are also exported, which commodities are altogether the produce of the states of Central America, and are brought to Belize merely in the course of transit to Europe. The total value of the exports in 1851 was 411,443*l.*; in 1852 it was 391,223*l.* The commerce of British Honduras is centred in the capital, and indeed only town of any size, Balize, or Belize, under which it is more fully noticed, and where will also be found mentioned various other facts relating to the settlement. [BALIZE, or BALIZE.]

HONEY-GUIDES. [INDICATORINÆ.]

HONEY-STONE. [MELLITE.]

HONEYSUCKLE, FRENCH. [HEDYSARUM.]

HONKENEJA, a genus of Plants belonging to the natural order *Caryophyllaceæ*, and the sub-order *Alsineæ*. It has 5 sepals, 5 large petals, 10 stamens alternating with glands, 3 styles and valves, and very few large seeds.

H. peploides is a British species found on sandy sea-coasts. It has ovate-acute sessile leaves, fleshy, glabrous, and 1-nerved; the petals obovate; sepals ovate-obtuse, 1-nerved, shorter than the petals; the stems are dichotomous, procumbent, rhizomateus; the flowers proceed from the forks of the stem frequently diœcious; capsules large, globose; seeds few, and large.

HOOPER. [SWANS.]

HOPPER, THOMAS, architect, was born at Rochester, in Kent, July 6th, 1775 or 1776, and, according to a family tradition, was descended from a natural daughter of Richard III. Thomas Hopper, when very young, was placed under his father, a clever measuring surveyor, and it is believed he very soon had the chief duty and responsibility of the business. Thus led to direct his attention to architecture, he became in some degree a self-taught architect; and being about this time introduced to Mr. Walsh Porter, a friend of the Prince Regent, and a sort of authority in matters of taste, Hopper was so fortunate as to please Porter, and was employed by him in extensive alterations and decorations to his house at Fulham, called Craven Cottage. This house became a remarkable specimen of the '*cottage-ornée*' style, afterwards so fashionable, and which Hopper perhaps was the means of introducing. The house contained a 'robber's cave,' entered from the top: an octagonal vestibule, with the roof supported by palm-trees; a 'gothic' chapel with stained glass, and other whimsies; and externally presented the appearance of a thatched cottage, with trellis-work and creeping plants. Here the Prince often supped. Hopper was made known to him, and was employed at Carlton House in some alterations, as well as on the conservatory there—a sort of imitation of Henry the Seventh's Chapel, which was erected at one end of the lower suite of rooms, and used at the fête to the allied sovereigns in 1814. Here supper tables were placed—down their length being a narrow tank for water, in which live fish disported. Hopper's taste, and the art of the day—the character of which last has been sufficiently pointed out above—were suited to one another; and, favourably introduced, and possessing great energy, a wonderful flow of conversation, and high spirits, it is not surprising that, at a time when there were fewer professional architects than there are now, Thomas Hopper should have speedily entered upon a large practice. Amongst the buildings of all kinds which he was employed in either erecting or altering, may be named—Slane Castle, in Ireland, for the Marquis of Conyngham; Penrhyn Castle, near Bangor, North Wales; Gosford Castle, Armagh; Easton Lodge, Dunmow, for Viscount Maynard; Leigh Court, near Bristol; the house at Kimmel Park, near St. Asaph, for Lord Dinorben; one at Amesbury Park, near Salisbury; Danbury Palace, Essex; Gatton House, Surrey; Wyvanhoe Park; Llanover Court, Monmouthshire, for Sir Benjamin Hall; Stansted Park, near Havant, Hants; Margam, in South Wales; Alton Towers, Staffordshire; Rood Ashton, near Trowbridge; and many others of the same class—the works which were of the nature of alterations generally involving complete re-modelling of the structure and of its architectural character. He attempted several different styles—the baronial castellated, then in favour, being of course amongst the number. Penrhyn Castle is perhaps the best exemplification of the latter kind of taste, and is indeed in many respects impressive in effect, and may be regarded as Hopper's best work. A vast amount was expended on it. He designed a baronial castle for the Duke of Atholl, at Dunkeld, in Scotland, which if completed would have rivalled Windsor Castle in extent, though the building never got beyond the foundations. He erected several prisons, amongst them the Essex County Gaol, to which afterwards he made alterations costing 40,000*l.* on its conversion for the cellular system. In London he was the architect of Arthur's Club-House in St. James's-street, the Legal and General Life Insurance Office in Fleet Street, and the Atlas Fire Office in Cheapside. His general manner for such buildings was derived from the class of edifices to which the Banqueting House, Whitehall, belongs. His last work, St. Mary's Hospital, Paddington, which is inferior in character, was designed and superintended by him gratuitously; but in it he met with much vexation and legal expense. He was for many years the county surveyor of Essex, and surveyor to the Atlas Fire Office. He was a competitor for the General Post Office in St. Martin's-le-Grand, when nearly one hundred designs, by eighty-nine competitors, were submitted. Sir Robert Smirke, who had not been a competitor, was ultimately engaged to erect the building; and Mr. Hopper contended that his design had been used, with the omission of some columns and of a few other features; and this, in a letter to Lord Melbourne, in 1839 'On the Building of the Royal Exchange,' he showed, by the aid of plans and elevations, might have been the case. He was also a competitor for the new houses of parliament, and published his designs in folio at some expense. Amongst many designs which he has left, are one for an alteration of the National Gallery, and another for a column of Victory to be erected in India with cannon placed in successive tiers, from the base upwards, of the shaft.

Although not possessing those high qualifications in art and science which the architect now strives to bring to his profession, Hopper's life is not the less an important one in the later history of architecture. He lived to enter the eighty-first or eighty-second year of his age, dying on the 11th of August 1856 at his cottage, which had been built by him, at Bayswater Hill. In life, he possessed a frame which could support almost any amount of fatigue,—and although he was contemporary with the *bon vivants* of the Georgian era, he never drank anything but water. He practised athletic exercises with Jackson the boxer, and was active in command of a company of the volunteers. His features and form have been exactly given by Mr. J. Ternouth, the sculptor, in the relievo on the eastern compartment of the Nelson Column, to the sailor who is supporting a wounded boy. He was always connected with the leading personages of his day, and this circumstance afforded him inexhaustible anecdotes. The Prince Regent would have conferred on him the honour of knighthood, but this he declined, as well as offers from Alexander I., emperor of Russia, and the Duchess of Oldenburg, for him to settle at St. Petersburg. The obituary notice in the 'Builder' (vol. xiv., p. 481)—the facts of which are apparently, like those above, derived from family sources—calls him "a man of mark and power," a conclusion which may help to justify the position which we have given to his name.

HOREHOUND. [BELLOTA; MARRUBIUM.]

HORNBLENDE, a Mineral belonging to the group of the Anhydrous Silicates of Magnesia. An account of its general characters and formation is given under AUGITE. It is subject to numerous varieties differing much in appearance, arising from isomorphism and crystallisation. Alumina enters into the composition of some of them, and replaces part of the other ingredients.

The varieties are divided into light and dark coloured.

To the light coloured varieties belong *Tremolite* or *Grammatite*. It comprises the white, grayish, and light-greenish slender crystallisations, usually in blades or long crystals, penetrating the gangue, or aggregated into coarse columnar forms. It is sometimes nearly translucent. The specific gravity is 2·93.

The light-green varieties are called *Actinolite*. *Glassy Actinolite* includes the bright glassy crystals of a rich green colour, usually long and slender, and penetrating the gangue like tremolite. *Radiated Actinolite* includes olive-green masses, consisting of aggregations of coarse acicular fibres, radiating or diverging. *Asbestiform Actinolite* resembles the radiated, but the fibres are more delicate. *Massive Actinolite* consists of angular grains instead of fibres. The specific gravity is 3·02 to 3·03. [ACTINOLITE.]

Asbestus is also included under this division. [ASBESTUS.]

To the dark-coloured varieties belongs *Pargasite*, a term which is applied to dark-green crystals, short and stout, of bright red lustre, of which Parga in Finland is a notable locality.

The term *Hornblende* is applied to the black and greenish-black crystals and massive specimens. It contains a large per centage of oxide of iron, and to this it owes its dark colour. It is a tough mineral. Pargasite and Hornblende both contain alumina.

The varieties of Hornblende fuse easily with some ebullition, the pale varieties forming a colourless glass, and the dark a globule more or less covered with iron. Hornblende is an essential constituent of certain rocks, as syenite, trap, and hornblende-slate.

Actinolite is usually found in magnesian rocks, as talc, steatite, or serpentine. *Tremolite* occurs in granular limestone and dolomite; *Asbestus* occurs in the above rocks, and also in serpentine.

(Dana, *Manual of Mineralogy*.)

HORNBY. [LANCASHIRE.]

HORNSEA. [YORKSHIRE.]

HORNSEY. [MIDDLESEX.]

HORNSTONE. [QUARTZ.]

HOUGHTON-LE-SPRING. [DURHAM.]

HOUNSLOW. [MIDDLESEX.]

HOVINIA, a genus of Plants belonging to the natural order *Rhamnaceæ*. The peduncles of *H. dulcis* become extremely enlarged and succulent, and are in China in much esteem as a fruit, resembling in flavour, it is said, a ripe pear. Some species are astringent.

HOWARD, HENRY, R.A., Professor of Painting in the Royal Academy, was born on the 31st of January 1769. He was a pupil of Philip Reinagle, R.A., and was admitted a student at the Royal Academy in March 1788. As a student his success was very decided; and it was his fortune, for the first time in the history of the institution, to receive on the same occasion, December 10th, 1790, two of the highest premiums—the first silver medal for the best drawing from the life, and the gold medal for the best historical painting; and he at the same time received the special commendations of the president, Sir Joshua Reynolds, for the excellence of his historical design. In the following year he visited Italy, and at Rome he and Flaxman pursued their studies in conjunction.

On his return to England Mr. Howard was employed to make drawings for the Dilettanti Society, and designs for book-plates; he also painted some portraits. His first contributions to the Royal Academy, 'Æneas and Anchises' and the 'Planets drawing Light from the Sun' (1796), were much admired by persons of classic tastes; and from this time for more than half a century Mr. Howard continued, without a single intermission, to send to each annual exhibition some paintings almost invariably of the classes of which these may be taken as the types. In fact the enormous number of pictures which he executed, though illustrating themes from the Scriptures, and from Greek, Roman, Italian, and English history, poetry and mythology, have all or nearly all the same character, for which perhaps there is no word so descriptive as that of 'academic.' His figures are almost always well drawn; of elegant proportions; have the established 'classic' contour and expression, or absence of expression; are clothed, or partly clothed, in the same conventional 'drapery' which nymphs and goddesses, whatever their position, wear so easily and gracefully in pictures and statues, despite the ordinary laws of gravity, which however may fairly be regarded as not applying to such beings; and they are so arranged as to afford a pleasing flow of line and an agreeable conformity to the rules of pictorial composition; while the colouring, if not rich and glowing, is chaste and harmonious. They were in fact good 'academic' pictures, and they are no more. Always strictly attentive to the proprieties, there is nothing in any one of his works, whether it be a 'Venus rising from the Sea,' a 'Love animating the Statue of Pygmalion,' or a cold 'Primeval Hope,' that can by any chance give the slightest shock to the nerves of the most susceptible—who is not shocked by any representation of undraped female beauty. But if his "bevies of fair forms" are never like those of Etty trembling on the verge of the voluptuous, they never like them are buoyant with the exuberance of life and youthful vigour—never exhibit the free abandon of riant enjoyment and unrestrained spontaneous action. They are works to be looked at with a certain quiet admiration of the artist's skill, not to seize the attention and linger in the memory. In a word, they are works of taste, not of genius.

Mr. Howard was elected an associate of the Royal Academy in 1801; in 1808 he became an academician; and in 1811 he was appointed secretary to the Academy, an office he held till his death, though for some years previously its active duties were performed by an assistant. He died on the 5th of October 1847.

The titles of a few of his pictures will sufficiently indicate the range and character of his subjects. Of his scriptural paintings, the most ambitious are 'Christ blessing Little Children,' placed as an altar-piece in the chapel in Little Berwick Street; 'the Angel appearing to St. Peter in Prison;' and 'Aaron staying the Plague.' The great bulk of his pictures as already mentioned are however those in which the subjects were chosen with a view to afford the opportunity of painting the nude female form; and to this class his best pictures belong. The most admired of these is his 'Birth of Venus,' painted in 1829. Others are 'The Marriage of Cupid and Psyche,' 'Proserpine,' and like stock subjects; but a large number consists of figures floating in the air with such titles as the 'Pleiades,' the 'Solar System,' the 'Circling Hours,' 'Morning,' 'Night,' &c. Besides numerous pictures from Spenser, his favourite poet, Milton, Shakspere (especially the 'Midsummer Night's Dream') &c., he painted many as 'Fairies on the Sea Shore,' with merely fancy titles; and he also painted many portraits. It deserves to be mentioned as illustrative of his life-long devotion to his art, that not only did he continue to paint pictures for the Academy exhibitions up to the year of his death, but that on the occasion of the first cartoon competition in 1843, he did not shrink from entering the lists, though then seventy-three years of age, and in the rude encounter with the young artists fresh from the schools, his cartoon, 'Man beset by contending Passions,' carried off one of the premiums of 100*l.*

In 1814 Mr. Howard won the prize for a medal for the Patriotic Society, and thenceforward he was generally employed in preparing the designs for the medals and great seals required by the government. He also made numerous designs for works to be executed in silver, chiefly for the house of Rundle and Bridge. Frank Howard, the son of Mr. Howard, is well known as an able designer, and the author of several elementary works on art. To a brief memoir of his father, contributed by him to the 'Athenæum' for November 13, 1847, we are indebted for most of the facts in this notice.

HOWLET. [STRIGIDÆ.]

HOYA, a genus of Plants belonging to the natural order *Asclepiadaceæ*. It has 5-cleft, rotate corolla. Coronet of appendages depressed, 5-leaved; leaflets spreading, fleshy, with the inner angle extended into a tooth lying upon the anther. Anthers terminated by a membrane. Pollen-masses fixed by the base, converging, compressed. Stigma not pointed, or scarcely so. Follicles smooth.

H. viridiflora is a native of Coromandel, Sylhet, and the

Nilgherry Hills. It has opposite, stalked, broad, cordate, or ovate leaves, not sinuate at the base, pointed, membranous, smooth, from 3 to 4 inches long; petioles from 1 to 2 inches long; umbels lateral or axillary, simple, many-flowered. Flowers numerous, green, with pedicles as long as the peduncle. Corolla flat; crown of appendages turbinate, truncate. Anthers reflected over the stigma. Follicles horizontal, obtuse, about 3 or 4 inches long, and 4 inches in circumference. The root and tender stalks produce nausea, and promote expectoration. The leaves peeled and dipped in oil are used by the natives of India as a discutient in the early stages of boils; when the disease is more advanced they are employed in the same way to promote suppuration.

Several species of this genus are cultivated in our gardens on account of their elegant flowers, which, from their curious wax-like appearance, give rise to the name of Wax-Plants.

HUME, JOSEPH, was born at Montrose in the year 1777. His father was the master of a small coasting-vessel, and after his death his widow supported herself by keeping a shop in Montrose. Having received the merest rudiments of education, including Latin and a smattering of accounts, at a school in his native town, he was apprenticed in his fourteenth year to a surgeon. In 1793 he entered the University of Edinburg for the purpose of prosecuting his medical studies; and having taken a medical degree, and passed the London College of Surgeons, he was appointed surgeon to an East Indiaman in 1797. He distinguished himself not only in his medical capacity, but also by acting as purser on his voyage out, and conducting a most complicated business in a very successful manner. On reaching India he mastered the native languages, and, in addition to his functions as an army surgeon, he became Persian interpreter, commissary-general, and pay-master and post-master of the forces in the prize agencies. It is said that he owed the first step of his promotion to his knowledge of chemistry, which enabled him to detect the presence of damp in the government stores of gunpowder on the eve of Lord Lake's Mahratta war. Nothing is more surprising than the amount of hard work performed by the young civilian at this time, and its success enabled him to return to England in the prime of life with a fortune of about 30,000*l*. On returning to England he commenced studying the history and resources of Great Britain, and acquired that insight into the condition of both the government and people which formed the foundation of his subsequent exertions in the cause of reform. In the same spirit he visited a large portion of the Continent, and made a tour through Spain, Portugal, Turkey, Greece, and Egypt, to increase his stores of political experience.

In 1813 he entered parliament under the auspices of the late Sir J. Lowther Johnstone, Bart., as member for Melcombe Regis, which now forms part of the borough of Weymouth, but failed to secure his re-election in the autumn of the same year. In the interval between this date and 1818 he became acquainted with Place, Mill, and other disciples of the school of Jeremy Bentham; and devoted considerable time and energy to the foundation of savings banks and of schools on the Lancasterian system. He was also a candidate—though an unsuccessful one—for a seat at the Board of East India Directors. In 1818 he re-entered parliament as member for the Montrose burghs, for which he continued to sit without interruption until 1830, when he was chosen by the constituency of Middlesex. He represented that county during all the period of agitation which preceded the passing of the Reform Act and down to 1837, when he was defeated, but he was returned through the influence of Mr. O'Connell for Kilkenny. In 1841 he contested Leeds without success; but in the following year was re-elected for his native Montrose burghs, which he represented down to his death, a period of thirteen years.

For many years Mr. Hume stood nearly alone in the House of Commons as the advocate of Financial Reform: indeed in the cause of reduction of taxation and public expenditure no man ever did so much practical good as Joseph Hume, through a long career of perseverance and industry. Disregarding the fashion of the age and the opinions of the world, he adhered in the smallest matters to what he thought just and right. In most of the political and social movements of the last quarter of a century he was an important actor: the working man eats bread which he helped to cheapen, walks through parks which he helped to procure for him, and is in a fair way to attain further educational advantages in consequence of his exertions. He more than once refused to accept office under Liberal governments, and he devoted a part of his own wealth to the social and political objects which he had in view. His speeches delivered in parliament occupy in bulk several volumes of 'Hansard's Debates.' He incessantly advocated reforms in our army, navy, and ordnance departments, of the Established Church and Ecclesiastical courts, and of the general system of taxation and the public accounts. He early advocated the abolition of military flogging, naval impressment, and imprisonment for debt. With little active assistance, he carried the repeal of the old combination laws, the laws prohibiting the export of machinery, and the act for preventing mechanics from going abroad. He was unceasing in his attacks on colonial and municipal abuses, election expenses, the licensing systems, the duties on paper and printing, and on articles of household consumption. He took an active part in carrying Roman Catholic emancipation, the repeal of the Test and Corporation Acts, and in the passing of the Reform Act of 1832. A remarkable passage in his life was his discovery, in 1835, of an extensive Orange plot, commencing before the accession of William IV. An account of this transaction, in all the minuteness of detail, will be found in Miss Harriet Martineau's 'History of the Thirty Years' Peace.'

The health of Mr. Hume began to break soon after the parliamentary session of 1854, and he died at Burnley Hall, his seat in Norfolk, on the 20th of February 1855. At the time of his death he was a magistrate for Norfolk, Westminster, and Middlesex, and a deputy lieutenant for the latter county. As a proof of the general esteem in which he was held, we may add, that in the House of Commons speakers of all parties took occasion to pay a tribute to his character. He married a daughter of the late Mr. Burnley, by whom he left a family of several sons and daughters. His eldest son is Mr. Joseph Burnley Hume, barrister-at-law.

HUMOPINIC ACID. [CHEMISTRY, *S.* 1.]

HUSBAND. [DIVORCE, *S.* 2; SEPARATION, JUDICIAL, *S.* 2; WIFE, *S.* 2.]

HYACINTHE, ST. [CANADA, *S.* 2.]

HYÆNANCHE, a genus of Plants belonging to the natural order *Euphorbiaceæ*. *H. globosa* yields a fruit which is collected by the Cape Colonists, and when powdered is used as a poison for hyænas by being rubbed over meat.

HYDRA (Linnæus), a genus of Polypiferous Animals, including the Fresh-Water *Hydra*, or Polype. It has the following technical definition:—Polypes locomotive, single, naked, gelatinous, subcylindrical, but very contractile and mutable in form; the mouth encircled with a single series of granulous filiform tentacula.

As of all the forms of polypiferous animals the *Hydra* is the most interesting, we give an abstract of their history, from Dr. Johnston's 'British Zoophytes:'—

Leeuwenhoek discovered the *Hydra* in 1703, and the uncommon way its young are produced; and an anonymous correspondent of the Royal Society made the same discovery in England about the same time; but it excited no particular notice until Trembley made known its wonderful properties about the year 1744. These were so contrary to established experience, and so foreign to every preconceived notion of animal life, that by many they were regarded as impossible fancies. Leading men of our learned societies were daily experimenting on the creature and transporting it by careful posts from one to another, while even ambassadors were forwarding to their respective courts early intelligence of the engrossing theme. The *Hydræ* are found in fresh waters only. They prefer slowly-running or almost still water, and adhere to the leaves and stalks of submerged plants. The body is exceedingly contractile, and hence liable to many changes of form; when contracted it is like a tubercle, a minute top or button, and when extended it becomes a narrow cylinder, being ten or twelve times longer at one period than another, the tentacula changing in size and form with the body. On the point opposite the base, and in the centre of the tentacula, we observe an aperture, or mouth, which leads into a wider cavity, excavated as it were in the middle of its body, and from which a narrow canal is continued down to the sucker. When contracted, and also when fully extended, the surface appears smooth and even; but in 'its middle degree of extension' the sides seem to be minutely crenulated, an effect probably of a wrinkling of the skin. The tentacula encircle the mouth and radiate in a star-like fashion; but they seem to originate a little under the lip, for the mouth is often protruded like a kind of small snout; they are cylindrical, linear, or very slightly tapered, hollow, and roughened, at short and regular intervals, with whorls of tubercles, which under the microscope form a very beautiful and interesting object.

Each tentaculum forms a slender membranaceous tube, filled with an albuminous nearly fluid substance, intermixed with some oleaginous particles; and at certain definite places this substance swells out into tubercles or denser wartlike nodules, which are arranged in a spiral line. Every nodule is furnished with several spinigerous vesicles, used as organs of touch, and with a very singularly constructed organ for catching the prey. The organ of touch consists of a fine sac, inclosing another with thicker parietes, and within this there is a small cavity. From the point where the two sacs coalesce above there projects a long cilium, or capillary spine, which is non-retractile and apparently immoveable. Surrounded by these cilia, and in the centre of the nodule, is placed the captor organ, called the 'hasta;' this consists of an obovate transparent sac, immersed in the nodule, with a small aperture even with the surface. At the bottom of the sac, and within it there is a saucer-like vesicle, on whose upper depressed surface is seated a solid ovate corpuscle, that gives origin to and terminates in a calcareous sharp sagitta, or arrow, that can be pushed out at pleasure, or withdrawn, till its point is brought within the sac. When the *Hydra* wishes to seize an animal, the sagittæ are protruded, by which means the surface of the tentacula is roughened, and the prey more easily retained; and Corda believes that a poison is at the same time injected—a conjecture offered to explain the remarkable fact of the almost instant death of the prey. The nodules of the tentacula are connected together by means of four muscular fibres, or bands, which run up, forming lozenge-shaped spaces by their intersections. These are the extensor muscles of the tentaculum. They are again joined together by transverse fibres, which Corda believes to be adductor muscles, and to have also the power of shortening the tentacula. But it may be doubted whether this muscular apparatus is of itself sufficient to effect the wonderful extensibility of these organs—from a line, or, as in *H. fusca*, to upwards of eight inches; and to produce this degree of elongation, it seems necessary to have superadded the propulsive agency of a fluid. Water flows, let us say by suction, into the stomach through the oral aperture, whence it is forced by the vis-a-tergo, or drawn by capillary attraction, into the canals of the tentacula, and its current outwards is sufficient to push before it the soft yielding material of which they are composed, until at last the resistance of the living parts suffices to arrest the tiny flood, or the tube has become too fine in its bore for the admission of water attenuated to its smallest possible stream—how inconceivably slender may indeed be imagined, but there is no thread fine enough to equal it, seeing that the tentacula of *H. fusca*, in tension, can be compared to nothing grosser than the scarce visible filaments of the gossamer's web.

The *Hydra*, though usually found attached, can nevertheless move from place to place, which it does either by gliding with imperceptible slowness on the base, or by stretching out the body and tentacula to the utmost, fixing the latter, and then contracting the body towards the point of fixture, loosening at the same time its hold with the base; and by reversing these actions it can retrograde. Its ordinary position seems to be pendant, or nearly horizontal, hanging from some floating leaf or weed, or stretching from its sides. In a glass of water the creature will crawl up the sides of the vessel to the surface and hang from it, sometimes with the base and sometimes with the tentacula downwards; and again it will lay itself horizontally. Its locomotion is very slow, and the disposition of the zoophyte is evidently sedentary; but the contractions and mutations of the body are very vivacious, while in seizing and mastering its prey it is surprisingly nimble, seizing a worm with as much eagerness as a cat catches a mouse. It enjoys light, and expands more freely under its influence; hence we generally find the *Hydra* near the surface and in shallow water. The *Hydræ* are very voracious, feeding only on living animals. In confinement, however, Trembley found they might be fed on minced veal, fish, or beef and mutton. They will sustain long fasts with no other change than a paler colour indicates. Small worms, crustaceans, and insects seem to form a favourite food. Sometimes two polyps will seize upon the same worm, and most amusing is it then to witness the struggle that ensues, sometimes resulting in the swallowing of the weaker polyp by the stronger, which however is soon disgorged with no other loss than his dinner. This is the more curious when contrasted with the fate of the worms on which they feed. No sooner are they seized than they evince every symptom of painful suffering, but their contortions are merely momentary, and a certain death suddenly follows their capture. How this effect is produced is still a matter of conjecture. Worms are in ordinary circumstances most tenacious of life, and hence one is inclined to suppose that there must be something poisonous in the *Hydra's* grasp. To the *Entomostraca* the touch is not equally fatal, their shells evidently protecting them from the poisonous secretion. The *Hydra* is chiefly celebrated on account of its manner of propagation. It is like zoophytes in general, monœcious, and every individual possesses the power of continuing and multiplying its race, principally however by the process of subdivision. During the summer season a large tubercle arises on the surface, which lengthening and enlarging every hour, in a day or two develops in regular succession and in successive pairs a series of tentacula, and becomes in all respects except in size similar to its parent. It remains attached for some time, and grows and feeds, and contracts and expands after the fashion of its parent, until it is at length thrown off by a process of exfoliation or sloughing. They develop with great rapidity in warm weather, and sometimes the young ones themselves breed others, and they again a third or fourth generation before they become separated from the original parent. Trembley found that an individual of *H. grisea* produced forty-five young ones in two months. In autumn the *Hydra* generates by internal oviform gemmules, which extrude from the body, and lie during the winter in a quiescent state, and are stimulated to evolution only by the returning warmth of the spring. Few observations have been made on these ova, so that their structure, source, manner of escape, and condition, are scarcely known.

These are the modes in which the *Hydra* naturally multiplies its kind, but it can be increased by artificial sections of the body in the same manner that a perennial plant can by shoots or slips. If the body be halved in any direction each half in a short time grows to a perfect *Hydra;* if it is cut into four or eight or even minced into forty pieces, each continues alive, and develops a new animal, which is itself capable of being multiplied in the same extraordinary manner. If the section is made lengthwise so as to divide the body into two or more slips connected merely by the tail, they are speedily reunited into a perfect whole, or if the pieces are kept asunder each will become a perfect polyp. If the tentacula are cut away, new ones are quickly produced, and the lopt-off parts are not long without a new body. When a piece is cut out of the body the wound speedily heals, and as if excited by the stimulus of the knife, young polyps sprout from the wound more abundantly; when a polyp is introduced by the tail into another body, the two unite and form one individual, and when a head is lopt off, it may safely be ingrafted on the body of any other which may chance to want one. And the creature suffers nothing itself by all these apparently cruel operations; for before the lapse of many minutes the upper half of a cross section will expand its tentacula and catch prey as usual, and the two portions of a longitudinal division will after an hour or two take food and retain it. A polyp cut transversely in three parts requires four or five days in summer and longer in cold weather for the middle piece to produce a head and a tail, and the tail part to get a body and head, which they do in pretty much the same time. And what is still more extraordinary, polyps produced in this manner grow much larger and are far more prolific in the way of their natural increase than those which were never cut. When such things were first announced, when to a little worm the attributes of angelic beings were assigned, and the wild fictions of antiquity realised, it is not wonderful that the vulgar disbelieved when naturalists, familiar with all the miracles of the insect world, were amazed and wist not what to do.

The following are British species of this genus:—

H. viridis (Polypes Verds of Trembley), is of a grass-green colour. The body cylindrical or insensibly narrowed downwards; tentacula 6 to 10, shorter than the body. It is commonly found in ponds and still waters. The polyps of this species differ from the following, not only in colour, but likewise in their arms, which are much shorter in proportion to their bodies, capable of but little extension, and narrower at the root than the extremity, which is contrary to the other species. Their arms were so short they could not clasp round a very small and slender worm, but seemed to pinch it fast till they could master and devour it, which they did with as much greediness as any. It was first observed in England in the spring of 1743 by a Mr. Ducane of Essex. It appears to be a hardy animal, and is easily kept for a length of time in a phial of water.

H. vulgaris is of an orange-brown or yellowish colour, body cylindrical, tentacula 7 to 12, as long or longer than the body. It is found in weedy ponds and slowly-running waters. This does not exceed *H. viridis* in size, which it resembles also in its habits and form. It is always of an orange-brown or red colour, the intensity of the tint depending on the nature of the food, or the state of the creature's repletion. Every part of the body is generative of young, which may frequently be seen hanging from the parent at the same time in different stages of their growth.

H. attenuata is of a light oil-green colour, the body attenuated below, with pale tentacula longer than itself. It is found in ponds, and in Yetholm Lough, Roxburghshire. This is a larger animal than *H. vulgaris*, and comparatively rare, less sensible to external impressions, and of a more graceful form. Its colour is a pale olive-green, with paler tentacula, which are considerably longer than the body, and hang like silken threads in the water, waving to and fro without assuming that regular circular disposition which they commonly do in *H. viridis*. Dr. Johnston says he has not observed more than one young at a time, which pullulated from near the middle of the body, and after this has attained a certain growth the polyp has the appearance of being dichotomously divided.

H. oligactis (Polypes à Long Bras of Trembley) is brown or griseous; inferior half of the body suddenly attenuated; tentacula several times longer than the body. It is found in still waters in England, rare. In a pond at Hackney, and in a pond at Cranmore, near Belfast, September 1812. The tails of these are long, slender, and transparent, and when placed under the microscope a long straight canal may be seen passing from the body or stomach to an opening at the end thereof; these are rather lighter coloured than *H. vulgaris*, and have seldom more than 6 or 8 arms, but those capable of great extension. It may be worth while to call attention to the remarkable resemblance of the *Hydra fusca* to the *Cucullanus cirratus* of Müller, which is an intestinal worm.

(Johnston, *History of British Zoophytes;* Landsborough, *Popular History of British Zoophytes;* Trembley, *Mémoires pour servir à l'Histoire d'un Genre de Polypes d'Eau douce*, the Hague, 1743; Baker, *Natural History of the Polype.*)

HYDRIDÆ, a family of Snakes belonging to the Colubrine sub-order of Dr. J. E. Gray's arrangement, and the first section of this sub-order, which includes the *Hydridæ* and *Boidæ*. [BOA.] It is thus characterised:—Belly covered with narrow elongate shields or scales, nearly resembling those of the back.

The following is a synopsis of the genera, and a list of the species, compiled from the Catalogue of the specimens of Snakes in the British Museum:—

Hydridæ.—The ventral shields narrow, hexagonal or band-like; the hinder limbs not developed; the eyes and nostrils superior, vertical, the latter valvular, generally placed in the middle of a shield, with a slit or groove to its outer edge; fangs moderate, intermixed with the maxillary teeth; pupil small, round; tail compressed or conical. They live in the sea or salt-water lakes, or in fresh water.

Synopsis of the Genera.

I. Tail compressed (except in *Acrochordus*). Belly keeled, with two rows of small scale-like shields, often united together in a single, rather broad, 6-sided shield.

A. Head shielded to the nape. Nasal shields very large, with a large, operculated, superior nostril in their hinder edge; the frontal shields two pairs, small; loreal shield none; labial shields high, large. *Hydrina.*

These are the true Sea-Snakes. They coil themselves up on the shore, and appear to live on sea-weed, and lay their eggs on the shore. They are often found asleep on the surface of the sea, where they are easily caught, for they cannot descend into the sea without throwing themselves on to their backs. This arises apparently from the necessity of expelling the air from their large lungs. They are often thrown ashore in the surf, and are occasionally carried up rivers by the tide, but they cannot live in fresh water. Their bite is venomous, and they are held in great dread by fishermen wherever they occur, on this account. In spite of their venomous properties, one species at least, the *Hydrus (Pelamis) bicolor* is said by Cuvier to be eaten at Taheite.

a. Scales square or 6-sided, placed side by side.

* Head elongate, depressed.

1. *Pelamis.*
P. bicolor. Pacific Ocean. For figure see HYDRUS.
P. ornata. Borneo.

** Head moderate, rather compressed; gape moderate.

2. *Lapemis.*—Head moderate, short, rounded in front; dorsal scales square: ventral shield broad, 6-sided.
L. curtus. Madras.
L. Hardwickii. Borneo.

3. *Aturia.*—Head moderate, short, rounded in front; dorsal scales 6-sided; ventral shield 6-sided.
A. ornata. Indian Seas.
A. Belcheri. New Guinea.

4. *Microcephalophis.*—Head small; scales 6-sided; ventral scales keeled.
M. gracilis, the Kadel Nagam. Madras.

b Scales ovate, 6-sided, imbricate, keeled, or with the keel reduced to a tubercle on the centre of the scales; head and gape moderate.

* Labial shields occupying the greater part of the lips; the eyes over the fourth, or rarely over the third, or the fourth or fifth shield; ventral shield united.

5. *Enhydrina.*—Rostral plates narrow, erect; lower linear, sunken; nasal narrowed in front; ventral shield flat; head moderate, short; eyes moderate.
E. Bengalensis. Madras.
E. Valakadyen. Madras.

6. *Hydrophis.*—Rostral broad, transverse; lower triangular; nasal truncated or notched in front; ventral shield flat; head short; eyes small.
H. obscura, the Shootur Sun. Madras.
H. Lindsayii. China.
H. fasciata. Indian Ocean.
H. nigrocincta, the Kerril. Bengal.
H. doliata, the Black-Headed Kerril. Australia.
H. subcincta, Shaw's Chittul. Indian Ocean.
H. sublævis, the Chittul. China and Indian Ocean.
H. mentalis, the Pale Chittul. Indian Ocean.
H. ocellata, the Eyed Chittul. Australian Seas.
A. spiralis, the Shiddil. Indian Ocean.
H. subannulata, the Ringed Sea-Snake. India.
H. aspera, the Rough Sea-Snake. Singapore.
H. cærulescens, the Bluish Sea-Snake. Bengal.

7. *Chitulia.*—Rostral broad, transverse; lower triangular; nasal truncated or notched in front; ventral shields flat: head elongate, depressed; eyes large.
C. inornata. Indian Ocean.
C. fasciata. Indian Ocean.

8. *Kerilia.*—Rostral broad, transverse; lower triangular; nasal truncated in front; ventral shield broad, convex, forming a slight keeled ridge; the hinder ones with a keel on each side; head short, shelving; scales very large, broad, 6-sided; eyes rather large, over third and fourth labial shields.
K. Jerdonii, the Kerilia. Madras.

** Labial shield occupying the front half of the lip; eyes over the fifth or sixth shield; hinder part of the face covered with small scales; ventral scales generally 2-rowed, forming a keeled ridge, some united in pairs into 6-sided shields.

9. *Hydrus.*
H. major, the Sea-Snake. India; Australia.
H. annulatus, the Ringed Sea-Snake. Singapore.

c. Body covered with smooth polished imbricate scales; head as large as the body; ventral shields rather large, transverse, smooth, folded together and keeled.

10. *Tomogaster.*—Head with regular shields; superciliary shields simple; ventral shields entire.
T. Eydouxii. Indian Ocean.

11. *Stephanohydra.*—Head shields numerous; superciliary shields 3 or 4; ventral shields nicked behind.

S. fusca, Jukes's Hypotrophis. Darnley Islands.

B. Head covered with scales, like the body; nostrils surrounded by a small, continuous ring; eyes surrounded by a series of small scales; labial shields small, with a larger series above them; pupil round; ventral shields very small, scale-like, separated on each side of a keeled ridge. The species are all inhabitants of rivers. *Acrochordina.*

12. *Chersydrus.*—Tail compressed, sword-shaped, prehensile; body fusiform, covered with small rhombic scales, with a central tubercular keel.

C. granulatus, the Chersydrus. Madras. For figure see HYDRUS.
C. annulatus. Madras.

13. *Acrochordus.*—Tail conical, tapering, moderate; body fusiform, covered with tricuspid scales.

A. Javanicus. Java.

II. Tail conical, tapering. Belly rounded beneath, with more or less broad band-like shields. Rivers or ponds.

A. Head shielded; tail scaly beneath; abdominal shields flat, small, 6-sided, with a keel on each side, as if formed of two united scales; nostrils in a ring of small scales; scales keeled. *Erpetonina.*

14. *Erpeton.*
E. tentaculus, the Erpeton. [ERPETON.]

B. Head shielded; tail with two series of shields beneath; nostrils between two shields; abdominal shields broad, keeled on each side; scales smooth. *Bitiana.*

15. *Bitia.* Head small.
B. hydroides.

C. Head shielded; scales striated, and keeled or smooth; tail conical, tapering, with two series of shields beneath; nostrils in centre of a large nasal shield, with a groove to the outer side; ventral shields rounded (or rarely slightly keeled on the sides): frontal shields 3, rarely 2 or 4, all small. *Cerberina.*

a. Crown scaly; occipital rudimentary; frontals 4; anterior pair very small.

16. *Cerberus.*—Scales keeled, striated; hinder labial shield low.
C. cinereus, the Raroo Bokadam. India.
C. acutus. Borneo.
C. unicolor. Philippines.
C. australis. Australia.

b. Crown shielded; occipital moderate.

* Head distinct, depressed; frontals 4; anterior pair small; rostral rounded.

17. *Ferania.*—Scales smooth; seventh upper labial low, with a large shield over it.
F. Sieboldii. Bengal.

** Head distinct, depressed; frontals 3; anterior transverse; rostral rounded.

† Fourth and fifth hinder labial shields small or divided.

18. *Homalopsis.*—Scales keeled.
H. buccata. Java.
H. Hardwickii. India.

19. *Phytolopsis.*—Scales smooth.
P. punctata. India.

†† Hinder labial large, like others; scales keeled; rostral rounded.

20. *Uranops.*—Scales truncated, strongly keeled, striated; eye over fourth shield.
U. angulatus. Tropical America.

21. *Tachynectes.*—Scales truncated, strongly keeled.
T. Leopardina.

22. *Tropidophis.*—Scales ovate, keeled, striated; eye over fourth and fifth shield.

T. Schistosus, the Chittee. Ceylon.

23. *Myron.*—Scales ovate, slightly keeled, smooth.
M. Richardsonii. Australia.
M. trivittatus. India.

24. *Helicops.*—Scales ovate, polished; of back and tail keeled.
H. carinacaudus. North America.

††† Hinder labials large, like others; scales smooth; rostral rounded.

25. *Hypsirhina.*—Seventh labial large; eye over fourth and fifth labial; loreal distinct.
H. plumbea. Borneo.
H. Hardwickii. Penang.
H. Aer, the Ular Aer. Borneo.
H. bilineata. China.
H. Chinensis. China.
H. Bennettii. China.

26. *Farancia.*—The seventh labial large; eye over the third and fourth labial.
F. fasciata, the Wampan-Snake. New Orleans.

27. *Hydrops.*—The seventh labial large; eyes over the fourth labial; ventral shield broad; body thick; loreal none.
H. Martii. Brazil.

28. *Hygina.*—The seventh labial large; eyes over the fourth labial; ventral shield narrow; body slender; loreal none.
H. fasciata. Demerara.

29. *Dimades.*—The seventh labial short, small; eye over third and fourth labial; loreal none.
D. plicatilis. New Orleans; North America.

*** Head moderate, depressed; frontal 3; anterior elongate, erect, between the nasals; seventh smooth; rostral rounded.

30. *Fordonia.*—Scales broad, rhombic; ventral shield rounded; loreal none; eye over third labial.
F. leucobalia. Timor.
F. unicolor. Borneo.

31. *Gerarda.*—Scales broad, rhombic; ventral shields rounded; eye over fourth shield; loreal square.
G. bicolor, the Gerard. West Indies.

32. *Hipistes.*—Scales narrow, flattened; ventral shields keeled at each end; loreal square.
H. fasicatus. West Indies.

**** Head indistinct; frontal 4; anterior 4-sided, rather smaller; scales smooth; body cylindrical.

33. *Abastor.*—Body cylindrical; loreal shield none; anterior frontal 4-sided; posterior ocular 2.
A. erythrogrammus, the Striped-Wampum. North America.

34. *Raditia.*—Head small, conical; body subcylindrical: anterior frontal very small, triangular; loreal distinct; posterior ocular.
R. Indica. India.

35. *Miralia.*—Head small, conical; body compressed; frontal plates 2 pairs; loreal none; posterior ocular 2.
M. alternans. Java.

***** Head moderate, depressed; frontal shields, 2, small lateral; rostral shield angular, high, erect, between frontals and nasal.

36. *Ficinia.*—Head small; rostral plate large, produced between the frontal, angular and recurved in front.
F. olivacea. Mexico.

****** Head small; frontal shields 2, transverse, band-like; rostral triangular, subangular.

37. *Prosymna.*
P. meleagris. Guinea.

D. Head covered with small scales; tail with one row of shields beneath; abdominal shield broad, rounded, smooth; nostril in a shield, anterior, sublateral; scales granular, with rows of keeled scales. *Xenodermina.*

38. *Xenodermus.*
X. Javanicus, the Gonionote. Java.

Dr. Gray says, "The separation of the specimens of this family into species and genera is attended with great difficulty; the form and number of the shields of the head, lips, temple, and chin are liable to great variation, not only in the different specimens, but often in the two sides of the same individual. The two ventral series of scales are, in the same specimen, sometimes separate, and at other times united into a shield; and many specimens have a series of small triangular shields on the edge of the lips, between the sutures of the lip-shield, not found in other individuals of the same species.

"The distribution of the colours on the body appears to be one of the most permanent characters of the species; but this becomes less distinct in the older specimens, and is often lost in the specimens that have been carelessly or long preserved in a museum."

The existence of this family of Water-Snakes has undoubtedly given rise to the notion that a large Ophidian, which meets the popular view of a Great Sea-Serpent, exists. In all cases however the reports of the existence of such a creature have been traced to the capture or sight of some other animal, or to the exaggerated representations of some other natural object. The *Hydridæ* amongst the *Ophidia* are of comparatively small size, seldom equalling the *Boidæ* in this respect, and falling far short of the enormous dimensions popularly attributed to the Great Sea-Serpent.

HYDROBORACITE. [MINERALOGY, *S.* 1.]

HYDROCYON, a genus of Fishes belonging to the *Malacopterygii Abdominales*. The species are very numerous. They have the point of the muzzle formed by the intermaxillaries, the maxillaries nearer, before the eyes, and completing the aperture; the tongue and vomer smooth, the jaws with conical teeth, and the large suborbital covers the cheek like an operculum.

A large number of species inhabit Brazil. They are also found in the Nile.

HYDROIDA, a name given to a section of the order *Polypifera*, embracing forms resembling the fresh-water *Hydra* in the simplicity of their organisation. The following is Dr. Johnston's arrangement of the families of British Zoophytes referred to the *Hydroida*:—

* Ovisacs or bulbules naked, bud-like, pullulating from the bases of the tentacula.

Tubularina, Ehrenberg (*Tubularia*, Linnæus; *Tubulariadæ*, Johnston; Les Tubulaires, Van Beneden).

Family I.—Polyps naked, or with only a rudimentary polypidom. *Corynidæ*.

† Polyps naked.

The tentacula scattered. *Clava*.
The tentacula in one row. *Hydractinia*.

†† Polyps with a horny cuticle.

The tentacula with globose tips. *Coryne*.
The tentacula filiform. *Cordylophora*.

Family II.—Polypidom fistular; the tentacula whorled. *Tubulariadæ*.

† The tentacula in a single whorl. *Eudendrium*.

†† The tentacula in a double whorl.

Polypidom rooted. *Tubularia*.
Polypidom unrooted and deciduous. *Corymorpha*.

** Ovisacs in the form of horny capsules or vesicles scattered on the polypidoms, and deciduous.
Sertularina, Ehrenberg (*Sertularia*, Linnæus).

Family III.—Cells of the polyp sessile. *Sertulariadæ*.

† Cells biserial.

Cells alternate, tubular. *Halecium*.
Cells vasiform, everted. *Sertularia*.
Cells conico-tubular, appressed. *Thuiaria*.

†† Cells uniserial.

The branchlets plumose or pectinate. *Plumularia*.
The branchlets whorled. *Antennularia*.

Family IV.—Polype-cells on ringed stalks. *Campanulariadæ*.

Cells alternate, campanulate. *Laomedea*.
Cells irregular, or whorled. *Campanularia*.

*** Polyps propagating by buds and ova, which develop themselves on and in the body of the parent.

Hydrina, Ehrenberg (*Hydra*, Linnæus; *Hydraidæ*, Johnston). One genus only. *Hydra*.

HYDROPELTIDEÆ, *Watershields*, a natural order of Exogenous Plants (*Cabombaceæ* of Torrey, Gray, and Lindley). The species are aquatic plants, with floating peltate leaves. Flowers axillary, solitary, yellow, or purple. Sepals 3 or 4, coloured inside. Petals 3 or 4, alternate with the sepals. Stamens definite or indefinite, hypogynous, arising from an obscure torus. Anthers linear, turned inwards, continuous with the filaments. Carpels 2 or more, terminated by a short style. Ovules orthotropal, pendulous. Fruit indehiscent, tipped by the hardened style. Seeds definite, pendulous. Embryo minute, 2-lobed, inclosed in the fleshy sac of the amnios, at the apex of the nucleus, and external to an abundant fleshy albumen. There can be no doubt of the near relationship of these plants to the Water-Lilies. They are American water-plants, found from Guyana to New Jersey, and also on the coast of Australia beyond the tropics.

Hydropeltis purpurea is said to be nutritious, but slightly astringent. The leaves are employed as a remedy for phthisis and dysentery.

HYDROPHITE. [MINERALOGY, *S.* 1.]

HYDROTALCITE. [MINERALOGY, *S.* 1.]

HYMENOPHYLLEÆ, a family of Ferns including the British genera *Hymenophyllum* and *Trichomanes*. The fronds consist of branched veins, each accompanied throughout by a membranous wing or margin; a cluster of capsules, nearly spherical, is seated on one of these veins which project beyond the edge of the leaf, the cluster being inclosed in a kind of cup-like involucre.

I. *Trichomanes* has thecæ on an elongated filiform receptacle within a cup-shaped involucre of the same texture with the frond.

T. radicans, Babington, the Bristle-Fern (*T. speciosum*, Wildenow), has fronds three or four times pinnatifid, glabrous; segments uniform, linear; involucres solitary, in the axils of the upper segments; setæ at first included, ultimately very prominent. The frond in fact consists of hard wiry branched ribs, each furnished throughout with a rather membranous wing. Rhizome black, downy, very long. Fronds rather triangular, very much divided, from 4 to 8 inches long. Involucres scarcely winged.

This is a very interesting fern, on account of its beauty, its rarity, its susceptibility to injury from exposure when in cultivation, and its entire absence from all European countries or islands, with the single exception of Ireland. In texture as well as in scent it resembles some of the marine *Algæ*, and it has been observed to assume a life-like appearance on being immersed in water after being kept perfectly dry for years. At the present time this plant is to be found nowhere but in Ireland, though formerly it is said to have grown at Bell Bank, in Yorkshire. It has been lately supposed by some botanists that there are two Irish species of *Trichomanes*, the Killarney and the Glouin Caragh plants. Mr. Newman however believes the latter to be merely a variety of *T. speciosum*, and calls it *T. s. Andrewsii*. It differs from the former in having lanceolate fronds and winged involucres. It is found in very damp shady places. No other fern will thrive well in a case with the *Trichomanes*, the treatment required for one being destructive to the other. The *Trichomanes* will live or even grow lazily in a glass with other ferns, but will never attain a vigorous state of growth.

II. *Hymenophyllum* has the thecæ on a narrow subclavate receptacle within a 2-valved involucre of the same texture with the frond.

H. Tunbridgense, the Tunbridge Filmy Fern, has pinnate fronds; pinnæ distichous; segments linear, undivided, or bifid, spinosely serrate; involucre compressed, spinosely serrate; rachis broadly winged. It is slender and delicate, the rhizome very long and thread-shaped. Pinnæ, rachis, and involucres in the same place. . Valves of the involucre adpressed throughout the greater part of their length, slightly gibbous at the base. It is found amongst moss and in shady places, on the surface of rocks and stones, in many places in England, Wales, and Ireland. This plant is the *Trichomanes Tunbridgense* of Linnæus, Hudson, and many of our earlier authors.

H. Wilsoni, Wilson's Filmy Fern, has pinnate fronds, pinnæ recurved; segments linear, undivided, or bifid, spinosely serrate; involucre inflated, entire; rachis slightly bordered. It resembles the preceding species, but the pinnæ curve backward and the involucres forward. The valves of the involucre are convex or gibbous throughout, touching only by their edges, which are quite entire. The range of this species seems to be much more extensive than that of *H. Tunbridgense;* it also appears to be a more northern species, and generally to prefer a greater elevation; still the two plants are often intermixed, particularly about the waterfalls in the vicinity of Killarney, and it is frequently very difficult to distinguish the one from the other. (Newman, *British Ferns.*)

HYOSCIAMA. [CHEMISTRY, *S.* 1.]

HYPERURIC ACID. [CHEMISTRY, *S.* 2.]

HYPOXIDACEÆ, *Hypoxids*, a natural order of Endogenous Herbaceous Plants, with a tuberous or fibrous perennial root. Leaves always growing from the root and crown, nowhere else, linear entire, plaited, of a dry texture. Scapes simple or branched, occasionally very short. Flowers complete, hermaphrodite. Perianth petaloid, adherent to the ovary, 6-parted, with the sepals coarser than the petals. Stamens 6, inserted into the base of the segments of the perianth; filaments distinct; anthers turned inwards, 2-celled, erect, opening lengthwise. The number of the plants of this order is very inconsiderable. Those that are known inhabit the Cape of Good Hope, Australia, the East Indies, the tropics of America, and the warmer parts of the United States.

The roots of *Curculigo orchioides* are somewhat bitter and aromatic, and are employed medicinally in India. The tubes of *C. stans* are eaten in the Marianne Islands; those of *Hypoxis erecta* are employed by the aborigines of North America in healing ulcers and against intermittents.

I

IBALIA. [GALLICOLÆ.]

IBRAIL, IBRAILOW, or BRAILOW, a large town in Wallachia, is situated on the left bank of the Danube, 15 miles S. from Galatz, 103 miles N.E. from Bukharest, and has about 20,000 inhabitants. It stands nearly opposite the Turkish fortress of Matchin, and is the chief shipping port of Wallachia, whence the corn and other products of that principality are exported. The town has of late years risen rapidly in extent and importance. Its population in 1838 was estimated at only 6000. The harbour, formed by an arm of the Danube, is sheltered by an island. There are extensive granaries and warehouses in the town. Between 600 and 700 vessels enter and leave the harbour annually. Many of the inhabitants are engaged in the sturgeon fisheries of the Danube. In the wars between the Turks and Russians in the 18th century, the town was more than once besieged and taken by the Russians, who burnt it in 1770. After the peace of Kutschuk-Kainardji in 1774, the town was strongly fortified in the European manner; but the Russians took it again in 1828, and demolished its defences. It was restored to Turkey by the treaty of Adrianople.

ICARIAN SEA. [ÆGEAN SEA.]

ICTERIA. [MERULIDÆ.]

ICTINIA. [FALCONIDÆ.]

IDE. [LEUCISCUS.]

IDRIALINE. [CHEMISTRY, *S.* 2.]

IERAX. [FALCONIDÆ.]

IGNATIA, a genus of Plants belonging to the natural order *Loganiaceæ.* One of the species of this genus, *I. amara*, yields the St. Ignatius's Beans of India, where, under the name of Papeeta, they are said to be a remedy for cholera. No proof has been afforded of their efficacy in this disease, and Dr. Lindley ('Vegetable Kingdom') says that convulsions and giddiness are known to follow their exhibition when given in an over-dose.

ILKESTON. [DERBYSHIRE.]

ILMINSTER. [SOMERSETSHIRE.]

ILSLEY, EAST. [BERKSHIRE.]

IMPERATORIN. [CHEMISTRY, *S.* 1.]

IMPROVEMENTS, PUBLIC. [PUBLIC IMPROVEMENTS.]

INDIAN EMPIRE. The British Empire in India now extends from the Indus on the west to the Tenasserim Provinces and the Eastern Straits Settlements on the east, and from the Himalaya Mountains and the frontiers of Nepaul on the north to Cape Comorin on the south. Under the head HINDUSTAN an ample description has been given of the whole of that great peninsula, including the Panjab, Goojerat, and the island of Cutch. Sinde is described separately [SINDE, *S.* 1], as are also the Tenasserim Provinces [TENASSERIM], and the Eastern Straits Settlements [MALACCA; PENANG, PULO; SINGAPORE].

The administration of British India is now under the Governor-General of India in Council (who is Governor of the Presidency of Bengal), the Lieutenant-Governor of Bengal, the Lieutenant-Governor of the North-Western Provinces, the Governor of the Presidency of Madras, and the Governor of the Presidency of Bombay. A Return furnished by the East India Company, and presented to the House of Commons, July 23, 1857, gives the following summary of the areas and population of the various states comprised under these governments:—

	Sq. Miles.	Population.
BRITISH STATES under the		
Governor-General of India	246,050	23,255,972
Lieutenant-Governor of Bengal	221,969	40,852,397
Lieutenant-Governor of N. W. Provinces	105,759	33,655,193
Governor of the Presidency of Madras	132,090	22,437,297
Governor of the Presidency of Bombay	131,544	11,790,042
Total of British States	837,412	131,990,901
NATIVE STATES Included		
In the Presidency of Bengal	515,533	38,702,206
In the Presidency of Madras	51,802	5,213,671
In the Presidency of Bombay	60,575	4,460,370
Total of Native States	627,910	48,376,247
FOREIGN POSSESSIONS.		
French Possessions	188	203,887
Portuguese Possessions	1066	313,262
Total of Foreign Possessions	1254	517,149
Total	1,466,576	180,884,297

The total revenue of British India for the year ended April 30, 1856, was 28,891,299*l.*; the total expenditure was 29,864,090*l.*, showing an excess of expenditure over income of 972,791*l.* The total amount of the public debts bearing interest, April 30, 1852, was 48,014,244*l.*, on which the annual amount of interest was 2,279,931*l.*

The total value of the imports in 1854 from British India into the United Kingdom was 10,672,876*l.*, and the total value of the exports thereto, being the produce and manufactures of the United Kingdom was 9,127,556*l.*, exclusive of exports of foreign and colonial produce valued at 493,753*l.*

Previous to the breaking out of the great mutiny, the army of the British government in India, including her Majesty's troops and the Company's European and native troops of all arms, consisted of 289,529 men; namely, Queen's troops, Europeans, 29,480; Company's troops, Europeans, 19,928; native troops, 240,121. The contingent troops of the native states, commanded by British officers, and available, under treaties, for use by the British government, amounted to about 32,000 men.

The Indian navy consists of about twelve steam-vessels of war and transports, and about the same number of sailing vessels, armed with guns, besides a steam-flotilla for inland navigation.

The history of Hindustan, and the origin and progress of the East India Company are narrated under HINDUSTAN and EAST INDIA COMPANY. Further historical details are given under AFGHANISTAN, *S.* 1; SINDE, *S.* 1; and TERRITORIES OF INDIA, *S.* 1; in which last article the narrative is brought down to the date of the treaty of Lahore, March 9, 1846.

We shall now add the additional historical details down to the present time (March, 1858), in the form of a chronological account, arranged under each of the successive years.

1847.

January 13. The Vizier Lal Sing deposed, on evidence of treasonable correspondence with insurgent Sikhs.

August 4. Earl of Dalhousie appointed governor-general.

1848.

April 20. Mr. Vans Agnew and Lieut. Anderson, with a small body of troops, arrived in the city of Mooltan on the 19th of April, accompanied by the newly appointed governor. Mr. Agnew and Lieut. Anderson were murdered on the following day, by order of Moolraj, the ex-governor, who immediately began preparations for a war with the British. Lieut. Edwardes, who was then on the west bank of the Indus, having made a junction with the troops under General Cortland, they descended by the western bank of the Indus, while 10,000 troops sent by Moolraj descended by the eastern bank. Edwardes crossed the Indus with 3,000 irregular troops and about 80 cavalry, but no artillery, in order to make a junction with the army of the Nawab of Bahwulpoor, leaving Cortland to procure boats and bring over the rest of the troops and guns. Before this could be done, the troops of the Nawab were defeated, and Edwardes, with his small body of men, was attacked by Moolraj's force of 10,000 men and 10 guns. Edwardes resisted the reiterated attacks of the enemy, till at length Cortland got over gun after gun, and gradual reinforcements of men. The Sikh forces were then defeated, and fled to the city of Mooltan. This was the battle of Kennyree, June 18, which lasted nine hours.

July. Lieut. Edwardes and the Nawab of Bahwulpoor invest the city of Mooltan.

August 18. General Whish arrives with additional troops before Mooltan, and a bombardment is commenced on the 12th of September.

September 22. General Whish, in consequence of the desertion of Shere Sing with 5,000 troops and a quantity of artillery, is obliged to raise the siege, and take up a position in the vicinity, waiting for reinforcements.

November, December. Various movements by the Sikh forces under Shere Sing and Chuttur Sing, and the British under General Gough and Major-General Thackwell. The Sikhs are driven from an advantageous position at Rhamnuggur by Thackwell, November 2, who again defeats them, December 3, below Vizierabad.

December 27. Reinforcements having arrived, the entrenchments of Mooltan are again attacked.

1849.

January 2. The city of Mooltan taken by storm.

January 13. Battle of Chillianwallah, between the forces under Sir Hugh Gough and the Sikhs. In this battle Sir H. Gough attacked precipitately; and though the enemy suffered great loss and retired, the loss of the British was 2,357, and the Sikhs were still in force, and expecting to be joined by Chuttur Sing with a large force of insurgents from Attock. Sir H. Gough, in his despatch, said the victory was complete; but the Duke of Wellington and the British government thought otherwise, and on the 7th of March Sir Charles Napier was appointed to supersede Sir Hugh Gough as commander-in-chief.

January 22. Practicable breaches having been made in the citadel of Mooltan, and preparations made for storming, Moolraj surrendered himself and the garrison unconditionally.

January 14 to February 16. After the battle of Chillianwallah there were several movements of the Sikh forces and the British.

February 17. General Whish crosses the Chenab, and brings his forces into communication with those of General Gough.

February 21. Battle of Goojerat. By this battle the brave old General Gough retrieved his character and won additional fame. The Sikhs under Chuttur Sing and Shere Sing, were strongly posted at the village of Goojerat, with 60,000 men and 59 pieces of artillery. The British force was 24,000 men and 97 pieces of artillery. The battle lasted from six o'clock in the morning till four in the afternoon, when the Sikhs were in full retreat, which the British cavalry and horse-artillery soon converted into a rout. They were pursued fifteen miles. The two leaders escaped with about 8,000 men into the Salt Range Hills. The final result was that 53 of their guns and all their ammunition and warlike stores fell into the hands of the British, whose loss was only 807 killed and wounded.

March 14. Chuttur Sing, Shere Sing, and the principal chiefs of the Sikhs, together with 16,000 men of the Sikh army, surrender, with all their arms and 41 guns, to Major-General Gilbert, at Rawul Pindee.

March 29. Proclamation by the governor-general, announcing the annexation of the Panjab to the British possessions in India. Dhuleep Sing, the deposed Maha-Raja of Lahore, retires to Poonah, on a pension of 40,000*l.* a year.

May 6. Sir Charles Napier arrives at Calcutta as Commander-in-Chief.

September. Moolraj having been condemned to death in August, for the murder of Agnew and Anderson, is sentenced to transportation for life.

1850.

February 27. Sir Charles Napier, by a general order, disbands the 66th Bengal Native Infantry, for mutiny.

May 25. Embassy from the Raja of Nepaul arrives in England.

July 2. Sir Charles Napier resigns his office of Commander-in-Chief, and arrives in London, March 19, 1851.

1851.

January 28. Death of Bajee Rao, ex-Peishwa of the Mahrattas, at Bithoor. He enjoyed, by treaties, June 13, 1817, and June 1, 1818, a pension of eight lacs of rupees (80,000*l.*) a year. Sreemunt Nursee Punt, Nana Sahib, eldest son of Bajee Rao's brother, was adopted by his uncle as his heir, and on the death of Bajee Rao, claimed the continuance of the pension, which was refused by the Supreme Government of India, and the refusal was confirmed by the Court of Directors.

September 1. Prince of Wales Island, Singapore, and Malacca, formed into a separate government, independent of the Supreme Government of Bengal.

October 29. A British naval force arrives before Rangoon, in consequence of disputes between the government authorities of the Birman Empire and the Supreme Government of India.

1852.

January 4. The viceroy of Rangoon erects stockades and batteries, to prevent the British vessels from communicating with the shore or leaving the harbour. The British commodore destroys the batteries, and forces the passage of the river Irawaddy.

April 5. Martaban stormed by the troops sent from Hindustan.

April 14. Rangoon stormed and captured by General Goodwin.

June 4. Capture of Pegu. Afterwards evacuated.

July 9. Capture of Prome. Afterwards evacuated.

October 9. Prome recaptured.

November 21. Pegu recaptured.

December 3. Pegu invested by a Birmese army. A British force of 2,400 men sent from Rangoon defeats the besiegers, and relieves the garrison.

December 20. A proclamation of the Governor-General of India annexes the province of Pegu, which formed a part of the Birman empire, to the British possessions in India.

1853.

June 20. Proclamation by the Governor-General of India announcing the termination of the war with Birma.

The Charter of the East India Company, granted in 1833, being to terminate in April, 1854, an Act was passed, August 20, 1853, "to provide for the government of India." The following is the substance of the most important clauses:—August 20. Act 16 & 17 Vict. c. 95. 1. Until Parliament shall otherwise provide, the British territories in India are continued under the government of the East India Company. 2. After April 1854 there are to be only eighteen directors of the said Company, any ten of whom are to form a Council. 5. The Crown is to appoint six of the directors. 9. Six of the twelve elected directors must have resided at least ten years in India, as must also (sect. 3) three of the six appointed by the Crown. 30. The person appointed by her Majesty to be Commander-in-Chief of her forces in India is also to be Commander-in-Chief of the Company's forces.

December 11. Death of the Raja of Nagpoor, whose territories were then added to the British possessions in India.

1855.

March 31. Treaty with Dost Mahomed, who is afterwards re-instated on the throne of Cabul.

1856.

February 7. The Governor-General announces by a proclamation the deposition of the king of Oude, and the annexation of the kingdom of Onde to the British possessions in India. The King of Oude is granted an annual pension of twelve lacs (120,000*l.*).

February 29. Vicount Canning assnmes office as Governor-General, in place of the Marqnis of Dalhousie, who arrives in England, May 13.

For a notice of the dispnte between the British and Chinese authorities at Canton, see CHINA, *S.* 2.

1857.

The year 1857 is sadly distinguished by the mutiny of the native army of Bengal. In January, February, March, and April, there were mntinies of single regiments at Barrackpoor, Berhampoor, and Lncknow, which were suppressed; but on the 10th of May the 3rd regiment of Bengal cavalry broke ont into open mutiny at Meernt, and was joined by the 11th and 20th regiments of native infantry. After committing murders and appalling atrocities, they marched to Delhi, where they were joined by other native regiments, and where similar acts of barbarity were perpetrated. There the mutineers fixed their head-qnarters, and the old King of Delhi was proclaimed Emperor of Hindustan. Other native regiments broke out into mntiny at varions places, but were mostly disarmed and dispersed, till the native army of Bengal had ceased to exist, at least as the soldiers of the East India Company.

Jannary 24 to May 6. Mutinies at Barrackpoor, Berhampoor, Lncknow, and Meernt.

May 10, 11. Mutiny at Meernt, and march of the mutineers to Delhi.

May 11. Mntineers arrive at Delhi, and are joined there by three native regiments of infantry and a battalion of infantry. Lient. Willoughby blows up the magazine, containing large qnantities of ammunition, and escapes.

May 12. King of Delhi proclaimed Emperor by the insurgents.

May 13 to May 31. Mntinies at varions places.

May 27. General Anson, the Commander-in-Chief, with a body of British troops, arrives at Kurnaul, on the road from Umhalla to Delhi, and dies there of cholera. He is succeeded in the command by Sir Henry Barnard.

May 31. Mntiny at Lncknow of three native regiments of infantry and one of cavalry. They are attacked by the British under Sir Henry Lawrence, and dispersed.

Jnne 5. Mntiny at Allahabad. The Europeans secure themselves in the fort, where they are besieged.

June 6. Mntineers nnder Nana Sahib attack Sir Hngh Wheeler's small force in their entrenchments at Cawnpoor, bnt are driven back.

Jnne 8. Sir H. Barnard enters the cantonments before Delhi with abont 4000 troops. He entrenches himself on a ridge in front of the Cashmere gate of the city.

Jnne 8 to 19. Mutinies at various places.

Jnne 26. Sir Hngh Wheeler having been wonnded in making a sally on the 20th of Jnne, died on the 21st; the small force at Cawnpoor surrendered by capitnlation to Nana Sahib. On the 17th of June they embarked in boats, bnt were fired npon, and nearly all murdered.

July 2. Sir Henry Lawrence, wounded by a splinter from a shell which was thrown into the room where he was seated, at Lncknow, died on the 4th of Jnly. He was sncceeded by Colonel Inglis in the command of the Enropean force, which maintained itself in the Residency and fort.

Jnly 5. Sir H. Barnard dies of cholera before Delhi, and is snceeded in the command by General Reid.

July 7. General Havelock marches from Allahabad towards Cawnpoor, with a force of 1000 Enropeans, and 300 Sikhs.

Jnly 12. General Nicholson, with the Bombay flying colnmn ronts the mntineers at Sealcote on his road to join the force at Delhi.

Jnly 16. General Havelock defeats the insurgents nnder Nana Sahib before Cawnpoor.

July 17. Nana Sahib blows np the magazine, and retires to Bithoor. General Havelock enters Cawnpoor.

July 19. General Havelock attacks Nana Sahib at Bithoor, defeats him, takes 20 guns, and sets fire to the place.

July 22. General Reid, obliged to resign from illness, is succeeded in the command of the force before Delhi by General Wilson.

August 2. The Maha-Raja Gholab Sing dies at Cashmere.

August 10. General Nicholson arrives at the camp before Delhi in advance of his column, which arrives in a day or two.

August 16. General Havelock, operating with his small force against the insurgents between Cawnpoor and Lucknow, gains his ninth victory.

September 14 to 20. General Wilson, having received reinforcements and a siege-train, takes Delhi by assault, the fight being maintained in the city from the 14th to the 20th. On the 21st the British forces had entire possession of the city of Delhi.

September 25. General Havelock, accompanied by General Outram, with 2500 troops, arrives at Lncknow and relieves the Europeans besieged in the Residency, but is unable to force his way back again.

October 27. Sir Colin Campbell, having been appointed Commander-in-Chief, leaves Calcutta on his ronte to Cawnpoor.

November 3. Sir Colin Campbell arrives at Cawnpoor.

November 13. Sir Colin Campbell, with abont 12,000 troops, commences the attack on the rebels at Lncknow.

November 17. Sir Colin Campbell, after a series of operations and some severe fighting, forces his way into the Residency at Lncknow.

Sir Colin Campbell, having remained two or three days, evacnates the Residency at Lncknow, and by a well-devised feint, brings away the whole of the besieged garrison, with all the sick, the women, and children, withont the loss of an individnal, and the whole are placed in security in the fortress of Alumbagh, abont three miles from Lncknow.

November 24. Sir Henry Havelock dies at Alumbagh of dysentery occasioned by fatigue and anxiety.

December 7, 8. The Gwalior contingent force having overpowered the troops nnder General Windham, and obtained possession of the town of Cawnpoor, Sir Colin Campbell attacks the Gwalior mntineers, and defeats them.

December 10. The defeated Gwalior troops are pursued by General Hope Grant, with cavalry and artillery, and are completely dispersed with the loss of the remainder of their guns and all their baggage, stores, and ammunition.

1858.

In the early part of this year varions bodies of mntineers are defeated at different places. In the mean time Sir Colin Campbell at Futtehgur and Cawnpoor, having collected troops to the amonnt of about 20,000 and about 120 heavy guns, commences the siege of Lucknow on the 1st of March, in connection with the troops of Sir James Outram and other officers, altogether, it is stated, amounting to about 50,000 men.

The last mail from Bombay states that the old King of Delhi has been tried, fonnd guilty, and condemned to banishment.

Lord Palmerston's late government announced the intention to bring a bill into parliament, for the purpose of transferring the government of British India entirely from the East India Company to the British government, and Lord Derby's present government have introduced (March 26, 1858) a bill for the same purpose.

Having now brought down the historical details as far as they are known at the present time (March, 1858), we shall give an account of the chief prodncts of British India, and also of the material progress which has been made there in recent times.

The products of India are as numerons as its surface is diversified and its climate various. The staple products are cotton, indigo, sugar, hemp, flax, oil, opium; maize, wheat, rice, and other cereals; besides which there are tea, spices, gums, dyes, and many articles of minor note.

Cotton is the leading feature of Indian agriculture. There is little land, save that which is sterile, swampy, desert, or mountainons, upon which it cannot be grown. In most village lands npon the plain country, it forms part of a two years' course; and ontside the village walls, hand-weavers have been seen from time immemorial, making the coarse cloth universally worn by the natives. The home-consumption of Indian cotton is immense. Geographically its growth is confined to no particular limits in the Indian peninsula, for it is found at Travancore, the southernmost part, on the coasts of Chittagong and Arracan, of the Gulf of Cutch, in the valley of the Ganges, and in the northernmost part of the Panjab. For exportation, its principal localities have been the district of Goojerat, in the Bombay Presidency; of Kandeish, in the kingdom of Berar; from Bundelcund, in the Bengal Presidency; Belgaum, Darwar, and Bellary, in Madras, and from the Panjab and Sinde. More than five million acres are stated in the statistical returns, printed by anthority, to be under cotton cultivation in the three Presidencies. The quantity of raw cotton exported to Great Britain in 1854 was 1,042,358 cwts., valued at 1,641,714*l.*; but if, by means of railroads, the great cotton field of Berar, situate within the dominions of the Nizam of Hydrabad, were placed nearly on an equality in point of facility of transport, with the maritime cotton districts, then a breadth of land sufficient for the growth of a quantity perhaps equal to the full demand of Great Britain, might at once be made available.

The foregoing conditions relating to the province and prospects of Berar are partly in course of being fulfilled. When the great Indian Peninsula Railway shall be completed, the cotton of Nagpoor, Hydrabad, and of the Saugor and Nerbudda territories, will have an outlet to the port of Bombay on one side, and to Mirzapoor and the river Ganges on the other; and the railroad which is intended to connect the cities and presidencies of Madras and Bombay, will pass through the cotton districts of Bellary and Belgaum. The cotton of Bundelcund, of the Delhi territory, or of Oude, may be seen to this day, uncleaned and unpressed, passing down the rivers Jumna, the Ganges, and the Indus, in unwieldy country boats, which drift no faster than the current will bear them along. Still more to be deplored are the efforts required to convey it in country carts, or upon the backs of bullocks, from the great cotton-field of central India towards the sea-coast, or to the banks of the Ganges. From Nagpoor and the territories of Hydrabad, two streams of the cotton commerce may be seen struggling along nomade roads, extricated with difficulty from the sands of unbridged rivers, and passing at the rate of 10 to 14 miles a-day, on one side towards Bombay, and on the other to Mirzapore. This state of things it is expected that the railway will remedy; and if one line should not be sufficient, they should be multiplied, until the shipments of cotton from Nagpoor shall be as certain and as cheaply effected as they now are from Calcutta or from the mouths of the Indus.

Great importance is attributed to culture; but the natives of large tracts already employ a mode of cultivating the cotton plant in principle nearly the same as the American, but better suited in some respects to the locality. The great inferiority of much of the Indian article is the result of what befalls it subsequent to its production in the fields—that is, in the way in which it is gathered and stored, and chiefly in the way in which it is separated from the seed, and prepared for the market, as well as in its transmission to market. At the gathering the effort for improvement should commence.

The introduction of improved methods of cleaning and packing is of the first importance. The cultivation has to contend with sundry disadvantages, but these are compensated by the cheapness of the cost of production; this in many parts of India being only 1½*d.* per lb., while in America it is from 50 to 100 per cent. more, ranging from 2¼*d.* to 3*d.*

Indigo is one of the principal articles of produce of the Bengal Presidency. It is grown to some extent in the alluvial soil of the North-Western Provinces; but Bengal proper, below the junction of the rivers Jumna and Ganges, is its chief locality. There is a considerable cultivation of the plant in the Madras territory, and in Mooltan, the southernmost district of the Panjab, as well as in Sinde; but in none of these countries has the manufacture of Indigo had the benefit of that European superintendence and skill, which have brought this dye to such perfection as it has attained in Bengal. The manufacturers have attained a degree of skill which, in a climate favourable to the plant, and backed by the cheapness of labour in Bengal, has enabled them to bid defiance even to the more practised manufacturers of the west. The culture and manufacture being established, indigo has continued one of the staple products of Bengal. The quantity imported into the United Kingdom from India in 1854 was 64,964 cwts., valued at 1,546,143*l.*

The *Sugar-Cane* is another of the indigenous productions of India, from whence it has been supplied to other countries, where, especially in the West Indies, it has been brought, by European skill and culture, to yield a far better substance than the sugar of the country from which it was originally derived. Yet there is no reason why India, with regard to this article of commerce, should not compete with any other country in the world. In various parts, it has soils and climate which are capable of producing the cane in the greatest perfection. In the whole of Bengal, in the North-Western Provinces, the Panjab, in the Madras territories, and on the east side of the Bay of Bengal, the sugar-cane is grown with perfect ease and in the greatest abundance. But, so far as observation goes, the method of cultivation of this crop is faulty to a degree, and some of the leading principles of vegetable physiology are set at nought. The cane attains, in some places, a height of eight or ten feet; it has numerous ramifications in its roots, and several long drooping leaves at its upper extremity. Yet these canes are set so close together, that neither air nor light can sufficiently penetrate for the proper development of the plant, and the deposit of the full proportion of saccharine matter which is desired. It may be said of this plant, with regard to both its cultivation and the manufacture of sugar, that there is more room for improvement, as well as greater prospect of success, than with respect to any other agricultural product of India. A few sugar factories, superintended by Europeans, have been established and are successfully worked; but if one tithe of the attention should ever be paid to sugar in the East, which it has met with in the West Indies, the results to India, as well as to England, would be very great. Already it forms an important article of export from British India, the quantity imported into the United Kingdom in 1854 having been 779,189 cwts., valued at 891,708*l.* Samples of East India sugar sent to this country have been pronounced equal to any from the West-Indies. But to insure success, as well as to make it profitable, it is necessary to pay as much attention to the culture of the cane as to the manufacture of the sugar.

The true *Hemp-Plant* is common to nearly all Asiatic as well as European countries, but is believed to be of Eastern origin. In Hindustan however, except in some parts of the Himalayas, it is not cultivated for its fibre, but for the intoxicating juice it contains, which is manufactured into the deleterious drug termed Bhang. In almost every part of India it is cultivated and planted widely, for the better production of this substance; but if it were planted thickly, so as to exclude the air and light, and with the object of obtaining a long and pliant fibre, there is no reason to believe that this might not be done with such success, as to form a substitute for the quantities of hemp which we usually receive from Russia, Poland, and Italy. The hemp of Kangra, a district of the Himalayas, north of the Panjab, has recently acquired some celebrity, having proved on trial superior in strength to even the best Russian hemp. There can be no question with regard to the practicability of producing hemp of a quality suited to the European market, over vast tracts of country on the lower slopes of the Himalaya Mountains. It has been stated, on good authority, that Himalayan hemp may be landed in England, including all charges, at from 25*l.* to 31*l.* per ton, and it is said that its value here would be 35*l.*

But there are other fibres considered as substitutes for hemp, which are received from India, and have become most important articles of commerce. These are the Sunn of Bengal, and Jute, and gunny, which is made of jute. These products are from plants totally different from the true hemp, which has just been described.

Sunn, or Indian Hemp, under which name the article is exported from that country, is the produce of a leguminous or podded plant, and has a close resemblance to the Spanish broom, which is a sub-division of that order. It is cultivated everywhere in India for its fibre alone; and with this object, the natives affirm, that the thicker it is grown the better,—"so thick as to prevent the air from passing through it;" which is a proof that, without any acquaintance with the physiological reasons by which the correctness of this system can be shown, they have, by long practice and observation, arrived at the true method of culture. In their treatment of the plant however, after it has come to maturity, they have much to learn, in order that the fibre may be produced in the best state for the markets of Europe.

The fibre of *Jute*, or Jew's mallow, has not been till lately an article of commerce, but for the last seventeen years it has been much employed in our manufactories. In India it has been long employed for making both cordage and cloth. The material is obtained from two distinct plants, one of which appears to abound chiefly in India and China, and is styled Chinese Hemp. The fibre of both however is called *Jute*. The quantity of hemp, sunn, jute, &c., exported from the three Presidencies, but much the largest part from Bengal, amounted in the year 1854 to 570,250 cwts., valued at 209,476*l.*

Flax, or the linseed plant, has been cultivated in India from the earliest time, not for its fibre, but only for its seed, from which the well-known oil is expressed. It is accordingly sown, not thickly together, as is the case with sunn, which is grown for its fibre, but along the margins of fields of other crops, where the sun and air can freely reach it, and increase the secretions upon which the value of the seed depends. But, if in India this plant could meet with some portion of the attention which is bestowed upon it in Russia, Poland, Belgium, Germany, France, Italy, and Ireland, it would, no doubt, be a very important matter for India with respect to its fibre, as it is already for its seed. The quantity of linseed and flax-seed imported from India into the United Kingdom in 1854 was 196,570 quarters, valued at 601,996*l.*

It has been already stated, that the winters of Hindustan, and especially those of Upper India, in the north and north-western provinces, are so temperate as to resemble the autumns of Europe. For a season ranging, according to latitude, from October or November to March and April, all trace of the tropical heats seems to have disappeared, cultivation of nearly all the European types occupies the soil. Abundance of wheat and barley are grown in this interval, being sown towards the conclusion of the rains in August or September, and reaped in April before the heat sets in. The whole face of the country may then be seen as one sheet of golden corn; not a single hedge marks the boundary of one field from another, nor even of the numerous village lands; and on an apparently interminable level plain, there is nothing to arrest the eye over this rich expanse, save the groups of trees which denote the positions of villages or wells. No wheat comes from India to this country; but rice, which is grown in vast quantities as food for the inhabitants, is also exported to the United Kingdom; the quantity in 1854 having amounted to 1,251,325 cwts., valued at 875,927*l.*

Allusion has just been made to the introduction of the *Tea Plant* in India. In 1834 Lord William Bentinck determined upon attempting the cultivation of tea in India. Dr. Royle, who is our informant, in his volume on the 'Productive Resources of India,' says: "A committee were then assembled for the purpose of submitting to Government a plan for the accomplishment of this object." But so far back as the year 1827, Dr. Royle had drawn attention to this matter, and pressed it upon the notice of Government. "The tea plant," he stated, "delights particularly in sheltered valleys, the declivities of hills, or the banks of rivers, where it enjoys a southern exposure to the sun. But it is found also to grow on the rugged tops of mountains; and although it appears to attain the greatest perfection in the mild climate about Nankin, yet it flourishes in the northern latitude of Pekin, and in Japan, as well as about Canton, and these places are comprised within the parallels of 20° and 40° north latitude." Dr. Royle therefore suggested that "in the valleys at the foot of the Himalayas, or at moderate elevations, there was considerable prospect of success in the cultivation of the tea plant; for the different elevations allow of every variety of climate being selected, and the geographical distribution of the plant is sufficiently extended, and the natural sites sufficiently varied, to warrant its being beneficially cultivated. Taking the extreme limit, the Himalayas extend over 45° of longitude, but not making more than 10° of northing in its whole extent. Though variations of longitude no doubt produce difference in climate, yet as this is chiefly influenced by latitude and elevation, it is evident that along the whole extent of this mountainous country, there must be many localities which differ little in latitude and in elevation, and which must consequently resemble each other in climate, and therefore probably also in vegetation." In the hills of Assam, the tea plant was found to be indigenous. Plants also were procured from China, "as well as seeds and cultivators, to carry on the experiment; and it was resolved that when the practicability of producing tea fit for commercial purposes shall have been ascertained, it may be safely left to the enterprise of individuals. This course has been strictly followed." The Court of Directors, and the Government of India, having brought the experiment of the growth and culture of the tea plant to a successful issue, have handed over its further extension to a private company, who are carrying it forward with great advantage.

The receipts and disbursements of this Company, employed in the cultivation and preparation of tea in Assam, for the half-year ending the 31st March 1856, amounted to 19,655*l.*

In the Kungra district, quite at the other extremity of the British territory, still on the lower slopes of the Himalayas, in the Murree Hills, and in Ghurwal, Kumaon, and the Deyra Doon, and Darjeeling, similar successful experiments in tea culture have been made, and annual public sales of excellent tea take place. Its cultivation by the natives has been encouraged by grants of land on favourable terms; but too much care is required to produce a saleable tea, to hope that they will succeed except under European superintendence. It can only, therefore, be expected that tea will be produced over the great extent of the Himalayan range which bounds India on the north, through the agency of commercial companies, like that which has succeeded in Assam. Besides the Assam Company, another has been recently established for the growth and manufacture of tea in Darjeeling, a part of the Himalayas to the eastward of Nepaul.

The total amount of tea imported from India into the United Kingdom in 1854 was 386,221lbs., valued at 24,943*l.*

Only a brief allusion will be made to *Opium*; for although it is an article of great importance to the revenues of India, it is not a free product of its soil. It cannot be cultivated except by permission of the Government, who retain the monopoly of it in their own hands, and discourage, by heavy duties, any extension of its production. In the case of a drug so deleterious and so enervating, the high price which is maintained by these restrictions, is probably a benefit to that portion of the human family which is addicted to its use. The profit realised by the Government by its sale, exceeds three millions sterling. There is one fact in connection with this drug which is worthy of note. The poppy from which it is prepared, does not appear to be indigenous to India. It has been found nowhere in a wild state, but is a plant which is extensively distributed over both the European and Asiatic continents. The success with which it is cultivated in the Bengal Presidency, chiefly in Malwa, and in Central India, is due to the natives alone, unaided by science or European superintendence. The selection of soil and climate under which it has been found most to thrive, with manure and irrigation, seem to be all that has been necessary in its cultivation. Nature does the rest, ordinary care only being necessary, to collect the milk and secretions, which are exuded from the capsules of the plant, and to evaporate the moisture with which it is mixed, till the residue be sufficiently dry and prepared for sale.

With the exception of tin and salt, there can scarcely be said to be any export of mineral substances from India. In 1856, the value of the tin imported into the United Kingdom was 52,120*l.*

Several manufactured metals are specified in the tables of exports from the three Presidencies; but the probability is, that these are chiefly re-exportations of British goods from the ports at which they were first landed to other places on the coast. Neither copper, as a native product, either rough or manufactured, nor iron, lead, nor any other metal except tin, is yet known amongst the exported goods from India. Very extensive deposits, however, of both coal and iron are known to exist; and when these two substances occur together, or in the same country within any moderate distance of one another, to what extraordinary results may they not eventually lead? In Burdwan, a district of Bengal, an inexhaustible field of coal is known to exist, one of the seams of which has a thickness of thirty feet, and the coal-field has been worked for several years. The inland steam navigation of the Ganges has long been supplied, and much of the coal used by sea-going steamers has come from Burdwan; but its price in Calcutta has not always, having reference to quality also, been able to compete with English imported coal. Coal is also found in the valley of the Nerbudda, and in the Tenasserim Provinces; but from neither of these localities has it yet been profitably procured. Vast masses of the iron-ore have been examined and pointed out by many observers. All the agricultural implements of the natives are made with the iron of the country, smelted and worked by their own rude means; and in some places a considerable market for native iron already exists. At Monghyr, on the banks of the Ganges, fire-arms have long been made from the iron of the adjacent hills, and there is an annual export of manufactured iron from that place. The Gwalior iron is well known in the inland trade, so is that of Kangra and Kumaon; and all the large towns are supplied with rough malleable iron in small lumps from one or other of these districts. In the Kumaon Hills, vast beds of hæmatite iron-ore have been recently brought to notice by Colonel Drummond. Unfortunately no coal occurs, nor is likely to be found within any reasonable distance; but abundance of charcoal can be made from the boundless forests with which the lower slopes of the Himalayas and the plains adjacent to the ore are clothed.

There are copper mines worked by the natives in several districts of the Himalayas; but the produce is small, and India has never supplied herself with this metal. Brass vessels are in universal use; but copper, spelter, and manufactured brass are imported annually at the principal ports of the three Presidencies, to a large amount. The natives of Hindustan have neither possessed the capital nor the skill to mine deeply, and to abstract the riches which lie buried in the earth, and of which the scanty produce of their shallow workings are a sure indication.

The southern portion of the Tenasserim Provinces, from the province and latitude of Tavoy, to the Pakchan river, abounds with the ore of tin, which is found in the greatest purity in the beds of streams, and in hills of disintegrated granite on the plain. It is a pure peroxide of tin, requiring the application only of a moderate heat to produce the perfect metal. The quantity hitherto prepared in the British territory, can be regarded only as an indication of what might be obtained if labour and machinery were duly applied to the task. The extent of tin-working which has been carried on in Tenasserim, has not been by the natives of that province, but by the enterprising and more industrious Chinese, whose small and solitary settlements are to be seen dotted here and there in the forests. They have a smelting establishment at the mouth of the Pakchan river, and the tin is carried away in junks to Penang and Singapore.

Salt is an article of manufacture in India almost exclusively for domestic consumption, the value exported being insignificant.

Sufficient has now been said of the most important indigenous products of India, to show in what her real wealth and value to England consist;—above everything, it has been intended to prove that, in comparison with the actual produce of her soil, all else sinks into insignificance when we contemplate the resources, or endeavour to accelerate the material progress of that country.

There is no step which has a more direct bearing on this subject than the irrigation of the land by artificial means. There are traces in various parts of the country of works constructed in ancient times for this purpose. Canals of irrigation were formed either from the head waters of some of the rivers as they issue from the Himalayan range, or lower down, where, at one period of the year, they overflow the adjacent plains. In some of the minor hills the head waters were dammed up and reservoirs formed, from which the discharge could be regulated and distributed when the ground was parched. It has been commonly and with some justice remarked, that to furnish the native cultivator with the command of water is to give him nearly everything he requires to insure his prosperity.

The East India Company, following the example of the Moguls, their predecessors in the government of the country, have greatly extended the means of irrigation in the North-Western Provinces, in the Panjab, and in the Presidency of Madras.

With regard to irrigation canals, the waters of both the Jumna and the Ganges rivers have been freely drawn upon. The country on the right and left banks of the Jumna, from Saharunpoor to Delhi, and branching westward to Hissar, may be said to be secure against drought, cultivation now, over a large surface, being entirely independent of the periodical rains. The Eastern Jumna and the Western Jumna Canals, with their branches, are 580 miles in lineal extent. The volume of water available for irrigation from this river, has been calculated at 2,870 cubic feet per second, and each cubic foot has been found adequate for the annual irrigation of 218 acres of land; but as one-third of a district only is usually irrigated, the remainder bearing crops not requiring irrigation, one cubic foot of water per second will suffice for 654 acres of land, equal to about one square mile, so that the canals of the Jumna are supposed to serve for the irrigation of 2,870 square miles.

The Ganges Canal is a still nobler work. Nearly the whole tract of country comprised between the rivers Ganges and the Jumna, from Hurdwar to Allahabad, is included in this large system of irrigation for the North-Western Provinces. The main line of this canal, which was completed, and received water for the first time in 1854, in 525 miles in length. Its extreme breadth is 170 feet, and its greatest depth 10 feet; and, as truly described by the Lieutenant-Governor, "it is a work which stands unequalled in its class and character among the efforts of civilised nations." When all its branches shall be finished the canal will be about 900 miles in length, and the area which may be irrigated by its waters is stated to be not less than 1,470,000 acres. It is adapted also to navigation. No single canal in Europe has attained to half the magnitude of this Indian work. It nearly equals the aggregate length of the five greatest canals in France. It greatly exceeds all the first-class canals of Holland put together, and it is greater by nearly one-third than the greatest navigation canal in the United States of America. It is one of the greatest triumphs of the engineering art of which any country can boast. Its total estimated cost is 1,555,548*l.*, of which 1,400,000*l.* had been expended up to the beginning of the year 1857.

In the Panjab a system of similar canals has been projected and partially commenced, to afford the means of irrigation to the greater parts of the tract of country comprised between the rivers Ravee and the Sutlej. With the branches, the total length when finished will be 450 miles, and the cost 500,000*l.* The head waters, like those of the Ganges and Jumna canals, will be taken from the rivers at a high level, and carried along the slightly elevated ridge which is generally found to exist between two rivers, having a gentle declivity on each side, which favours the system of irrigation best suited to the country. But towards the southern part of the Panjab, at and below Mooltan, and on each bank of the Indus, another description of irrigation canal prevails, which is formed by taking advantage of the annual inundation of those rivers, and leading off bodies of water in channels to considerable distances inland. These canals have existed for long periods, and efforts are now being made to restore and bring them again into extensive use.

In the Madras Presidency another system of canals prevails, which is suited to the features of the country. The tract to be irrigated being narrow, in comparison with the extensive plains of the North-Western Provinces, and the body of available water considerably less, it has been found expedient to throw dams of great length across the channels of the Godavery, the Cauvery, and the Kristna rivers, so as to store up their waters and distribute them at pleasure during the dry season. These works on the Godavery have cost about 230,000*l.*, on the Cauvery 50,000*l.*, and on the Kristna 150,000*l.*; and, without doubt, the number of the localities are endless, both in that Presidency and in various other parts of India, where similar works might be constructed with the greatest advantage.

Next in degree of importance to the future progress of India, and in a still wider sense than may yet be known, not only with regard to its material interests, but to its social and moral advancement, is the continuous chain of iron roads by which it is hoped, that before many years shall have passed, the whole of the principal and most productive provinces in the Indian Empire will be linked together. Already the natives of every class and caste, contrary to general expectation, unmindful of any prejudices, herding together in the same railway carriage, have seized with avidity the advantages of the locomotive train in Bengal, Madras, and Bombay. The opening of the railway for short distances at Calcutta, and the two other Presidencies, has been hailed with acclamation by the whole people, who flocked from their villages for miles to witness it.

The grand trunk lines now in progress of construction are of great extent. From Calcutta the main line will lead through the entire valley of the Ganges, for a thousand miles to Delhi, with an eventual extension, in the same general direction, across the rivers of the Panjab to Lahore, and perhaps to Peshawur. From Bombay another main line has been commenced, and will stretch nearly across the continent of India at its broadest part, taking the general direction of the Nerbudda Valley, passing by the cotton districts of Kandeish, Saugor, and Bundelcund, branching into the great cotton-field of Central India to Nagpoor, and affording an easy outlet for that valuable product, either to be shipped at Bombay, or for conveyance down the river Ganges, from Mirzapoor to Calcutta. At Mirzapoor a junction will be formed with the Bengal line. There is also a line to the northward of Bombay, in order to bring down the cotton from Baroach, Baroda, and Surat. In Sinde there is a short line undertaken to connect the port of Kurrachee with the

Indns, which seems to be a first step towards a direct railway, or mixed railway and river steam communication, from the Panjab to the sea. In the Presidency of Madras, two trunk lines are projected: one to penetrate the peninsula in a longitudinal direction, and to connect Bombay, passing through some rich cotton ground in Darwar and Belgaum; the other to strike across to the western coast, having its other terminns at Beypoor.

At the beginning of 1857 the nnmber of miles of railway already opened for traffic at the three Presidencies, and the extent of each line actually in a state of progress, are as follows:—

	Main Lines.	Miles Opened.	Miles in Progress.
	From Calcutta to Delhi	120	1,100
32 Miles common to both	Bombay to Mirzapore	49	750
	Bombay to Madras	71	300
	Bombay and Baroda	...	150
	Madras to Bellary	...	296
	Madras to West Coast	90	300
	Total	330	2,896

When these grand trunk lines of railway shall have been completed, a glance at the map will show that, althongh the richest districts will have been penetrated, and the principal cities connected, the 2896 miles of which they consist, are bnt the foundation and gronndwork of what will be nltimately reqnired, before it can be said that India is completely provided with railway commnnication; before, in fact, many of the inlying districts can be supplied with food, when their own internal resonrces may fail.

Inland steam navigation has existed for several years on the river Ganges, and also npon the Indns; bnt not by any means to the extent which even the private traffic of Bengal and the Panjab requires.

The ordinary highways of India is a subject which cannot be regarded with mnch satisfaction. Until the period when Lord William Bentinck governed the country, the subject of roads does not appear to have attracted much attention from the State. The communications of the conntry were in a most neglected condition, consisting of native wheel-tracks, or little else. Above Allababad, and in various other parts, so recently as the year 1830, a regiment proceeding in conrse of relief from one station to another, had to be preceded by a native gnide. This is now altered. Roads, even if unbridged and nnmetalled, exist in almost every district; and there are three great lines of communication of considerable length; the earliest begun only in 1836, from Calcutta, and recently prolonged to Peshawur: this, however, is not yet complete in parts.

The three grand trunk roads constructed and maintained, are as follows:—

	Length in Miles.	Cost. £	Annual Repairs for Maintenance. £
From Calcutta to Peshawur, when completed	1,423	1,423,000	50,000
From Calcutta to Bombay, as estimated	1,002	500,000	35,000
From Bombay to Agra	734	243,676	5,000
Total	3,159	2,166,676	90,000

The average annual expenditure npon pnblic works of all kinds in India during fifteen years, between 1837 and 1852, was 299,732*l*. In this are comprised roads, bridges, embankments, canals, tanks, and all works of irrigation; bnt since 1852 the ontlay has been mnch greater, inclnding the snms spent npon the Ganges and Panjab Canals, and the guaranteed interest npon Railway Stock, which must be regarded as a contribntion to pnblic works.

The electric telegraph, which has been recently established with so much rapidity and snccess, can scarcely be regarded as bearing so directly npon the wants and welfare of the people, as other pnblic works which have been briefly described. Except inasmnch as it is an aid to good government and to the preservation of peace, the rapid transmission of intelligence from one part of the conntry to the other, is as yet sligbtly regarded by the native commnnity, bnt when traffic shall be accelerated by the railways, it will not be long before the telegrapb will be rightly valned. More than 4000 miles of telegraphic wire are now set np in India, and in constant use. The superintendent, Dr. O'Shanghnessy, availing himself of the executive officers of Government throughout the conntry, to set np the posts and to bnild pillars for the snpport of the wires, and with his own trained establishment and materials previously prepared and brought from England, was enabled to complete the communication between Calcntta and Agra, a distance of 800 miles, in the course of five months. In fifteen months, all the lines from Calcutta to Attock on the Indus, from Agra to Bombay, and thence to Madras, extending over 3050 miles of space, were ready for use. Other places more distant have since been embraced in the electric circle, and the average cost of these 4000 miles does not exceed 50*l*. per mile, althongh the physical obstacles enconntered have been nnnsually great.

INDIAN TERRITORY, United States of North America, an extensive tract of country set apart by the Congress and federal government, for the permanent residence of the various tribes of native Indians removed from the settled states and territories of the Union. It lies generally between 33° 30′ and 39° N. lat., 94° and 100° W. long., bnt the limits are not very strictly defined. It is bounded S. by Texas; E. by Arkansas and Missouri; and N. by the newly created Territory of Kansas. The area, as given in the 'Report of the Census' of 1850, is 187,171 square miles, bnt this is considerably more than in previous statements of the area of what is sometimes called the Indian Territory proper, and perhaps inclndes a portion of the country since appropriated to Kansas Territory. The Indian inhabitants are estimated at from 100,000 to 120,000, four-fifths of whom have been transported from countries east of the Mississippi.

In the sonth-eastern part of the Territory there is a range of hills of moderate elevation; the remainder is a plain, or at most has a gently undulating surface. A considerable portion of the country is prairie gronnd, bnt along the rivers there is a good deal of timber. The country is well supplied with water, having several good-sized rivers running through it or along its borders on their way to the Missouri and the Mississippi. The Arkansas flows throngh the midst in a sonth-eastern direction, and receives in its passage numerous tribntaries, some of considerable size. The chief of these tribntaries is the Canadian River, which also has numerous affinents or 'forks.' The Red River waters the sonthern, and tbe Kansas the northern portion of the state: both of these, as well as the Arkansas, are navigable within the territory at certain seasons by steam-boats. The country possesses capabilities for the prosperons maintenance of a large population. The middle, and by far the larger part of the country, appears to belong to the Lower Carboniferous series of rocks. On the east are Upper Carboniferous strata, or coal-measures, a part of the great coal-basin of Missouri and Illinois. The western and north-western districts belong to the Cretaceons group of rocks. On the sonth is a narrow belt of Lower Silurian rocks, consisting along the Red River of blne limestone, with ernptive rocks. Coal is not the only mineral obtained. Both lead and iron are found; and there are saline springs, from which a large quantity of salt might be manufactured. The climate is generally healthy. The northern parts are snbject to keen westerly winds from the Rocky Mountains, and tbe winters are rather cold; but in the sonthern parts the winters are mild, and all the plants are cultivable which are raised in other parts of the United States of the same latitnde. The soil on the eastern side of the Territory is generally fertile; the northern parts are well adapted for grazing cattle. Maize, wheat, and other grains, prodnce good crops in almost every place where they have been tried.

As already said, this large tract of country has been appropriated for the permanent residence of the Indian tribes transported from the settled parts of the United States. It need hardly be said that they have not turned to full account the capabilities of the conntry. Bnt they have shown that they are capable of steady indnstrial efforts, and they have made very considerable advances in civilisation. Under the guidance of missionaries, who have settled amongst them, and with the sanction and assistance of the Commissioner of Indian Affairs, some of the larger tribes have established regular governments, legislatures, jndicial officers, churches, schools, newspapers, &c.; have introduced the manufacture of agricultnral implements, cloth, and most articles of ordinary farm and domestic use; cnltivate the land with a considerable amonnt of skill; rear horses and cattle; build houses; and export to neighbonring states maize, cotton, hides, &c. By the treaty of removal and settlement, the federal government furnishes them with blacksmiths, wheelwrights, and some other mechanics, and at their first settlement gave them a stock of cattle, &c. Many of the tribes possess slaves.

The principal Indian tribes settled in the Territory are the Cherokees, who numbered according to the Commissioner of Indian Affairs, about 17,600 in 1853, but whose numbers are usually estimated much higher; the Creeks, who numbered 25,000; the Choctaws, 16,000; the Osages, 4941; the Chickasaws, 4709; the Pottawatomies and Chippewas, 4680; the Pawnees, 4500; the Seminoles, 3000; the Sacs and Foxes, 2373; the Shawnees and Senecas, 1400; Delawares, 1130, &c. The Cherokees occupy a considerable tract lying on the north of the Arkansas River, and adjoining the state of Arkansas, and are the most civilised of all the Indian tribes. [CHEROKEES.] The Choctaws occupy the most southern part of the territory between the Red River and Canadian River. The Chickasaws occupy a part of the same country, and are governed by the same laws. The country of the Choctaws is the most hilly and broken in the Indian Territory, and is well watered by the above mentioned rivers and their tributaries. The Choctaws are extensively engaged in agriculture, raise large quantities of cotton and maize, and have good stocks of horses, cattle, and sheep. On the streams are numerous grist- and saw-mills, and cotton-gins. The houses and farms are well built, and the grounds fenced; the mechanical occupations are chiefly carried on by mechanics provided by the United States' government. The Choctaws have a written constitution and laws. The country is divided into four districts (one of which is occupied by the Chickasaws), each of which elects its own chief every fourth year. A general-council of 40 members is elected annually, who meet in the council-house, and pass all laws, &c., subject to a qualified veto by the chiefs. Trial by jury is established: with appeals to the higher courts. At the head of military affairs is a general elected by the people at large; and there are 32 captains in each district. Numerous missionaries are settled among both the tribes. The Creeks, with whom are united the Seminoles, occupy the country between the tracts of the Cherokees and Choctaws, watered by the Canadian River and the forks of the Arkansas. The country is less fertile than the districts occupied by those tribes, and the Creeks are on the whole a good deal less advanced in civilisation. But they have similar government, organisation, and judicature; they dwell together in towns, and to a certain extent cultivate their land in common. Numerous missionaries are settled amongst them, under whose advice they have built several churches, and established good schools: and altogether the prospect of the future progress of the tribe is spoken of as highly promising. A proposition is said to have been lately made by the executive of the federal government through the Commissioner of Indian affairs, to the Cherokees, Choctaws, and Creeks, offering to form a state out of the territory occupied by them, and thus admit them into the Union as citizens; but the Cherokees, it is said, were unwilling to be placed on the same level with the other tribes not so far advanced in civilisation, and the proposal fell to the ground.

Of the lesser tribes it may be enough to mention that the Shawnees and Senecas are settled in the northern part of the Territory bordering on the Kansas River. They are a frugal industrious people, carefully cultivating their farms, and raising considerable crops of maize, cotton, vegetables, &c., and breeding horses, cattle, and swine. The Osages, Pottawatomies, and Chippewas occupy a tract north of the Cherokees; they are much less advanced in the arts of civilised life, and retain most of their old wandering habits. Their country is not very fertile, and they suffer much from the cold of winter, and from occasional droughts in summer. INDIN. [CHEMISTRY, *S.* 1.]

INDINIC ACID. [CHEMISTRY, *S.* 1.]

INFLORESCENCE. [INFLORESCENCE.] The following is a survey of the kinds of inflorescence and their names, from Professor Schleiden's 'Principles of Scientific Botany.'

A. The Solitary Flower, as terminal or axillary-flower (Flos Solitarius, terminalis vel axillaris). The latter may be situated in whorls, and then form a Verticil (Verticillus).

B. Simple Inflorescence.

* *a.* Inflorescentia Centripeta.

1. The Capitulum. The undeveloped axis is here usually enlarged upward, with a fleshy or spongy substance, and the more so if the number of flowers is very great. It may be more minutely designated as simple, discoid, cupulate, lageniform, conical, and cylindrical, as it approaches nearer to one or another. The last form then passes gradually into the spadix. Special varieties are :—

* The Calathium (Anthodium, Ehrh.; Flos Compositus, Linn.), a many-flowered capitulum, whose single flowers stand in the axils of more or fewer stunted bracts, and are surrounded with one or more circles of sterile bracts, as in the family of the *Compositæ.*

** The Cœnanthinum, Nees (Hypanthodium, Link.). Exactly like the preceding inflorescence in some *Urticaceæ.* The cup-shape of the peduncle in *Ficus* is no distinction, since it is wanting in *Dorstenia;* and it exists in some *Compositæ;* the same may be said with regard to the sterile bracts, which are as much stunted in *Dorstenia* as they are clearly present in *Ficus.*

2. The Spike (Spica) in very various forms. The kinds are :—

* The Catkin (Amentum), distinguished by the fact that it falls off entire, or by its imperfect flowers. The male inflorescence of *Cupuliferæ, Salicaceæ, Betulaceæ,* and some few other plants.

** The Spadix, a closely crowded spike, or partially a cylindrical capitulum with fleshy peduncle; in *Araceæ,* Maize, and some other Grasses, and in Palms, in the last of which it is often compound (Spadix Ramosus).

*** The Cone (Strobilus or Conus), a cylindrical capitulum or solid spike, on which the individual foliar organs become woody scales; as in the *Coniferæ,* the *Casuarinaceæ,* the *Betulaceæ,* and some others.

**** The Spikelet (Spicula), the simple inflorescence of the Grasses and *Cyperaceæ;* namely, a few-flowered spike, whose flowers have no bracts, surrounded at the basis by one or two sterile bracts (Glumæ).

3. The Umbel (Umbella) in the *Umbelliferæ;* when compound termed Umbellule (Umbellula).

4. The Raceme (Racemus) occurs in very different forms; it is usual to distinguish in it—

The Corymb (Corymbus), a pyramidal raceme.

β Inflorescentia Centrifuga.

5. The Cyme or False Umbel (Cyma), is a corymb with Inflorescentia Centrifuga.

That only singular cases are distinguished in these is a proof of the totally unscientific patching together of our terminology. The compound raceme, the compound umbel, and capitulum, with inflorescentia centrifuga are all called a Cyme (Cyma), which is contrary to the commonest scientific laws. De Candolle has further applied the term Cyme to the inflorescence of the *Boraginaceæ,* which, on account of the peculiar manner in which it unrolls itself, he terms Cyma Scorpioides; and he adds the fiction, that the undermost first-blooming flower is really the terminal blossom, and the second, the terminal blossom of side axis, is developed in a disproportionate degree, &c. From the rolling up there is just as little to be deduced as from the same phenomenon in the leaves of *Ficus* and *Cycadaceæ.* The position of the bracts, as seen in *Cerinthe,* contradicts this fiction; and the history of the development, which can alone determine the point, appears to prove that here a one-sided raceme or spike is present, whose unrolling is only a peculiar situation of the buds.

C. Once-Compound Inflorescence.

a. Pure or Homomorphous.

* Inflorescentia Centripeta.

6. The Spike of the Grasses (Spica), several spikes united in a spicate arrangement, as in the Grasses; the component spikes are termed Spikelets (Spiculæ).

7. The Umbel (Umbella). Umbels united in umbels; the components are termed Umbellules (Umbellulæ).

Sound terminology would have long ago rejected these words, and exchanged them for Spica and Umbella Composita.

8. The Panicle (Panicula); see No. 11.

None of these remaining combinations deserve special names, and may probably be classed among those mentioned under 9 and 11.

** Inflorescentia Centrifuga.

9. The Cyme or False Umbel (Cyma); see No. 5 and No. 14.

10. The Anthela; see No. 16.

β Mixed or Heteromorphous.

* Inflorescentia Centrifuga.

See No. 14.

** Inflorescentia Centripeta.

See No. 11.

D. Many-Times-Compound Inflorescence.

* Inflorescentia Centripeta.

11. The Panicle (Panicula), every many-branched inflorescence; in Grasses universally, and otherwise wholly in developed pedicels.

12. The Thyrse (Thyrsus), a panicle, with very short pedicels; with the exception of Grasses, found almost universally.

Both terms are applied also to once-componnd inflorescences. De Candolle uses the term Thyrsus for those in which Inflorescence Centrifuga and Centripeta are mingled; others differently; all arbitrarily.

13. The Anthurus, an inflorescence that has the kind of aspect of that of the *Amaranthus caudatus* or the *Chenopodiaceæ.*

** Inflorescentia Centrifuga.

14. The Cyme (Cyma), also in manifold combinations, in which however we do not consider whether the side ramifications follow the Inflorescence Centripeta or Centrifuga in longer pedicels.

15. The Bunch (Fascicnlus), a manifold compound cyme, with short pedicels, and rather crowded.

16. The Anthela, all kinds of inflorescences in the *Juncaceæ* and *Cyperaceæ.*

17. The Glomerule (Glomerulus), many inflorescences that appear almost like a capitnlnm, and consist only of ill-formed, imperfect flowers, as in some *Chenopodiaceæ, Urticaceæ,* and *Juncaceæ.*

We subjoin Professor Schleiden's closing remarks:—

"I leave every one with thinking faculties to draw for himself the sad conclusions which the preceding survey affords; and I think that I have not to defend myself to any one who is acquainted with our literature, against the charge that the foregoing is a frivolous vagary of my humour. Röper first attempted a scientific development of the inflorescence. No one that I know of has followed him. except Lindley. Physiologists seem not to have accounted it of sufficient importance. Systematists have too mnch to do with their herbaria, and it is much easier to coin a new word than to stndy minntely the progressive development through a large series of plants. For the sake of those unacquainted with these matters I will insert the following examples:—In *Lotus corniculatus,* Koch ('Syn. Fl. Germ.') has a Capitulum, Knnth ('Fl. Berol.'), an Umbella, Reichenbach ('Fl. Excurs.'), actually a Fasciculus. To *Eriophorum vaginatum* Kunth gives a Spica; Koch, a Spicula. For *Cladium Mariscus* Knuth has Umbellæ Axillares et Terminales; Koch, Anthelæ Axillares et Terminales; Reichenbach, Cymæ Axillares et Terminales; in *Isolepis supina* Koch has Spiculis in Fasciculnm aggregatis; Kunth, Spicis Conglomeratis. I have here omitted the French and English botanists, or the matter would have been still more glaring."

INFUSORIA. At the time the classification given under the head POLYGASTRICA was drawn np, the distinctions that limit the vegetahle and animal kingdoms were less perfectly understood than at present. One of the first members of this group of organised beings that was withdrawn from the animal kingdom, was the *Desmideæ,* which are now generally recognised as plants. [DESMIDEÆ, *S.* 2.] The group of *Pseudopodia loricata* must also be placed amongst doubtful creations, although many physiologists do not hesitate to group them amongst plants [DIATOMACEÆ, *S.* 2], whilst the gronps *Monadina* and *Volvocina* have recently undergone the most searching investigation, with the result that many of these forms are more decidedly vegetable than animal in their character. Some have even gone further than this, and Agassiz in the 'American Journal of Science,' for 1852, thus writes to Mr. Dana:—"You may remember a paper I read at the meeting at Cambridge, United States, in August 1849, in which I showed that the embryo which is hatched from the egg of a *Planaria* is a genuine polygastric animalcule of the genus *Paramecium,* as now characterised by Ehrenherg. In Steenstrup's work on the 'Alternation of Generation' [GENERATIONS, ALTERNATION OF, *S.* 2], you find that in the extraordinary succession of alternate generations, ending with the prodnction of *Cercaria* and its metamorphosis into *Distoma,* a link was wanting—the knowledge of the young hatched from the egg of *Distoma.* The deficiency I can now fill. It is another *Infusorium,* a genuine *Opalina.* With such facts before us there is no longer any doubt left respecting the character of all these *Polygastrica*—they are the earliest larval condition of worms. And since I have ascertained that the *Vorticellæ* are true *Bryozoa,* and botanists claim the *Anentera* as *Algæ,* there is not a single type of these microscopic beings left which hereafter can be considered as a class hy itself in the animal kingdom." Few naturalists wonld perhaps indorse this statement of Professor Agassiz. The *vorticellæ* are not yet admitted as members of the family *Bryozoa;* nor are all the *Anentera* of Ehrenherg regsrded indiscriminately as *Algæ.* The passage however indicates the direction in which inquiry is gradually hreaking np the great polygastric family of Ehrenherg. It is nevertheless very certain that many of the species enumerated hy Ehrenberg are only transitionary forms in which the same being exists. To no one has this department of science been more indebted than to Dr. F. Stein, who in his recent work, entitled 'Die Infnsionsthiere anf ihre Entwickelungs-Geschichte untersncht' (Leipsic 1854), has given the resnlt of a long series of investigations on this snhject. The followiug is a summary of Dr. Stein's researches, as recorded in this volnme. (It ought however to be premised that Föcke, Dujardin, and Siehold had previonsly pointed out that the great mass of the Polygastric *Infusoria* were mnch simpler than Ehrenherg had supposed, and that the interual organs he had described were referrible to the general conditions of unicellular organisms, whether animal or vegetahle.)

"In a glass in which were contained a great variety of ciliated *Infusoria,* and among them also numerons individuals of *Euglena viridis, Eacus,* and *Edeses,* Dr. Stein remarked, after the lapse of some days, the formation of a thin film on the surface of the water, composed of an interlacement of confervoid filaments and *Oscillatoriæ.* This film swarmed with *Euglenæ,* many of which had lost their beaks, and crawled about with a worm-like movement among the *Confervæ* and *Oscillatoriæ* filaments. Besides these, he discovered, to his great joy, a great many transparent gelatinons or qnite soft cysts, which sometimes contained only a single *Euglena* contracted into a glohular form; sometimes two of a hemispherical form appressed together. The encysted *Euglenæ* proved to he still living, inasmuch as they moved abont in the cysts, and if the cysts were ruptnred the previously globnlar individnals re-assumed their pristine elongated figure, and crawled about in the same manner as the other beakless iudividuals among the *Confervæ.*

"For what purpose was this eucysting? The cyst was evidently intended for something more than a coffin. Farther observations soon showed that the encysting process of the *Euglenæ* had really reference to their multiplication. The process however appeared to be different in *Euglena* from that in *Gregarinæ,* inasmuch as in the latter case two individnals are conjoined before the cyst is developed, whilst in the *Euglenæ* the case is formed usually around but one; for where two individuals were found inclosed iu a cyst, it was at once apparent that they had proceeded from the division of an originally single individual. Whilst thus investigating the *Euglenæ* his notice was also directed to other forms of *Infusoria* contained in the same water, such as *Paramecium aurelia, Prorodon niveus,* and *Holophrya discolor,* the latter two of which species he frequently observed inclosed in well-defined gelatınons cysts; and as these *Infusoria* belonged to quite another principal division of the class, he began to hope that the process of becoming encysted would prohahly turn out to be of general occurrence in the infnsory world.

"This proved to be the case, and the work then proceeds to describe the way in which Dr. Stein was led to detect the connection hetween *Epistylis plicatilis* with a species of Ehrenberg's genns *Acineta,* an observation which pointed the way in his future researches. One of his earliest additional observations was that of the heterogeneous generation of *Epistylis digitalis.* In this species he traced first the metamorphosis of the *Epistylis* into an *Acineta;* and, secondly, observed in the latter the extraordinary fact of the development and evolution of a *Tricodina*, a discovery which Ehrenberg has attempted to explain by the supposition that the *Tricodina* had been previously swallowed by the *Acineta*. Dr. Stein's important researches are continued through the family of the *Vorticellinæ*, and his observations given upon *Actinophrys*, *Podophrya*, the genus *Tricodina*, and on the nature of the *Opalinæ*, the propagation of the *Chlorogonium euchlorum* and *Vorticella microstoma*, and particularly upon the quiescent condition of the latter *Infusoria;* upon *Spirochona gemmipara* and *S. Schentenii*, and upon the *Acineta* state of *Dendrocometes paradoxus*, *Zoothamnium affine*," &c., &c. ('Quarterly Journal of Microscopical Science,' July, 1854.)

At the present time it would undoubtedly be premature to state that no organisms ought to be referred to Ehrenberg's class *Polygastrica*. It would however be probably better to substitute the term *Protozoa*, to receive organisms having an animal character, and yet presenting the same simple conditions that we find amongst the *Nostochineæ*, and other groups of lowly developed plants. We may state generally that Ehrenberg's *Polygastrica* embrace the following groups of beings:—

1. True plants, as in the *Desmideæ* (*Closterina*), *Volvocina* (*Cryptomonadina*), and some others.
2. Organisms which evidence at present assigns to the vegetable kingdom, as *Diatomaceæ* (*Bacillaria*, *Fragillaria*, &c.), and a large number of the *Monadina* and *Vibrionina*.
3. The ova of *Entozoa*, as *Cercaria* and others, and probably even of higher animals.
4. Minute forms of animals referrible to previously established groups; this seems to be the case with the whole of the *Vorticellina*, which may with more propriety probably be referred to Hydroid than to any other form of polypiferous animals.
5. Dujardin has pointed out the identity between the structure of organisms like *Amœba* with such forms as *Difflugia* and *Arcella*. In all these creatures there is no trace of mouth or digestive cavity, and the entire body is a single cell or an aggregation of cells, which derives its nutriment by absorption from without. Professor Kölliker has recently described the method by which one of these creatures, the *Actinophrys*, takes its food:—

"As regards the vegetable functions," says the Professor, "the mode in which the *Actinophrys* is nourished is one of the highest and most special interest. Although the creature has neither mouth nor stomach, yet it takes in solid nutriment, and rejects what is indigestible. This miracle, for so it may almost be called, is thus effected with minute Crustaceans (*Rotifera*, minute species of *Lynceus*, the young of *Cyclops*, &c.), and the lower *Algæ* (*Diatomaceæ*, spores of *Vaucheria*, *Closterium*, &c.). When in its progress through the water it approaches one of these little plants, or when an *Infusorium* has come into proximity with it, both plant and animal, as soon as they touch one of the tentacular filaments, usually adhere to it. Now, as the filament with its prey slowly shortens itself, and the latter approaches the surface of the body, all the surrounding filaments apply themselves upon it, bending their points together so that the captive becomes gradually inclosed on all sides. According to all appearance these filaments also become more or less shortened. In this way the morsel is gradually brought to the surface of the body, the filament by which it was seized, being finally so much shortened as to disappear altogether, and having, as not unfrequently happens, relinquished its hold upon the prey, after the latter has become encompassed by the surrounding filaments. These gradually apply themselves more and more closely together around it, forcing it towards the surface of the body.

"The following proceeding now takes place: The spot of the surface upon which the captured animalcule is lying slowly retracts, and forms at first a shallow depression gradually becoming deeper and deeper, in which the prey, apparently adherent to the surface and following it in its retraction, is finally lodged. The depression by the continued retraction of the substance now becomes deeper; the imprisoned animalcule, which up to the time had projected from the surface of the *Actinophrys*, disappears entirely within it; and at the same time the tentacles, which had remained with their extremities applied to each other, again erect themselves and stretch out as before. Finally, the depression acquires a flask-like form by the drawing in of its margin, the edges of which coalesce, and thus a cavity closed on all sides is formed in which the prey is lodged. In this situation it remains for a longer or shorter time, gradually however approaching the central or nuclear portion, and at last passing entirely into it, in order to await its final destination. In the mean while the external portion of the *Actinophrys* regains in all respects its pristine condition. The engulfed morsel is gradually digested and dissolved, as is readily seen by its change of appearance from time to time. If entirely soluble, as for instance an *Infusorium*, the space in which it is contained contracts as the dissolution of its contents goes on, and finally disappears altogether. Should there be however an indigestible residue (a membrane composed of cellulose, a portion of chitine, a shell of a *Lynceus*, or case of a rotifer, &c.), a passage for its exit is formed, and it is expelled by renewed contractions of the homogeneous substance, and in the same direction, or nearly so, as that which the morsel followed in its introduction. The passage and the opening through which the expulsion was effected disappear again without leaving any trace."

In the *Actinophrys* we have an animal closely resembling the creature which inhabits the shell of the large family known as *Foraminifera*, and Dujardin suggests that the loricated forms of *Difflugia* and *Arcella* are transitions to the more decided forms of *Foraminifera*. Hence he proposes to include several forms of Ehrenberg's *Infusoria*, with the *Foraminifera* or *Polythalamia*, under the term *Rhizopoda*. Little therefore is left us to say of what may be regarded as true *Polygastrica*. They all appear to have a distinct mouth or entrance to the cavity of the body, and this is usually surrounded by vibratile cilia, as is seen in *Monas atomos* and *Leucophrys patula*. These cilia apparently bring the food to the mouth of the animal. An anal orifice is described by Ehrenberg in the majority of species. When finely divided soluble colouring-matter as carmine or indigo (a writer in the 'Microscopical Journal' recommends the red pigment which lines the cornea of the common house-fly) is introduced into the water in which they are contained, the transparent body of the animalcule is speedily seen to be studded with coloured globules, consisting of an aggregation of the particles of colouring-matter. Ehrenberg regarded these globules as distinct sacs, which he supposed were given off from a central intestinal canal, as seen in *Leucophrys patula*. Regarding these sacs as so many stomachs, he gave them the name of *Polygastrica* (many-stomached). It is however still a question as to whether in any case these masses are contained in a distinct sac. The whole body of the animalcule is often covered with vibratile cilia, and it is to the constant action of these organs that the varied movements of these animalcules are due. The movements thus effected are perfectly automatic, and in no way connected with any intelligent consciousness. All the movements of these animals are not due to cilia, as the whole of the tissue of the animal is observed to contract in *Amœba*, *Amphileptus*, and the stalk of the *Vorticellina*.

Although Ehrenberg has described a complicated apparatus for reproduction, no instances of conjugation are recorded amongst the true *Polygastrica*. Their modes of multiplication are by fission and gemmation. In a large number of cases a simple division of the unicellular organism into two equal parts takes place. This process goes on so rapidly that, according to Ehrenberg, a single *Paramecium* could produce 268,000,000 of cells in a single month. From analogy we must suppose this process would not go on continually, and, as in plants, we must regard the separate cells thus produced as belonging to the same individual. Further observation is probably only needed to demonstrate the existence of a union of two cells—a sperm cell and a germ cell—as is now known to be almost universal in the vegetable kingdom. In the account above given of Stein's researches it will be seen, that it is not improbable that one of the modes by which these beings are enabled to spring suddenly into existence, is the production of winter-eggs, or reproductive bodies of a kind that will resist the influence of an absence of moisture from the spots in which they ordinarily abound.

The true *Polygastrica* seem universally diffused. Wherever organic matter exists in a decomposing state, there they abound. They exist in incredible numbers in the waters of the ocean, in rivers, lakes, ponds, pools, and ditches. They are found in the secretions of the higher animals, and even in man. Wherever the organic elements, carbon, hydrogen, nitrogen, and oxygen, are capable of uniting to form water, carbonic acid, and ammonia, there they may be expected to be found. The composition of the liquids in which they are found, seems to determine the forms they assume. One set of forms inhabits salt water, another fresh. Every mineral spring has its peculiar inhabitant. The sulphureous springs of the Pyrenees, the chalybeate waters of the Rhine, the siliceous, calcareous, and aluminous waters of Europe, all contain them. They are found with the red snow of the Alps and the poles, and with the *Conferva thermalis* of the hot springs of Aix and Baden. They are always accompanied by plants. Perhaps it would be wrong to call any beings animals that are not found feeding on plants, as it seems to be a law of organic existence that plants should subsist on mineral matters, and animals on organised matters.

What are the uses of these beings? To this question Professor Owen gives the following reply: "Consider their incredible numbers, their universal distribution, their insatiable voracity, and that it is the particles of decaying vegetable and animal bodies which they are appointed to devour and assimilate. Surely we must in some degree be indebted to those ever-active invisible scavengers for the salubrity of our atmosphere. Nor is this all: they perform a still more important office in preventing the gradual diminution of the present amount of organised matter upon the earth; for when this matter is dissolved or suspended in water, in that state of comminution and decay which immediately precedes its final decomposition into the elementary gases, and its consequent return from the organic to the inorganic world, these wakeful members of nature's invisible police are everywhere ready to arrest the fugitive organised particles and turn them back into the ascending stream of animal life. Having converted the dead and decomposing particles into their own living tissues, they themselves become the food of large *Infusoria*, as the *Rotifera*, and of numerous other small animals, which in their turn are devoured by larger animals, as fishes; and thus a pabulum, fit for the nourishment of the highest organised beings, is brought back by a short route from the extremity of the realms of organic matter.

"There is no elementary and self-subsistent organic matter, as Buffon taught; the inorganic elements into which the particles of organic matter pass by their final decomposition, are organically recomposed and fitted for the sustenance of animals through the operations of the vegetable kingdom. No animal can subsist on inorganic matter. The vegetable kingdom thus stands, as it were, between animal matter and its ultimate destruction; but in this great office plants must derive most important assistance from the Polygastric *Infusoria*. These invisible animalcules may be compared, in the great organic world, to the minute capillaries in the microcosm of the animal body, receiving organic matter in its state of minutest subdivision, and, when in full career to escape from the organic system, turning it back by a new route towards the central and highest point of that system."

INGHIRAMI, CAVALIERE FRANCESCO, a distinguished Italian archæologist, was born in 1772, at Volterra in Tuscany. From the completion of his education he devoted himself with unwearied diligence to the study of ancient art. He wrote several papers in the artistic and antiquarian journals, which secured him a high place among the Italian art authorities; but the work which acquired for him a European reputation was the splendid publication entitled 'Monumenti Etruschi,' of which the first part appeared in 1821, and which was finally completed, in 6 vols. 4to, in 1826. This great work was intended to comprise a complete survey of all the existing remains of ancient Etruria; and it has formed the great treasury of all subsequent writers on Etruscan antiquities and the Etruscan people. His other more important works are—'Lettere di Etrusca Erudizione,' 8vo, 1828-30; 'Galleria Omerica,' 3 vols. 8vo, 1829-31, a work intended to illustrate the 'Iliad' and 'Odyssey' by the monuments of antiquity; 'Pitture di Vasi Fittili esibite dal Cav. F. Inghirami,' 4 vols. 4to, 1835-37, in which it was his avowed object to illustrate the mythology and the history of the ancients; and 'Storia della Toscana, in Sette Epoche distribuita,' 16 vols. 12mo, 1841-43, the last two volumes being devoted to the bibliography and index. He also wrote many memoirs and papers on particulars in archæology and history in the 'Archivo Storico Italiano,' &c. Cavaliere Inghirami was for several years keeper of the Laurentine Library at Florence. He died on the 17th of May 1846.

INGLIS, SIR ROBERT HARRY, Bart., many years M.P. for the University of Oxford, was the only son of Sir Hugh Inglis, Bart., formerly chairman of the East India Company. He was born in 1786, and received his early education at Winchester, and Christchurch, Oxford. Soon after taking his degree, he became private secretary to the late Viscount Sidmouth, and was appointed by him one of the commissioners for settling the affairs of the Carnatic. In 1824 he entered parliament as member for Dundalk, a borough at that time in the patronage of the Earl of Roden. In 1826 he was elected for Ripon, the representation of which borough he resigned in the spring of 1829, in order to contest the University of Oxford against the late Sir Robert Peel, when the latter accepted the Chiltern Hundreds on introducing the Roman Catholic Relief Bill. From that time he continued to represent the University until January 1853, when he retired from parliamentary life, and was sworn a member of the Privy Council. His public life was devoted to the cause of Church and State, upon which question he inherited the ancient opinions of Lords Sidmouth and Liverpool; he steadily opposed the Repeal of the Test and Corporation Acts, the Roman Catholic Relief and Reform Bills, and the admission of Jews into parliament, and every measure which he religiously thought would tend to unchristianise the legislature. On these points his opposition was strong and consistent, though to a certain extent characterised by partiality and prejudice. He took an active part in the management of the religious societies of the Established Church, and also of the learned societies of the metropolis. In private life he was highly respected as an amiable and accomplished gentleman. He died in Bedford Square, London, May 5, 1855.

INGROSSING, is no longer an offence either at Common Law or by Statute. (7 & 8 Vict. c. 24.)

INJUNCTION, in Chancery. One of the recent improvements in the procedure of the Courts of Equity, consists in the abolition of the distinction between Common and Special Injunctions. An injunction is not now obtainable as it was formerly, merely as a matter of course. Sufficient *primâ facie* grounds must be stated in all cases before it will be granted, thus in effect making all injunctions proceed on special grounds.

INJUNCTION, at Law. The Common Law Procedure Act, 1834, among other improvements, has enabled the Superior Courts of Common Law to grant writs of injunction after action brought, in order to restrain the repetition or continuance of the wrongful act complained of, the suitor in this way avoiding the necessity of a resort to the Court of Chancery. This process is, it will be observed, of very limited application, an injunction being generally sought to prevent an injury, and not the repetition of one.

INNS OF COURT AND CHANCERY. A Report on the present state of those societies was laid before Parliament in 1856, by certain Commissioners appointed to examine into the nature of the legal education thereby afforded. This Report being however in many respects erroneous and incomplete, founded on imperfect information, and unsatisfactory in its conclusions, nothing has as yet been done towards carrying out the recommendations of the Commissioners.

INOSITE. [CHEMISTRY, *S.* 2.]

INSOLVENCY. [CESSIO BONORUM, *S.* 2.]

INSOLVENT. The Commissioners of the Court for the Relief of Insolvent Debtors no longer make circuits through England, to hear the petitions of prisoners confined for debt in the country districts. This branch of the jurisdiction of the Insolvent Court is now exercised by the County Court Judges, to whom the petition and schedule of the prisoner are for that purpose transmitted. The County Court Judge exercises the same authority as the Court in London, his decision being final and conclusive. (10 & 11 Vict. c. 102.) See also PROTECTION ACTS, *S.* 2.

INTESTINES. The structure of the coats of the intestines has been most carefully observed by means of the microscope. The minute structure of the intestines corresponds to a considerable extent with what is met with in the stomach. There are however differences of structure especially in the mucous coat of the intestines. We shall describe first the muscular structure, and in doing this we shall follow Professor Kölliker in his 'Manual of Human Histology.'

The muscular coat of the smaller intestines is somewhat thicker in the duodenum and the upper portions, than in the lower; it has in general a thickness of $\frac{1}{4}'''$—$\frac{1}{8}'''$, and is composed only of longitudinal and transverse fibres. The former are always less developed, and do not form a continuous layer, since they are very few or entirely absent along the attachment of the mesentery; they are usually most distinct upon the free border, though even here they may be readily torn away with the serous membrane, so as at once to leave the second layer exposed. The latter is complete and continuous, consisting of circular bundles, which not uncommonly anastomose at very acute angles.

In the large intestines the longitudinal fibres are reduced to the three ligamenta coli, muscular bands of 4'''—6''', or even 8''' broad, and $\frac{1}{3}$'''—$\frac{1}{2}$''' thick, which commencing upon the cœcum are united upon the sigmoid flexure into a single longitudinally fibrous layer, thinner than in the small intestines, and more especially developed in the duplicatures, which are known under the name of the plicæ sigmoideæ. All the fibres belong to the smooth or non-striated system of muscular fibres. Many of them present knot-like enlargements and frequently zig-zag flexures, which produce the transversely striated appearance of the entire bundles of such muscles so frequently met with in spirit preparations. The arrangement of the fibre-cells in the different strata is simply this, mutually applied in their length and breadth, and coherent:—They are united into thin muscular bands, which when invested with a coating of connective tissue, and frequently also united into secondary bundles, constitute the thicker or thinner muscular tunics of the different regions; which, again are surrounded and separated from the contiguous parts by considerable layers of connective tissue.

Blood-vessels are very abundant in the smooth muscles; and their capillaries, of 0·003'''—0·004''', constitute a characteristic network with rectangular meshes. Nothing is known about the lymphatics; nor are the relations of the nerves yet ascertained, except that Ecker has observed the division of fine nervous tubules in the muscular tunics of the stomach of the frog and rabbit.

The mucous membrane of the small intestines is thinner than that of the stomach, but more complex in its structure, inasmuch as besides the tubular, or Lieberkühnian glands it presents a great number of permanent folds and villi, also imbedded in its substance, peculiar closed follicles, the so-called solitary and Peyer's glands, and, in the submucous tissue of the duodenum, Brunner's glands. The mucous membrane consists of connective tissue which is internally homogeneous, or indistinctly fibrillated: except where certain glands exist there is but little submucous tissue, so that it is pretty closely connected with the muscular tunic. Upon the inner surface of the mucous membrane there rests a cylinder-epithelium, whilst externally towards the submucous tissue it is bounded by a layer of smooth muscles discovered by Brücke, which measures at most 0·0177'''. They are disposed longitudinally and transversely, but in man their slight development renders it often very difficult to discover them.

The villi of the small intestines are small whitish elevations of the innermost portion of the mucous membrane, readily distinguishable with the naked eye, and which distributed upon and between the valvulæ conniventes through the whole extent of the small intestines, from the pylorus to the sharp edge of the ileo-cœcal valve, are set so close together as to give the mucous membrane its well-known velvety appearance. They are most numerous (50 to 90 upon a square line) in the duodenum and jejunum, less so in the ileum (40 to 70 upon a square line). In the duodenum they are broader and less elevated, resembling folds and laminæ $\frac{1}{10}$'''—$\frac{1}{4}$''' in height, $\frac{1}{6}$'''—$\frac{1}{2}$''' or even $\frac{3}{4}$''' in breadth. In the jejunum they appear for the most part to be conical and flattened; frequently they are even foliated or cylindrical, clavate, or filiform, the three latter forms predominating in the jejunum. The length of the villi is from $\frac{1}{5}$'''—$\frac{1}{3}$''', the breadth from $\frac{1}{6}$'''—$\frac{1}{10}$''', or even $\frac{1}{25}$''', the thickness in the flattened forms $\frac{1}{30}$'''.

The villi are composed of two portions, a deeper coat belonging to the mucous membrane, and an epithelial superficial coat. The contour of the former, or villus proper, is similar to that of the entire villus; it is simply a solid process of the mucous membrane containing blood-vessels, lymphatics, and smooth muscles, whose matrix, through which a variable number of roundish nuclei are scattered, in general exhibits no morphological peculiarity more decided than that of the mucous membrane itself, yet must most undoubtedly be regarded as a metamorphosed connective tissue without any intermixture of elastic tissue. The blood-vessels of the villi are so numerous that when well injected those whose epithelium has been detached become coloured throughout; and in living animals, or in those which have just been killed, each villus if viewed from above appears as a red dot surrounded by a clear ring. In man every villus contains a close network of capillaries of 0·003'''—0·005, with rounded or elongated nuclei, which lies immediately beneath the homogeneous external layer of the matrix, and is supplied by one, two, or three small arteries of 0·01'''—0·016'''. The blood is usually carried back directly into the larger trunks of the submucous tissue by a vein of 0·022''', which does not arise as in animals, by the arching round of the artery, but proceeds from the gradual confluence of the finest capillaries. The relations of the lacteals in the villi of man, have not hitherto been perfectly made out; for although the majority of investigators are inclined, like the older observers, to suppose that they commence by one or two cœcal branches, yet recently several observers have contended for the view that they originate in a filiform manner. On this subject Professor Kölliker remarks that in the human subject he has never succeeded in meeting with villi distended with chyle, and in empty ones, he has been unable to obtain any decisive evidence; on the other hand, in animals, he feels certain that in many cases only a single lacteal, which has a cœcal and frequently enlarged end, and whose diameter is much greater than that of the capillaries, traverses the axis of the villus. He says he believes that all the narrow cylindrical and filiform villi will be found to present this condition, but that, on the other hand, the number and mode of origin of the lacteals may possibly be different in the broad and foliaceous forms.

In addition to these organs the villi also contain, as Brücke discovered a short time ago, a thin layer of longitudinal smooth muscles, situated more centrally round the lacteals; these however are not always distinct in man, they produce contractions of the villi, which are very evident immediately after death, and which, according to Brücke, are also perceptible in the living animal. They have in all probability an important influence over the propulsion of the chyle, and of the venous blood in the villi—always supposing that there is no objection to the assumption that they perform repeated contractions during life. Nothing is known of nerves in the villi. The epithelium of the villi and of the rest of the surface of the mucous membrane, although it is very intimately united with the deeper-seated parts during life, only becoming detached accidentally or by disease, separates very readily in the dead subject, and can only be observed in perfectly fresh portions of intestine. It consists everywhere of a simple layer of cylindrical cells slightly narrowed below of 0·01'''—0·012''' in length and 0·004''' in breadth, whose contents are usually nothing but fine granules, and an oval, clear, vesicular nucleus, provided with one or two nucleoli. During life, these cells, which agree in all their chemical characters with the deeper cells of the oral epithelium, are so intimately united, that even after death their contours in a longitudinal view, are at first either not at all or only indistinctly distinguishable, though on the surface they have the appearance of a beautiful mosaic. The cylinders only become quite distinct when they are either spontaneously or artificially detached, a process which usually takes place in such a manner that they hang together in continuous portions, all the cells covering a villus sometimes coming off together like the calyptra of a moss.

The addition of water to these cells produces a separation of the cell-contents from the broad end, giving rise, in separate cells, to the appearance of a membrane thickened upon one side, and, in series of cells or entire villi, to that of a peculiar structureless coat, like the cuticle of plants; by its long action, however, or by that of the intestinal fluids, the bursting of the cells produces apertures in them, or they become distended into large pyriform clear vesicles.

We may here refer to the changes which the epithelial cells and the villi in general undergo during digestion. The most striking circumstance is the occurrence of fat-globules in different parts of the villi, which may always be observed during the formation of a fatty milk-white chyle. The succession of the morphological steps is as follows:—The fat contained in the chyme at first enters only isolated epithelial cells in different regions of the villi, so that in each we soon observe a large ovate shining drop.

The number of these fat-cells rapidly increases, and then the villi acquire a very peculiar appearance, often as if beset with pearls, from the irregular alternation of cells filled with fat, and consequently bright and shining, with those which are empty and pale. In the end all the cells become filled with these drops, and the epithelium appears quite dark by transmitted, but whitish by reflected light, giving its aspect to the whole villus.

With the repletion of the entire epithelial covering of the villus, absorption commences, but up to this time nothing has entered the lacteals. This however soon takes place, and the first indication we observe is the breaking up of the large drops of fat in the cells into many tolerably minute fatty molecules. When this has occurred, these drops penetrate by degrees from all sides into the parenchyma of the villus itself, fill it more and more, and at last enter the central lacteal, whose whole length they eventually occupy. In the mean while, fresh fat has been continually passing in from the intestinal canal, not in the form of large drops however, but henceforward in small molecules or drops of the same kind as those which were at first developed secondarily in the cells. On the other hand, at a subsequent period, wo not uncommonly meet in the interior of the villi with large round drops, which appear especially inclined to form considerable accumulations at their apex. In man the process is probably the same as in animals. These observations demonstrate that fatty matters are absorbed as such, and are not saponified; on the other hand, it cannot at present be certainly stated how it is possible that they penetrate the membrane of the epithelial cells, the parenchyma of the villi, and the walls of the lacteals.

The whole process may be compared to the imbibition of an emulsive fluid, such as milk, by a porous body; and the fatty molecules of the chyme are probably absorbed simply in consequence of their being carried along with its fluid part. While digestion is going on, we frequently find the whole parenchyma of the villi densely filled with small nuclei, here and there surrounded by cell-membranes—elements which are never entirely absent in a villus, but are at other times far fewer, and particularly are not to be distinguished in its interior.

The small intestines contain two kinds of true glands; 1, tubular glands, which are disposed over the whole mucous membrane; 2, racemose glands, in the submucous tissue of the duodenum.

The Racemose Glands, or as they are commonly named, after their discoverer, Brunner's Glands, form, at the commencement of the duodenum, upon the outer side of the mucous membrane, a continuous layer, which is best developed and thickest close to the pylorus, where it constitutes a considerable glandular ring, and extends about as far as the aperture of the biliary ducts. If the two layers of the muscular tissue be dissected off a stretched or distended duodenum, the glands may readily be recognised as yellowish flattened bodies of ¼'''—1½''' (on the average ¼'''—½'''), with their angles rounded off, which inclosed within a little connective tissue, lie close to the mucous membrane, and send short excretory ducts into it. In their minute structure Brunner's glands, the terminal vesicles of which measure 0·03'''—0·06''', even 0·08''', agree perfectly with the racemose glands of the mouth and œsophagus. Their secretion is an alkaline mucus, in which no formed elements are contained, having no digestive action upon coagulated protein compounds, and probably merely subservient to mechanical ends.

The Tubular, or Lieberkühnian Glands (cryptæ mucosæ), are distributed over the whole small intestines including the duodenum as innumerable straight narrow cœca, which occupy the entire thickness of the mucous membrane, and are frequently slightly enlarged at their extremities, though hardly ever dichotomously divided. The best idea of their number is obtained by viewing the mucous membrane either from above or in vertical section, under a low power. In the latter case we see the cœca standing close together, almost like palisades; in the former we observe that the glands do not occupy the whole surface, but only the interspace betwen the villi; here however they exist in such numbers as to leave no intervals of any width, the mucous surface between the villi appearing pierced like a sieve. Even on Peyer's patches, and over the solitary follicles, these glands are to be met with; but in man they leave those portions of the mucous membrane which lie immediately over the centre of the follicles free, and therefore are arranged like wings around the follicles.

The length of the Lieberkuhnian glands equals the thickness of the mucous membrane and varies from ⅙'''—¼'''; their breadth is 0·028'''—0·036''', that of their aperture, 0·02'''—0·03'''. They are composed of a delicate homogeneous membrana propria, and of a cylindrical epithelium, which even during chylification never, like that of the intestine, contains fat; their cavity is filled during life by a clear fluid secretion, the so-called intestinal juice, which however becomes rapidly changed after death, or on the addition of water, so that the glands appear to be filled with cells, or with a granular mass.

The most important of the closed Follicles are Peyer's patches (glandulæ agminatæ). They are rounded flattened organs, invariably situated along that surface of the intestine which is opposite the mesentery; they are most distinct upon the inner surface, where they appear as rather depressed smooth spots, without any very sharp definition, but they are also recognisable from the exterior by the slight elevation to which they give rise; by transmitted light they look like mere opaque portions of the membrane. These patches are usually the most abundant in the ileum, but they are not uncommonly to be met with in the lower part of the jejunum; occasionally they exist in the upper portion close to the duodenum, and even in the inferior horizontal portion of the duodenum itself. Ordinarily there are 20 to 30 of them; but when they are found higher up there may be as many as 50 to 60; but they are always most closely set in the lowest portion of the ileum. The dimensions of the separate patches are in general the larger the closer they are to the cœcum; their length is usually 5'''—1½'', but may diminish to 3''', and increase to 3''—5'', or even 1'; their breadth varies from 3''' to 5''', or 9'''. Where the patches lie the valvulæ conniventes are usually interrupted; in the jejunum however these folds are also to be met with upon the Peyer's patches and in the ileum; rows of closely-set villi often take their place. More minutely examined, every Peyer's patch is seen to be an aggregation of closed follicles of ⅕'''—¼'''—1''' in diameter, either rounded or slightly conical towards the intestinal cavity, which lie partly in the mucous membrane itself, partly in the submucous tissue; and are on the one side not more than 0·02'''—0·03''' distant from the mucous surface, while on the other they are in immediate contact with the muscular tunic, which is here somewhat more closely united with the mucous membrane.

Viewed from the interior of the intestine their most striking feature in man is the presence of many small rounded depressions ¼'''—½'''—1''' apart, which corresponds with the separate follicles, and whose floor is indeed rendered slightly convex by the latter, but which present no villi whatever. The remainder of the patch is occupied by common villi, or by reticulated folds, and by the apertures of the Lieberkühnian glands; the latter are disposed around the slight elevations produced by the follicles in circlets of 6 to 10 and more apertures, the coronæ tubulorum of authors.

The Solitary Follicles (glandulæ solitariæ) resemble the separate elements of Peyer's patches so closely in size, contents, and general structure, that there is no reason for considering them as distinct, particularly as the number of follicles is subject to all possible varieties, and since, in animals at least, we find Peyer's patches with 2—3—5 follicles. In man, as all writers justly agree, their number is exceedingly inconstant; sometimes not one can be found, whilst in other cases the whole intestines, as far as the margins of the ileo-cœcal valve, is thickly beset with them: or, lastly, they may occur in the ileum and jejunum, but in no very great number. Their entire absence must probably be considered abnormal, since they are constant in newly born children, being more abundant in the jejunum than in the ileum. The milliary vesicles however, which are often met with in immense quantities in the small intestines and stomach in catarrhal affections of the alimentary tract, may very probably be entirely or partially pathological, since the occurrence of such follicles has been demonstrated in other organs also (in the liver according to Vorhow). The solitary follicles have the same structure as the elements of the patches, only they occur also in the mesenteric border, and support villi upon their intestinal surface, which is usually somewhat convex.

Professor Kölliker expresses himself as decidedly opposed to the notion that the follicles of Peyer's patches have any apertures. Of their functions he says: "They and the follicles of the intestine in general appear to me to be closed glandular organs, analogous to the splenic follicles, the tonsils, and the lymphatic glands, which contain peculiar elements and a vascular network. In these a constant development of cells takes place, and at the same time substances are elaborated from the plasma, supplied by the blood-vessels, and perhaps also from matters not of a fatty nature, absorbed from the intestine, a part of which in all probability is at once taken np by the internal blood-vessels, while the larger proportion is excreted, and absorbed hy the lymphatics."

The structure of the mncons memhrane of the large intestines agrees so closely with that of the small intestines, that it need not be described separately. With the exception of the rectum it has no proper folds, for the transversely fibrous muscular layer also enters into the plicæ sigmoideæ. The villi are absent from the edge of the ileo-cœcal valve. The glandular organs are Lieherkühn's glands and solitary follicles. The latter are arranged close together in the processus vermicnlaris, and are very frequent in the rectum and cœcum, and are also nsnally more abundant in the colon than in the small intestines. INULIN. [CHEMISTRY, *S.* 1; TISSUES, ORGANIC, *S.* 1.]

INVERKEITHING. [FIFESHIRE.]

INVERURY. [ABERDEENSHIRE, *S.* 1.]

IODOFORM. [CHEMISTRY, *S.* 1.]

IOLITE, a Mineral, also called *Dichroite* and *Cordierite.* It belongs to the gronp of anhydrous silicates of alnmina. It crystallises in rhombic and hexagonal prisms, and usually occurs in 6- or 12-sided prisms, or disseminated in masses without distinct form. The cleavage is indistinct; but the crystals are often separahle into layers parallel to the hase. The colour is of various shades of blue—often deep blue in the direction of the axis, and yellowish-gray transversely. The streak is uncoloured. Lnstre and appearance mnch like that of glass. Transparent to translncent. It is hrittle, and has a hardness of 7 to 7·5. Its specific gravity is 2·6 to 2·7. A specimen from Connecticnt, United States, had the following composition:—

Silica	48·3
Alumina	32·5
Magnesia	10·0
Protoxide of Iron	6·0
Protoxide of Manganese	0·1
Water	3·1
	100

Before the hlow-pipe it fnses with difficulty to a hlue glass resembling the mineral. It is distinguished hy this property from hlue quartz, for which alone it conld be mistaken.

Iolite is found at Bodenmais in Bavaria, Arendal in Norway, Cabo de Gata in Spain, Tnnaberg in Finland, also in Greenland, Ceylon, and the United States. It is occasionally employed as an ornamental stone, and when cnt it presents different shades of colour, hence one of its names, Dichroite (δίχροια). Iolite refers to its violet colonr (ἴον).

When Iolite is exposed to the air and moistnre it nndergoes a gradnal alteration. It absorhs water, and becomes converted into a hydrate. It then assumes a foliated micaceous structure resemhling talc. Hydrons *Iolite, Chlorophyllite,* and *Esmarkite* are names that have been given to altered Iolite, and *Fahlunite* and *Gigantholite* have probably the same origin.

IPHÆROCERA. [BORBORUS.]

IPS, a genus of Insects belonging to the order *Coleoptera,* to the section *Pentamera,* and the family *Empidæ.* The body is of an oblong-oval form and depressed, with the third joint of the antennæ longer than the second, and the clnh large and ronnded. The species are generally fonnd nnder the bark of decayed trees. They are chiefly confined to Europe. The British species, of which there are four or five, are rare.

IRAWADDI. [BIRMA.]

IREBY. [CUMBERLAND.]

IRELAND. [CENSUS OF 1851, *S.* 2.]

IRIDIOCYANOGEN. [CHEMISTRY, *S.* 2.]

IRIDOSMINE. This name is given to a compound of the metals Iridinm and Osminm, found in the platina mines of Russia, South America, and the East Indies. The crystals are hexagonal prisms of a pale steel-gray. It occurs in flat grains. Their composition varies. One variety contains rhodinm. They are distinguished hy the odour of osmium.

IRON, OXALATE OF. [MINERALOGY, *S.* 1.]

ISABEY, JEAN-BAPTISTE, an eminent French miniature painter, was born at Nancy, on the 11th of April, 1767. Having received elementary instruction in art nnder Clandot and Dumont, he, in 1790, entered the atelier of David, with a view to becoming an historical painter. But he commenced his professional career hy taking portraits in hlack crayons, a style which in his hands, hy a free nse of the stnmp, produced very pleasing effects; and hecoming extremely popular, was usually called by his name. One of his most successful pieces in this manner was a portrait of Napoleon I. in the garden of Malmaison, the engraving from which, hy Lingé, had a great run. This style was however soon abandoned hy Isabey, who, having resolved to try whether, by carrying the principles of high art into miniatnre-painting, he could not elevate that hranch of art in pnblic estimation, executed in 1802 a piece of nnusual size, containing numerons small figures, of 'Le Revue de Premier Consul dans la cour des Tuileries.' It caught the public taste, and established the painter's repntation, as the first in his line. From that time Isabey was the most fashionable miniature-painter of the day. Whilst Napoleon I. was a plain officer of artillery, Isabey had been on terms of friendship with him, and when the empire was founded Isabey continued in favonr, and was appointed miniatnre-painter in ordinary to the emperor. In this capacity he painted many miniatnre-portraits of Napoleon I., the empress, the yonng king of Rome his son, the members of the Bonaparte family, and the favourite courtiers and generals. Among the most famons of the imperial pictures was one on a large slah of porcelain, representing Napoleon I. and the most illnstrious of his generals, and known as the 'Tahle des Maréchaux.' Besides the portraits, he executed several court and ceremonial pieces, one of which, a 'Visite de l'Empereur à la Manufactnre d'Oberkampf à Gouy,' was greatly admired. He was likewise entrusted with the direction of works relative to the coronation of the emperor, when he was named officer of the Legion of Honour.

On the first abdication of Napoleon I., Isabey accompanied the empress Marie Lonise to Vienna, where he painted a large tablet of 'One of the Conferences at the Congress of Vienna,' chiefly remarkahle for the faithfnl likenesses of the nnmerons important personages assemhled. On Napoleon's retnrn from Elba, Isabey repaired to Paris, and propitiated the emperor by presenting him with a miniature of his son, which he had just painted at Vienna. The restoration of the Bonrbons hrought no loss of fortnne to Isahey; hut a picture which he exhibited at the Salon in 1817 of 'A child playing with Flowers,' cansed some 'sensation' among the Parisians, from the child, who was holding np a hnnch of forget-me-nots, bearing a striking resemblance to the yonng Napoleon. The 'Constitntionel' having ventured to make a pointed allusion to the likeness, received a warning from the police. Isabey soon after accepted an invitation to the conrt of St. Petersbnrg, where he painted the emperor Alexander, the empress, the grand-dnkes Nicholas and Michael, and many of the magnates of the conrt. On his retnrn to Paris he painted the portrait of Louis XVIII., and as long as he continued to paint he found ample occupation; his sitters, it is said, having included most of the sovereigns, as well as a large proportion of the most distinguished personages, of Enrope. Isabey survived till the 18th of April, 1855. He may be said to have formed a new school of miniatnre-painters in France. His likenesses have much character, and are generally esteemed faithful. His style is marked by force as well as delicacy, hnt almost necessarily from the nnmherless works he executed, also hy a good deal of mannerism.

ISARIA, a genns of *Fungi,* belonging to the division *Trichosporei,* and the tribe *Isareii* of Léveillé. It is characterised hy a compound, solid, capitulated, or elongated receptacle. The species are fonnd parasitic npon caterpillars and the larvæ of various insects. Rohin enumerates the following species:—

I. Eleuteratorum has been found upon the *Carabidæ* in the antnmn of the year.

I. floccosa, npon the larvæ and chrysalides of *Bombyx Jacobæa.*

I. strigosa, npon the chrysalides of *Noctua Upsilon.*

I. arachnophila, npon small spiders belonging to the genus *Geometra,* in the autnmn.

I. leprosa, on the chrysalides of *Noctua instabilis.*

I. Tartarica, observed by Rohin npon an nnknown spider, in the antnmn.

I. crassa, npon decaying chrysalides.

I. sphecophila, upon a dead hornet.

I. exoleta, npon the larva of a moth.

I. Aranearum, an American species, fonnd on spiders in Carolina.

I. Sphingum, also found in America, npon the caterpillars of the silk-worm moths.

I. gigantea, found upon a Mygale in the island of Cuba. (Rohin, *Histoire Naturelles des Végétaux Parasites.*)

ISMAÏL, a strongly fortified town of Turkey, in the province of Silistria, is situated on the left bank of the northern or Kilia arm of the Danube, 20 miles east from the mouth of the Pruth, and about double that distance from the Black Sea, in 45° 21′ N. lat., 28° 50′ E. long., and has about 20,000 inhabitants. It was taken by storm by the Russians under Suwarroff, Dec. 22, 1790, when the Turkish garrison numbering 30,000 men were put to the sword; the Russians lost 20,000. Under the Turks Ismaïl was important, not only in a military but in a commercial point of view; it contained 17 mosques, a large number of khans and bazaars, and many splendid houses. On its capture by the Russians all was put to fire and sword, and the town remained in a ruinous condition till 1812, when it was ceded to Russia by the treaty of Bukharest. Since then it has been rebuilt, and now contains about 2300 houses and 12 churches. The Kilia arm of the Danube is navigable for steamers and for vessels of considerable burden, of which about 150 enter the harbour of Ismaïl annually, and are chiefly engaged in the corn trade. There are remains of a fine Turkish palace in the town. Ismaïl is now chiefly of importance in a military point of view, and the Russians rendered its defences very strong. It was restored to Turkey after the late war in the Crimea, by the new adjustment of boundary consequent on the treaty of Paris of 1856.

ISONANDRA, a genus of Plants belonging to the natural order *Sapotaceæ*. It is distinguished by the stamens being all fertile, and twice as numerous as the lobes of the corolla.

I. Gutta (Hooker), the Gutta-Percha Tree, has its leaves on long stalks, obovate-oblong, with a short point golden beneath; flowers axillary, fascicled; stamens 12. This tree is a native of the Malayan Archipelago.

The substance yielded by this tree, and designated by the name of Gutta-Percha (pronounced 'Pertsha') is, like Caoutchouc, a carburet of hydrogen, and isomeric with that substance, and possesses a great number of the properties which characterise India-Rubber [CAOUTCHOUC], but exhibits certain special properties which admit of its being applied to particular uses to which caoutchouc is not adapted. Gutta-Percha possesses as great an indestructibility by means of chemical agents as caoutchouc. It has an intermediate consistence between that of leather and wood; it is capable of being softened by heat, and of regaining its primitive consistency on cooling. It is therefore at the same time capable of taking and of retaining the most delicate impressions. The important uses to which it has been latterly applied are only the forerunners of those to which it will be adapted hereafter, provided a scarcity of this precious material (which unfortunately is produced in much less quantities than India-Rubber, and in localities much more circumscribed) does not present an obstacle to it.

Whilst the plants which furnish caoutchouc abound in the whole of the territorial zone which extends between the tropics, the *Isonandra Gutta* is the only tree which yields Gutta-Percha. It grows scarcely anywhere except in certain parts of the Malayan Archipelago, and up to the present time has been almost exclusively obtained from Singapore. It was brought for the first time into England in the days of Tradescant, as a curious product, under the name of Mazer-Wood; and subsequently it was frequently brought from China and other parts of the East, under the name of India-Rubber, in the form of elastic whips, sticks, &c. In 1843 Doctors D'Almeida and W. Montgomery drew particular attention to it, together with its various singular properties, its easy manipulation, and the uses for which the Malays employed it. The most common employment of it was for whips; and it was by the introduction of a horse-whip made of this substance, that its existence was for the first time known in Europe. The specimens of the products of the East Indies, shown in the Great Exhibition of 1851, proved that the natives of the country in which the *I. Gutta* grows know also how to appropriate it to the manufacture of different kinds of vases, and that European industry has little more to do than to imitate their processes.

The importation of Gutta-Percha into England, where the employment of this substance first drew attention, was in 1845 only 20,600 lbs.; but in 1848 it had increased to above 3,000,000 lbs.; and during the following years the importation has amounted to a much larger quantity, and one which begins to cause some apprehension as to the possibility of the supply sufficing for the requirements of the novel uses in store for it in the future. It is true that during its use Gutta-Percha is but little consumed, and the waste from the articles in this material, submitted to a proper softening, can be made to serve new uses; nevertheless its constantly increasing consumption, added to the barbarous manner in which the product has hitherto been extracted, may well justify some apprehension.

During the first few years of the employment of Gutta-Percha it was the custom to cut down the tree for the purpose of obtaining the juice, which, left to itself, very soon allowed the Gutta-Percha to separate and coagulate of its own accord. There is reason to hope that European industry will soon be embarked in the cultivation of this product, and that the Niato (which is the name that the Malays give to the tree which produces Gutta-Percha), multiplied by means of a regular culture, naturalised in other countries than those to which it is indigenous, and worked by regular incisions, which will only take from the tree a portion of its juice without hindering its development, will be the means of furnishing at a low price a substance which is destined to render notable services to industrial and domestic economy.

The Gutta-Percha which arrives in Europe in the form of lumps of some pounds weight is far from being pure. The natives of the Malayan Archipelago make no scruple of introducing into it stones, earth, &c.; the presence of which in the interior of these blocks renders a purification indispensable, which purification however is capable of being attained without much manipulation.

Indestructible by water, and at the same time a bad conductor of electricity, Gutta-Percha has been found available for inclosing the metallic wires employed in the electric telegraph; and the use of this substance may certainly claim its share in the success of the submarine telegraph, by means of which London and Paris and the other great cities of Europe are now brought within a few minutes of each other.

It may be conceived to what a variety of forms a substance can be turned which, becoming soft without adhering at the temperature of boiling water, regains at the ordinary temperature the slight elasticity and the consistence of leather.

ITACONIC ACID. [CHEMISTRY, *S.* 1.]
ITCH-MITE. [ACARUS.]
IVINGHOE. [BUCKINGHAMSHIRE.]

J

JACK, a common name of the Fresh-Water Pike. [Esox, S. 1.]

JACK-TREE. [Artocarpus.]

JACOB'S LADDER. [Polemonium, S. 1.]

JAMAICINE. [Chemistry, S. 2.]

JANIPHA, a genus of Plants belonging to the natural order *Euphorbiaceæ*. It has monœcious flowers; calyx campanulate, 5-parted; petals wanting; stamens 10 in the male flowers, filaments unequal, distinct, arranged round a disc. In the female flowers the style is one; stigmas 3, consolidated into a rugose mass; capsule 3-coccous.

J. Manihot (*Jatropha Manihot* of Linnæus) is a native of Brazil. It has an oblong tuberous root, as big as a child's head, full of a wheyish venomous juice. The stems are white, brittle, having a very large pith, and several knobs sticking out on every side like warts, being the remains of the foot-stalks of the leaves, which have dropped off, usually 6 to 7 feet high, with a smooth white bark; branches crooked, and have on every side near their tops leaves irregularly placed on long terete petioles, broadly-cordate in their outline, divided nearly to their base into 5 spreading lanceolate entire segments, alternate at both extremities, dark-green above, pale-glaucous beneath; the midrib strong, prominent below, and there yellowish-red: from it there branch off several oblique veins, connected by lesser transverse ones; stipules small, lanceolate, acuminate, caducous; panicles, or compound racemes, axillary and terminal, 4 to 5 inches long, bearing sometimes all male or female flowers, at other times these are mixed on the same peduncle; pedicels with small subulate bracts at their base. Male flowers smaller than the female. Calyx purplish on the outside, fulvous-brown within, cut about half-way down into five spreading segments; disc orange-coloured, fleshy, annular, 10-rayed; stamens 10, alternate with the lobes of the disc; filaments shorter than the calyx, white, filiform, free; anthers linear, oblong, yellow. Female flowers of the same colour as the male, deeply 5-parted; the segments lanceolate, ovate, spreading; disc an annular orange-coloured ring, in which the purple ovate furrowed ovary is imbedded; style short; stigmas 3, reflexed, furrowed and plaited, white; capsule ovate, 3-cornered, 3-coccous; seeds elliptical, black, shining, with a thick fleshy funiculus. The expressed juice is dangerously poisonous. Fecula of the root harmless when separated from the juice and exposed to heat. It is called Cassava—a principal article of diet in South America. The nutritious substance known as Tapioca is the Cassava differently prepared and granulated. These preparations are obtained by crushing the roots after the bark has been removed, and straining off the water, when the mass is gradually dried in pans over the fire.

JARROW. [Durham.]

JASMINUM, a genus of Plants belonging to the natural order *Jasminaceæ*. It has a tubular 5 or 8-cleft calyx; a 5 or 8-parted corolla; stigma 2-lobed or bifid; berry didymous, having one of the lobes usually abortive: seeds without albumen. The species are usually twining shrubs. Leaves simple or compound; petioles articulated; flowers white or yellow.

J. Sambac, Single-Flowered Arabian Jasmine, is a twining plant; the leaves almost sessile, membranous, from cordate to oblong, acute or obtuse, glabrous; berries globular; branches, petioles, and peduncles downy. It is a native of the East Indies. The flowers generally form small trichotomous umbellets, white and fragrant. The berries are black. A perfume, known as Oil of Jasmine, is obtained from this species.

J. angustifolium, Narrow-Leaved Jasmine, is a native of the Coromandel coast. It is a twining bright plant, with ovate or oblong leaves, smooth, of a shining deep-green colour. The flowers are large, white, with a faint tinge of red, star-shaped, having a peculiar but very pleasing fragrance. The bitter root of this species, ground small and mixed with powdered *Acorus Calamus* root, is considered in India as a valuable external application in cases of ringworm. The plant being constantly covered with leaves of a bright deep-green, sometimes as small as those of Box, render it always beautiful, and well adapted for screening windows and covering arbours in warm climates.

J. officinale, Common Jasmine, is a native of the South of Europe. It has opposite leaves, pinnate; leaflets ovate-accuminate; buds erectish. The plant is glabrous, the branches angular. Calycine segments 5, subulate: corolla white, 4 or 5-cleft, sweet-scented; the terminal leaflet is the longest. The Common Jasmine has been a favourite wall-shrub from time immemorial. Its native country, as well as the date of its introduction, are unknown. Gerarde in 1597 says it was in common use for covering arbours. There are golden and silver-edged leaved varieties of the Common Jasmine, as well as a double-flowered variety.

J. grandiflorum has opposite pinnate leaves, leaflets bluntish, the outer ones 3 to 5-confluent, buds horizontal. It is a native of the East Indies, and greatly resembles *J. officinale*, except in the size of the leaflets, and in the exterior ones being confluent, and the flowers larger and reddish underneath. Both this and the former species yield the true essential oil of jasmine of the shops.

The leaves of *J. undulatum* are slightly bitter. The root of *J. pubescens* is thought to be elexiteric.

JATROPHA, a genus of Plants belonging to the natural order *Euphorbiaceæ*. It has monœcious flowers; a 5-parted or lobed calyx; corolla 5-parted or absent; stamens 8 or 10, with unequal monadelphous filaments; styles 2, bifid or dichotomous; capsule 3-coccous.

J. Curcas, Physic-Nut, is a very common small tree, or bush, on the coast of Coromandel. The bark is smooth and light ash-coloured; leaves scattered, stalked, broad, cordate, 5-angled, smooth, about 6 inches each way; petioles round, smooth, 4 to 6 inches long: stipules absent; panicles terminal or from the exterior axils cymose, bearing many small yellow flowers. The male flowers at the extremities of the ramifications on short articulated pedicels, and the female ones in their divisions with their pedicels not articulated. Bracts, a small one below each subdivision of the panicle, and generally one pressing on the calyx; calyx 5-leaved; corolla 5-petaled, campanulate, somewhat hairy; disc of 5 glandular bodies round the base of the filaments; filaments 6, the central one very thick, columnar, the 5 exterior ones filiform towards the base, adhering to the central one, all erect, and a little longer than the calyx; anthers 10, sagittate, equal: 5 supported by the large general filament, and 1 by each of the others. The leaves are rubefacient and discutient; warmed and rubbed with castor-oil, they are applied by the natives of India as poultices. The seeds are violently emetic and drastic; their expressed oil is reckoned a good application in itch and herpes, and also, a little diluted, in rheumatism. The milky juice is considered detergent and healing: it dyes linen black. The oil, boiled with oxide of iron, forms a varnish used by the Chinese for covering boxes. In large doses the seeds are energetic poisons.

J. glauca is found in Arabia Felix. It has leaves from 3-5-lobed, mucronate serrate, toothed; petioles naked; stipules palmate, with setaceous branched divisions, glandular at the apex. The seeds yield a stimulating oil recommended by the Hindoos as an external application in cases of rheumatic and paralytic affections.

J. glandulifera is a native of the East Indies. The leaves about the extremities of the branchlets are alternate, petioled, and generally palmate; the lobes from 3 to 5, oblong, serrate, with each serrature ending in a short green glandular-beaded bristle; stipules bristly; many-cleft, each division ending in a glandular head; panicles terminal, about as long as the leaves. Male flowers most numerous and terminal, small, of a pale yellowish-green colour. The female flowers few, and subsessile in the divisions of the panicle. The pale or whey-coloured thin juice which exudes from a fresh wound is employed by the Hindoos as an escharotic to remove films from the eyes.

J. multifida is a native of tropical America. It has palmate 11-lobed smooth leaves, the segments wedge-shaped and pinnatifid; stipules setaceous, multifid; flowers corymbose, scarlet, with coloured pedicels. The seeds are one of the best of all emetics and purgatives, acting briskly, but without inconvenience; their effects are readily stayed by the administration of a glass of good white wine.

J. Manihot is now referred to the genus *Janipha.* [JANIPHA, *S.* 2.]

JAY, REV. WILLIAM, was born on the 8th of May 1769 at Tisbury, Wiltshire. His father, who was the son of a small farmer, worked as a stone-cutter and mason, and young Jay's first employment was that of mason's boy. While still young he was placed under the tuition of the Rev. Cornelius Winter of Marlborough Academy, an institution connected with the Congregational body, in which young men were trained for the ministry. His abilities soon became known, and he began to preach before he was sixteen years of age. For about a year he officiated as the minister of Lady Maxwell's Chapel at the Hotwells, Clifton; and on January 31st, 1791, he was settled as pastor of the church assembling in Argyle Chapel, Bath, a position which he maintained for the long period of sixty-two years. Mr. Jay retired from the pastorate in January 1853, and died on the 27th of December in the same year, at the age of eighty-four. His reputation as a preacher was very high, and was by no means confined to his own denomination, that of the Independents. His published sermons have had very extensive circulation, and many a congregation throughout the kingdom has often listened to Jay's sermons without knowing to whom they were primarily indebted for the instruction they were receiving. That which made his pulpit addresses so useful also in the family, and so well adapted for reproduction in other pulpits, was their simplicity of style, combined with a clear and methodical statement of the lessons sought to be conveyed. The effect of his own ministrations was much enhanced by his earnestness of manner, and by a full command of his excellent vocal powers. Mr. Jay's regular congregation was large, and visitors to Bath usually repaired to his chapel to hear him preach. He generally made an annual visit to London and to the coast, and in the metropolis and elsewhere he attracted crowded congregations. When he had completed fifty years of his ministerial labours his people held jubilee services, in connection with which, at a public breakfast in the Assembly Rooms on the 2nd of February 1841, a handsome piece of plate and a purse containing 650*l.* were presented to Mr. Jay. Besides his sermons, of which several editions have been published, Mr. Jay wrote an 'Essay on Marriage;' 'Memoirs of the Rev. Cornelius Winter;' 'Memoirs of the Rev. John Clark;' 'Lectures on Female Scripture Characters' (published since his death); and an 'Autobiography,' from which and other sources a memoir of Mr. Jay was prepared by the Rev. Dr. Redford and the Rev. J. A. James, and published in 1854. A uniform edition of Mr. Jay's works was published under the author's superintendence in 1845-49 in twelve volumes, post octavo.

JEFFREY, FRANCIS, was born in Edinburgh, on the 23rd of October 1773, in the upper part of a house now marked No. 7, Charles-street, George-square. His father, George Jeffrey, was one of the depute clerks of the Court of Session; his mother, Henrietta Loudoun, was the daughter of a Lanarkshire farmer. They had a rather numerous family, Francis being the eldest son, though not the eldest child. In the year 1781 he was sent to the High School of Edinburgh, where he was for four years under the care of one of the under-masters, Mr. Luke Fraser—a worthy man, whose celebrity depends on his having, in three successive classes, three pupils no less famous than Walter Scott, Jeffrey, and Brougham. Jeffrey's class-fellows, while he was under Mr. Fraser, used afterwards to remember him as "a little clever, anxious boy, always near the top of his class, and who never lost a place without shedding tears." From Fraser's class, he passed, in regular course, in the year 1785 to that of the rector, Dr. Adam, the author of the 'Roman Antiquities,' and noted alike for his scholarship and the simple integrity of his character. Jeffrey, as well as Scott, used afterwards to speak with the highest respect of this good old man. It was in the winter of 1786-87, while still attending Dr. Adam's class, that Jeffrey, then a boy in his fourteenth year, saw the poet Burns. He was walking along the High Street, when he was attracted by the appearance of a man on the pavement, who, from his dress and manner, seemed to be from the country, but in whose looks otherwise there was something uncommon. It was Burns, then on his first visit to Edinburgh; and as "the little black fellow was gazing at him, some one standing at a shop-door near said to him "Ay, laddie, you may weel look at that man; that's Robert Burns!" Jeffrey never saw Burns again; but he used to dwell with pleasure on the incident.

In the winter of 1787, Jeffrey (his mother being then just dead) was sent to the University of Glasgow; his father for some reason or other preferring that university to the University of Edinburgh. Here he attended the Greek classes under Young, the logic class under Jardine (then recently appointed, but already with something of that reputation as a teacher which he afterwards maintained and increased), and the moral philosophy class, then taught by a Professor Arthur, the successor of the philosopher Reid. That he did not also attend the law class, then taught by the able and speculative Millar, is accounted for by the fact that his father, who was a strict and rather gloomy man, was a bigoted Tory, and likely to regard the teaching of a Whig like Millar with suspicion. Jeffrey's class-fellows at Glasgow remembered him afterwards as being there one of the cleverest of the younger students, somewhat 'petulant' in his manners, and conspicuous for a little black moustache which he persisted in wearing on his upper lip in spite of remonstrance and ridicule. It was in the debating societies of the college however that he first broke on his companions of that day in the full display of his superiority. He was even then a fluent and rapid speaker, a ready and ingenious writer, and a merciless critic of the essays and opinions of others. It was at this time also that he commenced the habit of serious and versatile reading, and of note-taking and essay-writing for the purposes of private culture. This habit he kept up assiduously after his removal from Glasgow back to Edinburgh in the year 1789. In his little room in his father's house in the Lawnmarket, he read and wrote continually, filling quires of manuscript with notes and abstracts from books and miscellaneous dissertations of his own. His biographer Lord Cockburn gives a list of 31 different manuscript essays on literary and metaphysical topics, all written by him between November 1789 and March 1790. About the same time he attended the Scotch law and the civil law classes in the University of Edinburgh. In 1791 he went to Queen's College, Oxford, intending to complete his studies there. While at Oxford he was very solitary and melancholy; he disliked the place; and after nine months was overjoyed to leave it. "Except praying and drinking," he wrote to a friend during his stay at Oxford, "I see nothing that it is possible to acquire in this place." On his return to Edinburgh, in July, 1792, his friends found that his stay at Oxford had altered him in at least one thing: he now no longer spoke in his former natural Scotch accent, but in a sharp, and, as some thought it, an affected English style of pronunciation. "Jeffrey," Lord Holland used afterwards to say, "had lost his broad Scotch at Oxford, but he had gained only the narrow English." Very soon however his friends, who knew his real intellectual force and the genial goodness of his heart, became reconciled to his new style of speech; and Lord Cockburn certifies that to his latest years, Jeffrey had never really forgotten his native Doric, but could talk broad Scotch, and mimic even the provincial dialects of his countrymen when he chose. He had a strong relish, too, for Scottish anecdotes and humours. For a while after his return from Oxford, it seemed uncertain whether he might not be called upon by his father to give up the law, and become a merchant; but the legal profession was at last definitely resolved on. In 1792-93 he again attended the law classes of Edinburgh University under Professors Hume and Wyld, as also the class of history under Alexander Tytler. Strange to say, he did not attend Dugald Stewart—Stewart's Whiggism being an objection in his father's eyes. On the 12th of December 1792 he became a member of the famous Speculative Society, then at the height of its fame; and here he first formed the acquaintance of Scott and many other young men of the Edinburgh set, who afterwards rose to distinction as lawyers, literary men, and statesmen. For several years Jeffrey was one of the ornaments of this society, reading essays in his turn, and figuring with peculiar eclât in almost every debate. Indeed, it used afterwards to be said of Jeffrey, as well as of Horner and Brougham, that never in their most glorious days did they speak better than they did when young members of the Speculative. Already in these debates, Jeffrey, despite the Toryism of his father, was a Whig of the keenest and most pronounced order. Meanwhile he continued his habits of various though desultory reading, and of incessant composition in private on all sorts of subjects. He had even a dream at this time that he was born to be a poet; and he wrote, his biographer tells us, a great quantity of verse. Of this verse Lord Cockburn says, from inspection, that though "viewed as mere literary practice it is rather respectable," it could never have been accepted as poetry. He adds that in one constitutional quality of the poet, Jeffrey was certainly highly endowed—the love of external nature and the delight in beautiful scenery. On the 16th of December, 1794, Jeffrey was called to the Scottish Bar. It was the time when Scotland was politically stagnant under the so-called Dundas reign; when the whole country was managed by corruption and patronage; when such a thing as the free expression of political opinion by meetings or through the press was unknown; when three-fourths of the entire million and a half who then constituted the population of Scotland were Tories, at the absolute bidding of Dundas; and when such few leading Whigs as there were in Scotland were chiefly to be found in Edinburgh, where they were watched and laid under a kind of social ban. Of these Whigs the most zealous were lawyers, bold enough to avow their principles even at the expense of the hostility of the Bench, and the loss of all hope of preferment. The party however was increasing; and year after year young lawyers of talent were attaching themselves to it. Among these young Whig lawyers, beating their heels idly in the Parliament House with no chance of briefs, and amusing themselves by social meetings at each other's lodgings and by essays and debates in the Speculative, Jeffrey was confessedly one of the chief, if not *the* chief. His prospects of practice were so small that for a time he had ample leisure for reading and literature. He began to contribute to the 'Monthly Review' and other periodicals; and for a time contemplated the pursuit of literature professionally. In 1800-1 he attended Dugald Stewart's lectures on political economy. At last, in November 1801, his talents as a pleader had procured him an income verging upon 100*l*. a year; and on this, with what other resources he had, he ventured to marry his second cousin, Catherine Wilson, of St. Andrew's. The young couple took up their residence in a modestly furnished third story of the house No. 18, Buccleugh-Place; and it was here, at a convivial meeting of Jeffrey, Sidney Smith, Horner, and Brougham, that the 'Edinburgh Review' was projected. Smith was the originator of the idea, but the others immediately concurred, and Constable, a rising bookseller, became the publisher. The first number of the new journal saw the light on the 10th of October, 1802; that number and two more were edited by Smith; but, on Smith's return to London, the entire management devolved on Jeffrey.

The great fact in Jeffrey's life, and that which makes his name memorable in the literary history of Britain, is that for a period of twenty-six years (1803-1829) he was the editor of, and one of the principal contributors to, the 'Edinburgh Review.' With the history of that journal, his career is identified, and it became what it was under his hands. To use Jeffrey's own phrase, it stood on two legs—the one leg being the criticism of current literature; the other being Whig politics. Both as a literary critic and as a politician, Jeffrey was the soul of the 'Review.' To enumerate his articles in both capacities; to estimate the vast influence exerted by the 'Review' during his management, on the contemporary literature and contemporary politics of Britain; to revive the numerous controversies both literary and political, in which the 'Review' was engaged; or to reconsider the right and the wrong of its literary judgments, in particular, on the distinguished poets of the period, such as Scott, Byron, Southey, Coleridge, Wordsworth, &c., is here unnecessary. All this belongs to the well-known literary history of the first quarter of the present century. Suffice it to say, that Jeffrey's honesty in the expression of his opinions was never doubted; and that, where he was wrong, it was because his judgments, though honestly given, were limited by the essential nature of his own intellect. As a literary critic, he proceeded on what has been called "the beauty and blemish" principle of reviewing; that is, it was his regular habit first to state in clear, sharp, opinionative language what he considered the 'beauties' of a poem or other work, and then, as a necessary drawback, to append a list of the 'blemishes.' And, although in following this method, he undoubtedly remained constitutionally insensible to the higher poetry of Wordsworth and his kindred associates, he unquestionably exercised a healthy influence on the many by his chastisements. Where he praised, he praised heartily; and it is to his credit that, if his negative judgments have not been always ratified, his favourable decisions generally have. In politics there is now less question as to the value of his influence in promoting what was on the whole good and useful. He was uniformly on the side of progress and improvement; and, though he never was a Democrat, nor what would now be termed a Radical, but only a moderate Whig, his fighting, in his earlier days, was uniformly uphill. It is significant of the adaptation of his writings, both literary and political, to the purposes of rapid immediate effect, that, when a selection of his essays from the 'Edinburgh Review' was published in four volumes in 1843, the work did not take such rank in our permanent literature as has been accorded to the similar collections of the essays of Macaulay, Sidney Smith, Carlyle, and others.

To return to Jeffrey's life, apart from the 'Review:' his professional practice rapidly increased, as his powers as a lawyer found opportunities of displaying themselves. In some respects he was without a rival at the Scottish bar—combining good knowledge of law with singular perspicuity and ingenuity, and a rapid, fluent, and brilliant style of eloquence. As a speaker, he was so rapid, that once, at Glasgow, the defendant in a libel case, where he was conducting the prosecution, after listening to his torrent of words, declared that, by calculation with his watch, "that man had actually spoken the English language twice over in three hours." Jeffrey's triumphs as a pleader, both in criminal and civil cases, were numerous; but nowhere was he more successful, or more in his element, than at the bar of the General Assembly of the Scottish Church, at its annual meetings in May, when he was usually retained in important ecclesiastical cases. With his gradual increase of practice his wealth increased correspondingly, till at last he was in the receipt of a handsome annual income. But his wife did not live to share the full flush either of his fame or his fortune; she died in 1805: and it was while he was on a visit to London in 1806, to distract his mind from this calamity, that the famous 'leadless' duel between Jeffrey and Moore took place at Chalk Farm—occasioned by Jeffrey's notice of Moore's early poetry, and immortalised by Byron's reference to it in his 'English Bards and Scotch Reviewers.' Byron, Moore, and Jeffrey were all afterwards the best of friends; and both the duel and the satire were laughed over among them. With Scott also, notwithstanding that their original political differences were somewhat intensified by Scott's secession from the 'Edinburgh Review' to aid in founding the 'Quarterly' in 1809, Jeffrey always remained on terms of personal friendship; and nowhere were Scott's novels more cordially welcomed and praised than in the 'Edinburgh.' At length, after remaining a widower eight years, Jeffrey married again. His second wife was an American lady, Miss Charlotte Wilkes, the daughter of Mr. Charles Wilkes of New York, and the grand-niece of Wilkes the notorious politican. He had met this lady during a visit of her family to Britain; and, in order to marry her, he undertook a voyage to America in 1813. During his brief stay in America, he saw some of the most important men in the United States, and formed an acquaintance with American society and American institutions. After his return, he and his wife resided for some time in the new town of Edinburgh: but ultimately he removed to Craigcrook, a beautiful little property at the foot of the Corstorphine Hills, about two miles from Edinburgh, the old turreted mansion of which, and the wooded grounds, were much improved by him in subsequent years. The vicinity of the place to Edinburgh made it perfectly convenient for his professional engagements; and till the time of his death he here received as his guests his professional and other friends, and all strangers of distinction who visited Edinburgh. The elegant hospitalities of Craigcrook were proverbial; and the house and grounds retain their associations with Jeffrey, as Abbotsford is associated with the name of Scott. Here Moore sang his songs under the roof of his former adversary, and here, in later days, Dickens formed that acquaintance with the venerable critic which ripened into so strong a friendship.

In the year 1821, Jeffrey was elected Lord Rector of the University of Glasgow. Whig politics were by this time in the ascendant in Scotland; and Jeffrey, as the Whig leader, took his part in the public meetings and other demonstrations which heralded the approach of the era of Reform. Having been chosen Dean of the Faculty of Advocates in 1829, he deemed this office incompatible with the editorship of the 'Review,' which accordingly he resigned into the hands of Mr. Napier. He still took an interest in the 'Review' however; and at a considerably later period, when his son-in-law, Mr. Empson, succeeded Mr. Napier as editor, it was his delight to revise proofs and correct articles, as his son-in-law's deputy. In the meantime however he had passed through new phases of his life. In 1830 he was elected a member of the first parliament of William IV., being returned for the Perth, Forfar, and Dundee district of burghs. In March 1831 he was unseated on petition, but was immediately returned again by Earl Fitzwilliam for the borough of Malton. He represented this borough till 1832, taking part in the Reform debates; and in the end of that year he was returned to the first reformed parliament for the city of Edinburgh, along with Mr. Abercromby, the speaker (now Lord Dunfermline). He remained in parliament till 1834, and was Lord Advocate of Scotland under the Grey government. His parliamentary success however did not answer the expectations that had been formed from his fame as a critic and a forensic orator; and he seems himself to have welcomed the change when, in 1834, he was raised to a vacant judgeship on the Scottish bench, and so relieved from the cares of parliament. Scottish judges have the courtesy-title of 'Lord;' and hence Jeffrey was thereafter distinguished as Lord Jeffrey, though still legally only Francis Jeffrey, Esq. As a judge, he had a very high reputation for soundness, conscientiousness, and rapidity. He was noted for a habit of interrupting pleaders when they wandered, so as to bring them back to the point; and so long as he was in the second division more business was sent before him than before any other judge. He continued in the discharge of his duty almost to the last, dying in his seventy-seventh year, after a short illness, at Craigcrook, on the 26th of January 1850. In the relations of private life, Lord Jeffrey was a singularly affectionate and amiable man, soft-hearted to a degree which surprised those who, till they saw him, had figured him only as a sharp and severe critic. A very genial impression of him in this respect is to be gathered from the selections from his correspondence published by his friend Lord Cockburn, as an appendix to his Biography, in 1852.

JEFFREYSIA, a genus of *Mollusca* belonging to the family *Littorinidæ*, established by Mr. Alder, and named after Mr. Jeffreys of Swansea. The species were originally referred to *Rissoa*. Forbes and Hanley give two species, *J. diaphana* and *J. opalina*, as inhabiting British seas.

JELLALABAD, Afghanistan, is situated in 34° 26′ N. lat., 70° 36′ E. long., in the valley of the Cabul River, on its right or southern bank, at a nearly equal distance from Cabul and Peshawer. Though the river begins to be navigated by rafts at this place, Jellalabad does not appear to be a commercial town. The ordinary population is between 2000 and 3000, but this is much increased in the winter season. The houses are low, and the streets narrow. The town was occupied by the British during the Afghan war, 1839-42. General Sale held it under great disadvantages against Akbar Khan, who besieged the place with a large force in January 1842. At the conclusion of the war the British forces under General Pollock left Jellalabad in October 1842, first destroying its mud walls, and the fortifications which had been erected for its defence.

JERROLD, DOUGLAS. With the higher order of minds every surrounding circumstance, especially of their earliest years, is education. The education of the child Douglas Jerrold was within the verge of a theatre; the education of the boy was on the deck of a man-of-war; the education of the youth was in a printing-office. We can trace the fields of observation in which the dramatist, essayist, and journalist gathered his materials, and in which his habits of thought and study were formed. Douglas Jerrold was born in London, on the 3rd of January 1803. His father was manager of the Sheerness Theatre: the "many-coloured life" of the drama was thus familiar to him in his first years; and those who know how strong are the impressions which an intelligent child thus receives will understand the influence of this experience upon the pursuits of the man. But the boy was surrounded by grand and most attractive realities: the docks and the arsenal of Sheerness—ships coming home to refit after tedious cruises—sailors who could talk of the Nile and Trafalgar. The lad, delicate, sensitive, was smitten with a passion for the life at sea; and, his wishes prevailing, a midshipman's appointment was obtained for him from Captain Austen, brother of Miss Austen, the novelist. At the end of the war he quitted the service, and another calling had to be chosen. He was apprenticed to a printer in London. The labours of a printer's apprentice are not ordinarily favourable to intellectual development; the duties of a compositor are so purely mechanical, and yet demand such a constant attention, that the subject-matter of his employ can rarely engage his thoughts. It was not in the printing-office that the mind of Douglas Jerrold was formed, although the aspirations of the boy might have thought that there was the home of literature. He became his own instructor after the hours of labour. He made himself master of several languages. His "one book" was Shakspere. He cultivated the habit of expressing his thoughts in writing; and gradually the literary ambition was directed into a practicable road. He was working as a compositor on a newspaper, when he thought he could write something as good as the criticism which there appeared. He dropped into the editor's letter-box an essay on the opera of 'Der Frieschütz,' which performance he had witnessed with wonder and delight. His own copy, an anonymous contribution, was handed over to him to put in type. An earnest editorial "notice," soliciting other contributions from our "correspondent," &c., was the welcome of the young writer, whose vocation was now determined. His first dramatic production, 'Black-Eyed Susan'—the most popular drama of modern times, or of any time—was written before Mr. Jerrold had attained his twenty-first year. It was produced at the Surrey Theatre, with a success which Elliston, the manager, very unequally shared with the struggling author. It deferred the ruin of Drury Lane Theatre for a season. The original 'William' boasted, a year or two ago, that he had appeared in the part seven hundred times. 'The Rent Day' followed this first triumph. Jerrold was now the most popular dramatist of the period; and he continued to write for the stage till within the last few years of his life. Equally a master of wit and of pathos, all his plays have a decided originality; they are thoroughly English. His serious dramas are built upon English home affections. The joys and griefs of his scenes are not the tawdry sentimentalities and extravagant passions of adaptations from the French—gaudy exotics, which flower for a little while under artificial cultivation, and then are thrown away as worthless weeds. Jerrold's comedies are also as thoroughly English in their characterisation and their language: they have the true ring of the old national currency of wit and humour and keen satire; but they require excellent actors and intelligent audiences, and, according to some authorities, these requisites for a high drama are passing away. In our day the gratification of the eye, in preference to every other faculty, has degraded even Shakspere from a poet to a showman; and this false taste naturally extends to other walks, to make exaggeration the great requisite of the dramatic artist. Mr. Jerrold's most successful plays, in addition to those we have mentioned, were 'Nell Gwynne,' 'The Prisoner of War,' and 'The Housekeeper;' and amongst his comedies we may especially mention 'Time works Wonders,' and 'The Bubbles of the Day.' Of the latter there has been recently published a German translation, executed with remarkable spirit and fidelity.

A portion of Mr. Jerrold's dramatic works, with the more important of his stories and miscellaneous writings, were collectively published in eight volumes. Here we find the 'Men of Character,' originally published in 'Blackwood's Magazine;' 'Clovernook,' which appeared in 'The Illuminated Magazine;' 'St. Giles and St. James,' written for 'Jerrold's Shilling Magazine;' 'The Story of a Feather,' and 'The Candle Lectures,' which gave such an impulse to the popularity of 'Punch.' For this famous journal he wrote regularly from the second number. In this constant round for thirty years of a very peculiar form of literary labour, where the strongest effects are produced by epigrammatic terseness, we trace a life of unremitting industry, combined with very rare natural gifts improved by diligent cultivation. The flippant satirist—and we have many such amongst the young race of periodical writers—who pours out his invectives without impartial observation or accurate knowledge, belongs only to the passing hour. Jerrold's satire has always a foundation of truth and earnest purpose, and therefore it lives. In his most ephemeral writings we may trace that wide acquaintance with the best literature which is somewhat too much despised by those who believe that a brilliant writer, to use a familiar phrase, can make everything out of his own head. For the last four or five years of his life Mr. Jerrold was the editor of 'Lloyd's Weekly Newspaper'—a journal of so enormous a circulation that its conduct involved a serious moral responsibility. Whatever objection there may have been to the strongly expressed opinions, the invective, or the sarcasm of this paper under his management, it never aimed at popularity by false and dangerous doctrines upon the great principles of society and government. Its success, compared with its previous position, is one of the many proofs that the largest number of readers are not to be propitiated by what has been falsely considered as essential to popularity—to write down to an imaginary low intellectual standard. Douglas Jerrold died June 8, 1857, at his residence, Kilburn, near London. The amount derived from some performances in honour of his memory was invested for his widow and daughter. A pension of 100*l.* has also been granted to Mrs. Jerrold.

JERVINA. [CHEMISTRY, *S.* 1.]

JET. [COAL, *S.* 2.]

JOHANNOT, TONY, was born at Offenbach, November 9, 1803, and, with a brother, Alfred, has been long known in England as a designer of book-engravings. Like his brother, Tony commenced his professional career as an engraver. His first painting was exhibited at the Exposition of 1831, 'Un Soldat buvant à la porte d'une Hôtellerie.' Like his brother he looked to English as well as French history and literature for subjects for his pencil. Among his chief pictures are enumerated the 'Chanson de Douglas' (1835); 'La Sieste' (1841); 'André et Valentine' (1844); 'Bataille de Fontenoy,' now at Versailles; 'Petits Braconniers' (1848): and 'Scène de Pillage' (1851). Though on the whole less successful than his brother as a painter, when, like him, he turned to designing for the wood-engraver, he proved at least equally happy; and as his life was more prolonged, he enjoyed greater opportunities of displaying the versatility of his pencil. Among the more important of his book illustrations may be mentioned 'Werther,' the designs for which he etched himself; Molière's works; 'Manon Lescant;' 'Jerôme Paturot;' the Romances of George Sand; the 'Vicar of Wakefield;' Sterne's 'Sentimental Journey,' &c. His illustrations, though not unfrequently a little exaggerated, and sometimes verging on caricature, are almost always characteristic, and full of knowledge and refinement, rendering the works he illustrated among the very best examples of their class. He died suddenly from an attack of apoplexy, August 4, 1852.

JOHNSTON, JAMES F. W., late Professor of Chemistry in the University of Durham. He was born at Paisley, about the year 1796. His father subsequently removed to Manchester, and afterwards returned again to Scotland, residing at Kilmarnock. During this time the education of young Johnston depended chiefly on his own efforts; he was however so successful that he was enabled to obtain his own livelihood by giving private instruction to pupils in the University of Glasgow. In 1825 he removed to Durham, where he opened a school. In 1830 he married the daughter of Thomas Ridley, Esq., of Park-end. By this marriage his circumstances were so much improved that he gave up his school, and determined to put in execution a plan he had long conceived of devoting himself to the study of chemistry. He accordingly repaired to Sweden, and became a pupil of the celebrated Berzelius. He made so much progress in his chemical studies, and became so well known as a chemist, that on the establishment of the University of Durham he was invited to take the readership in chemistry and mineralogy. This took place in 1833, whilst he was yet pursuing his studies on the Continent, and the chair was not occupied till he returned to fill it. On his return, he took up his residence at Edinburgh, and devoting himself to the department of agricultural chemistry he became appointed chemist to the Agricultural Society of Scotland. On the dissolution of this society, he left Edinburgh, and resided permanently in Durham. He now occupied himself principally with the production of works on the relation of chemistry to agriculture. In this he was very successful, and few writers have been more extensively read in this department of literature. His 'Lectures on Agricultural Chemistry and Geology' are an able exposition of the application of the principles of chemical and geological science to the art of agriculture. He also published a 'Catechism' on the same subject, which at the time of his death, in 1855, had gone through thirty-three editions, and has been translated into almost every European language. He had travelled in America, and was well known as an agricultural chemist in the New World; and his works there have as large a circulation as in his own country. His experience of America he gave to the world in a work entitled 'Notes on North America,' in which he discusses many of the important agricultural questions connected with the resources of that great country. He was an eminently popular writer and teacher, and all his writings exhibit an enthusiasm which renders them attractive even to the unscientific reader. One of the most popular and the last of his works was his 'Chemistry of Common Life,' which has had a vast circulation, and done much for diffusing a knowledge of the principles of chemistry involved in the ordinary occupations of human beings. In some parts of this work he has unintentionally fallen into error; and it is perhaps only right to state here that the remarkable statement made in that work with regard to arsenic-eating amongst the inhabitants of Styria and other parts of Europe, has been recently shown to be without foundation. This work originally appeared as a series of magazine articles. Professor Johnston contributed to the 'Edinburgh Review' and other journals. He has also published many papers in the Transactions and Proceedings of scientific societies. In the summer of 1853 he was travelling on the Continent in his usual health, when he was suddenly seized with spitting of blood, which terminated in a rapid decline, and he died at Durham on the 18th of September of that year. He was made a Fellow of the Royal Society in 1837, and was a member of other learned societies.

JOINT-STOCK COMPANIES. The great alteration in the principles which have influenced modern legislation with reference to Joint-Stock Companies calls for some repetition of what has been already stated with reference to them. [BANK, BANKER, BANKING; PARTNERSHIP.]

These Companies are distinguished from other Corporations by being associated, not for any public or administrative purpose merely, but for carrying on a trade or business with a view to individual profit. They possess other peculiarities equally deserving of notice.

This system of association, which has received such gigantic development in modern times, is by no means of recent origin. Institutions founded on the same principle as the trading guilds of the middle ages seem to have existed among the Saxons; and soon after the conquest we find companies of different trades established in the various seaports and other towns of importance in the kingdom. These fraternities generally became in course of time chartered corporations; each possessing the exclusive privilege of following the particular occupation which it professed to protect. After the Reformation they mostly became merged in the municipal corporations, the franchises of which could in many cases be enjoyed by those only who were *free* of one of the companies into which the community was divided. In this position they remained until the Municipal Corporation Reform Act. Besides these guilds, or companies, other trading associations sprung up from time to time. The general company of Germans, called also the Merchants of the Hause, dates from 1220, and became in the fifteenth century the Company of the Steelyard. In 1505 the 'Merchant Adventurers of England, for trading in woollen cloths to the Netherlands,' obtained a charter of incorporation, prohibiting the former from interfering with them, and the Steelyard Company seems thereafter to have gradually declined. In 1553 was established the 'Merchant Adventurers for the discovery of lands, countries, isles, &c., not before known by the English,' which resulted in the establishment of a trade with Russia. This company subsequently obtained several Acts of Parliament, and still elects its officers. The Turkey Company, the African Company, the Eastland Company, the East India Company, were all chartered monopolies; but the Hudson's Bay Company alone remains on this ancient footing.

Soon after the Revolution, the principle of association began to be applied to a variety of purposes besides those of foreign adventure. Numerous projects were started, the execution of which could not be compassed by private means, but which it was thought might be attained by raising capital on the joint-stock principle. Hence arose, in the early part of the eighteenth century, the speculative mania, remembered in connection with the famous South Sea Company; of which we have seen counterparts more than once in our own times. To meet the evils occasioned by this novel development of the associative tendency, the 'Bubble Act' (6 Geo. I, c. 18), was passed, declaring all companies which presumed to act as corporate bodies, and to pretend to raise transferable stock, public nuisances, and the promoters of them punishable accordingly. This statute was directed not so much against the offence of acting as a corporation without authority, as with a view to prevent the frauds of unprincipled adventurers, who proposed schemes merely as baits to extract money out of the pockets of the thoughtless. Such an object, however, is not to be effected by mere legislation. The gambling in stocks and shares which seems to be periodically revived among us, and which, in 1719, produced the 'Bubble Act,' came to an end during the crash following the wild speculation which led to the statute; but the Act, nevertheless, had some effect in restraining for the future projects of a similar character to those against which its provisions were directed.

During the last century a large number of useful public undertakings, such as the making of canals, bridges, harbours, docks, and the like, have been carried into effect by companies formed on the joint-stock principle, and incorporated by Acts of Parliament; and more recently our gigantic system of intercommunication by railway has been obtained in a similar way. In these undertakings, the assistance of the legislature was necessary, not so much to give a corporate existence to an association of capitalists, as to enable the company to carry out its project by the compulsory purchase of property, and to make by-laws binding on the public for protecting the rights of the corporation. These companies, like the old trading associations, partake of the advantages derived from incorporation; advantages in which mere associations of individuals joined together to promote such common objects cannot possibly participate. A mere assemblage of adventurers cannot, for instance, by any agreement among themselves, sue or be sued in the name of any one of their body, or of any officer they may select for the purpose; they are liable, on the contrary, to the same laws as ordinary partnerships, and each individual is responsible to his last shilling for the acts and omissions, the contracts and debts, of the body generally. To facilitate the operations of such associations, various statutes have been passed; but owing to the fluctuation in opinion regarding the true policy to be pursued, the legislation relating to them has not been altogether consistent.

The original mode of forming a joint-stock company was by means of a deed of settlement, which constituted trustees of the partnership property, directors of its affairs, auditors of its accounts, and other officers, defined the number of shares into which the capital was divided, and the form and mode of transferring them, and laid down rules for periodical meetings of the shareholders. In the absence of legislative interference, the rights and liabilities of the members of such bodies, in relation to the public, were the same as those of other members of ordinary partnerships; their rights and liabilities *inter se* depended on the provisions of the deed of settlement. The difficulties which were soon found to arise, in carrying on the business of such undertakings, induced the earlier joint-stock companies to obtain private Acts of Parliament, which usually enabled the company to sue and be sued in the name of the Secretary or some public officer appointed for the purpose, and almost invariably concluded with a proviso that nothing therein should tend to *incorporate* the partnership; for one effect of incorporation would have been to destroy the individual responsibility of the members for the acts of the association, which the Legislature, until quite recently, most carefully retained. As joint-stock companies, however, increased in number and in usefulness, the cost and trouble necessary to obtain a private Act of Parliament were felt to be extremely burdensome; and the attention of Parliament being called to the subject, it was thought expedient by the Legislature to empower the Crown to grant to joint-stock companies such powers as were likely to be most useful to them, without, however, conferring all the incidents of a corporation. The first attempt at legislation in this direction was the statute 6 Geo. IV. c. 91, which enabled the Crown, in any charter of incorporation thereafter to be granted, to provide that the members should be individually liable for the debts and engagements of the corporation. This Act proving inoperative, another mode of proceeding was tried by 4 & 5 Will. IV. c. 94, which enabled the Crown to grant to joint-stock companies the privilege of sueing and being sued in the name of any of their officers. This Act was soon repealed, and another attempt made in the same direction by 7 Will. IV. and 1 Vict. c. 73. At length the 7 & 8 Vict. c. 110 was passed, for the registration, incorporation, and regulation of all future joint-stock companies not requiring nor obtaining a charter or Act of Parliament. This statute introduced a system of public *registration*, by which the company became *incorporated*, for the purpose of carrying on the business for which it was formed, according to the provisions of its deed of settlement; but every shareholder remained liable individually for the debts and contracts of the company, and might be proceeded against as though he were not a member of the corporation. Banking companies were excepted from this statute, the 7 & 8 Vict. c. 113 being passed for their special regulation.

A great many joint-stock companies were formed, and by registration obtained the corporate privileges, which they were now enabled to do; but before long the affairs of several became involved; and the difficulties which then presented themselves in attempting to adjust the rights and liabilities of the shareholders led to the Winding-up Acts, 11 & 12 Vict. c. 45, and 12 & 13 Vict. c. 108, which for several years exercised the acumen of the Judges of the Court of Chancery, in a series of hopeless attempts to interpret and follow out their provisions. The effect of the flood of litigation carried on under these Acts was to throw a very strong light upon the principles of legislation applicable to joint-stock companies; and the knowledge was purchased at an enormous expense, which has recently led to the repeal of the Registration and Winding-up Acts, and to a total remodelling of the law regarding these associations. This has been effected by the statute 19 & 20 Vict. c. 47, which provides for the registration, under the provisions of these Acts, of all companies previously registered under the former statute. The Act itself has been amended by 20 & 21 Vict. c. 14.

The principle of limited liability, or the restriction of the responsibility of each member to the amount of the capital subscribed by him, which had long been conceded to companies incorporated by Act of Parliament, without baneful effects to the common wealth, has been at length extended to all joint-stock companies coming within the operation of these Acts, which choose to adopt their provisions, on the simple condition of obtaining registration and conforming to a few simple rules, whereby the personality of the company is defined. From its operation are excepted all companies established by Act of Parliament, royal charter, or letters patent, all banking or insurance companies, and associations engaged in mining in the Stannaries, where companies with a limited liability may be formed conformably to certain local customs, which are generally known as the *Cost-Book System*.

There now exist, therefore, four classes of joint-stock companies.

1. Trading companies incorporated by special Acts of Parliament. This class includes railway, dock, harbour, and canal companies, many insurance companies, and a vast number of other bodies engaged in every species of profitable employment. Formerly each company thus incorporated was governed by the peculiar provisions of the Act which it obtained; but in order to introduce uniformity, a general Act, applying to all future companies, was passed under the title of 'The Companies' Clauses Consolidation Act,' 8 & 9 Vict. c. 16. This statute contains a complete code for the regulations of the proceedings, the transfer of the shares, and the general management of companies incorporated by Act of Parliament. 'The Lands' Clauses Consolidation Act,' 1845, was passed at the same time, consolidating all those provisions which it had previously been necessary to insert in the special Act of any company, which required powers of acquiring land compulsorily for the purposes of the undertaking.

The peculiar character of railway undertakings rendered necessary 'The Railways' Clauses Consolidation Act,' 1845; which lays down regulations as to the construction of railway works, the amount and mode of enforcing the payment of tolls and fares, and the making of by-laws for the conduct of their business, which are binding upon all persons whatsoever.

2. A second class of joint-stock companies are the very few established under the statute 1 Vict. c. 73, or the preceding Act, 6 Geo. IV. c. 91, which have been already referred to.

3. Banking companies formed since 1844 form a distinct class. They were until recently regulated by the statute 7 & 8 Vict. c. 113, but must now be registered under 'The Joint-Stock Banking Companies' Act,' 1857, which preserves the individual liability of the partners, and contains provisions for the company being wound up. Banking companies constituted previous to 1844, may avail themselves of the advantages of the statute, by being registered under its provisions.

4. The last class of trading corporations are the registered joint-stock companies, regulated by the Joint-Stock Companies' Acts, 1856 and 1857, under which seven or more

persons may, by subscribing a memorandnm of association, and otherwise complying with the reqnisitions of the statute in respect of registration, form themselves into an incorporated company, with or withont limited liability.

This registration is obtained by delivering to the registrar of joint-stock companies a memorandnm of association, stating certain particulars in a prescribed form. Upon registration being effected, the subscribers, together with snch persons as from time to time are admitted to be shareholders in the company, become a body corporate, having a perpetual snccession and a common seal, and power to hold lands to a certain extent, and with consent of the Board of Trade to any extent whatever.

The company may hold itself forth to the pnblic as one of which the members are liable either with or withont limit, according as the fonnders of it choose to adopt the principle of limited liability or not. Where the liability of the shareholders is limited by the memorandnm of association, the word '*limited*' mnst be the last in the registered title of the company, and must be inseparably attached to its name.

The statute requires that a register of shareholders shall be kept; and that this list be annually revised, and a copy furnished to the registrar of joint-stock companies. This copy is open to pnblic inspection, so that all the particnlars of importance respecting the company can be at any time ascertained by persons dealing with it.

The affairs of a registered company are also liable to examination by the Board of Trade; while the statutes contain a complete code of regulations for winding np a company unable to meet its engagements, or which it is thought desirable to wind np for other reasons. Directors, who declare a dividend when the company is insolvent are jointly and severally liable to the extent of the dividend, for all the debts of the company; and every person concurring or carrying on the hnsiness of the company when the number of the partners is less than seven, is severally liable for its debts.

This species of corporation may be dissolved by being wound up, either voluntarily or compnlsorily. A volnntary winding np may take place: 1. Whenever the period, if any, fixed for the dnration of the company expires, or the event, if any, occurs npon which it is to be dissolved: 2. Whenever the company has passed a special resolution requiring its winding np.

A company may be wonnd np compulsorily: 1. By virtne of a special resolution to that effect: 2. Whenever it does not commence business within a year of its incorporation, or suspends hnsiness for a year: 3. Whenever the shareholders are less than seven in nnmber: 4. Whenever the company is nnable to pay its debts: or, 5. Whenever three-fonrths of the capital have been lost or become unavailable.

A company is to be deemed unable to pay its debts: 1. Whenever a creditor for 50*l.* has served a demand of payment, and the company has for three weeks neglected to pay the claim, or to secure or compound for it to the satisfaction of the creditor: and, 2. Whenever an execution is returned nnsatisfied, in whole or in part.

The proceedings take place in the case of companies whose liability is nnlimited in the Court of Chancery; in the case of companies with limited liability in the Court of Bankruptcy. (Blackstone's 'Commentaries,' Mr. Kerr's edition, vol. i. p. 526.)

JOSÉ, SAN. [CALIFORNIA, *S.* 2.]

JOUY, VICTOR-JOSEPH-ETIENNE DE, was born in the hamlet of Jouy, near Versailles, in 1769. When only thirteen he accompanied the governor of French Guyana as sons-lieutenant to that colony, bnt remained there scarcely a year. He retnrned to Versailles, continued his education for two years, and then left France a second time for the French East Indian possessions as an officer in the Luxembourg regiment. In 1790 he was again in France, joined the revolutionary party, and rapidly attained military promotion, bnt dnring the Reign of Terror became snspected, and fled to Switzerland. On Robespierre's fall in July 1794 he returned to Paris, was placed on the staff of the army of Paris nnder General Menou, and contributed to the triumph of the Convention in the streets of that city on the 21st of May (2nd Prairial) 1795. Very shortly afterwards he was arrested; then released, and sent as commander to Lille; then again arrested on an accusation of being in communication with Lord Malmeshnry the English minister, bnt acquitted and restored to his fnnctions. Disgusted however with these repeated prosecutions he resolved to abandon his military career; he therefore solicited his discharge, which he obtained together with a pension for his good services and wonnds. He was now thirty years old, and after a few months' service in a civil capacity at Brussels, he took np his abode at Paris and devoted himself to literatnre. His first efforts were some vandevilles, written in conjnnction with Messrs. Delonchamp and Dienlafoy; bnt his first great snccess was the opera of 'La Vestale,' the mnsic by Spontini which gained him admission to the Academy in 1815. This was followed by several other operas, among which were 'Les Amazones,' with mnsic by Mehnl, and 'Les Abencerrages,' with music by Cherubini, which still retain possession of the stage. He also wrote comedies, both in prose and verse, with considerable snccess; and several tragedies, of which 'Sylla' obtained a marked success. The work however on which his reputation mainly rests is 'L'Hermite de la Chaussée d'Antin,' a series of essays on men and manners in France, which first appeared in the 'Gazette de France,' in 1813-14, and were afterwards collected and pnblished in five volumes, 12mo, 1815. They were considered in France as the snccessful rivals of the English 'Spectators,' 'Guardians,' and 'Ramblers.' They no doubt have considerable merit, the style is easy, the observation acnte, the description animated, and the characters often drawn with much quiet humonr. They may exhibit some resemblance to the essays of Addison or Steele, but none whatever to those of Johnson. They display with sufficient accnracy the snrface of society, bnt they have little depth. Some attempts are made at the pathetic, bnt they are rather mandlin. They were however very snccessful in France, and the anthor followed np his snccess by the 'France Parleur,' 'L'Hermite de la Guyane,' 'L'Hermite en Province,' the last a collection by several writers, bnt all infinitely inferior to the first. 'L'Hermites en Prison,' however, and 'L'Hermites en Liberté,' written in 1823 and 1824, in conjnnction with M. Jay, were of a better kind, and were received with much applanse by the liberal party in France. M. Jouy has also written on political economy, and likewise two novels, 'Ceoil,' and 'Le Centenaire,' in 1827 and 1833. He edited for some time the 'Journal des Arts,' and he contributed innumerable articles to various newspapers and journals. He died at Paris in October 1846.

JUDICIAL COMMITTEE. The appellate jnrisdiction of the Judicial Committee of the Privy Council has been already mentioned. [DELEGATES, COURT OF, *S.* 2.] It only remains to be added that besides its authority in ecclesiastical, admiralty, and colonial causes, the Judicial Committee has been recently constitnted the Court of Appeal from the jndgments of the Court of Probate. It also decides on applications for the confirmation and extension of patents; and the republication of books, which, after the death of the author, the proprietor of the copyright has refnsed to pnblish.

JUDICIAL SEPARATION. [SEPARATION, JUDICIAL, *S.* 2.]

JUDSON, ADONIRAM, fonnder of the American Baptist Mission in Birma, was born Angnst 9, 1788, at Malden, Massachusetts, where his father was a Congregationalist minister. Having passed through the classes of Brown University, where he took honours, he entered the Andover Theological Seminary; and whilst there, a sermon by Dr. Clandius Buchanan, which he chanced to meet with, turned his thoughts towards the missionary service in India. Some fellow-students, to whom he commnnicated his views, became similarly impressed, and they eventually formally stated to the college authorities their desire to devote themselves to the missionary office. There was then no missionary society in America, bnt the council referred the matter to a general committee, who resolved that it was advisable to institute a 'Board of Commissioners for Foreign Missions.' Whilst this board was in process of organisation, yonng Judson proceeded in 1811 to England, to consult with the directors of the London Missionary Society. On his way the vessel in which he had embarked was captured by a French privateer and carried into Bayonne, but Judson was released, after a short detention, at the intercession of some of his countrymen. In London, he received only qualified promises of aid, but the American board, though as yet withont funds, resolved to found a mission in Birma, to which they appointed Judson and three other yonng students as missionaries.

Having on the 5th of February 1812 married Miss A. Hasseltine, he, twelve days after, embarked with his yonng wife for India. Four months later they landed at Calcntta, where they met with a warm welcome from Dr. Carey and the Serampore missionaries, but the Bengal government peremptorily ordered Judson and his companions to return to America by the same ship in which they had arrived. Judson however was not disposed to give up his purpose so easily. He accordingly took a passage to the Isle of France, proceeded thence to Madras, and from there to Rangoon, in Birma, where he arrived July 14, 1813.

Before leaving Calcutta, Mr. Judson, whose views on the subject of baptism had undergone a change, was, with his wife, re-baptised by immersion by Dr. Carey. He in consequence resigned his connection with the Board of Missions; and when he landed at Rangoon to commence his missionary work he was unconnected with any society, and without any means of future support. He addressed himself however without delay to the task of acquiring the Birmese language, unaided by dictionary or grammar, whilst the native he engaged as a teacher knew not a word of English. By persevering labour he in some two or three years was able to speak the language with some degree of readiness. The Baptists of America, on hearing of his devotion, had promptly formed a missionary society to support him, and sent him out some assistants, one of whom was a printer. The Serampore missionaries presented a printing-press and a fount of Birmese type. Mr. Judson, now not only engaged in preaching and personally instructing the natives, but desirous to benefit those whom his voice could not reach, drew up in Birmese a 'Summary of Christian Doctrine,' which was the first work issued from the Rangoon press; and portions of scripture and several tracts followed. As soon as the mission was fairly at work Mr. Judson made visits to other Birmese towns, and to Ava, where he had an interview with the king; and, having obtained permission set about establishing schools, in which Mrs. Judson, who had also mastered the language, was a very earnest and successful helper. The mission was going on favourably, when the sovereign of Birma provoked the English to declare war. Rangoon was made a point of attack by the British forces; but before they arrived, Mr. Judson, with the other missionaries, was seized and put into prison. There he remained for several months, subjected the greater part of the time to the most cruel treatment; but at length, when the success of the English was beyond question, he was employed to act as translator for the Birmese, and Mrs. Judson was sent to the British camp to mediate. A treaty of peace being signed, Mr. Judson and his companions were permitted to resume their labours. He returned to Rangoon; and there, worn out with toil and anxiety, the companion of his early dangers and the sharer of his labours died, October 1826, during his absence in Ava. Some eight years later he married a second wife, the widow of a fellow-missionary named Boardman.

From an early period Mr. Judson had regarded the translation of the Scriptures into Birmese as the great work of his life; and, after having been for several years engaged upon it, he at length, January 31st, 1834, had the happiness to complete his task. He lost no time in putting it to press, and by the end of 1835 the printing was finished of the first edition, in 3 vols. large 8vo. But he soon became convinced of its many imperfections, and he at once set about thoroughly revising the whole, with such assistance as he could obtain. This revision was completed in the autumn of 1840, and immediately printed in a thick 4to volume. It has since undergone careful correction by various Oriental scholars, and now holds a high place among the translations of the Scriptures into the eastern tongues. Almost as soon as the printing of this revised edition of the Bible was finished, with characteristic energy Judson commenced at Moulmein, whither he had removed, the preparation of a Birmese Dictionary. But his own ill-health interrupted the work, and the health of his wife failing also, he determined to return to America, in the hope that their native air might restore their vigour. Mrs. Judson died off St. Helena (September 1st, 1845), but he arrived in safety at Boston a month afterwards. His reception by the various religious societies in America was of the most enthusiastic kind. Special services were everywhere got up, and enormous crowds of persons assembled to greet him. His stay however was but brief; he had determined to return, and if possible, end his days in Birma. But he did not return alone. Anxious to find some one qualified to write a memoir of his second wife (a memoir of the first had already been written), he was introduced to an accomplished young lady, Miss Chubbuck, whose writings under the pseudonym of Fanny Forester, had had an unusually large amount of popularity in religious circles; and she not only undertook to write the life of the second Mrs. Judson, but soon consented to become the third. They were married in June 1846; in July they embarked at Boston, and in December they landed at Moulmein. The mission was now in a flourishing state, and Judson felt that he might devote himself to the easier task of supervision, and to the completion of his Dictionary. Of this he was permitted to see the first part printed in 1849, but he did not live to complete it. His health failed, and he was directed to proceed to the Isle of Bourbon to recruit. He embarked, but grew rapidly worse, and died at sea on the 12th of April 1850. His 'Burmese and English Dictionary' was completed from his papers by Mr. E. A. Stevens, and printed at Moulmein in 1852. It is regarded as a work of great value, and is in fact the only Dictionary that has been compiled of the Birmese language. With his Birmese Bible it formed a vast work for one individual to accomplish, in the midst of labours so many and so exhausting as those of the founder and director of an Indian mission. As a Christian missionary, Mr. Judson is regarded with the greatest respect by all sects among his countrymen, and also in England, though of course with especial reverence by the Baptists.

Several Lives of Mr. Judson have been published, of which the chief are those by Clements, Gilette, and Wayland. Memoirs of each of his wives have also been published: one, 'Lives of the three Mrs. Judsons,' having passed through several editions. Each of these ladies was an authoress. Besides various papers for the Birmese converts, the first Mrs. Judson wrote a 'History of the Burman Mission;' the second wrote poetry; and the third, besides her 'Memoirs of Mrs. Boardman Judson,' wrote, as Fanny Forester, the 'Records of Alderbrook,' a work very popular in America, and more than once reprinted in England; 'The Great Secret;' 'Missionary Biography;' 'The Kathayan Slave,' &c. She died June 1, 1854.

JUGLANS. [WALNUT-TREE.]

JULIS, a genus of Fishes belonging to the family *Labridæ*. The head is smooth; cheeks and gill-covers without scales, the lateral line bent suddenly downwards when opposite the end of the dorsal fins. In other respects this genus resembles *Labrus*. [LABRIDÆ.] An example of a very beautiful species of this genus, known under the name of the Rainbow-Wrasse, was described by Donovan as taken off the coast of Cornwall. It is the *J. Mediterranea* of Risso, the *J. vulgaris* of Fleming and Cuvier. This fish is most remarkable for its varied colours. Its back is greenish-blue; the longitudinal band is orange; beneath that are lilac-coloured bands on a silvery ground; the head is varied with brown, yellow, blue, and silver; the dorsal fin orange, with a purple spot on the membrane connecting the three spinous rays. (Yarrell, *British Fishes*.)

JUNCUS, a genus of plants belonging to the natural order *Juncaceæ*. This genus is distinguished by its inferior perianth, composed of 6 glumaceous leaves; its 3-celled 3-valved capsules, the seed-bearing dissepiments of the valves being in their middle. The species are numerous, and are found mostly in moist boggy situations in the colder parts of the world: several are however inhabitants of tropical regions.

J. effusus, the Soft Rush, and *J. conglomeratus*, the Common Rush, are used in many parts of the country for plaiting into mats, for chair-bottoms, and for constructing small toy-baskets. The wicks also of the candles known as rush-candles are made from the pith, or more properly speaking the softer inner portion of the stem of the same species, which is chiefly composed of cellular tissue. The species is cultivated in Japan like rice entirely for making floor-mats.

Rushes of various kinds form frequently very troublesome weeds in agriculture. They grow best on rich land that is wet and cold. They must be destroyed by covering them over with dry materials of various kinds, as ashes, lime, and drift from roads; but the best mode of getting rid of them is to fork them up by the roots in the summer, and after letting them lie for a fortnight or three weeks to dry to burn them. This however will be found only a temporary mode of getting rid of them unless the ground on which they grow is well drained.

JUNGMANN, JOSEF, an eminent Bohemian lexicographer and bibliographer, was born at Hudlitz, near Beraun, on the 16th of July 1773. His father was a peasant, who specially occupied himself with the management of bees, and Jungmann, who early showed a literary turn, had much to struggle with in devoting himself to his favourite pursuits. His example appears to have produced an effect on others of the family, for Antonin, a younger brother, became a physician, and Jan a priest. The German language was introduced into the schools of Bohemia in 1774, and Jungmann, though from his name he was evidently of German descent, and though, as his after life evinced, he had talents for acquiring languages, seems to have felt as a peculiar hardship the necessity he was under of obtaining a mastery of German. He made it the main business of his after life to restore and promote the study and cultivation of the Bohemian language, which, in his boyhood, was almost abandoned to the use of the peasantry, and which, owing in a considerable degree to his exertions, is now the ordinary language of Bohemian authors, who were formerly accustomed to employ either German or Latin. He studied first at Beraun, and then at the University of Prague; and in the year 1799 obtained an appointment as teacher of grammar at the gymnasium, or grammar school, of Leitmeritz, where he devoted part of his leisure to giving gratuitous instruction in Bohemian. While at Leitmeritz he translated several specimens of English poetry—Pope's 'Eloisa,' and 'Messiah;' Goldsmith's 'Edwin and Angelina;' Gray's 'Elegy in a Country Churchyard;' and above all the 'Paradise Lost,' which was completed about 1804, but not published till 1811, and which came to a second edition in 1843, in the 'Nowoceská Biblioteka,' a collection of the Bohemian classics. In 1815 he was transferred to Prague as professor of Latin at the grammar school of the Old-Town, of which, in 1834, he became the prefect, or principal. In 1840 he was chosen rector of the university, an office which was delivered to him by his brother Antonin, who had occupied it the year before, while his brother Jan read high mass as part of the ceremonies. Antonin, who has written several medical works in Bohemian, has also published an essay on the Sanscrit language, and Jan is likewise an author in the native tongue. In 1845 the infirmities of age compelled Josef to retire from the management of the gymnasium, but he was still occupied with correcting works for the press at the time of his death, on the 16th of November 1847. He had for several years been an object of affectionate veneration to the Bohemian public.

Jungmann is the author of two works which are certain to preserve his name. One, the 'Slownik Cesko-Nemecky,' the great Bohemian Dictionary, in five quarto volumes, comprising at least four thousand pages of close print in double columns, is a stupendous monument of zeal and diligence, which the Bohemians proudly place by the side of Johnson and Adelung. The only other dictionary of a Slavonic language which can be compared to it is the Polish of Linde, which is indeed more rich in points of derivation and comparison. In conformity with its title, 'Bohemian-German Dictionary,' equivalents to the Bohemian words are given in German in this elaborate work, but the main mass of information which it contains is only accessible to the Bohemian scholar, and even the Preface is given solely in Bohemian. This dictionary, which passed through the press between 1835 and 1839, was published at the expense of the Bohemian Museum, and in an imperial decree which was issued soon after its appearance, it was directed that the orthography adopted by Jungmann should be taken as a standard in the schools of the country. The triumph however was a short-lived one, for already in 1842 the Museum had adopted another system of orthography, to which Jungmann was obliged to conform in other works issued under its auspices, hoping, as he tells us in his 'History of Bohemian Literature,' that this new system might be the last. This 'History' is his other great labour, and it is a most useful compilation to all who take interest in a curious branch of literary research. The first edition, which was issued in 1825, was out of print for several years before the appearance of the second, which Jungmann was engaged upon at the time of his death, and which was published in 1849. It is not so much what its title indicates as a complete Bohemian bibliography. The narrative portion, which is somewhat dry, hardly occupies a tenth part of the work, the remainder is a complete and minute enumeration of every book in the Bohemian language, printed or manuscript, of which Jungmann could acquire information, from those of the earliest period, the manuscripts discovered by Hanka, to the year 1846. He even had the patience to form a list of the separate articles in periodicals, so that, with the assistance of very copious indexes, a reader may ascertain in a few minutes, which of the works of Dickens, Scott, and Shakspere were translated into Bohemian by the year 1846, who were the translators, and when the versions appeared. The miscellaneous writings of Jungmann were collected in one volume, and published by the Bohemian Museum in 1841. They mainly consist of translations from English, French, and German, but there are some essays on the favourite subject of his native language, which are curious in matter and animated in manner.

JUNOT ANDOCHE, DUC D'ABRANTES, was born at Bussy-les-Forges, on the 24th of September 1771, according to the Duchess's 'Memoirs,' whilst all the biographical dictionaries fix the date in October of the same year. He had begun to study for the law, when the political events of 1791 induced him to enlist in the battalion of volunteers raised in the department of the Côte-d'Or: he soon distinguished himself, and his fellow-soldiers made him a sergeant on the field for one of his acts of daring. In that grade he was serving at the siege of Toulon, when Bonaparte, not yet a general, commanded the artillery, and having discerned the soldierly qualities of Junot, attached him to his person. The capture of the place raised the commandant to a general of brigade, when Junot was made a captain, and became the first aide-de-camp to General Bonaparte. For nearly two years he continued the sole aide-de-camp of General Bonaparte; he is even said to have shared his purse with his superior officer during the few months that he remained unattached, prior to the 13th Vendemiaire (October, 1795).

He accompanied Bonaparte to Italy, in 1796, and was present at Lodi, Arcola, Castiglione, and Lonato, at which last battle he was badly wounded. In 1799, he took part in the campaign in Egypt, when at the combat of Nazareth, with a troop of three hundred horse, he held a body of several thousand Mussulmans in check, till Kléber came to his relief. He greatly assisted Bonaparte on the 18th Brumaire, in overthrowing the Directory. For this timely service, he was made Commandant of Paris, in 1800; married to Mademoiselle du Permon (whose family had long been connected with that of Bonaparte) on the 18th October of the same year; and created a general of division in 1801. In 1804 he was appointed Governor of Paris. On the 1st of February, 1805, he received the title of colonel-general of hussars, besides being decorated with the grand eagle of the Legion of Honour. He was likewise sent on several missions to the Court of Lisbon, his part of ambassador being suddenly changed at last into that of aggressor, when the good understanding between France and Portugal had ceased, in 1806. Junot then took forcible possession of Portugal, and held his ground there for nearly two years, when Sir Arthur Wellesley's victory at Vimiera, on the 21st of August 1808, and the conclusion of the Convention of Cintra, nine days after the battle, was followed by the evacuation of Portugal by the French army, and Junot's return to Paris. He had already received his title as Duc d'Abrantes; but from this period he lost all favour with Napoleon, having no chief command entrusted to his orders. In 1812 he was directed to join the grand armée, and the 8th corps was ostensibly placed under his command, but the orders from Berthier were transmitted rather to his lieutenants than to himself, and the only time his name was mentioned in a bulletin, he was reflected upon as having shown "a want of resolution." Under this reproach his spirit sank; he was refused employment in the campaign of 1813, and shortly afterwards was attacked with mental disease. In this state he was conveyed to the house of his father, at Montpelier, on the 22nd of July 1813; the following day he threw himself out of a window, broke one of his thighs, and it became necessary to amputate the leg. He died on the 28th.

Laura Permon, Duchesse d'Abrantes, was born at Montpelier, November 6, 1784, and was only sixteen when married to Junot, in 1800. She was a woman of great frankness of speech, and equally remarkable for the prodigality of her expenditure. As a consequence she made enemies at court, during her husband's life, and when his death and the fall of Napoleon had turned the tide of her fortune, she had no savings to support herself and family. She therefore had recourse to her pen for her subsistence. She wrote many tales and novels; but her principal work was her 'Mémoires au Souvenirs historiques sur Napoleon,' published in 1831. As these memoirs contained many incidents relating to the early life of the French emperor, its success was universal throughout Europe. The Duchesse d'Abrantes died in extreme poverty on the 7th of June 1838.

JUSSIEU, ADRIEN DE, son of Antoine Laurent de Jussieu, was born at Paris on the 23rd of December 1797. He was educated for the medical profession, but devoted himself to the study which had rendered his father famous, and became his successor in his chair of botany, and the inheritor of his virtue and talents. Adrien de Jussieu wrote no great work, but his communications to scientific journals, monographs, scientific biographies, &c., were very numerous. Among the more important of his writings may be named his 'De Euphorbiacearum Generibus,' &c., 1824; 'Sur les Plantes du Chili;' the 'Flora Basiliæ Meridionalis,' written in conjunction with M. Auguste de Saint-Hilaire; his contribution to the 'Cours Elémentaire d'Histoire Naturelle' of M. Milne-Edwards, &c. M. Adrien de Jussieu was chosen in 1831 a member of the Académie des Sciences, of which he was president the year of his death. He died on the 29th of June 1853.

JUSTICES, LORDS, OF APPEAL IN CHANCERY. These judges, who are two in number, were created by the statute 14 & 15 Vict. c. 83, to assist the Lord Chancellor in the determination of appeals from the Master of the Rolls and Vice-Chancellors. They possess besides an original jurisdiction, so that when all the appeals are disposed of, they may hear causes in the first instance. The Lord Chancellor may sit with them, or separately as a Court of Appeal. In Bankruptcy the Lords Justices constitute the Court of Appeal; in matters of lunacy they have, under the sign manual, the same authority as the Lord Chancellor.

JUSTICES OF THE PEACE. The authority of Justices of the Peace in petty sessions has been considerably extended of late years, especially with reference to juvenile offenders and persons guilty of petty larcenies. These cases may now be summarily dealt with by two magistrates, or one stipendiary magistrate, instead of being sent for trial by a jury, the punishment of the offender in no case however exceeding six months' imprisonment, with or without hard labour. Assaults on females or male children under fourteen may likewise be inquired into in a summary way, and the offender if convicted sentenced to a similar punishment. (Blackstone's 'Commentaries,' Mr. Kerr's edition, vol. iv., pp. 245, 333). Two magistrates in petty sessions, or one stipendiary magistrate, have also recently received authority to grant orders protecting the earnings of a married woman, who is deserted by her husband, from him or his creditors (20 & 21 Vict. c. 85, s. 21.)

JUVENILE OFFENDERS. [Justices of the Peace, *S.* 2.] Numerous statutes have been passed of late years with the view of providing for the effectual reformation of criminal children; but the law is still in a transitional if not experimental state. Criminal Courts are now however enabled to sentence juvenile criminals to confinement in reformatories, which the magistrates of counties and districts are enabled to provide for this purpose, the parents being compellable, if able, to provide for their maintenance and education. The progress of public opinion and of legislation on this subject of deep interest and of national importance will be found traced in a work recently published by Mr. M. D. Hill, the Recorder of Birmingham, which is devoted to an account of the means to be taken for the repression of crime.

K

KAFFRARIA. [Caffraria.]

KAFFRARIA, BRITISH. This name is applied to a dependency or military possession, recently annexed to the Cape Colony in South Africa. The annexation arose out of the Kaffir War of 1847. For twenty years before that date the settlers in the Albany district of the Cape Colony, being near the eastern frontier, were often exposed to irruptions from the Kaffirs. Successive governors of the colony—Sir B. D'Urban, Sir. P. Maitland, and Sir H. Pottinger—had endeavoured in vain to suppress these inroads. In 1847 Sir H. Smith subdued for a time the Kaffirs, but their deep-seated resentment against the white settlers broke out again with great force in 1850. On the last day of that year Sir H. Smith issued a proclamation from King William's Town establishing martial law in the colony, and ordering all colonists between the ages of 15 and 20 to rise *en masse* to defend the frontier against the Kaffirs. The British troops suffered much annoyance and loss in the harassing bush-warfare which ensued. On the 8th November, 1851, in an encounter with the Kaffirs in the Waterkloof, Lieutenant-Colonel Fordyce and several officers and men of the 74th regiment were killed, and a considerable number wounded; the Kaffirs escaping unhurt. In January 1852 Major-General Cathcart replaced Sir H. Smith. On the 20th December General Cathcart defeated the Basitos, a Kaffir tribe, on Berea Mountain in the Orange Sovereignty, shortly after which three chiefs named Macomo, Sandili, and Kreili submitted to the British, and the war was virtually at an end. A treaty of piece was ratified at a conference between the General and the Kaffir chiefs held near King William's Town on the 9th of March, 1853. This war cost England about a million and a half sterling. The country called British Kaffraria is a large district eastward of Cape Colony, over which the British government hold a kind of sovereignty or protectorship, the precise character of which has not been very clearly defined. British military posts are maintained at various points over the area. The district is divided into counties. Buffalo River is considered the harbour. A town called London is to be established at the mouth of Buffalo River.

KALE, or KAIL, SEA. [Crambe.]

KAISARIYEH, a town in Asia Minor, is situated in a plain to the north of the Erjish-Dagh (the ancient *Argæus*) in about 38° 41′ N. lat., 35° 25′ E. long., and has a population variously estimated at 25,000, 40,000, and 50,000, consisting of Turks, Greeks, and Armenians. The plain is laid out in corn-fields, and screened on the east and west by low hills covered with gardens and vineyards, and the whole neighbourhood abounds with volcanic deposits. The town is surrounded by an old walled moat, and further defended by an old citadel partly in ruins. The houses, which are from 8000 to 10,000 in number, are built of stone and lime, but many of them have a cracked and dilapidated appearance caused by the frequent earthquakes. The streets are narrow and dirty, the squares and market-places also abound with filth; and the naturally healthy climate is poisoned by the absence of all sanitary arrangements. The bazaars are extensive and well supplied with European manufactured goods, woollens, silks, hardware, iron, &c. The Armenian merchants display their wares in a large place called the Vizir Khan; these consist of hardware, snuff-boxes, glass beads, Red Sea shells for ornamentation, paper, cards, padlocks, &c. Of native articles exposed for sale the chief are yellow berries, which are grown in the plains of Cæsarea, wool, gall-nuts, goats'-hair, tragacanth, cotton, skins, furs, sultana raisins and other fruits, madder and other dyestuffs. Among the principal structures in the town are the mosques, the convent of Siddi-Battal, and some mausoleums. The Armenians have a bishop and two churches in Kaisariyeh; the Greeks also have a church. The manufactured products of the town are chiefly yellow marocco leather, cotton stuffs, and cotton-yarn.

Kaisariyeh in site and sound is identical with the ancient *Cæsareia*, the capital of Cappadocia, which was originally called *Mazaca*. The plain in which it stands is watered by the Melas, now called the Kara-Su, which was dammed up by king Ariarathes to form a lake a little above its entrance into the Halys (not Euphrates as erroneously stated by Strabo). Mazaca was called also *Eusebeia*, and numerous coins with this epigraph have been found on the site. It was taken by Tigranes, and its inhabitants carried off to his new capital Tigranocerta. When Cappadocia was made a Roman province in the reign of the emperor Tiberias, Mazaca was named Cæsareia. It became a place of great importance in the later times of the empire. When taken by Sapor in the reign of Valerian (about A.D. 259) it had a population of 400,000. In the reign of Justinian the walls were repaired. There are many ruins and heaps of rubbish of ancient structures about the town. Cæsareia gave title to a Christian bishop from an early period of the Church; it is the birth-place of St. Basil the Great, who became bishop of Cæsareia, A.D. 370.

(Strabo; Suidas; Eutropius; Hamilton, *Researches in Asia Minor; Dictionary of Greek and Roman Geography.*)

KAKODYLE. [CACODYL, in CHEMISTRY, *S.* 1.]

KAMMERERITE. [MINERALOGY, *S.* 1.]

KANDY. [CANDY.]

KANE, ELISHA KENT, M.D. of the United States Navy, was born February 2, 1820, in the city of Philadelphia. He was a son of Judge Kane, of Philadelphia, and the eldest of seven children. He was educated at the University of Virginia, and studied medicine in the University of Pennsylvania, where he graduated with honours as M.D. in 1842. He was almost immediately afterwards appointed Surgeon to the American Mission to China. He visited the interior of the island of Ceylon, and availed himself of the facilities afforded by his position to explore the Philippines, which he accomplished chiefly on foot, and made charts and maps which are still preserved. He descended into the great crater of Tael, in the island of Luzon. The descent had only once before been attempted by an European, and was unsuccessful. Dr. Kane was lowered into the crater by means of a rope formed of bamboos, and reached ground at a depth of more than 200 feet. He then detached himself from the rope, and clambering downwards dipped his specimen-bottles into the smoking lake. In returning, the hot ashes charred his boots; and owing to their giving way under his feet, he fell repeatedly before he was able to get back, and fasten the rope round his body, by which he was at length hauled up nearly insensible. After remaining some time in China, he traversed a part of Hindustan. He afterwards proceeded to Egypt, where he examined the interesting antiquities of the Upper Nile, but unfortunately lost his journals and other papers in the river as he was returning; and being attacked with violent fever, narrowly escaped death. He afterwards went to Greece, and ascended to the top of Mount Helicon. Subsequently he sailed to the west coast of Africa, examined the slave-marts, and intended going to the kingdom of Abomey, but was unable to accomplish this purpose owing to another attack of dangerous fever, from the effects of which he suffered during the remainder of his life. After his return to America he was engaged in the war with Mexico, where he distinguished himself by his skill and bravery, and was severely wounded at the battle of Nopaluca.

Dr. Kane was engaged in the American coast-survey of the Gulf of Mexico, when he received a notice by telegraph, May 12, 1850, of the intended expedition in search of Sir John Franklin, by means of two vessels furnished by Mr. Grinnell of New York, and fitted out at the expense of the government of the United States. He immediately hastened to New York, and on the 22nd of May the two vessels, the Advance and the Rescue, sailed from the harbour of that city. Dr. Kane was attached to the expedition as senior medical officer, on board the Advance, under Commander De Haven. The expedition left Baffin's Bay, on its return, September 6, 1851, and after a favourable passage of twenty-four days reached New York. Dr. Kane published 'The U. S. Grinnell Expedition in search of Sir John Franklin, a Personal Narrative by Elisha Kent Kane, M.D., U. S. N., with Illustrations,' 8vo, 1853, London and New York. Before he had completed the preparation of this work for the press, Mr. Grinnell of New York, in conjunction with Mr. Peabody of London, prepared a second searching expedition, in the Advance, which was placed under the command of Dr. Kane, and sailed from New York on the 31st of May, 1853. The Advance sailed up Baffin's Bay, and through Smith's Strait, and reached 78° 43′ N. lat., the highest latitude attained by any of the expeditions, except that of Parry in his attempt to reach the North Pole. The Advance was frozen up during twenty-one months, provisions became scarce, and the supplies were at length exhausted, the men were affected with scurvy and other sickness, and two of them died, as did also the sledge-dogs. Dr. Kane, under these circumstances, resolved to quit the ship, and endeavour, partly in boats and partly in sledges, to reach the Danish settlements on the coast of Greenland, 1300 miles south from the position of the Advance. During the greater part of this journey their daily provision consisted of six ounces of bread-dust and a piece of frozen tallow the size of a walnut per man. Fortunately, after ten weeks travelling, and when almost in a state of starvation, they killed a seal. At the end of eighty-four days they reached the Danish settlements of Upernavik, where they were kindly received and hospitably treated. Only one man was lost on this terrible journey, and he by an accident. Meantime, nothing having been heard of Dr. Kane and his party, the government of the United States fitted out a relief-expedition, consisting of a small screw-steamer and a clipper-bark, under the command of Lieutenant Hartstene, of the United States navy. This expedition sailed from New York on the 31st of May, 1855, and, having reached the Danish settlements, the missing party were found, and arrived at New York on Oct. 11, 1855. In May, 1856, the gold medal of the Royal Geographical Society was awarded to Dr. Kane, "for his distinguished services and important discoveries in the polar regions, and for his valuable memoir and charts."

In 1856 Dr. Kane published his 'Arctic Explorations: the Second Grinnell Expedition in Search ef Sir John Franklin, in 1853-55,' Philadelphia, 2 vols. 8vo. In the autumn of the same year he paid a visit to England, and being in a state of failing health proceeded thence to the island of Cuba, in hope that he might derive benefit from the climate, but died at Havaña, February 16, 1857. His remains were conveyed to his native city of Philadelphia, and were interred there with unusual demonstrations of public respect and grief.

A badly written 'Biography of E. K. Kane,' by W. Elder, was published in 1858.

KANSAS, a Territory of the United States of North America, established by Act of Congress 1854, occupies the country lying along the river Kansas, north of the Indian Territory, and extending northward to the Nebraska River. It is bounded E. by the river Missouri, which divides it from the States of Iowa and Missouri; S. by the Indian Territory; W. by offsets of the Rocky Mountains; and N. by the Territory of Nebraska. The area is 114,798 square miles. The estimated population in 1856 was 36,000.

By far the larger part of the Territory consists of an unreclaimed wilderness, over which roam tribes of native Indians in search of game. The eastern and southern portions are broad open prairies, well watered and very fertile, but thinly timbered. The centre of the Territory forms a portion of the Great American Desert, which is said to be for the most part wholly irreclaimable, and to present scarcely an oasis. On the west are outlying members of the Rocky Mountains. The chief river of the Territory is the Kansas, the head streams of which rise near the eastern base of the Rocky Mountains, between the sources of the Arkansas and Nebraska. Its two principal branches, the Republican and Smoky Hill forks, run for a considerable portion of their course at a distance of 120 miles apart. Republican Fork issues from a rather large lake, in 39° 52′ N. lat., 103° 30′ W. long.; Smoky Hill Fork rises in the mountain region east of South Peak: their junction is near 39° N. lat., 96° 30′ W. long. The united stream is known as the Kansas: its general course is east-by-north to its confluence with the Missouri, in 39° N. lat., 94° 32′ W. long. It has a full body of water, is 340 yards wide at its mouth, and is said to be navigable for steam-boats for 150 miles, and for keel-boats, with its forks, for some hundred miles higher. Republican Fork, the larger of the two main branches of the Kansas, receives on its right side two considerable affluents, Solomon's Fork and the Grand Saline. Numerous smaller tributaries swell the main stream and its affluents. The chief of the secondary streams belonging to this Territory which fall into the Missouri are the Nemawhaw and the Independence. The Missouri itself forms the eastern boundary of Kansas, and affords an invaluable outlet for its products. The Nebraska River, on the northern side of the Territory, is a very wide but shallow river, with a rapid current and a bed full of shifting sand-banks: it is navigable by steam-boats for about 50 miles. The great emigrant and Frémont routes to Oregon, Utah, and California lie across the Territory of Kansas, and follow the line of one or other of these rivers.

As far as the country has yet been examined geologically, its southern and eastern parts appear to belong to the Lower Carboniferous system; the rocks consisting largely of mountain limestone and sandstone. In the south-eastern corner is perhaps some portion of the basin of Upper Carboniferous Rocks, or Coal-Bed of the Indian Territory. The western and northern parts of Kansas seem to consist chiefly of strata of the Cretaceous group, but we have no detailed account of the rocks. The country, with the exception of the central wastes, is considered to possess a fertile soil and a salubrious climate, while almost every part is well watered. The prairies are of the best kind, but are deficient in timber. The river bottoms have a rich alluvial soil. The few settlers who have established themselves within the Territory are said to report very highly of its capabilities, but as yet even the surface of the country is very little known. The only settlement beyond the recently-founded city of Worcester and a few scattered farm-houses, is the military station of Fort Leavenworth on the Missouri.

The vast tract known as Nebraska, including an area of upwards of 136,000 square miles, of which Kansas forms the southern part, was a portion of the country purchased by the United States from the French in 1803. It has been left till the last few years to the undisturbed occupation of the native Indians, but the constant stream of western migration, which caused the growth of one and another Territory and State on its eastern and southern borders, and still more perhaps the flood of emigration which poured across it to Utah and California, led to propositions which increased yearly in urgency for its organisation as a Territory. The first bill for the organisation of the Territory of Nebraska was introduced into Congress in 1845, but rejected. Subsequent measures met with a similar fate. But in the session of 1854 a bill was introduced for forming out of this extensive tract two Territories, Nebraska in the north, and Kansas in the south; and as the form of the bill re-opened the question of the admission into the Union of new slave states north of 36° 30′ N. lat., which the measure known as the Missouri Compromise was understood to have settled should not be done, it was made the occasion of a most earnest struggle between the supporters and opponents of slavery. Eventually the bill was passed, empowering the organisation of the Territories, but throwing open the occupation of the soil to all citizens of the United States, and to all who shall make the usual declaration of their desire to become citizens; and providing that the inhabitants of each Territory shall determine for themselves whether the institution of slavery shall exist among them. The consequence of this provision is said to have been that a considerable number of the more ardent slaveholders of the southern states at once prepared to remove with their property into Kansas with a view to obtain possession of it in the interest of the south, as well as to avail themselves of its rich agricultural and other resources. But the movement was immediately met by a counter-movement in the north. A corporation was at once organised, and received a charter, having for its primary object the colonisation of Kansas by free labour. The dispute between the two parties has not only led to much violence in Kansas, but has occasioned a severe struggle in Congress; but the matter seems not yet (March, 1858) to be terminated.

KANTURK, county of Cork, Ireland, a market- and post-town, and the seat of a Poor-Law Union, in the barony of Duhallow, is situated in 52° 11′ N. lat., 8° 52′ W. long., 126 miles S. W. from Dublin, at the confluence of the rivers Allua and Dallua, which after their junction flow into the Blackwater, 3 miles south of the town. The population of the town of Kanturk in 1851 was 3125, besides 3352 inmates of the workhouse. Kanturk Poor-Law Union, which is divided into 33 electoral districts, contains an area of 186,523 acres, and had in 1851 a population of 41,801.

The town of Kanturk is neatly built. The chief industrial products are beer, flour, and serge: wool-combing is carried on. Six yearly fairs are held. The Roman Catholic chapel, the bridewell, and the workhouse, which occupies a site of six acres, are the chief public structures. Near the town are the remains of Kanturk Castle, which was built by the Mac-Donough Mac-Carthy, prince of Duhallow, in the reign of Elizabeth. The building, which occupies the four sides of a quadrangle, 120 feet long by 80 feet wide, is four stories high: in each of the angles is a square embattled tower, five stories high. The estates of Kanturk were forfeited in the rebellion of 1641, and were conferred on Sir Philip Perceval, from whom they have descended to the earl of Egmont.

KARAMAN, a town in Asia Minor, which gives name to a pashalic, though the pasha resides at Koniyeh, is situated 65 miles S.E. from Koniyeh, in 33° 23′ N. lat., 37° 8′ E. long., and has about 2500 houses and 15,000 inhabitants. As each house is surrounded by a garden inclosed by a wall, the town appears very extensive for its population. Most of the houses are in a dilapidated condition. The bazaars are ill supplied. The Turkish castle consists of a square keep strengthened by several round and square towers, and surrounded at a little distance by an outer wall within which about a hundred small houses are built. In the wall are inserted stones with Arabic and Turkish inscriptions, which probably were taken from other buildings. Among several ruined mosques of Saracenic architecture is one of striking gracefulness, with an entrance of marble adorned with arabesques. The Armenians, who are pretty numerous, have a large and handsome church in Karaman. A little way north of Karaman is Kara-Dagh, an isolated tractytic mountain steep, rocky and barren, rising to the height of 8000 feet above the sea. To the south of it is the range of the Taurus. This town is supposed to have given name to the district of Asia Minor called Karamania, or Caramania, which is marked on some maps, but is wholly unknown to the Turks. Karaman was the seat of a flourishing petty sovereignty in the 14th and 15th centuries. It is identified with the ancient *Laranda*.

The name Karamania has been sometimes given also to the Persian province of Kerman. [PERSIA.]

KARIA, or CARIA, a division of Asia Minor, which comprised the south-western corner of that peninsula. It was bounded S. and W. by the Mediterranean Sea, N. by the valley of the Mæander, and E. by Phrygia and Lycia. Herodotus (i. 142) places Priene, which was north of the Mæander, in Caria, and it is most probable that Caria comprised the lower valley of that river; and that the Messogis range, now the Kastaneh-Dagh, which forms the watershed between the Mæander and the Caystrus, was its northern limit. The natural limit towards the east would be Mount Cadmus and its great southern offshoot, now the Bos-Dagh, which runs at a little distance from the right bank of the Calbis (Dolomon-Chai); but according to Strabo it seems that Caria comprised a large portion of the basin of the Calbis also, which lies east of this range, and extended to the western base at Mount Dædala and to the mouth of the river Glaucus, the towns of Dædala, Araxa, and Calynda being included in Caria.

With the exception of the valley of the Mæander (Mendereh), and a strip along the south coast, west of the Gulf of Glaucus (now Bay of Macri), the surface of Caria is extremely rugged and mountainous. From the mass of Mount Cadmus (now the Baba-Dagh) ranges run west and south, and cover with their ramifications the greater part of the surface. The Bos-Dagh, the southern range, runs parallel to the Calbis (Dolomon-Chai), and at a little distance from its west bank, attaining in its highest point an elevation of 8000 feet above the sea. Near 37° N. lat. it divides into two branches, one of which forming the high land, anciently called Lide, runs west and terminates in the peninsula of Halicarnassus, between the Ceramic and Iassic gulfs, now respectively the gulfs of Kos or Budrun, and Mandeliyeh. The Gulf of Iassus extended northward as far as the promontory of Poseideion, now Cape Monodendri. The other branch range has a south-west direction, and terminates in the lofty Mount Phœnix, and in the remarkable peninsula the Rhodian Chersonese, which stretches southward towards Rhodes and along the eastern side of the Gulf of Syme. The Cnidian Chersonese, which screens the Bay of Syme or Doris on the north, terminates westward in the Triopian promontory, now called Cape Krio. The Rhodian Chersonese terminates in two remarkable promontories — the Kynosema, now Cape Alonpo, opposite Rhodes, and the Paridion promontory, opposite the island of Syme. Between this Chersonese and the island of Syme lies the Gulf of Syme; and the part of the same inlet north of the island is called the Bay of Doris, which washes the Cnidian Chersonese on the south. On the north-western side of the Rhodian Chersonese, forming a subordinate part of the Gulf of Syme, were the bays of Thymnias, Schœnus, and Bubessius, or Bubassus. This last bay was the most north-eastern part or head of the gulf; it was named from a town of the same name; and near it, to the west, was the narrow isthmus which connected the Cnidian Chersonese to the mainland. The coast along these bays is bold, the limestone rocks rising perpendicularly in many places from the water, which is clear, deep, and abounding with sponges. The shores are remarkably well wooded. The Cnidian or Triopian Chersonese, which divides the Ceramic and Dorian gulfs, consists of two peninsular portions, the more western of which was formerly an island, and was connected by the Cnidians with the eastern portion by means of a causeway. [CNIDUS.] Through the narrow isthmus which connects this Chersonese with the mainland, the Cnidians attempted to cut a canal in the time of Cyrus to protect their city and Chersonese from the Persians.

The high land called Lyde extends to the valley of the Mæander. Its northern slope is furrowed by several streams, the largest of which are the Mosynus (Kara-Su), the Harpasus

(Arpa-Su), and the Marsyas (Tshina-Su), which last rises in a region called Idrias by Herodotus (v. 118), and is skirted on its western side by the range of Latmus. Except the Calbis, which was also called Indus, no stream of importance flowed to the south coast. The Mæander, which carries off the drainage of the greater part of Caria, flows in a west-by-south course, and in ancient times entered the sea to the north of the peninsula of Miletus by the harbour of Latmus, which is now filled up by the deposits of the river.

On the south coast, east of the Rhodian Chersonese and the lofty Mount Phœnix, was a land-locked bay, at the head of which stood the town of Physcus. There was a road from Physcus to Ephesus. Farther east was another small Chersonese, which sheltered the Bay of Panormus on the west; and on the coast between this and the Bay of Glaucus or Macri, were the towns of Imbrus and Caunus, and the promontory of Artemisium. A few miles inland from the head of the Bay of Panormus and to the west of the Calbis is a large lake six or eight miles across, and with a number of small streams running into it; a channel twelve miles in length connects it with the sea. Fellowes says its waters are brackish. All the southern coast of Caria eastward from Mount Phœnix, and extending to the mountains inland belonged to the Rhodians, and was called Peræa. This district is very beautiful, and contains many fertile tracts. The irregular coast of Caria is most picturesque, indented by countless bays and inlets, whose shores, generally bold and well-wooded, are in parts diversified by extensive ancient ruins, and belted by numerous islands.

Though Caria is extremely mountainous it contains some extensive high plains, and there is a good deal of fertile land in the valleys of the Mæander and its feeders. The mountains are in most parts well clothed with timber; furs, oaks, and plane-trees being the prevailing species. The chief products are wheat, figs, olive-oil, fruits of all kinds, and wine. The vine is trained to go up the highest trees. The wine of Cnidus was celebrated in ancient times. The palm-tree and the orange grow luxuriantly. Cattle are fed on the mountain pastures, and sheep are numerous; the green slopes along the valley of the Marsyas are covered with flocks, the climate owing to difference of level varies greatly; in the lower grounds it is hot, while the high lands are cold, wintry, and snow-covered. At the source of the Mosynus the winter lingers to March or April. The limestone which everywhere abounds affords excellent material for building. Among other mineral products Fellowes mentions iron-stone of great purity as abundant between Stratoniceia and Mylasa, mica-schist, marble, &c. Warm springs abound, and there are gaseous flames.

The Carians maintained that they were an autocthonous people descended from Car, the brother of Lydus and Mysus. According to Cretan accounts they originally inhabited the Ægean islands, were subject to Minos, whose ships they manned, but they paid no tribute; and that driven from the islands by Ionians and Dorians, they came to the mainland where they displaced the Leleges and Pelasgi. Homer mentions the Carians with the Leleges, Caucones, and Pelasgi, among the auxiliaries of the Trojans; and they were probably all continental people and related to each other. The Caunii, whose town Caunus was on the south coast, spoke a language akin to that of the Carians. Thucydides says that the early inhabitants of the Ægean islands were Carians and Phœnicians, and that they were pirates. There seems little doubt from Thucydides (i. 8.) that the Carians with some other people occupied the island of Delos at some early period.

In Homer's time the Carians occupied Miletus, the banks of the Mæander, and the heights of Mycale to the north of the river. The Ionian emigration drove the Carians from Mycale near which Priene was built, from Myus, and from the city of Miletus. The Dorians dispossessed them of Halicarnassus, Cnidus, the Triopian Chersonese, and probably from the island of Kos. The south coast was probably seized by the Rhodians about the same time. Thus the principal parts of the sea coast were occupied by Greek colonies, but not all, for in the time of Xerxes the Carians furnished 70 ships to the Persian fleet, while the Dorian settlements supplied only 30 ships. North of the Mæander and in the neighbourhood of the Greek colonies there was probably some intermixture between the Carians and their neighbours; but they maintained their language, and in the interior the population was pure Carian. They lived in small towns or villages, and formed a federation with common religious rites to Zeus Chrysaoreus. The federation was called Chrysaoreum; its place of meeting for sacrifice and deliberation was the spot where the Macedonians after the time of Alexander founded Stratoniceia.

Caria was included in the kingdom of Crœsus, on whose defeat by Cyrus it came under the Persian dominion. In the Ionian revolt (B.C. 499-494) the Carians fought bravely side by side with the Greeks, but were at last compelled to submit. Under the protection of Persia, Caria was ruled by a dynasty of princes, whose capital was Halicarnassus. Artemisia, who accompanied Xerxes to the battle of Salamis with five ships, was one of these petty sovereigns. The Athenians afterwards made the inhabitants of the coast tributary, but the Carians of the interior maintained their independence. In the time of Alexander the Great there was a queen of Caria, named Ada. She surrendered to Alexander the strong town of Alinda, in consideration for which he restored her to the royal authority of which she had been deprived. Caria afterwards became successively subject to the Greek kings of Egypt and Syria. The Romans having defeated Antiochus (B.C. 190) shared Caria between Eumenes king of Persia and the Rhodians, but left certain towns free. About B.C. 129 Caria was added to the Roman province of Asia.

The Carians were a warlike race, not addicted to commerce like the Greeks; they hired themselves as mercenaries, and served under the kings of Egypt.

Among the towns of Caria were CNIDUS and Halicarnassus, which were members of the Dorian hexapolis in Asia. *Halicarnassus*, now Bondroum, or Budrun, is particularly interesting as the birthplace of Herodotus and Dionysius the historians. It was founded by a colony from Trœzene in Argolis, was the largest and strongest city in all Caria, and became the seat of a Carian dynasty under the protection of Persia. One of its rulers, Artemisia, wife and sister of Mausolus, erected in his honour the celebrated sepulchral monument called the Mausoleum, of which there are still remains as well as of the ancient walls. Some interesting sculptures, supposed to have formed part of the decoration of the Mausoleum, are now in the British Museum. Halicarnassus continued to be a stronghold of Persia till the time of Alexander, who after a long siege burnt the city, but was unable to take the acropolis. Though afterwards rebuilt Halicarnassus never recovered from the blow.

Among the other towns were *Alabanda*, now supposed to be *Arab-Hissa*, on the Tshina, or Marsyas, where are remains of a theatre and other buildings; it was noted for its luxury: *Coscinia*, higher up the Marsyas, identified by Leake with the village of Tshina where Pococke found considerable remains: *Labranda*, to the south-west of Alabanda, famous for its Carian temple to Zeus Stratios, to which the Carians went in procession from Mylasa along the sacred road which connected the two places (the site of Labranda is unknown): *Iakli* which Fellowes erroneously takes for Labranda was Euromus, where are the remains of a beautiful Corinthian temple. *Mylasa*, in the interior and to the north-east of Halicarnassus, is now *Mellassa*, which is built chiefly from the ruins of the old town. There are still many beautiful remains of ancient architecture at Mellassa, which was visited by Fellowes. East by south from Mylasa was *Stratoniceia*, which was either founded or rebuilt on a spot called Idrias by a Macedonian colony after the time of Alexander. Stratoniceia is identified by Fellowes with Esky-Hirsa, which stands in a delightful country. There are remains of several temples, the marble walls of which are covered with inscriptions. The ruins of the ancient town extend far beyond the village of Esky-Hirsa.

Caunus, the chief town of the Caunii, was a place of considerable trade, on the south coast in the Rhodian Peræa. It was the birth-place of the painter Protogenes, and famous for its figs. It was for a long time subject to the Rhodians. In the massacre of the Romans in Asia in the time of Mithridates Eupator, the Caunii distinguished themselves by their ferocious cruelty to their victims. On a height above Caunus was the fortress *Imbrus*. Between Caunus and the Gulf of Glaucus was *Calynda*, which has not been identified, but is supposed to be in the basin of the Talaman, or Dolomon-Chai, the Calbis of Strabo and the Indus of Livy.

In the north-east of Caria, near the Phrygian frontier, was *Antiocheia* at the junction of the Mosynus with the Mæander; its remains, which are described by Hamilton and Fellowes, consist of the massive walls of the acropolis and an inner castle, some substructures of buildings, a stadium, and a small theatre. Southward from Antiocheia, on high ground to the east of the Mosynus, stood the city of *Aphrodisias*, now *Ghera*, where are remains of a beautiful Ionic temple of Aphrodite, from whom the town was named. There was a city *Plarasa*, probably not far from Aphrodisias. Fellowes ('Asia Minor') says that Ghera is the representative of the ancient *Caroura*, which was east of Mount Cadmus, near the confines of Caria, Lydia, and Phrygia. It was famous for its hot springs on the banks of the Mæander, by which its site has been identified. Hamilton ('Researches') conjectures that the town was named from its position on the boundary of Caria towards Phrygia (Καρῶν ὅρος.)

North of the Mæander were *Tripolis*, near the point where the river enters the plains (38° 1′ N. lat.), where are remains of the city walls, a theatre, and some other buildings: *Mastaura*, west of Tripolis and north-east of the modern Nazeli, and near the modern village of Mastaura, has some ancient ruins, most of which are overgrown with underwood, and a fine spring of cold water: *Tralles*, situated on a plateau of the Messogis above the modern Aïdin (a town of about 6000 houses); the plateau is covered with ruins, among which the Turks have quarried materials for the houses and walls of Aïdin; the most remarkable ruin is that of a palatial structure, which is probably not ancient: *Magnesia* farther west near the mouth of the Lethæus in the Mæander: and *Priene*, on a lofty rock near the modern town of Samsun, where many ancient walls remain, and a theatre cut out of the rocky hill. Several of these towns north of the Mæander are usually given to Lydia, to which in later times they seem to have belonged.

Along the west coast beyond Halicarnassus were *Myndus*, once the capital of Caria: *Caryanda*, a city which seems to have stood partly on an island and partly on the mainland, the two parts being united by a causeway (now a narrow sandy isthmus), alongside of which was the harbour which Leake takes to be that of Pasha-Limani: *Bargylia*, on the southern shore of the Iassic Gulf, between Myndus and Iasus, celebrated for its statue of Artemis Cindyas, upon which, though exposed to the open sky, neither rain nor snow (it was said) ever fell. *Iasus*, or *Jassus*, now *Askem*, *Asyn Kalesi*, on a small island at the head of the Iassic Gulf, was founded early by Argive colonists, but received additional settlers in the Ionian emigration under Neleus; it became a wealthy place owing to its fisheries; part of the city walls and a theatre cut out in the side of a rock still remain. *Branchidæ* was famous for its oracle and temple of Apollo Didymeus, of which there are still some remains; the temple was robbed and burnt by the Persians (B.C. 494), but it was afterwards rebuilt. A sacred way led from the sea to the temple bordered with monolithic statues seated on chairs, the feet close together and the hands on the knees—an imitation of the avenues of the temples of Egypt. (Leake, 'Asia Minor.') Branchidæ stood near a harbour, called Panormus, on the south of the Poseideion. *Miletus*, one of the most ancient and flourishing towns of Caria and famous for its woollen manufactures and for the numerous colonies founded by it on the Black Sea, was situated on high ground on the south bank of the Mæander and near its mouth. Its citizens were great traders and powerful by sea. They carried on long wars against the Lydian kings. It was subjected to the Persians by Cyrus the Great, and notwithstanding internal dissensions continued prosperous until the Ionian revolt, instigated by its tyrant Aristagoras; this event brought down upon it the vengeance of the Persians, who utterly destroyed it B.C. 494. It was rebuilt, and made a long resistance to the army of Alexander; but it never recovered its former importance, although it was a prosperous place under the Romans. Its site is marked by the modern village of *Pallattia*, where are seen the remains of an enormous theatre, an aqueduct, and a Christian church formed out of a Greek temple. South-east of Miletus, in the interior near the brackish lake of Baffi, which is probably part of the ancient Latmicus sinus, was *Heracleia* at the western foot of Mount Latmus, where some ruins mark the spot. Near it was shown the cave of Endymion. To the north end of this lake, near the Mæander, was *Myus;* and on the east side of Mount Latmus lay *Amyzon*, ruins of the citadel and walls of which remain.

(Pococke; Leake, *Asia Minor;* Sir C. Fellowes, *Asia Minor;* Hamilton, *Researches in Asia Minor; Dictionary of Greek and Roman Geography.*)

KARS, a town in Turkish Armenia, is situated in a high rugged plain, between 6000 and 7000 feet above the level of the sea, on the Arpa, a feeder of the Araxes, about 100 miles straight-line distance N.E. from Erzerum, N.W. from Bayazid, and S.E. from Batoum on the Black Sea, in 40° 27′ N. lat., 43° E. long., and has about 12,000 inhabitants. It is about 45 miles W.S.W. from the Russian town and fortress of Gumri, or Alexandropol. It stands in a rocky amphitheatre of black basaltic hills, and has a dark dismal look, from the total absence of trees, and from the circumstance that all the houses are built of black basalt. It contains about 300 houses, 20 mosques, and 4 baths. Part of the town is walled and has a citadel built by Amurath III.: but it is untenable against artillery, being commanded by heights within musket range on the opposite side of a deep narrow ravine traversed by the Arpa. The two portions of the town are united by two stone bridges thrown across the river which encircles the walled portion of the town on three sides. Kars was formerly a large town with from 6000 to 8000 houses, but a great part of the Turkish population abandoned it during the Russian occupation in 1828-9, and on the retreat of the Russian army all the Armenians emigrated to the neighbouring provinces of Russia; so that from Russian violence and the desertion of its inhabitants it fell into a state of ruin and decay.

Soon after the commencement of the late war between Turkey and Russia, General Guyon was sent to Kars at the end of 1853 as chief of the staff and president of the military council. He disciplined the Turkish army, and constructed defences. He was succeeded in 1854 by Lieutenant-Colonel Williams (now Major-General Sir William Williams) as her Majesty's Commissioner with the Turkish forces in the East. The defences were extended and improved, so that when the Russian General Mouravieff, who had invested Kars, attempted to take it by assault, Sept. 29, 1855, he was repulsed with great slaughter. The brave garrison, however, after being reduced to the extremity of starvation, were obliged to capitulate. General Mouravieff treated the garrison, soldiers and inhabitants, as well as officers, with great humanity and kindness. By the treaty of peace concluded at Paris in 1856, Kars was evacuated by the Russian army, and restored to Turkey.

The pashalic of Kars includes the most northern part of Turkey in Asia, extending from the Araxes and Suvanli-Dagh to the Choruk-su, the Black Sea and the Russian frontier. It is a rugged country of lofty mountains and high plains, drained by the Araxes, the Kur, and the Choruk-su.

KAWRIE PINE. [AGATHIS.]

KEITH, Banffshire, Scotland, a market-town in the parish of Keith, is situated in 55° 33′ N. lat., 2° 59′ W. long., on the banks of the small stream called the Isla, about 20 miles S.W. from Banff, 178 miles N. by E. from Edinburgh. The population of the town of Keith in 1851 was 2101.

The town comprises three distinct villages, called Old Keith, New Keith, and Fife Keith. Old Keith is a very ancient village, and at one time was a regality. It is now a mere hamlet. New Keith dates from the middle of last century. It consists of five principal streets, intersected by several smaller ones, with a square or market-place in the centre of the town. It contains the parish church, a court-house, an Episcopal and a Roman Catholic chapel, besides chapels for congregations of the Free Church and United Presbyterian bodies. There are a library and a savings bank. A grain-market is held weekly; and several cattle-fairs are held annually, the most important of which is 'Summer-Eve Fair.' Fife Keith, a modern village, on the bank of the Isla, opposite Old Keith, with which it is connected by two bridges, consists of several well-built streets. Many of the inhabitants of Keith are employed in the manufacture of woollens, flax-dressing, weaving, bleaching, and the manufacture of tobacco.

KELLIADÆ, a family of minute *Mollusca* belonging to the Lamellibranchiate *Acephala*. Forbes and Hanley place this family between *Lucinidæ* and *Cycladidæ*. The British *Kelliadæ* embrace the genera *Montacuta*, *Turtonia*, *Kellia*, *Lepton*, and *Galeonura*. The genus *Kellia* has two British representatives, *K. suborbicularis* and *K. nitida*. They are small but elegant bivalves, living in the crevices of rocks, or on shells or sea-weeds, spinning a byssus, or lying free. There are about a dozen species known in different parts of the world. This genus, from which the family takes its name, was named after Mr. O'Kelly of Dublin.

KELLS. [MEATH.]

KEMBLE, CHARLES, was born on the 25th of November 1775, at Brecon (Brecknock) in South Wales. His father was Roger Kemble, an actor and theatrical manager. He was educated at the English Roman Catholic College at Douay, in the French department of Nord, whence he returned to England in 1792. He was placed, through the influence of his brother, J. P. Kemble, in the General Post-Office, London, but soon resigned his situation, and after a few trials in private theatres made his first appearance on the public stage at Sheffield, as Orlando in 'As You Like It.' He had engagements afterwards at Newcastle and other towns. On the 21st of April, 1794, he made his first appearance in London, as Malcolm, on the opening of the newly-built theatre of Drury Lane, John Kemble performing Macbeth, Mrs. Siddons Lady Macbeth, and Mr. Palmer Macduff. He continued for a considerable time to play secondary characters, but gradually improved in his art. On the 28th of November, 1796, he performed George Barnwell at Drury Lane, Mrs. Siddons taking the character of Millwood. In 1797 he was engaged at the Haymarket Theatre, where in 1800 he brought out his adaptation of Mercier's 'Deserteur,' under the title of 'The Point of Honour,' which was performed successfully, and became a stock-play. On the 2nd of July, 1806, he married Miss Marie Therese De Camp, of French parentage, but born at Vienna in 1774. Miss De Camp was engaged by her father as a danseuse at the Opera-House, London, at a very early age. Her father died when she was in her twelfth year; she was then patronised and instructed by some ladies, and had become, when Charles Kemble married her, a favourite actress in the walk of high comedy, and she so continued as Mrs. Charles Kemble till she left the stage in 1818. She died on the 3rd of September, 1838. In 1807 Mr. Charles Kemble brought out with success at Covent Garden 'The Wanderer, or the Rights of Hospitality,' which is an adaptation of Kotzebue's 'Eduard in Schottland;' and in 1808, at the Haymarket, with still greater success, the farce of 'Plot and Counterplot,' an adaptation of a French piece called 'Le Portrait de Michel Cervantes.' Three or four other dramatic pieces from the German and French, which he brought out afterwards, were less successful. Meantime he continued to improve in his profession, took a wide range, and in some of his characters was without a rival. Among his best characters may be mentioned Orlando, Falconbridge, Cassio, Leon, Benedick, Young Mirabel, Mercutio, Petruchio, Archer, Ranger, Charles Surface, and Friar Tuck. For several of these characters his handsome features, fine voice, and tall well-formed athletic person, peculiarly fitted him. He closed his career as an actor on the 10th of April 1840, shortly after having been appointed to the office of Examiner of Plays. He appeared in public occasionally afterwards as a reader of Shakspere. During some of his latter years he suffered the inconvenience of deafness. He was well acquainted with modern languages, and a tolerable classical scholar. He died on the 12th of November, 1854, aged seventy-nine years within a fortnight.

Mr. Charles Kemble left one son and two daughters. His son, John Mitchell Kemble, is noticed in a separate article. His eldest daughter, Frances Anne Kemble, known as Fanny Kemble, was married to Mr. Butler, of Philadelphia, but they separated. The other daughter, Adelaide Kemble, distinguished herself as an operatic singer. She became the wife of Mr. Sartoris, and then quitted the stage.

KEMBLE FAMILY. The Kemble family form probably the most extraordinary group of actors and actresses ever known. Macklin, when nearly 100 years of age, addressing John Philip Kemble, said, "Sir, I have known your family from generation to generation. I have seen you act, young man; and I have seen your father, sir; and I have seen your grandfather, sir. Sir, he was a great actor." Of the grandfather there appears to be no record but the testimony of Macklin. The father, ROGER KEMBLE, was born on the 1st of March, 1721, in the city of Hereford. He was an actor, and the manager of a company that performed in the principal towns of Wales and the west of England. He married in 1753 Sarah Ward, born September 2nd, 1735, at Clonmel in Ireland. She also was an actress. They had twelve children, of whom Mrs. Siddons and John Kemble were the two eldest. [SIDDONS, MRS. SARAH; KEMBLE, JOHN PHILIP.] Charles Kemble was the 11th child and youngest son. Roger Kemble died in 1802, and Mrs. Sarah Kemble in 1806.

STEPHEN KEMBLE (George Stephen Kemble), the third of the children, was born on the 3rd of May 1758, at Kington, in Herefordshire. He was intended for the medical profession, and was placed with a surgeon at Coventry, but gave the preference to the stage. After a course of practice in the country he made his first appearance in London, at Covent Garden, on the 24th of September, 1783. In the same year he married Miss Satchell, a favourite actress. After acting for some time at Covent Garden he was engaged at the Haymarket. He became afterwards the manager of a company that performed at Edinburgh and Glasgow, and subsequently of another that acted at Newcastle, Durham, Sunderland, Lancaster, and Whitehaven. He was a good actor, but became so bulky in person as to be almost unfit for any character but Falstaff, which he performed frequently, both in London and the country. His last performance was in the character of Sir Christopher Curry, in the farce of 'Inkle and Yarico,' a few days after which he was attacked by inflammation of the bowels, and died on the 5th of June 1822, at the Grove, near Durham.

FRANCES KEMBLE, the fourth child of Roger Kemble, was born on the 28th of December 1759, in the city of Hereford. She also became an actress, and performed in London; but having become the wife of Mr. Francis Twiss, quitted the stage. She died in 1812, at Bath.

ELIZABETH KEMBLE, the fifth child of Roger Kemble, was born on the 2nd of April 1761, at Warrington, in Lancashire. She was apprenticed to a mantua-maker, but left that occupation for the stage. After some practice in the country, she made her first appearance in London at Drury Lane Theatre, on the 22nd of February 1783, as Portia in 'The Merchant of Venice.' After repeating Portia she repaired to York, where she had previously accepted an engagement. In face, figure, and voice she bore a striking resemblance to Mrs. Siddons. On the 21st of June 1785 she was married to Charles Edward Whitlock, an actor and joint-manager of a theatrical company in the north of England, known as Austin and Whitlock's company, of which Mrs. Whitlock became the principal actress. The circuit of this company embraced Newcastle, Durham, Lancaster, and Whitehaven. Cooke and Munden were members of it before they appeared in London. In 1792 Mrs. Whitlock accompanied her husband to America, where she became almost as great a favourite as Mrs. Siddons was in England. She performed mostly at Philadelphia and Charleston, and frequently before General Washington. Having acquired an independence, Mr. and Mrs. Whitlock returned to England about 1807, and quitted the stage. Mr. Whitlock died about 1820. Mrs. Whitlock was much admired in society for the liveliness of her conversation. She died on the 27th of February 1836.

The other children of Roger Kemble died young, except a daughter, Anne, born in 1764, who was alive in 1834.

KEMBLE, JOHN MITCHELL, well known as one of the chief Anglo-Saxon scholars of his age, and also distinguished in historical literature generally, was the son of Charles Kemble, and was born in 1807. He was educated at Trinity College, Cambridge, where he took the degree of B.A. in 1830, and that of M.A. a year or two later. From the very first his studies were directed towards the Anglo-Saxon language and literature; and in 1833 he signalised his acquirements in this department by the publication of 'The Anglo-Saxon Poems of Beowulf, the Traveller's Song, and the battle of Finnesburgh, edited, together with a Glossary and an Historical Preface.' The work reached a second edition in 1837, when an additional volume, containing 'A Translation of the Anglo-Saxon Poem of Beowulf, with a Glossary and Notes,' was appended to the first. The more important of Kemble's subsequent works, were the 'Codex Diplomaticus Ævi Saxonici, operâ Johannis M. Kemble,' vol. i. 1839, vol. ii. 1840; 'The Anglo-Saxon Charters;' the 'Vercelli Codex: Poetry of the Codex Vercellensis, Anglo-Saxon and Latin, with an English translation,' published in 1843 as one of the works of the Ælfric Society; the 'Dialogue of Salomon and Saturnius, with an Historical Introduction and English Translation,' published in 1848 by the same Society; an edition of Twysden's 'Considerations upon the Government of England,' published in 1849 by the Camden Society; and lastly, 'The Saxons in England, a History of the English Commonwealth till the period of the Norman Conquest,' published in 2 vols. in 1849. This last work comprehends the main results of Mr. Kemble's Anglo-Saxon and historical studies. For a good many years Mr. Kemble was editor of the 'British and Foreign Quarterly Review,' a periodical of the highest class, which exercised considerable political and literary influence, but ceased to exist about the year 1845. He held the office of Examiner of Plays under the Lord Chamberlain, his acting assistant in this office being Mr. Donne. Mr. Kemble was a Fellow of various learned societies, including the Academies of Sciences of Berlin and Munich, and the Historical Societies of Stockholm and Copenhagen. He died March 26, 1857.

KENFIG, OR KENVIG. [GLAMORGANSHIRE.]

KENMARE, county of Kerry, Ireland, a market and post-town, and the seat of a Poor-Law Union, is situated at the head of Kenmare Bay, on the north shore of the æstuary of the Roughty, in 51° 52′ N. lat., 9° 34′ W. long., 16 miles S. by W. from Killarney, 163 miles S.W. from Dublin. In 1851 the population was 1501. Kenmare Poor-Law Union contains 16 electoral divisions, with an area of 198,146 acres, and a population in 1851 of 21,282.

The town was a mere hamlet till the close of the 18th century; it now consists of one large street of neat well-built houses from which others diverge towards the Sonnd, a narrow part of the bay, which is spanned by the Lansdowne suspension-bridge. In the town are a Protestant church, a large Roman Catholic chapel, a news-room, market-house, petty-sessions house, a bridewell, and the workhouse, which affords accommodation for 540 inmates. A little below the town is a substantial pier; the depth of water at high-tide is 16 feet, and vessels of the largest size can come at all times within a mile of the pier. Coal, timber, iron, and slates are the chief imports: corn, salmon, and other fish, and copper-ore from the neighbouring mines, are the principal exports. The country on both sides of the bay for several miles belongs to the Marquis of Lansdowne.

KENNINGTON. [SURREY.]

KENSINGTON. [MIDDLESEX.]

KEROLITE. [MINERALOGY, *S.* 1.]

KEYNSHAM. [SOMERSETSHIRE.]

KHIVA. [KIVA.]

KIDWELLY. [CAERMARTHENSHIRE.]

KILBARCHAN. [RENFREWSHIRE.]

KILBEGGAN. [MEATH, WEST.]

KILMALLOCK. [LIMERICK.]

KILRUSH, conuty of Clare, Ireland, a sea-port town and the seat of a Poor-Law Union, is situated at the head of a small bay on the north shore of the æstuary of the Shannon, 26 miles S.W. from Ennis, 145 miles W.S.W. from Dublin, in 52° 38′ N. lat., 9° 29′ W. long. The population in 1851 was 4471, besides 4796 inmates of the workhouses. Kilrush Poor-Law Union contains 27 electoral divisions, with an area of 136,788 acres, and a population in 1851 of 51,247.

Kilrush Harbour is the first above the mouth of the Shannon, and the roadstead opposite it, sheltered by Scattery Island, is the first secure anchorage from westerly gales. The pier, which projects in the direction of Hog Island from the entrance of the creek, has been recently extended, and affords shelter and accommodation to sailing-craft and steamers. Kilrush is a market for the sale of the in-shore and deep-sea fisheries of the Milltown Malbay fishing district. Large quantities of fish are shipped to Limerick. A considerable trade is also carried on with Limerick in turf, cnt in the extensive bog which extends northward from Kilrush to Dunbeg Bay. The town is much resorted to for the benefit of sea-bathing. It has a good weekly market on Saturday, and annual fairs on May 10th and October 12th. The town consists mainly of two wide streets running along two sides of a large square, the centre of which is occupied by a handsome market-house. There are a new church, a spacious Roman Catholic chapel, a custom-house, a bridewell, police barracks, fever hospital, workhouse, and several large corn-stores. The Methodists have a chapel, and there are several schools. Quarter and petty sessions are held in the town. The island of Scattery abounds in ancient ecclesiastical remains, among which is a round tower 120 feet high. The mansion and extensive demesne of C. M. Vandaleur, Esq., the proprietor of Kilrush, are close to the town. Steamers ply regularly between Kilrush and Limerick. Kilrush is one of the stations of the Royal Western Yacht Club.

KILSYTH. [STIRLINGSHIRE.]

KINETON, or KINGTON. [WARWICKSHIRE.]

KINGSCLERE, a village in Hampshire, remarkable for the exhibition of the Greensand Formation in the midst of the elevated chalk downs, on the line of an anticlinal axis passed east and west. The anticlinal axis passes through the middle of a valley (hence called a 'a valley of elevation') in which the greensand appears; and it might seem on a first view that the discontinuity of the chalk was simply owing to elevation and fractnre, bnt by considering the areas and slopes of the strata, in plans and sections on a true scale, it will immediately appear that a considerable mass of chalk must have been removed by denudation. For the knowledge of this interesting 'valley of elevation' we are indebted to Dr. Buckland. ('Geol. Trans.,' 2nd series, vol. ii.) Sir Charles Lyell has contemplated it in connection with the more extensive denudation of the Weald of Kent and Sussex. (*Principles of Geology.*)

KINGSTON. [CANADA, *S.* 2.]

KINGSTOWN, county of Dublin, Ireland, a sea-port town and the mail-packet station of the city of Dublin, is situated in the parish of Monkstown, barony of Rathdown, distant 6 miles E.S.E. by railway from Dublin. The population in 1851 was 10,453. This place was called Dunleary till September 3rd, 1821, when the name was changed to Kingstown to commemorate the embarkation of George IV. for England, which circumstance is recorded on a granite obelisk near the wharf. Although an ancient place, it was a mere fishing village and collier haven till the new harbour-works were commenced in 1817. Since then the town has been greatly extended, so that Kingstown may now be said to include not only Dunleary, bnt also Monkstown, Bullock, and Dalkey. The harbour is formed by two piers inclosing an area of 250 acres, with a depth of from 15 to 27 feet, and approaching each other within a distance of 760 feet. The eastern pier, on the extremity of which there is a bright revolving light, is 3500 feet long; the western is 4950 feet long; and along both piers there are quays 40 feet wide, which are protected from the sea by parapets 9 feet high. The harbour has not proved so useful as was expected, owing to the anchorage being very much exposed. The number of vessels that entered Kingstown harbour in 1851 was 2126, of the aggregate burden of 257,367 tons, exclusive of men-of-war, cruisers, and mail packets; of this number 1117 were vessels trading to or from the port of Dublin. The city of Dublin royal mail steam-packets sail twice a day with the mail and government dispatches to Holyhead; there is besides daily communication by steamers with Cork, Liverpool, Holyhead, and Chester, and packets sail regularly to London and other important towns. The chief exports are cattle, corn, lead-ore, and granite; the imports consist chiefly of coal, iron, and timber. The beauty of the situation, the salubrity of the air, the picturesque country around the town, the arrival and departure of the steam-vessels, and the bustle connected with the shipping, have contributed to make Kingstown a place of great resort: it is also much frequented as a watering-place. The principal street is George's-street, extending above half a mile in length. There are numerous avenues, terraces, and parades, some of which are uniformly built, and present a handsome appearance. Besides the parish church, which is at Monkstown, there are a large and handsome Roman Catholic chapel, St. Mary's convent, a Free church, the Mariner's church, and places of worship for Presbyterians, Methodists and Quakers. The Kingstown terminus of the railway to Dublin, and the tunnel of the atmospheric railway to Dalkey, are in front of the harbour. There are a petty sessions court-house, police and coast-guard stations, a savings bank, lying-in hospital, dispensary, National and other schools, and commodious baths. The town is lighted with gas, and partially paved. The paving and lighting of the town is managed by a board of 18 commissioners. There are remains of old castles at Monkstown and Bullock, and of three in the village of Dalkey. Kingstown is the station of the Royal St. George's Yacht Club.

KINGTON. [HEREFORDSHIRE.]

KINIC or QUINIC ACID. [CHEMISTRY, *S.* 2.]

KIRBY, THE REV. WILLIAM, one of the most distinguished naturalists of his day, and celebrated for his knowledge of entomology. He was the grandson of John Kirby, a miller at Wickham Market, in Suffolk, and the author of the 'Suffolk Traveller,' which was published in 1785, and was a work of great repute in its day. Joshua Kirby, a brother of the father of the subject of our present notice, was the friend of Gainsborough the artist, and distinguished as an architectural draughtsman, and the author of a work on Perspective. William Kirby, his father, was a solicitor, and lived at Witnesham Hall, where the entomologist was born, on September 19th, 1759. His mother, whose name was Meadows, of a family of some consideration in the county of Suffolk, early gave him a taste for the study of natural history. A collection of shells, and the plants of the fields, were the first objects to which his attention was directed. His natural history studies were however interrupted by his being sent to the grammar school at Ipswich, where it appears he did not distinguish himself. From thence he was entered at Caius College, Cambridge. Here again he failed to distinguish himself, for Cambridge had at that time no honours for those whose tastes led them to cultivate the natural sciences. He took his degree of B.A. in 1781; and having entered upon holy orders, was appointed shortly after to the cure of Barham, in his native county. In 1784 he married Miss Ripley of Debenham. At this time he became acquainted with the Rev. Mr. Jones of Nayland, whose writings on controversial divinity were highly estimated. Mr. Kirby had however no taste for polemics, and although he never neglected the duties of his office for the pursuit of natural history, his taste for the latter became so decided, that he published very little on subjects directly connected with his profession as a clergyman.

Left to the natural bent of his genius, and surrounded with objects of natural history, his early love of plants was rekindled, and he cultivated a knowledge of the plants of his neighbourhood. An accident drew his attention to insects. "About half a century since," he says, in a letter to a friend in 1835, "observing accidentally one morning a very beautiful golden bug creeping on the sill of my window, I took it up to examine it, and finding that its wings were of a more yellow hue than was common to my observation of these insects before, I was anxious carefully to examine any other of its peculiarities, and finding that it had twenty-two beautiful clear black spots upon its back, my captured animal was imprisoned in a bottle of gin, for the purpose, as I supposed, of killing him. On the following morning, anxious to pursue my observation, I took it again from the gin and laid it on the window-sill to dry, thinking it dead, but the warmth of the sun very soon revived it; and hence commenced my farther pursuit of this branch of natural history." These facts were communicated to Dr. Gwyn of Ipswich, who was a good naturalist, and led him to recommend to his young friend the pursuit of entomology. So diligent was Kirby in the pursuit of his new science, that we find him warmly taking up the cause of natural history science, and becoming one of the first members of the Linnæan Society, founded by Sir James Edward Smith in 1788. In 1793 he contributed his first paper to the Linnæan Society. It was entitled 'A description of three new species of Hirudo,' and was published in the second volume of the 'Transactions.' His next paper, which was published in the third volume of the same 'Transactions,' was 'A History of three species of Cassida.' In the same volume is a 'Letter to Mr. Marsham, containing observations on the Insects that infested the Corn in the year 1795.' He became early alive to the importance of making the pursuit of entomology of practical value, and paid particular attention to those insects which attacked wheat and other plants of importance to man. The last paper was followed by others on the 'Tipula Tritica,' on 'Insects that prey upon Timber;' and in the fifth volume of the 'Linnæan Transactions' is a paper entitled 'Observations upon certain Fungi which are Parasites of the Wheat.' These and other papers indicate great accuracy of observation, and prepared him for a work of higher and more important scientific interest. The family of *Hymenoptera*, including the bees and wasps, had been but imperfectly studied in this country, and he devoted himself to the production of a separate and complete work on English Bees. This work was published at Ipswich, in two volumes, with plates, in 1802, and was entitled 'Monogrphia Apum Angliæ, or an attempt to divide into the natural genera and families such species of the Linnæan genus Apis as have been discovered in England, with descriptions and observations.' This work embraced also general remarks on the class *Hymenoptera*, and a table of the nomenclature of the external parts of these insects. The publication of this work at once gave him a high position amongst the naturalists of Europe, and brought him into correspondence with Fabricius, Latreille, and other naturalists on the continent of Europe, as well as all the more eminent naturalists of his own country. This work was followed up by several papers, containing important additions to the literature of entomology, but was perhaps surpassed in scientific interest by his discovery of the genus *Stylops*, which he indicated as the type of a new order of insects, to which he gave the name *Strepsiptera*. These insects were found parasitical during their larva state in the bodies of bees, and the novelty of their history and beautiful forms excited a lively interest in the entomological world.

But whilst these discoveries were going on, he was preparing for a work by which his name became more widely known and imperishably associated with the popular literature of his country. We allude to the 'Introduction to Entomology,' which he published conjointly with Mr. Spence. Mr. Kirby's acquaintance with the latter gentleman commenced in 1805, and resulted in Mr. Spence proposing in a letter dated November 23, 1808, that they should write in partnership a "popular Introduction to Entomology." This proposition was readily acceded to by Mr. Kirby, and in 1815 the first volume of this work appeared. It speedily went through three editions, and in 1817 the second volume was published. On account of the illness of Mr. Spence the third and fourth volumes did not appear till 1826. This work at once took a position amongst the classical productions of our language, and few scientific publications have been so extensivly read. Since the death of Mr. Kirby, Mr. Spence has published a seventh edition, to which is added an appendix giving an account of the origin and history of the work. It is written in the form of letters, and gives in a familiar style an account of the structure, habits, and forms of insects. It is a model of the manner in which works on natural history to be popular should be written, and is almost exhaustive of the subject of the habits, uses, injuries, and instincts of insects. Of the fifty-one letters of which this work consists, it appears that twenty were written by Mr. Kirby, nine by Mr. Spence, and twenty-two by the two authors conjointly.

In 1830 Mr. Kirby was applied to by the trustees appointed under the will of the late Earl of Bridgewater to write one of the works since so well known as the 'Bridgewater Treatises.' Although he was then in the seventieth year of his age, the production of such a work was so congenial to his tastes and the spirit in which he had conducted all his natural history researches, that he at once consented. The subject was the 'Habits and Instincts of Animals.' From his previous history it would appear that Mr. Kirby had not had such extensive opportunities of studying the other groups of animals so accurately as he had done insects. It is therefore, especially considering his age, not surprising to find that this work did not equal in merit his previous productions. It contains, however, a great number of interesting facts which he collected with great diligence, in reference to all departments of the animal kingdom, and the spirit in which it was written was eminently in accordance with the object of the founder of the treatises.

Mr. Kirby's other principal labours are as follows:—'A Description of several new species of Insects collected in New Holland by Robert Brown, Esq., F.R.S.' ('Linn. Trans.' xii.); 'An Account of the Animals seen by the late Northern Expedition whilst within the Arctic Circle,' 4to, London, 1821, being a supplement to the appendix of Captain Parry's 'Voyage for the Discovery of a North-West Passage.' The insects were described by Mr. Kirby. The insects in 'Fauna Boreali-Americana, or the Zoology of the Northern parts of British North America,' 4to, Norwich, 1837.

Although most exemplary in the performance of his clerical duties, Mr. Kirby was never promoted in the church of which he was so great an ornament. The only appointment he ever received in addition to the cure of Barham was that of chaplain to the district workhouse in 1794. In scientific circles his name was one of influence. He was chairman of the first meeting of the Zoological Club of the Linnæan Society, which was founded in 1827. This was one of the first offshoots of the Linnæan Society, and was followed by the establishment of the Entomological Society in 1833. Of this society Mr. Kirby was elected Honorary President, and he presented it before his death with his very valuable collection of insects. He was made a Fellow of the Royal Society in 1818, and of the Geological Society in 1807. He also received the honorary diplomas of many scientific societies on the continent and the United States of America. In 1847 a museum of Natural History was founded at Ipswich; he was present at the opening of this institution, and held the office of President till his death.

Mr. Kirby was twice married, his second wife being Miss Rodwell of Ipswich, to whom he was married in 1816. She died in 1844. He had no family by either wife, and died on the 4th of July, 1850, at the great age of ninety. His 'Life,' to which we are indebted for many of the above particulars, has been written by the Rev. John Freeman, M.A., and was published in 1852.

KISCHENEFF, or KICHENEV, a town in European Russia, capital of the government of Bessarabia, is situated on the Byk, or Bouk, a feeder of the Dniester, 40 miles N.W. from Bender and Tiraspol, on the latter river, 70 miles E. from Jassy. It was a small place with narrow dirty streets darkened by the projecting roofs of the houses, and a population of about 4000 when it came into the possession of Russia in 1812. Since then the town has been enlarged so as to cover three adjacent hills, and it now contains 15 churches, a synagogue, a Greek theological seminary, a gymnasium, several schools, and a public library. In 1838 the population had reached 13,000. The town is adorned with handsome marble fountains, and has a fine public garden. The inhabitants, who consist of Russians, Cossaks, Poles, Jews, Germans, Armenians, Bulgarians, Greeks, and gipsies, carry on a considerable trade in corn, cattle, sheep, flax, hemp, tobacco, fruit, wine, &c. The principal industrial products are brandy, leather, soap, candles, some woollen stuffs, &c.

KITTA. [CORVIDÆ.]

KITTS, ST. [CHRISTOPHER'S, ST.]

KITTO, JOHN, was born at Plymouth, December 4, 1804. His father had been a respectable builder, but soon after his son's birth became much reduced in circumstances through the adoption of intemperate habits. At four years old John Kitto was transferred to the care of his maternal grandmother, by whom his intellect was called into activity by the relation of marvellous stories, and by leading him to notice and admire the natural objects around him in the fields and woods. He early learned to read, and read with avidity all the books he could procure. By the time he was twelve years old, his father had descended to the rank of a jobbing mason. He was unable to keep his son at school regularly, who, whenever he could be made available, was required to attend his father in his labours. On February 13, 1817, having ascended a ladder with a load of slates, he fell from a height of thirty-five feet. He was taken up senseless, conveyed home, and lay for a fortnight in a state of unconsciousness. He recovered, but was himself unaware at first that he was deaf. He wondered at the silence around him, and at length, asking for a book, was answered at first by signs, and next by writing on a slate. He inquired with astonishment, "Why do you not speak?" His attendants wrote again, "You are deaf." No efforts could restore his hearing. He still continued his reading, but in 1818 his grandmother was obliged to quit Plymouth, and he was left to the care of his father. For nearly a twelvemonth he lived with his parents in a state of great destitution. At length, on November 15, 1819, he was placed in the workhouse, where he was treated with much indulgence, and began to learn shoemaking. His deafness occasioned him to write often, and by constant practice he acquired great facility. In August 1820 he commenced a journal, which he continued till January 1822, and he was encouraged to write lectures which were read to the other boys. In 1821 his grandmother died, which event made a great and serious impression on his mind. In November 1821 he was apprenticed to a shoemaker; but his master was harsh, he was somewhat awkward, and still passionately devoted to reading. Finding himself uncomfortable, he wrote to some of his friends, and after pleading his cause in writing before the magistrates, he was taken back to the workhouse in May 1822. Early in 1823 he wrote some essays which were published in Nettleton's 'Plymouth Journal,' and he also wrote some imaginary correspondence. In April 1824, Mr. Grove, a dentist, who had known something of him in Plymouth, but who was then settled at Exeter, engaged him in order to teach him his art, and he accordingly removed to Exeter, where he succeeded in attaching Mr. Grove to him as a sincere friend. In 1825 he published his first work, a volume entitled 'Essays and Letters, by John Kitto.' It produced but little profit, but it contributed to make him known, and excited the interest of many of the inhabitants of Plymouth. By their efforts, greatly assisted by Mr. Grove, he was sent to the Missionary College at Islington, there to be taught printing, which it was thought might render him useful in some of the missionary establishments abroad. He entered that institution in July 1825, and was despatched to Malta as a printer in June 1827, but his health being unequal to his work, he returned to England in February 1829. In the following May he agreed to accompany Mr. Grove on an extensive tour to the East, during which he was to instruct Mr. Grove's children. In this journey he visited St. Petersburg, Astrachan, the Calmuck Tartars, the Caucasus, Armenia, Persia, and Baghdad. At this latter town he was detained during the plague. Mr. Grove there lost his wife, and Kitto thence returned to England in June 1833.

In July of that year, Mr. Woolcombe of Plymouth wrote a letter of introduction for him to Mr. Coates, the secretary of the Society for the Diffusion of Useful Knowledge, recommending him for employment on the 'Penny Magazine.' On the 18th he waited on Mr. Coates with a letter written by himself, in which he proposed a plan of writing his travels, either in the form of weekly numbers, "like the 'Penny Magazine,'" or as volumes of the 'Library of Entertaining Knowledge.' Mr. Coates referred him to Mr. Charles Knight, as editor of those works, telling him he thought the society could not undertake the travels in the 'Entertaining Knowledge.' On the 19th he wrote to Mr. Knight, stating his willingness to use his journal for separate papers in the 'Penny Magazine.' On the 20th he called on Mr. Knight: the conversation was carried on by Mr. Kitto speaking, which he did very imperfectly, and Mr. Knight writing. A few letters afterwards passed, specimen articles were sent and approved of, and on the 4th of August he accepted Mr. Knight's proposals for a general engagement at a salary, saying that "the terms offered would be sufficient not only for my present but my prospective wants." He continued for two years in various literary employments. In 1835 Mr. Knight formed the plan of publishing a Pictorial Bible with notes, and asked Mr. Kitto if he would like to furnish a few of them, illustrating particular passages from what he had observed in his travels. He not only eagerly embraced the proposal, but earnestly entreated to be allowed to undertake the responsibility of the entire work. A specimen was prepared, and eventually it was approved of: the whole was then entrusted to him. The 'Pictorial Bible' was finished in 1838. During its progress, for about two years and a half, Mr. Kitto received an annual payment of 250*l.*; but upon its completion he was presented with an additional sum, which seemed to him a little fortune. In 1838 he embodied a great portion of his experience in Persia in two small volumes, 'Uncle Oliver's Travels.' In 1839 and 1840 he was engaged in writing the 'Pictorial History of Palestine,' also for Mr. Knight. He was entitled to ask, and he received for these and subsequent works, payments according to the highest scale of literary remuneration. From 1841 to 1843 he found employment with Mr. Fisher in preparing the letter-press for the 'Gallery of Scripture Engravings,' in 3 vols. In 1843 he wrote a 'History of Palestine,' published by A. and C. Black of Edinburgh; and 'Thoughts among Flowers,' published by the Religious Tract Society. In 1844 the degree of D.D. was bestowed upon him by the University of Giesen in Prussia.

In 1845 he renewed his connection with Mr. Knight, and prepared 'The Pictorial Sunday Book,' and wrote 'The Lost Senses—Deafness and Blindness' for 'Knight's Weekly Volume.' In this year he commenced the 'Cyclopædia of Biblical Literature,' published by A. & C. Black. In 1847 he undertook for Mr. Knight a new edition of the 'Pictorial Bible,' of which he greatly improved the notes, and which was completed in four volumes in 1849. For this revised edition he received upwards of 600*l.* It is right to mention, that although Mr. Kitto in his latter years was uneasy in his circumstances, his difficulties were not caused by inadequate payments by his various publishers; nor did he sustain any loss whatever by any one of them, as is stated in his 'Biography.' In 1848 he had commenced on his own account the 'Journal of Sacred Literature,' which was continued periodically under his editorship till 1853, but he says himself that it never produced him any profit. He also engaged in various other works, among the most considerable of which were 'Daily Bible Illustrations,' two series, in seven volumes, of which the first series appeared in 1849-51, and the second in 1851-53. In February 1854 he was attacked by a paralytic stroke, from which he never completely recovered. In August he went to Ramsgate without experiencing much benefit. He had received a pension of 100*l.* a year in 1850 from her Majesty, and his friends having raised a subscription to a considerable amount to relieve him from embarrassments, he went to Germany, and settled at Cannstadt in Würtemberg. Here he died on November 25, 1854. He had married a lady in 1833, by whom he had a large family. She was a most effective assistant to him in his literary labours, and a sedulous promoter of his comforts. Since his death she has published a biography of her late husband, prepared by the Rev. J. E. Ryland, founded on materials left by himself either in the form of journals or of letters.

KLAGENFURT. [CLAGENFURTH.]

KNIGHTON. [RADNORSHIRE.]

KNOT-GRASS. [POLYGONUM, *S.* 1.]

KOBELLITE. [MINERALOGY, *S.* 1.]

KOLLAR, JAN, a poet and preacher, the originator of the idea of Panslavism, was born on the 29th of July 1793, according to Jungmann's 'History of Bohemian Literature,' at Moschowze, in the county of Trentschin in Hungary, being by birth a Slovak, or one of the Slavonic race of northern Hungary, who speak a language akin to that of their neighbours the Bohemians. After studying at Presburg and Jena, he became in 1819 pastor of a Slovakian evangelical congregation at Pesth. In 1823 and 1827 he issued in two volumes, under the title of 'Narodnie Zpiewanky,' or 'National Songs,' an interesting collection of the popular poetry of the Slovaks, which reached a second edition, with additions, in 1834 and 1835. Unlike some other Slovakian authors however, he was far from exhibiting a narrow and exclusive attachment to his native dialect. Considering the Slovakian as too circumscribed in its range to be equal to the dignity of literary composition, he took for the language of his writings the Bohemian, though it was at the time rejected for German in Bohemia itself by several of the native authors. In 1821 he published at Prague a volume of Bohemian sonnets, under the title of 'Basne' ('Poems'); and in 1824 at Buda, a new edition, under the title of 'Slawy Dcera' ('The Daughter of Glory'). The copy of the second edition, in the British Museum, formerly belonged to Bowring, to whom it was presented by Safarik, and who has written in it, "This is a very remarkable book, and how its true and fiery spirit should have burst this Austrian censorship is altogether unintelligible to J. B." The leading idea of the poems is that of the common bond of union between all the Slavonic nations, and the work was in consequence not looked upon with favour by the Hungarians, who were anxious to see their Magyar language extended over the whole of Hungary, and observed with apprehension that the Slavonians to the north of the kingdom, and the Slavonians to the south, were beginning to become conscious of their relationship. Kollar proceeded more and more to develop his idea in his 'Slawa Bohynie' ('The Goddess Slava or Glory'), a collection of philological and mythological essays, and in a work in German, on the connection between the Slavonic races and dialects, 'Ueber die literärische Wechselseitigkeit zwischen den Stämmen und Mundarten der slawischen Nation' (Pesth, 1831). In this publication the wish for a general combination of the Slavonic races is more openly expressed than in any previous one. The same idea pervades the 'Cestopis' (Pesth, 1843), a record of a journey to Upper Italy, the Tyrol, and Bavaria, made by Kollar in 1841, chiefly for the purpose of discovering traces of Slavonic antiquity.

Among his other productions is a volume of sermons, 'Kazne' (Pesth, 1831), which were found so eloquent that they were translated into several languages. Kollar was obliged to leave Pesth by the revolution of 1848, and must in the same year have seen many of his hopes destroyed by the breaking up of the Slavonic Congress at Prague by the cannon of Windischgrätz. In the next year he was, probably by way of compensation, named professor of archæology at the University of Vienna. In 1851 he made a journey to Mecklenburg, to study the remains of the Obotrites, and on his return to Vienna was surprised by death on the 29th of January 1852, when he was preparing for the press a German work, 'Das slawische Altitalien,' intended to prove that the ancient inhabitants of Italy spoke a Slavonic language.

The work of Kollar which is chiefly admired by his admirers, is his 'Slawy Dcera,' which in its latest shape, as it appears in his 'Dila Básnická' ('Poetical Works') published at Buda in 1845, is called a 'lyrico-epic poem,' in five cantos, and extends to 622 sonnets, having little connection except the common idea of 'Panslavism' which pervades them. Whatever the merit of some of the earlier portions, there can be no doubt that some of the later additions are scarcely calculated to awaken respect for the writer; in particular some coarse attacks on Mr. Paget and Miss Pardoe, apparently dictated by a feeling of resentment at their having spoken well of the Hungarians. The prose works of Kollar contain some valuable information, which is however disfigured by an occasional outbreak of the same spirit of mere Slavonic nationality. Several of Kollar's sonnets are translated in Sir John Bowring's work on the Bohemian poets.

KOLLYRITE. [MINERALOGY, *S.* 1.]

KÖLN, or CÖLN. [COLOGNE.]

KONIYEH (Konieh, Koniah), a city in Asia Minor, capital of the pashalic of Karaman, which includes the greater part of Phrygia and Pamphylia, is situated in a wide plain in 37° 54′ N. lat., 32° 40′ E. long., 305 miles E. by S. from Smyrna, and the same distance S.E. from Constantinople. Population, 30,000. The town is surrounded by walls built with well-cut blocks of stone, and strengthened by square towers, some of them richly ornamented with cornices, arabesques, lions'-heads, and Arabic inscriptions. The walls rise from the brink of a wide fosse, and are pierced by handsome gateways, some of which are constructed with fragments of ancient structures. Within, the city, when seen by Hamilton, presented little except ruin and decay; large spaces lay covered with heaps of dilapidated mosques and deserted houses. The modern town and the bazaars occupy the more eastern part of the site, where also is the konak, or palace of the pasha. The houses are low, and mostly built of sun-dried bricks and wood. The old castle, which stands in the centre of the town, is crumbling to pieces, its stone-facings having been removed to build the pasha's konak. Koniyeh contains many beautiful remains of Saracenic architecture, among which may be mentioned the mosque of Sultan Alettin on the castle hill, and the Injemi Minareh Djami (Mosque with the Minaret reaching to the Stars), which is exquisitely adorned with delicate tracery, fretwork, and mouldings. The minarets are chiefly of glazed tiles and bricks of various colours, red and blue prevailing. The old Turkish prison, which forms part of the western wall, is an interesting half-ruined structure, bearing some resemblance to a gothic castle with its ruined towers, battlements, and keep. The pasha's konak is a large straggling building approached by a raised causeway between extensive burial-grounds, part of the site being now used as a cemetery. The other objects of note in the town are its large bazaars, several medresseh, or colleges, several sepulchral chapels, a few Armenian churches, the public baths and khans, and the tomb of a Moslem saint venerated all over Turkey. The manufactures are confined to carpets and blue and yellow marocco leather. Cotton, wool, and skins are sent to Smyrna. The immediate neighbourhood of the town is belted by a small breadth of garden-ground, which is kept in a state of verdure by irrigation. The rest of the plain in summer is a dusty desert; in winter flooded and impassable. The city is supplied with fruit and vegetables chiefly from the Greek village of *Zillieh*, which is two hours' distant, and situated in a gorge among the trachytic hills westward of Koniyeh. This village is inhabited by about 5000 Greeks, descendants of the ancient inhabitants of Koniyeh, who were driven out and obliged to settle here by the Turks when they captured the city.

Koniyeh is the ancient *Iconium*, which Xenophon says ('Anab.,' i. 2) was in Phrygia; in later times it was considered the capital of Lycaonia. Under the Romans it seems to have risen in importance. Cicero spent ten days in Iconium on his way to Silicia ('Epist. ad Atticum,' v. 20). In the first age of Christianity it is described as a populous city inhabited by Greeks and Jews. St. Paul and St. Barnabas preached in the synagogue of Iconium. Under the Greek emperors the city continued to be the metropolis of Lycaonia; but it was wrested from them first by the Saracens, and afterwards by the Seljukian Turks about A.D. 1075, who made it the capital of their dominions. Under the Seljukian sultans, and during the period of the Crusades, Iconium acquired its greatest celebrity. The Seljukian dynasty and power terminated in 1294. After a period of anarchy the city was seized by Othman, the founder of the Ottoman empire in Asia, which had Brusa for its capital. From this time Koniyeh declined rapidly. Ibrahim Pasha, commander of the Egyptian army, completely defeated the Turks near Koniyeh, December 20, 1832.

A Christian synod held at Iconium about A.D. 230 pronounced against the validity of heretical baptism. Koniyeh is looked upon by the Moslems as a sacred city; many dervishes reside in it, and it is visited by many pilgrims.

(Hamilton, *Researches in Asia Minor; Dictionary of*

Greek and Roman Geography; London Geographical Journal, vols. viii. and x.; *Conversations-Lexicon; L'Art de Vérifier les Dates*.)

KOSTENDJE, or KUSTENDJI, a sea-port town or rather village of Turkey in Europe, is situated in the Dobrudscha at the eastern termination of the fortification called Trajan's Wall, 225 miles in a straight line nearly due north from Constantinople, and about 40 miles E. from Rassova. The town, which consists of about 500 houses, is built on the west shore of the Black Sea on a peninsular projection of limestone rock, which rises precipitously from the sea to the height of about 100 feet, and shelters the harbour on the northern side. The harbour is exposed, except on the north side, and ill adapted for large ships, having in places only 7 feet water. Kostendje occupies the site of an ancient town, *Constantiana*, which is said to have been founded and named from Constantine the Great. It retains in its ruined mole traces of Roman masonry. The town has some trade in corn. The project of opening a channel for the Danube across the Dobrudscha by the chain of lakes called the Kara-Su into the harbour of Kostendje has been often mooted. [DOBRUDSCHA, *S.* 2.]

KÖTHEN. [CŒTHEN.]

KOZLOFF. [EUPATORIA.]

KRAIN, or CARNIOLA, a crownland of the Austrian empire, is bounded N. by Carinthia, E. by Styria and Croatia, S. by Croatia and the Küstenland, and W. by Friuli and the circle of Görz. The area is 3838 square miles, and the population, according to the census of 1850-51, was 463,956.

The surface is extremely rugged and mountainous. The principal chain of the Carnic Alps penetrates into the north-west of the crownland, where it terminates in the mass of Mount Terglou, the highest point of which rises to 10,800 feet above the level of the sea. The northern boundary is formed by an offset or continuation of the Carnic Alps, which springs from the main chain near the village of Weissenfels in the north-western angle of the crownland, forming the watershed between the Drave and the Save, and running in a general south-east direction between Carinthia and Carniola, through Croatia and Slavonia, where it terminates in the valley of the Danube. This range, which is distinguished by different names, covers with its ramifications all that part of the crownland which lies north of the Save, its highest points being the Loibelberg (5477 feet), the Sattelberg farther east, and the Steiner Alps to the north of the village of Stein, which rise 10,000 feet above the level of the sea. These mountains are distinguished by their singular forms, and consist of steep, rugged, and for the most part naked masses of limestone, with but scanty vegetation and little timber. They are crossed by three roads, one from Villach to Laybach by the Wurzen Pass and the Upper Sauthal; a second from Klagenfurt to Laybach by the Leobel or Loibel Pass (4032 feet); and a third from Marburg and Cilli to Laybach by the Trojana Pass, which is also traversed by the Vienna-Trieste railway, now open as far as Laybach. In the angle between the main chain of the Carnic Alps and the chain that forms their continuation south-eastward, the Save has its rise in the glaciers that cover the northern flanks of Mount Terglou.

The central and southern parts of the crownland are covered by the Julian or Krainer Alps, and their ramifications. The Julian Alps run south-east from Mount Terglon between the Upper Save and the Isonzo to Mount Kleck in Croatia, reaching the height of 7458 feet above the sea in the Suisnik, or Schneeberg, close to the Croatian frontier. A branch runs southward from the main chain near Idria along the northern and eastern edge of the peninsula of Istria; and along the western side of this ridge to the south of the Wippach extends a stony wilderness called the Karst, which is a plateau of limestone rocks abounding with strange chasms and fissures and funnel-shaped cavities, infested by furious winds, and almost entirely destitute of vegetation. In all this region there is not a single tree; in a few sheltered spots a little corn is grown, and the vine is seen to creep along the crevices of the rocks. The Karst is connected by the Nanas Mountains (4000 feet) near Wippach with the main chain of the Julian Alps, here called Birnbaumerwald. From the Schneeberg a branch of the Julian Alps runs between the Kulpa and the Gurk, reaching in the summit of Jauernig an elevation of above 6000 feet, and stretching up to the Save in the most eastern part of the crownland. The Julian Alps consist of granulous limestone which is shattered into rugged fragments, rent by chasms, and full of grottoes, caverns, and underground passages, abounding with the most beautiful stalactites. The rain that falls and the snow that melts upon them, form streams, which for the most part flow in subterranean channels, and the want of moisture at the surface gives these mountains an aspect of the most repulsive barrenness. It is said that there are above 1000 grottoes and caverns in the Julian Alps, the most celebrated of which are those in the neighbourhood of ADELSBERG. [*S.* 1]. Innumerable rivulets disappear in the calcareous soil, and periodical fountains spring forth; even large streams plunge more than once into the chasms, which intersect the surface of the region, and pursue for a time an underground course. Nevertheless, some of the valleys present picturesque scenery, especially those of the Save and its feeders, and the Wippach. The principal roads that cross the Julian Alps in Carniola lead from Laybach to Idria, and from Laybach by the Adelsberg Pass (2159 feet) across the Karst to Trieste. This last is intersected by a road from Görz through St.-Veit, and Senosetsch to Fiume.

Except in the river-valleys which form a comparatively small portion of the surface, the soil is very unfruitful, naked mountains, rocky levels, marshes, or sandy flats, being the prevailing characters of the country. The climate on the mountains and uplands is sharp; the winters severe and long; snow disappears from the mountain tops only in the height of summer. The Bora, or north-east winds, at times sweep the Karst and the more exposed parts of the country with forious violence. In the glens and valleys the soil is better, in many parts fertile, the climate much milder, and the vine, the chestnut, and maize flourish. Rye, barley, oats, some wheat, potatoes, pulse, flax, hops, and fruit are grown. In some parts the mountain slopes are clothed with pine, oak, and beech forests, but they have been considerably thinned for the use of the smelting-furnaces. On the mountains many rare Alpine plants, medicinal herbs and roots are found. Horned cattle and horses are small; swine and poultry abound. Among the wild animals are deer, wild boars, the chamois goat, foxes, &c. Bears and wolves are rare. Birds of prey are numerous. Of game-fowl the principal kinds are pheasants, bustards, partridges, snipes, and water-fowl. Among the minerals the most important are iron, quicksilver, copper, lead, cinnabar, alum, coal, marble, gypsum, rock-crystal, &c. The great quicksilver mines of Idria in the west of the crownland, have been long famous; the entrance to them is in the middle of the town of Idria; they formerly yielded 16,000 cwts. yearly. The industrial products comprise chiefly bar-iron, iron and steel articles, such as scythes, sickles, nails, files, &c.; copper articles, woollen-cloth, leather, linen, lace, pottery, paper, straw-hats, canvass, horse-hair sieves, tiles, German tinder, &c. A good number of the population are employed in mining and metallurgy. There is a considerable trade in timber and firewood.

The principal rivers are the Save and the Isonzo. The *Save*, or *Sau*, rises on the northern flank of Mount Terglou, and runs first eastward along that mountain mass, and then southward for a short distance to its junction with the Savenitza; its course is then south-south-east to the neighbourhood of Laybach, in which the river Laybach joins it on its right bank. The river then runs eastward till it reaches the boundary, along which it runs in a south-east direction till it enters Croatia a few miles below its junction with the Gurk, which passes Neustädtl. The *Isonzo* (the ancient *Sontius*) rises on the southern slope of Mount Terglou, from which it runs southward through the western part of Carniola and the circle of Görtz in the Kustenland. At a short distance above Aquileia the Isonzo divides into two branches, the Isonzato and the Sdobbo, which inclose the isle of Morosina, and after their re-union enter the Gulf of Trieste. The principal feeders of the Isonzo are, on the right, the Torre, which drains a part of the province of Friuli, and on the left the Idria and the Wippach, both of which flow in a north-west direction, the former passing the town of Idria and entering the Isonzo above Canal, the latter falling into it between Görez and Gradisca. Both the Save and the Isonzo are subject to inundations on the melting of the snow in spring and after the autumnal rains. The Save is navigable in Carniola, and a river-port has been formed at Steinbruck, a station on the Vienna-Trieste railway to the south of Cilli. The Isonzo is navigable for small vessels for about 10 miles above its mouth. Both streams are available for floating timber down from the mountain forests. The Isonzo formed part of the eastern boundary of Italy under the French empire. The *Laybach*, above mentioned, rises near

Adelsberg under the name of *Polk;* this stream loses itself in the grotto of Adelsberg and reappears in the *Unz*, which again sinks below the surface, but reappears at the village of Ober-Laybach, where it becomes navigable for boats. The remarkable Lake of Czirknitz, or Zirknitz, is noticed in a separate article.

The crownland is divided into 10 circles. With the exception of Laybach and Idria the towns are small. *Laybach*, or *Laibach*, the capital of the crownland, is situated in 46° 1′ 48″ N. lat., 14° 30′ E. long., 258 miles S. by E. from Vienna by the Vienna-Trieste railway; in an extensive valley near the mouth of the navigable river Laybach, which divides the city into two parts, connected by five bridges; and has with its eight suburbs about 13,000 inhabitants. It is a bishop's see, and has a fine cathedral, twelve other churches, a lyceum, a gymnasium, and many other public institutions. The chief industrial products of Laybach are porcelain, linen, and refined sugar; there is an active transit-trade from the interior to Trieste, in which direction a railway is in course of construction. The citadel, situated on a commanding eminence, is now used as a prison. At a short distance to the north of the town there is a stone bridge of 11 arches, 540 paces in length, over the Save. Laybach is celebrated for the congress held there in 1821. The other towns are Stein, which gives its name to the Steiner Alps, from the summits of which, 10,274 feet above the level of the sea, there is a magnificent prospect over Carniola; Krainburg, with the castle of Kieselsteen; Neumarktl, famous for the manufacture of scythes, sickles, &c.: none of these towns have so many as 2000 inhabitants.

Neustädtl, the capital of a circle, is beautifully situated on the river Gurk, 38 miles E.S.E. from Laybach. It is a very pretty regularly-built town, with three churches, a gymnasium, a Franciscan convent, and about 2000 inhabitants.

The only other place of importance is *Idria*, a mining town, famous for its quicksilver mines, which were accidentally discovered by a peasant in the year 1497. It is situated partly at the bottom of a narrow valley, surrounded by high mountains, 22 miles W. from Laybach, on the banks of the little river Idria, and partly on several low hills, of which that called Mount Calvary is distinguished by its height and picturesque form. The town consists of between 400 and 500 houses, and has about 5000 inhabitants, who subsist partly by lace-making and straw-plaiting; but the greater part are employed in the mines and works. A large building called Schloss, in the middle of the town, contains the offices of the manager of the mines; close to it is the entrance to the mine by a large iron gate, which opens to a horizontal passage hewn in the solid rock, leading to a flight of 757 steps cut in the limestone rock, which are kept in perfect order and provided with a hand-rail. At the foot of this staircase there is a small aisle serving as a chapel where the miners perform their devotions before they proceed into the mine, and where a couple of tapers burning on the altar help to cheer the gloom that reigns in these subterranean caverns. The visitor proceeding from this chapel soon reaches various adits running in all directions, and would soon be bewildered in the labyrinth without a guide. This mine is one of the greatest curiosities in the Austrian empire, and unequalled for the order, beauty, and safety which are remarked in every part. The noxious exhalations of the quicksilver, which sensibly affect respiration, and the suffocating heat, soon make the visitor anxious to return to the light of day, to which he ascends by a perpendicular shaft in a kind of box or case, which lands him on the surface of the earth, at a great distance from the spot at which he entered. The greatest depth of the mine is 750 feet. About 150 tons of mercury are produced annually. The stamping-mills, washing-houses, furnaces, and roasting-houses for the refinement of the mercurial ore are at a short distance below the town. Besides the quicksilver-works there is a manufactory of cinnabar, which produces 1800 cwts. annually. In the vicinity there are marble, jasper, and freestone. All the establishments for smelting, refining, &c., are admirably arranged, and there are various benevolent institutions for the poor miners, whose health is most dreadfully impaired by the deleterious atmosphere in which they ply their sickly trade. These mines, the grottoes of Adelsberg, and the Lake of Czirknitz, are celebrated as 'the three sights of Carniola.'

Carniola was, until the political arrangement of the Austrian empire in 1849, divided into the three circles of Laybach, Neustädtl, and Adelsberg, which corresponded with the older divisions of Upper, Lower, and Inner Krain respectively, and formed the government of Laybach. Krain was early inhabited by a people of Slavonic stock, and formed in the 10th century an independent margraviate, which at a later period the dukes of Austria and Carinthia divided between them, and which was raised in the 12th century to a dukedom. The duchy on the death of the Earl of Tyrol in 1335 fell to the Earl of Görz, from whom it came, through failure of male issue, to the house of Austria in 1364. By the treaty of Vienna in 1809 Krain was ceded to France, and constituted part of the Illyrian provinces. In 1813 it again came into the possession of Austria, and formed part of the kingdom of Illyria. [ILLYRIA.]

KRASINSKI, COUNT VALERIAN, was a native of the ancient Polish province of White Russia, and was descended from a noble family. The branch to which he belonged embraced at an early period the Protestant faith, to which he adhered. He received a superior classical education, and while yet a young man was appointed chief of that department of the ministry of public instruction in the kingdom of Poland which was charged with the superintendence of the various classes of dissenters. He was zealous in his endeavours to promote instruction among them, and especially exerted himself in the establishment of a college at Warsaw for the education of Jewish rabbis. In order to lessen the expense of valuable works, especially those on scientific subjects, he was the first to introduce stereotype printing into Poland, and this was not accomplished without a considerable diminution of his own income. When the Polish revolutionists of 1830 had proclaimed the throne of Poland vacant, and organised a national government, with Prince Czartoryski as president, a diplomatic mission was sent to England, of which Count Valerian Krasinski was a member. When the Russian armies in 1831 had overpowered the revolutionary movement of his countrymen, he was still in England, where he then became, with many others of his countrymen, a penniless exile. After having instructed himself in the English language, he attached himself to literature as a means of support, and became the author of several valuable works. He resided in London during the first twenty years of his exile, and during the last five in Edinburgh, where he died December 22nd, 1855. He was a man of varied learning, and possessed extensive information, especially on all matters connected with the Slavonic races. His conversation was instructive and his manners elegant, and he was admitted to the best society.

His most important works are the following:—'The Rise, Progress, and Decline of the Reformation in Poland,' 2 vols. 8vo, 1839-40; 'Panslavism and Germanism,' 12mo, London, 1848; 'Lectures on the Religious History of the Slavonic Nations,' 8vo, London, 1849; 'Sketch of the Religious History of the Slavonian Nations,' 8vo, Edinb., 1851; 'Montenegro and the Slavonians in Turkey,' 8vo, Edinb. 1853; 'A Treatise on Relics, by J. Calvin, newly translated from the French Original, with an Introductory Dissertation on the Miraculous Images of the Roman Catholic and Russo-Greek Churches,' 8vo, 1854. He published also some smaller works and pamphlets on recent political subjects, especially on those connected with the restoration of Poland.

KROKYDOLITE. [MINERALOGY, S. 1.]

KUGLER, FRANZ THEODOR, Professor of the History of Art in the Royal Academy, Berlin, was born on the 19th of January 1808, at Stettin in Pomerania. On the completion of his collegiate studies Herr Kugler especially devoted his attention to the early history of painting and architecture, for which purpose he made a prolonged stay at Heidelberg, and subsequently visited Italy. Poetry and music also occupied much of his attention, and he in 1830 gave evidence of his attainments in these arts by the publication of his 'Sketch Book,' in which he included original compositions in poetry, music, and linear design; he also in 1833 published with Reinick an artists' song-book. But the more important as well as the most numerous of his writings about this time, were those on the history of art during the middle ages; though the arts of ancient Greece and Rome (and particularly the subject of polychromy, on which he published 'Ueber die Polychromie der Griechischen Architectur und Sculptur und ihre Grenzen,' 4to, Berlin, 1835) also engaged his pen. His great work the 'Handbuch der Geschichte der Malerei' (Handbook of the History of Painting from the Age of Constantine to the Present Time) appeared in 2 vols. in 1837. It was received with great approbation by his learned countrymen and by students of art generally, and was quickly translated into the leading languages of Europe. In

England the translation appeared in parts, the 'Schools of Painting in Italy, translated by a Lady [Lady Eastlake], with Notes by Sir Charles Eastlake,' in 1842; and subsequently, the 'German, Flemish, and Dutch Schools of Painting,' and the 'Spanish and French Schools of Painting,' under the editorship of Sir Edmund Head. A second edition of the 'Handbuch' was issued in 1850, in which, with the assistance of Dr J. Burckhardt, the work was to a great extent remodelled, and a large amount of new materials embodied; and from this revised work a new edition of Sir Charles Eastlake's version of the 'Italian Schools' was published in 2 vols. 8vo, with additional notes and upwards of a hundred outlines from the old masters, by Mr. G. Scharf, thus rendering the English translation of this portion of the work of even more value than the original. Of Dr. Kugler's other works, which are somewhat numerous, may be named his 'Geschichte Friedrichs des Grossen: gezeichnit von A. Menzel' (8vo, Leipz., 1840), translated into English by A. Moriarty, under the title of 'History of Frederic the Great' (Lond. 1844); 'Beschreibung der Kunst-Schätze von Berlin und Potsdam' (1840) ('Description of the Art-Treasures in Berlin and Potsdam'), a work of much more labour and research than its title would indicate; 'Karl Friedrich Schinkel: eine Charakteristik seiner Kunstlerischen Wirksamkeit' ('Schinkel: the Influence of his Theories of Art'), 1842; 'Handbuch der Kunstgeschichte' (Stuttg. 1842), a distinct work from the 'Handbuch der Geschichte der Malerei.' Both these works appeared at Stuttgart in 1848, where also was published (1845-53) a folio atlas of plates to illustrate his histories of art. For more than twenty years Dr. Kugler lectured in the University of Frederick William, as well as in the Royal Academy of Berlin; and also filled for some years an important position in the Ministry of Public Instruction. He died March 18, 1858.

KUPFERSCHAUM. [MINERALOGY, *S.* 1.]

L

LABUAN, an island in the Malay Archipelago, and the seat of a British colonial government, is situated near the north-west coast of the island of Borneo, and 30 miles N. from the town of Borneo, in 5° 22′ N. lat., 115° 10′ E. long. The island is about 10 miles in length, 5 miles in breadth, and 25 miles in circumference. The population in 1855 was 1696. The island is well supplied with good water, and contains coal. It was ceded to the British in 1846, and the colonial government was established on it at the beginning of October 1848.

The locality on which the government establishment was formed consists of a narrow and slightly raised ridge on the sea-shore, forming the outer edge of a low flat, called the Plain, which is in many parts below the level of the sea, and was converted into a marsh during the rains. The area of the Plain probably does not exceed 100 acres. It is bounded on the inland side by swampy tracts of jungle. The harbour is tolerably good. The unhealthiness of the marshy ground in the Plain has been considerably abated in consequence of the construction of a canal, by which the water is carried off.

The coal is wrought on the north-east point of the island. The mines have been taken by the Eastern Archipelago Company, who in 1851 exported 5032 tons of coal, of which 938 tons were supplied to vessels belonging to the British navy. During 1852 there entered inwards 1198 ships and prahus, of an aggregate burden of 6223 tons; and there cleared outwards 27, of an aggregate burden of 5052 tons. The imports in 1852 were valued at 30,970*l.*; the exports at 16,564*l.* The principal exports were:—Coal, 5448*l.*; sago, 2879*l.*; birds'-nests, 1937*l.*; pearls, 1680*l.*; and camphor, 1559*l.* The principal item of revenue is the royalty on coal. Farm licences are increasing in value, improved rentals being obtained at each succeeding sale.

LACHMANN, KARL, professor in the University of Berlin, and member of the Academy of Sciences, occupied a high rank among the critics and philologists of Germany. He was born at Brunswick on the 4th of March 1793. In that town he received his early education, and under his teacher, Konrad Heusinger, was first awakened his love for literature. For one session, in 1809, he attended the lectures of Hermann in the University of Leipzig, and next pursued his studies in that of Göttingen, where, in conjunction with Dissen, Schulze, and Bunsen, he founded a philological society in 1811. While at Göttingen, Benecke lectured upon the old German literature, which probably directed Lachmann's attention more particularly towards it, and at a later period led to much valuable criticism upon and editions of many of the early German writers. During the short war occasioned by Bonaparte's return from Elba to France in 1815, Lachmann served as a volunteer in the Prussian service, in which he continued till the end of that year. In 1816 his edition of Propertius, which he had prepared at Göttingen, was published at Leipzig; and at Easter of that year he read his probational essay before the University of Berlin, 'Ueber die ursprüngliche Gestalt des Gedichts von der Niebelungen Noth' ('On the Original Form of the Poem on the Niebelungen Calamities'). After this he was appointed, in rapid succession, teacher at the Gymnasium and professor at the University of Königsberg, and professor of the University of Berlin, the last promotion being attained in 1827. Highly esteemed as an academic teacher, and sedulous in the discharge of his duties, he nevertheless actively continued his literary labours. Many of these were critical or philosophical essays contributed to periodical works. Of his distinct works, the more important have been his essays on the Niebelungen Lied and on Homer ('Betrachtungen über die Ilias'), which are both masterly specimens of criticism. His last was the substance of two lectures delivered before the Berlin Academy in 1838 and 1841. In 1834 and in 1842 he published two editions of the New Testament, the last with the Vulgate translation, in which he endeavoured to restore the text to that of the 3rd and 4th centuries. In the classical department he published: 'De Choricis Systematis Tragicorum Græci,' Berlin, 1819; and 'De Mensura Tragœdiorum,' Berlin, 1822; with carefully-prepared editions of Catullus, Tibullus, Terence, Babrius, and Avianus, at intervals from 1829 to 1845; one of Gaius, so important to the students of the Roman jurisprudence, in 1841; and essays upon Dositheus and Ulpian in the ninth volume of Savigny's 'Zeitschrift.' Most of these works have gone through more than one edition. His attention however was never diverted from the early literature of the north of Europe. In 1816 he translated the first volume of P. E. Müller's 'Sagabibliothek;' in 1820 a selection from the High-German poets of the 13th century; in 1826 an edition of the 'Niebelungen Lied;' in 1827 an edition of the poems of Walther der Vogelweide; in the same year, in conjunction with Benecke, an edition of Hartmann's 'Iwein;' in 1833, an edition of the poems of Wolfram von Eschenbach; in 1838, Hartmann's 'Gregor,' and the poems of Ulrich von Lichtenstein in 1841. These were all prepared with great care, and accompanied with valuable remarks. He also contributed numerous papers to the 'Rheinischen Museum,' and read others before the Berlin Academy. The most noticeable are 'Ueber althochdeutsche Betonung und Verskunst' ('On the early High German Accentuation and Versification'), 'Ueber Singen und Sagen,' and 'Ueber das Hildebrandslied.' He also published an excellent critical edition of Lessing's collected works, in 13 vols., Berlin, 1838-40; and an edition of Klenze's 'Philological Essays.' Lachmann is likewise the author of a translation of Shakspere's sonnets, published in 1820; and of 'Macbeth,' published in 1839. He died in March 1851.

LAMBOURN. [BERKSHIRE.]

LAMENNAIS, FELICITE-ROBERT, ABBÉ DE, the son of a ship-owner of Saint-Malo, was born at that port, on the 6th of June, 1782. Prevented by the turbulence of the times from being sent to school at the usual age, he received from his elder brother his first lessons in Latin, and then finished alone his stinted education. For all that, he was able to read Livy and Plutarch when he was only twelve years old. In 1794, having been sent to live with an uncle, this relation not knowing what to do with a wilful boy, used to shut him up for whole days in a library, consisting of two compartments, one of which, called "Hell," contained a large number of prohibited books, which little Robert was enjoined not to read. But the lad already cared for none but books of reflection, and finding some of these on the prohibited shelves, that division became his favourite. Long hours were thus spent in reading the ardent pages of Rousseau, the thoughtful volumes of Mallebranche, and other writers of sentiment and philosophy. Such a course of reading, far from producing its usual effects of precocious vain-glory and unbelief on so young a mind, served rather to ripen his judgment, and to develop that religious fervour which was a part of his nature. Thus left to himself for many years, he declined his father's repeated offers to settle him in some mercantile office, and in 1807 found means to enter the college of Saint-Malo, as teacher of mathematics.

He produced in 1808 his first work, 'Réflexions sur l'État de l'Église en France, pendant le 18 Siècle, et sur sa Situation actuelle.' In this book he denounces the materialism propagated by the philosophers of the 18th century, and bitterly deplores the apathy thence induced to religion. His vocation being the Church, he took the tonsure, of his own accord, in 1811; and in 1812, in concert with his brother, published his 'Tradition de l'Église sur l'Institution des Evêques.' As the power of Napoleon I. was dissolving, and the time seemed propitious for the diffusion of unfettered thoughts, he went to Paris in 1814, his first production being a violent pamphlet against the fallen emperor. This untimely philippic drove him from France during the Hundred Days; he sought refuge in England, spent several months as usher at a school kept by the Abbé Caron, near London; and then returning home in 1816, was at length ordained priest.

The following year was signalised by the appearance of his 'Essai sur l'Indifférence en matière de Religion;' a book which produced an impression so sudden and so deep, that in a single day, said his disciple Lacordaire, he rose like a new Bossuet above the horizon. But in this, as in all his former works, the Abbé Lamennais still adhered to the orthodox standard of Catholicism, no other theological writer going beyond him in upholding the clerical authority in preference to private judgment. In 1824 he visited Rome, met with the most flattering reception from Pope Leo XII., but declined the offer of the Cardinal's hat, made to him by that pontiff. His next work, 'La Religion considérée dans ses Rapports avec l'Ordre Civil et Politique,' began to exhibit that freedom of thought, reaching to the last boundary of revolution (but which, however, independent of church interests, abandons nothing in spiritual faith), for which he subsequently became so widely known. For this book he was summoned to appear before the Cour Correctionnelle, and condemned to a fine.

The general agitation and the ferment in the public mind, which preceded the fall of Charles X., had gradually produced a modification in the opinions of this enthusiast, whose faith was too sincere to be stagnant: the revolution of July induced him to adopt the principle of the people's supremacy. Still he continued the same full believer, and earnest worshipper in the Christian doctrine, as it is understood in the Roman Catholic Church. In attaching himself with equal warmth to the democratic principles, he pointed his objections at the temporal abuses of the Church; whilst his reverence for her spiritual authority remained unaltered. In September 1830, he brought out a journal called 'L'Avenir,' in which several young men who had adopted his opinions, assisted him with their contributions. Among these were the Abbé Gerbet, the eloquent preacher Lacordaire, and M. de Montalembert. The object of this journal was to spread the system of the Abbé Lamennais, and to explain that it combined the advocacy of the interests of the Roman Catholic Church, and the defence of liberal opinions in connection with it; and to maintain that religion, so long neglected, and suffered to decline by the upper classes, ought to be, and might be regenerated by the common people. He likewise demanded, in this paper, the complete separation of the spiritual from the temporal power, insisting that political influence ought to be transferred to the multitude by means of universal suffrage. These bold opinions, expressed in a style of eloquence, somewhat biblical in form, and of remarkable power, produced upon an excitable people an effect so manifest as to provoke the censure of Rome, in the form of an encyclical letter, of the 18th of September 1832. Having submitted to this rebuke by suppressing his journal, the abbé received a gracious letter of congratulation from the pontiff on the 28th of December.

But in May 1834, the new champion of independence in church matters produced his most admired book, the 'Paroles d'un Croyant,' a pathetic lamentation, addressed alike to the suffering classes, and to the great and powerful; a work which sundered for ever the bond that united Lamennais to the see of Rome. Irritated by this new provocation, Gregory XVI., in a second letter, dated July 7, 1834, condemned the book in very severe terms; whilst the revolutionary party applauded their advocate for his independent spirit and original powers of mind. Thus stigmatised by the Church, prosecuted by government, and by the people hailed as an apostle, the Abbé Lamennais set no bounds to his course. He now produced in rapid succession: 'Les Affaires de Rome,' in 1836; 'Le Livre du Peuple,' in 1837; Le Pays et le Gouvernement,' in 1840 (for which he was sentenced to a year's imprisonment); 'De la Religion,' in 1841; 'Le Guide du Premier Age,' in 1844; 'Une Voix de Prison,' in 1846; and 'Les Conseils de l'Abbé Lamennais au Peuple,' in 1849. His most elaborate work, 'Esquisse d'une Philosophie,' was published in 4 vols, 1840-46. He died February 27, 1854, unreconciled to the Church, though during his last illness the most strenuous efforts were made to induce him to retract his heterodox opinions. By his express desire he was interred without any religious ceremony. It was one of his last and most earnest injunctions that certain papers, which contained his latest sentiments, should be published without alteration or suppression; but the religious advisers of his niece (who was also his housekeeper) so far wrought on her susceptibility as to cause her to refuse to give up the papers to the persons whom Lamennais had authorised to superintend their publication. The matter was in consequence brought before the proper legal tribunal, when the judges directed (August 1856) that the papers should be handed over for publication in their integrity.

LAMPETER, Cardiganshire, a market-town, municipal and parliamentary borough, and the seat of a Poor-Law Union, in the parish of Lampeter-Port-Stephen, is situated in 52° 7′ N. lat., 4° 3′ W. long., distant 29 miles E. by N. from Cardigan, and 209 miles W. by N. from London. The population of the borough of Lampeter in 1851 was 907. The living is a vicarage in the archdeaconry of Cardigan and diocese of St. David's. The borough is a contributary to the Cardigan district of boroughs in returning one member to the Imperial Parliament. Lampeter Poor-Law Union contains 14 parishes and townships, with an area of 74,200 acres, and a population in 1851 of 9883.

The town is pleasantly situated on the left bank of the river Teify at the foot of the Tregaron Downs. Besides the parish church, which was rebuilt in 1836, there are places of worship for Wesleyan and Calvinistic Methodists and Independents; a National school, and a Free Grammar school. An agricultural society has been established here. A county court is held. The market is on Saturday; and there are 11 fairs in the course of the year. St. David's College, Lampeter, founded in 1822 by Bishop Burgess, was incorporated in 1828, and received by a supplementary charter in August 1852, authority to grant the degree of Bachelor in Divinity. The course of instruction is adapted especially for Welsh students, but others are admitted. The college grants at the end of the term a certificate to students who have satisfactorily completed their theological course; which is accepted by most of the bishops as a qualification to become candidates for orders. About 30 scholarships and exhibitions are attached to the college, and it possesses a library of 30,000 volumes. The college buildings, erected in 1827 from a design by C. R. Cockerell, R.A., stand on an elevated site near the town, and form a quadrangle of a picturesque appearance: they accommodate about 70 students: the number of students in 1851 was 50. The annual income of the college is about 3000*l*.

LAMPRIS, a genus of Fishes belonging to the family *Scomberidæ*. It has an oval body greatly compressed; small scales; a single elevated and elongated dorsal fin; sides of the tail carinated; teeth wanting; branchiostegous rays 7.

L. guttatus, the Opah, or King-Fish, has been taken on the British coasts. It is a very rare fish, and as beautiful as rare. The upper part of the back and sides are of a rich green, reflecting both purple and gold in different lights, passing into yellowish-green below; above and beneath the lateral line are various round yellowish white spots, from which the fish received the name of Luna. The irides are scarlet; all the fins bright vermilion. It has been remarked, on account of these showy colours, that the Opah looks like one of Neptune's lords dressed for a court-day.

This fish was formerly referred to the genus *Zeus*, and called *Z. Luna* and *Z. imperialis*.

LANARK. [LANARKSHIRE.]

LANARKITE. [MINERALOGY, *S.* 1.]

LAND-CRAB. [GECARCINUS.]

LANDSEER, JOHN, Associate Engraver of the Royal Academy, was born at Lincoln in 1769. He learnt engraving under Byrne, a landscape-engraver of much ability; as early as 1793 he acquired some celebrity by engraving some vignettes, after Loutherbourg, for Maclise's Bible; and increased his reputation by engravings executed for Bowyer's 'History of England' and Moore's 'Views in Scotland.' Mr. Landseer also published an excellent series of engravings of animals from the works of Rubens, Snyders, Gilpin, and other eminent artists. In 1806 Mr. Landseer delivered a course of lectures on engraving at the Royal Institution, which were published in the following year, and excited some discussion in the profession on account of some peculiar views promulgated in them. In the same year he was elected an Associate Engraver in the Royal Academy. The subordinate position assigned to engravers in the Academy—they not being admitted under any circumstances into full membership—was the source of considerable ill-feeling among engravers, and the post of associate engraver had been refused by several eminent engravers when Mr. Landseer accepted it. He announced however that he had only done so in the hope of being able to labour at a greater advantage in striving to remove the obnoxious restriction. Accordingly he memorialised the president and council on the subject, but after a year or two of correspondence and controversy the claim was rejected. Landseer's mortification is said to have been so great as to have disgusted him in a great measure with his profession itself, but, whether this be so or not, he appears from this time to have engraved comparatively little. The literary tastes however which lecturing and controversy had aroused, he seems to have cultivated. Delighting in controversy, he started an art periodical, which soon died; and one he set on foot long after to counteract the mild influence of the 'Art Journal,' under the title of 'The Probe,' soon shared a like fate. He published likewise, at various times, several pamphlets and letters. In 1817 he communicated to the Society of Antiquaries a paper on 'Engraved Gems brought from Babylon,' which was printed in the 'Archæologia,' vol. xviii. Although possessing little of the requisite learning or mental training for the successful prosecution of such a subject, he continued to follow the game thus started; and after having delivered a course of lectures on 'Engraved Hieroglyphics' at the Royal Institution, he in 1823 published an elaborate volume entitled 'Sabæan Researches.' This was followed in 1834 by a gossipping volume called 'A Descriptive, Explanatory, and Critical Catalogue of the Earliest Pictures in the National Gallery,' which, though of no more value æsthetically than his previous works were archæologically, is yet in its discursiveness a somewhat amusing volume. But it is rather as the father of Edwin Landseer than on his own account that Mr. John Landseer will be remembered; and it is noteworthy that one of his best engravings, the 'Dogs of Mount St. Bernard,' is from one of Edwin Landseer's earliest pictures. Mr. Landseer died on the 29th of February 1852 in his eighty-third year, leaving three sons, all of whom have won an honourable and one a pre-eminent place in the history of English art.

LARCENY. Petty larcenies may now be tried and summarily determined, with the consent of the accused person, by magistrates in petty sessions, the punishment in such cases being limited to six months' imprisonment (10 & 11 Vict. c. 82; 13 & 14 Vict. c. 37; 18 & 19 Vict. c. 126.) Persons confessing such offences may under the last named statute be similarly punished by the same tribunal. (Blackstone's 'Commentaries,' Mr. Kerr's edition, vol. iv. p. 333.)

LARDIZABALACEÆ, *Lardizabalads*, a small natural order of Plants, containing 7 genera and 15 species. The species are twining smooth shrubs with alternate compound leaves, without stipules. Racemes solitary or clustered; flowers coloured white, lilac, purple, or deep yellow, sometimes fragrant. The sepals of the male plant are 3 or 6 in 2 rows, deciduous; petals 6 in 2 rows, opposite the sepals, the inner ones smaller, or gland-like, or absent. Stamens 6, opposite the petals; filaments united into a tube, or even distinct; anthers turned outwards, rarely inwards, 2-celled, opening by a longitudinal slit. The female flowers as before, but larger, with 6 very imperfect stamens. Carpels distinct, 3, rarely 6 or 9, 1-celled, with a short style and a single stigma. Two of the genera inhabit the cooler parts of South America, the remainder are from the temperate parts of China. *Burasaia* is the only tropical form. These plants appear to be harmless. Some of them are eaten by the natives of Japan and India.

LARKSPUR. [DELPHINIUM.]

LARNE, county of Antrim, Ireland, a sea-port town and the seat of a Poor-Law Union, is situated in a sheltered bay near the mouth and on the north shore of Lough Larne, 18 miles N.N.E. from Belfast, in 54° 50′ N. lat., 5° 50′ W. long. The population in 1851 was 2728, besides 346 in public institutions. The town is governed by nine commissioners. Larne Poor-Law Union comprises 13 electoral divisions, with an area of 117,763 acres, and a population in 1851 of 34,710. The town originally sprung up under the protection of Olderfleet Castle, which was erected in the reign of Henry III. upon a little headland close to the town, where its ruins are still seen. In the older parts of the town the streets are narrow and ill-paved, and the houses very inferior; the modern part consists chiefly of one long wide street of well-built houses. The places of worship are the parish church, three Presbyterian meeting-houses, a Roman Catholic chapel, and a Methodist chapel. Cotton-cloth, sail-cloth, ropes, and leather are manufactured; and there are several bleach-mills and flour-mills. The bay forms a good natural harbour for small vessels. Lime is exported in large quantities from the extensive works of Magheramorne adjoining the town. The other exports consist chiefly of provisions. Larne is now a mere out-port of Belfast. Fairs are held on July 31st and December 1st. The town has a dispensary and a petty sessions court.

LATROBITE. [MINERALOGY, *S.* 1.]

LAUDER, Berwickshire, Scotland, a royal and parliamentary burgh in the parish of Lauder, is situated in 55° 42′ N. lat., 2° 45′ W. long., 25½ miles S.E. from Edinburgh. The population of the burgh in 1851 was 1105. The town is governed by a chief magistrate and 17 councillors; and unites with North Berwick, Dunbar, Haddington, and Jedburgh in returning one member to the Imperial Parliament.

There is only one street in the town. The parish church, the town-house and lock-up house, the Free church, and the United Presbyterian church are the public buildings. The burgh possesses an extensive common, which is exclusively used by a small body of privileged burgesses. Close by the town is the residence of the Earl of Lauderdale, Thirlestane Castle, which stands in a spacious park.

LAUDER, SIR THOMAS DICK, Baronet, was born in 1784. He was the seventh baronet, and was the only son of Sir Andrew Lauder, the sixth baronet. He succeeded his father in the baronetcy in 1830. He became a contributor to 'Blackwood's Magazine' at its commencement, and furnished numerous articles to that periodical and others. His first contribution to Blackwood, 'Simon Roy, Gardener at Dumphail,' attracted considerable attention, and was by some ascribed to the author of 'Waverley.' He also published in early life two novels, 'Lochandhu,' and 'The Wolfe of Badenoch.' His paper on 'The Parallel Roads of Glenroy,' which was read before the Royal Society of Edinburgh, and published in vol. ix. of their 'Transactions,' consists of a description of the geological strata of that district of the Highlands of Scotland. In 1830 Sir T. D. Lauder published an interesting 'Account of the Great Floods of August 1829 in the Province of Moray and the adjoining Districts,' 8vo, Edinburgh. In 1837 he published 'Highland Rambles, with Long Tales to shorten the Way,' 2 vols. 8vo, Edinburgh, and in 1841 'Legendary Tales of the Highlands,' 3 vols. 12mo. He also published a 'Tour round the Coasts of Scotland,' and a 'Memorial of the Royal Progress in Scotland' in 1842, 4to, Edinb., 1843. For the 'Edinburgh Tales,' conducted by Mrs. Johnstone, 3 vols. Edinb., 1845-46, he wrote the story of 'Farquharson of Inverey,' and 'Donald Lamont, the Braemar Drover.' Sir Thomas Dick Lauder married in 1808, and had issue two sons and seven daughters. He died May 29, 1848, at his residence, the Grange, near Edinburgh, and was succeeded by his son, Sir John Dick Lauder, who was born in 1813, and married in 1845. Sir T. D. Lauder was deputy lieutenant of the counties of Haddington and Elgin, and a Fellow of the Royal Society.

LAVENHAM. [SUFFOLK.]

LAW, CRIMINAL. Upwards of 65,000*l.* has been spent on various commissions, which have been issued during the last thirty years for the consolidation or codification of the criminal law; but that object has not yet been attained, nor have any really practical measures been adopted for such an annual revision of our statutes as would in a few years naturally produce their consolidation, if not a codification of the law itself. It is thought however that the well-grounded impatience of the House of Commons will before long compel the passing of general acts consolidating and so far codifying the criminal law; on this ground it is desirable to abstain from any attempt to enumerate those alterations in details which have been made therein. One or two points only need be referred to. The summary jurisdiction recently conferred on magistrates in petty sessions is noticed under LARCENY, *S.* 2; the liability of trustees to prosecution for breach of duty, under the head TRUSTEES, *S.* 2. Great improvements were effected in the procedure of the courts which take cognizance of crimes by the statute 14 & 15 Vict. c. 100, which abolished all technical objections for misnomers or nondescriptions, and invested the judges with ample powers of amendment. Finally, transportation as a punishment to be ordered by the court has been abolished by the statute 20 & 21 Vict. c. 3. *Penal Servitude*, as it is termed, created by statute 16 & 17 Vict. c. 99, has been substituted; but criminals sentenced to long terms of penal servitude continue to be transported as before.

LECANORIC ACID. [CHEMISTRY, *S.* 2.]

LECHLADE. [GLOUCESTERSHIRE.]

LEE, REV. SAMUEL, D.D., was born May 14, 1783, at Longnor, a village in Shropshire, about eighteen miles from Shrewsbury. He received the rudiments of education at a charity-school in that village, where at the age of twelve years he was apprenticed to a carpenter and joiner. At the age of seventeen he formed a determination to learn the Latin language, and though he had at first only six shillings a week, and afterwards seven, to subsist on, he contrived to buy rudimentary books and then classical writers, and by the end of his apprenticeship had accomplished his purpose. He then determined to learn the Greek, and this he also accomplished. The Hebrew, Chaldaic, and Syriac languages were next mastered. When in his twenty-fifth year he removed into Worcestershire to superintend on the part of his employer the repairing of a large house, in which however a fire broke out, when he lost all his tools, and was reduced to extreme poverty. In the meantime the Rev. Archdeacon Corbett had heard of his studious habits, saw him at Longnor, lent him books, and assisted him in pronunciation. In the course of a few months he acquired the Arabic and Persian languages, and afterwards a tolerable knowledge of French, German, and Italian. For two or three years previously to 1813 Mr. Lee held the mastership of Bowdler's foundation school in Shrewsbury. In 1813 he left Shrewsbury, and obtained an engagement with the Church Missionary Society. In the same year he entered himself of Queen's College, Cambridge, and in 1817 took his degree of B.A. Having received ordination, he preached in the following year at Shrewsbury a sermon in aid of the funds of the Shropshire Auxiliary Bible Society.

On the 11th of March 1819 Mr. Lee was elected Arabic Professor of the University of Cambridge, but not having been at College the time requisite for taking his degree of M.A. (which was necessary before he took the chair), a grace passed the senate to request the Prince-Regent to grant a mandamus, which was obtained accordingly. In 1822 the University of Halle conferred on him, without solicitation, the degree of D.D. In 1823 he was appointed chaplain to the jail at Cambridge, and in 1825 was presented to the rectory of Bilton with Harrowgate. He took the degree of B.D. in 1827, and in 1831 was elected Regius Professor of Hebrew to the University of Cambridge, and with it obtained the accompanying canonry in the cathedral of Bristol. The degree of D.D. was conferred upon him by the University of Cambridge in 1833. He was afterwards presented to the rectory of Barley in Hertfordshire. He died on the 16th of December, 1852, at Barley rectory. He was twice married.

Among the more important of Dr. Lee's works are the following:—'Hebrew Grammar,' 1830; 'Travels of Ibn Batuta, translated from the Arabic,' 1833; 'The Book of Job, translated from the original Hebrew,' 1837; 'Hebrew, Chaldaic, and English Lexicon,' 1840; 'An Inquiry into the Nature, Progress, and End of Prophecy,' 8vo, Cambridge, 1849; 'The Events and Times of the Visions of Daniel and St. John, investigated, identified, and determined,' 8vo, London, 1851. Besides these works, Dr. Lee published several pamphlets on subjects of religious controversy, sermons, and contributions to periodical literature.

LEE, SOPHIA and HARRIET, were the daughters of John Lee, a performer at Covent Garden Theatre in the last century. Harriet was born in 1756; Sophia was a few years her senior. Soon after their father's death they opened a school at Bath. In this undertaking they acquired a moderate competence, upon which they retired to Clifton, where both died, Sophia on March 13, 1824, and Harriet on August 1, 1851, aged ninety-five. Sophia first appeared in 1780 as author of a comedy, 'The Chapter of Accidents,' which was performed at the Haymarket with considerable success. Her next work was 'The Recess,' which appeared in 1785 in three volumes, one of the first so-called historical novels, a somewhat lachrymose tale of the adventures and calamities of a supposed daughter of Mary of Scotland, by a marriage with the Earl of Leicester, which contains as little of history either in the facts of the tale or in the depicting of the manners of the age, as in any resemblance to the characters of the personages introduced, but which obtained a considerable share of popularity from the attempts at pathos and sentiment with which it is full. In 1787 she published 'The Hermit's Tale,' a poem; in 1796 'Almeyda, Queen of Granada,' a tragedy, which was successfully performed, Mrs. Siddons sustaining the principal character. In 1804 was published in six volumes, a novel entitled 'The Life of a Lover,' which is said to have been her earliest production, the effort of her girlish years, and is certainly one of the weakest of her writings. Her last work was a comedy, performed at Drury Lane Theatre in 1804, called 'Assignation,' which was condemned on the first night, and was never published. Her chief claim to notice, like that of her sister, rests on the 'Canterbury Tales,' of which she furnished two, 'The Young Lady's Tale,' and 'The Clergyman's Tale,' which occupy a volume and a half of the five volumes to which the series extended; and she wrote the introduction to the whole. These tales are certainly superior to her novels, but they are not equal on the whole to those of her sister.

Harriet's first appearance as an author was in 1786, when 'The Errors of Innocence,' a novel in five volumes, was published; this was followed in 1787 by a comedy, 'The New Peerage; or, Our Eyes may deceive us,' 'Clara Lennox,' a novel in two volumes, in 1797, and 'The Mysterious Marriage, or the Heirship of Rosalva,' a play, in 1798: all have been forgotten. The 'Canterbury Tales' were published in successive volumes, the first in 1797, the fifth and last in 1805; they were so immediately popular that second editions of the first two volumes were published in 1799. They consist of twelve tales, of which one, 'The German's Tale—Kruitzner,' furnished Lord Byron with the idea and some of the materials for his tragedy of 'Werner,' and he says of the tale that he had formed a "high estimate of the singular power of mind and conception which it developes." It is undoubtedly the most powerfully interesting of the whole, contains the most definitely drawn characters, and a well-developed plot. Several of the other tales however show a considerable knowledge of the human mind, are unexceptionably moral, generally pleasing, and are narrated in a simple and unaffected style.

LEERSIA, a genus of Grasses belonging to the tribe *Oryzeæ.* It has 2 paleæ compressed, keeled, and awnless, the lower one much broader; stigmas protruding from the side of the florets; nut inclosed in the paleæ.

L. oryzoides has a patent panicle with wavy branches, spikelets triandrous, half oval, ciliated on the back. It is a creeping plant with a stem one to two feet high, never procumbent, and rooting at the joints. The leaves are broad and rough-edged, the uppermost horizontal at the flowering season; panicle rarely, if ever, protruded in this country, mostly inclosed in the sheath of the uppermost leaf. It is found in marsh ditches in Sussex and Hampshire.

LEEWARD ISLANDS. The British Leeward Islands, in the West Indies, form a distinct government, which includes the islands of Antigua, St. Christopher's, Anguilla, Montserrat, the Virgin Islands, Nevis, and Dominica.

LEIGH. [LANCASHIRE.]

LEIOCOME. [CHEMISTRY, *S.* 2.]

LEIXLIP, county of Kildare, Ireland, a small town finely situated at the junction of the Rye with the Liffey, 11 miles W. from Dublin, by road and railway from Dublin to Galway: population, 832. It consists of a single street. The parish church is in the pointed gothic style. The Roman Catholics have a chapel. The Liffey is here crossed by a bridge. Above the town is Leixlip castle, built by Adam de Hereford, one of Strongbow's followers. A little way beyond the castle, the Liffey forms a fine cascade, called the Salmon Leap. The town is a place of resort on account of the beautiful scenery near it. Fairs are held in May, July, and October.

LE KEUX, JOHN, architectural engraver, was born in 1784, in Sun-street, Bishopsgate, London, where his father was a manufacturer of pewter; and to him the youth was in the first instance apprenticed, but disliking the business, he was at the age of seventeen transferred as a pupil to Mr. James Basire, an eminent architectural engraver, and remained with him four years. Le Keux formed for himself, however, a true and bolder style than that of his master, and eventually in the engraving of gothic architecture attained an excellence equalled by few in the profession. Indeed, it would not be too much to say that gothic architecture was for the first time thoroughly well engraved in this country by him; and that his engravings did much to render the study of gothic architecture popular. He possessed a very considerable acquaintance with both the general principles and the details of gothic architecture, and consequently his engravings displayed, not only minute correctness, but that 'feeling,' as artists term it, which is always an evidence that the work is executed as a matter of enjoyment, and not merely as a task. Le Keux was in fact an artist and not a mechanic, and even the admirable architectural drawings of Mackenzie lost nothing in fidelity, and sometimes, perhaps, gained a little in spirit, under the rendering of Le Keux's burin. The first important work we believe on which Le Keux was engaged was 'Britton's Architectural Antiquities of England,' and he also engraved much of 'Britton's Cathedral Antiquities,' and other of Mr. Britton's works; the elder Pugin's 'Architectural Antiquities of Normandy,' 'Gothic Examples,' and 'Gothic Specimens;' Neale's 'Westminster Abbey,' and 'Churches' (vol. i.); 'The Oxford Almanacs;' and lately the 'Memorials of Oxford,' and 'Memorials of Cambridge,' both of which were projected by himself and executed with much elegance, though of course from their smaller size with somewhat less freedom than his larger works. Mr. Le Keux died April 2, 1846. His eldest son, J. H. Le Keux, has a high reputation as an architectural engraver.

LENTIL. [VICIEÆ.]

LENZINITE [MINERALOGY, *S.* 1.]

LEO. [LION.]

LEONHARDITE. [MINERALOGY, *S.* 1.]

LEPIDOGASTER, a genus of fishes belonging to the Subbrachial *Malacopterygii*, and to the family *Cyclopteridæ*, or *Discoboli.* [DISCOBOLI, *S.* 1.] The genus *Lepidogaster* is distinguished by its smooth body without scales; dorsal and anal fins opposite and near the tail; pectoral fins large, descending to the inferior surface of the body, and by an extension of the membrane surrounding an oval disc; ventral fins united by a membrane which extends circularly under the belly, forming a second concave disc.

L. Cornubiensis, the Cornish Sucker, Jura Sucker, and Ocellated Sucker, *Cyclopterus Lepidogaster* of Pennant and *L. biciliatus* of Risso, is occasionally seen on the Cornish coasts, and has been taken on the coasts of Antrim and Clare in Ireland. This fish is small, a specimen described by Mr. Couch not being more than two inches and a half in length. It adheres with its sucker to almost any substance presented to it, and even to the human hand. The general tint of this fish is a pale flesh-colour, with spots and patches of carmine about the upper and under surface of the jaws, around the eyes, on the top of the head, sides of the body, and abdomen.

L. bimaculatus, the Bimaculated Sucker, is a second British species. This fish is rarer than the last. It has been taken on the southern coasts of Great Britain. It seldom exceeds three-quarters of an inch to an inch in length. Its general colour is a carmine red; pale flesh-colour underneath, with a light-coloured patch between the eyes, and otherwise liable to some variation in the markings: the two spots on the sides not always very obvious. It lives in deeper water than the last species.

LEPIDOLEPRUS, a genus of Fishes belonging to the family *Gadidæ.* It is closely related to the genus *Morrhua*, to which the Common Cod belongs. The suborbitals are united with the nasal bone, and form a depressed muzzle, advancing before the mouth, which however retains its mobility. The head and body have hard spinous scales; the ventrals are a little on the throat; the pectoral of mean size; the first dorsal high; the second dorsal, anal, and caudal united; the jaws short; the teeth fine and short. The species inhabit deep water, and utter a grumbling noise when taken out of the water. Two species are known. They inhabit the Mediterranean and Atlantic.

LEPIDOLITE. [MICA, *S.* 2.]

LEPIDOMELANE. [MICA, *S.* 2.]

LEPIDOSTROBI. Detached petrified cones which are scattered through the various strata of the Coal Formation have been thus named. They are obviously organs of fructification, and have therefore belonged to some of the arborescent plants whose remains they accompany. Such of them as are preserved in the nodules of iron-stone, or are otherwise mineralised without pressure, alone offer the means of ascertaining to what existing families of plants they are most nearly allied; for in those that are crushed flat in the shales the internal structure is wholly destroyed. Many of the better-preserved specimens have been sliced, polished, and examined with the greatest care; but this expensive operation has hitherto thrown little light upon the true nature of the objects investigated. This is owing to the fact that the three conditions necessary for their complete illustration have never been displayed by one specimen, but the most important point, the nature of the organs of fructification, has hitherto wholly escaped observation in all. Every one being an aggregation of organs of some kind, it becomes necessary to ascertain, not only the arrangement of these organs, but the nature of the tissues composing them, and their contents, before satisfactory conclusions can be drawn as to their relationship to any of the vegetable remains they accompany, or to whatever existing order of plants they are allied. The three necessary conditions are these:—

1. The arrangement of the individual organs of fructification, of which the cone is an aggregation, and the nature of the scales supporting them. These are characters sometimes displayed on the fracture of the specimen by ordinary means, though rarely, from the parts appearing to have suffered partial decay previous to or during petrifaction. The imbricating apices of the scales, which lie over one another like those of a pine cone, are generally removed with the matrix wherein the fossil is embedded.

2. The tissues, or anatomical structure of the various organs composing the cone: namely, of the central axis, which is a continuation of the stem of the plant; of the scales, which being inserted into the axis support the individual male or female organs; and of the latter themselves. These tissues can only be displayed by slicing fossils in the very best state of preservation, and in such as are changed into a more or less transparent mineral. Specimens of this description are exceedingly rare.

3. The two preceding considerations are secondary to the remaining one—the nature of the contents of the cones. There may be stamens or male organs—ovaria or female ones—or, lastly, capsules containing reproductive spores (which are peculiar to plants having no sexual system); for these three kinds of organs all occur arranged in the form of cones, undistinguishable from one another by any external marks. Up to the present time no carboniferous fossil cone has ever been known to supply this great desideratum, without which we can arrive at no exact conclusion as to whether these curious objects are clusters of flowers or fruits, or are the spore-bearing organs of flowerless vegetables, as mentioned above.

Specimens of *Lepidostrobi* are mostly found in seams or nodules of clay iron-stone, and are very highly mineralised, sometimes containing crystals of iron, and the cavities in their substance being filled with white carbonate of lime and magnesia. Those which are most complete always form the nuclei to nodules of clay iron-stone; others again, including all in which the spores are preserved, have occurred as broken frustules within stems of *Lepidodendron elegans* and other species of that genus. Usually the fragments of *Lepidostrobi* are not more than half an inch long, and very frequently are mere discs; so that though there is often the appearance of one several inches long, and traversing the whole length of the fragment of *Lepidodendron*, it will generally be found that this is owing to two being placed each at an extremity of the truncheon, and opposite to one another. [See Figure, COAL PLANTS.] That all were exceedingly brittle cannot be doubted, for no modern cone of any natural order could be broken up into the shallow discs which many of these fossils present. It is difficult to account for the presence of these fragments of *Lepidostrobi* in the stems of *Lepidodendron*; we can but conjecture that the trunks of the latter were erect stumps, whose interior was hollowed out by decay—that these stumps were covered with water in which were fragments of *Lepidostrobi* and other vegetable matter, which were thus washed into the stumps. This supposition is founded on the following considerations:—

1. The stumps of *Lepidodendron* appear to have been rooted and erect, and to have received the cone fragments into their cavity as fern fronds find their way into the axis of *Sigillariæ*. Were the stumps mere prostrate portions of stems it is evident that cones would have lain horizontally in them, and that no washing or drifting could have induced the fragments of these cones to lie with their axes parallel to them, or could have introduced so many into one trunk; and the latter would certainly have been materially compressed had they received on one side the pressure of the superincumbent shales.

2. The stumps must have been submerged, and the fragments quietly deposited from the water. Had the cones fallen from an overhanging forest they would have alighted in all manner of irregular positions, and in some cases overlain one another, which is never the case.

3. The deposit appears to have been effected by the gradual subsidence of the water, and not by a sudden rush or current. This again is proved by the non-interference of the cones, and their uniformly vertical position with respect to the *Lepidodendron*.

It is hard to account for the accession ef so large a volume of water as would submerge these stumps and deposit these fragments, and yet exhibit no signs of drifting in its course. The sudden fall of a tropical torrent of rain on a *Lepidodendron* forest, in which were hollow stumps of these trees, must at once suggest itself. This would both carry down the *Lepidostrobi* from the trees and float up the fragments on the ground, depositing them together in the stumps. Another effect of such a fall would be to break down some of the older trees whose decaying stumps would be prepared to inclose other *Lepidostrobi* on the precipitation of the next similar torrent.

The extreme fragility of the *Lepidostrobi* displayed by these specimens is very satisfactory, as the Lepidodendrons, of which they are the fruit, no doubt partook of this character, which is eminently favourable to a rapid decomposition and intimate union with the silt or mud which is the basis of the clay-ironstone in the one case, and the formation of a homogeneous bed of vegetable matter, such as the coal presents, in another. The extraordinary abundance of the fragments too suggests a most vigorous vegetation, for they must indeed have been profusely scattered to be deposited in such numbers within narrow cylinders into which no current appears to have been directed.

It is worthy of remark that no fern-leaves are contained in any of these *Lepidodendron* stems; and their absence is the more singular from their being commonly deposited along with branches of *Calamites*, &c., in the erect stumps of *Sigillaria* resting on the coal-shales. This is no doubt connected with the well-known fact of the *Sigillaria* stumps being filled with sandstone, or the same materials as those composing the stratum above the shales they root into; whilst the fossil *Lepidodendron* of the clay-iron-stone seams is of the same mineral as that wherein it is embedded. Were the fragments of *Lepidostrobi* washed into their inclosing stumps by any current, that agent would in all probability have transported the remains of other plants to the same spot. The perfect preservation in which these fragments occur must be attributed to the protection afforded them by the surrounding *Lepidodendron* bark. That the circumference of the latter has been subjected to pressure may be inferred from the flattening of the prominences to which the leaves were attached. This pressure was moreover very considerable, as may be proved by comparing the evenness of their surface with that of a piece of *Lepidodendron* bark fossilised without pressure, and imbedded within the stem along with the *Lepidostrobi*.

If these cones be examined with reference to the known contemporaneous fossils which accompany them, it will appear impossible to deny their having the reproductive organs of *Lepidodendron*, not only from their association with the fragments of that genus, because the arrangement of the tissue in the axis of the cone entirely accords with that of the stem of *Lepidodendron*. Just as we find in modern cones of *Lycopodiaceæ* and *Coniferæ* that the axis is a continuation of the branch, which bears leaves modified into organs adapted to support and protect the parts of fructification. The most positive evidence that can be adduced of *Lepidostrobi* belonging to a genus allied to *Lycopodium* is afforded by the spores, the presence of which not only removes them from *Cycadeæ*, *Coniferæ*, or any other order of flowering plants, but directly refers them to the family of *Lycopodiaceæ*. It is well known to botanists not only that cones are far from being peculiar to one natural order of plants, but that their extreme form is no indication either of their contents or of the affinities of the plants which produced them. Accordingly we find that Dr. Lindley, the first English observer who published any extended views on the affinities of these plants, suggests the probability of their being referrible either to *Coniferæ*, *Lycopodiaceæ*, or more probably still to *Cycadeæ*. Dr. Hooker, after describing the nature of spurious cones which have no relation to the reproductive organs of the plant, as in the common cone-bearing willow, the larch, &c., and those produced by the puncture of an insect, as in a genus inhabiting Tierra del Fuego, where a cone is formed by this means from a leaf, says:—"Some of the so-called *Lepidostrobi* may be of this nature: witness the *Lepidodendron oöcephalum*, of which it is impossible to say whether it be a *Lepidostrobus* or the apex of a branch crowded with short leaves. Were the Fuegian plant to occur in a fossil state the probability is, that its cones would be regarded as undoubted reproductive organs, and the plants themselves be referred to *Coniferæ*."

(Hooker, *On the Structure and Affinities of Lepidostrobi*, in *Transactions of Geological Survey of Great Britain*.)

LEPTURUS, a genus of Grasses having solitary spikelets, imbedded alternately on opposite sides of the rachis of 1 flower and a superior rudiment. Glumes 1 or 2 opposite to the rachis, cartilaginous, covering the flower. Paleæ scarious. Stigmas feathery.

L. incurvatus has a cylindrical subulate spike; 2 glumes equalling or slightly longer than the flowers; stem from 2 to 6 inches long: spike long, curved when dry. In a variety of this species, *L. filiformis*, the spikes are much more slender, filiform, scarcely at all curved. It grows in sandy salt-marshes.

LERNÆA. [SUCTORIAL CRUSTACEANS.] The following is Dr. Baird's arrangement of the British species of the *Lernæadæ*, or Lernæans:—

Tribe I.—*Anchorastomacea.*

Females.—Attached to their prey by means of their foot-jaws, which are stout and armed with strong hooks. One pair of antennæ; generally very distinct. Thoracic feet nearly rudimentary, or represented by appendages of considerable size, but differing in form from ordinary feet.

Males.—Free and unattached; very small, and differing totally in appearance from the females.

Family *Chondracanthidæ*.

Organs representing thoracic feet, in form of considerable-sized, cartilaginous-looking, not articulated appendages; generally three pairs in number. Three pairs of foot-jaws.

Genus 1.—*Chondracanthus*.

Two pairs of foot-jaws prehensile, the third nearly rudimentary. Appendages of thorax representing the feet, in form of digitated, but not articulated, and not setiferous lobes or tubercles. Oviferous tubes very short, broad, and flattened.

C. Zei. Body short, and rather thick. Head rounded; antennæ short, and rather broad; neck narrow, short. Thorax carrying on the under surface two pairs of small appendages, each consisting of three divisions or fingers, and furnished laterally with three pairs of longer prolongations, of many divisions, the terminal one on each side larger than the others, and embracing the oviferous sacs; the upper part of the thorax is covered with short, conical, sharp-pointed spines. Abdomen rudimentary. Oviferous sacs flattened, containing many small ova.

It is found adhering to the gills of the *Zeus faber*.

Genus 2.—*Lernentoma*.

Foot-jaws and thoracic appendages as in *Chondracanthus*. Oviferous tubes long, either club-shaped and stout or slender and twisting.

1. *L. cornuta*. Female:—Head oval, rather elongated; antennæ flattened, of considerable size, and projecting. Thorax elongated, club-shaped; anterior portion narrow for about a third of its length, the other two-thirds much broader, and terminating posteriorly in two sharp lateral tubercles of moderate length, and a middle one representing the abdomen, which is nearly quite rudimentary. Two pairs only of thoracic appendages are visible, occurring at the upper portion of the narrow part, each divided into two digitations, and situated at a short distance from each other. The oviferous sacs are of considerable size, cylindrical, and about two-thirds the length of the body. Length nearly 3 lines.

Male:—Somewhat pyriform in shape. Head very large, swollen. Thorax conical, divided into five segments, and terminated by a rudimentary abdomen armed with two small hooks. Antennæ slender, setaceous, projecting from the anterior extremity of the head, and underneath them a pair of hook-shaped foot-jaws. Mouth situated far back, and provided with mandibles; and behind the mouth two other pairs of foot-jaws are visible. Following these we observe two pairs of setiferous tubercles representing the feet. Length, a quarter of a line.

It is found on the branchiæ of a sole.

2. *L. asellina*. Female:—Body somewhat square-shaped. Head small, and situated at the end of a long and slender neck; it is rounded at the anterior extremity, and a little below the antennæ exhibits on each side a round lobe or tubercle. The antennæ and foot-jaws are very small. The neck nearly equals in length the rest of the body. The thorax is broad, and of a somewhat quadrangular shape, with a deep indentation on each side about the middle of its length. On the upper half we see two pairs of prolongations or appendages, each divided into three digitations; and on the lower half there are three smaller appendages, but simple, not digitated. The posterior angles of the thorax are prolonged also into short horns or appendages, which are also simple. The abdomen is in form of a short tubercle, with a rounded blunt point. The oviferous sacs are of about the length of the whole animal, of considerable size, and cylindrical.

The male is similar, according to Milne-Edwards, to that of *Chondracanthus* (*Lernentoma*) *cornutus*.

It is found attached to the branchiæ of the *Triglæ*.

3. *L. Lophii*. Female:—Body rather elongate, and somewhat gibbous. Head small, having on each side a small horn-shaped appendage directed a little obliquely backwards.

Antennæ small, conical, and slightly curved. Thorax divided into four portions by as many contractions. The first narrow like a neck, having on the upper portion a short spine, and on the under surface a pair of appendages or prolongations of two divisions or digitations; the second is somewhat quadrilateral, with on the middle line of the back two conical tubercles and on the sides two others, the upper pair the longer, and having on the under surface a pair of appendages of two digitations; the third part is larger than the preceding, and has the same tubercles and prolongations, and in addition a small spine on the superior portion, and in the mesial line of the under surface; the fourth portion is rather the largest, with two horns or tubercles on the upper surface, a third on the median line of the under surface, and on each side a long terminal prolongation, rather blunt. Abdomen in form of a short tubercle in the centre of the posterior part of the thorax. Oviferous tubes very long, slender, and twisted. Length, 6½ lines; breadth 2½ lines.

The male is very similar to that of the *Chondracanthus cornutus* already described.

It is found on the *Lophius piscatorius*, in the pouches.

Tribe II.—*Anchoracarpacea*.

Attached to their prey by means of two long appendages which arise from the thorax. They unite together either at the base or near the tip only, and terminate there in a rounded knob like a button, by means of which the animal maintains its hold of the part to which it has attached itself. No thoracic feet, or they are represented by these arm-shaped appendages.

Males in general differ very much in appearance from the females, being greatly smaller and unattached.

Family I.—*Lerneopodadæ*.

Arm-shaped appendages long, wide apart from each other at their base, and united only at the tip.

Genus *Lerneopoda*.

Female.—Body generally elongated, oval. Head short and thick. Two pairs of foot-jaws, well-developed, and placed near each other. External ovaries of moderate length and cylindrical.

Male.—Body divided into two nearly equal portions of an ovoid shape; one representing the head, the other the thorax. Much smaller than the female.

1. *L. elongata*. The head is very distinct, of a horny texture, ovate, depressed, broad at the base, and obtusely pointed in front, resembling very much the shape of the body of the common Spider-Crab. The second pair of foot-jaws is large and well developed, consisting of a large rounded oval basal joint, and a more slender curved hooked terminal one, with a pretty strong tooth on its inner edge. The head is united to the body by a short narrow neck; the thorax is long and narrow, of a somewhat club-shaped form, and gives origin to two long cylindrical arms, which considerably exceed the length of the body. At the posterior portion, which is somewhat truncate, we see two small lobes; and on each side of these spring the ovaries, which are about the length of the entire body, thick, straight, and cylindrical.

Length of the whole animal nearly 3 inches. Head, one line and three-quarters. Body, 7½ lines. Arms, one inch and one line. Ovaries, one inch and one line and a half.

A specimen of this arctic species was found attached to the eye of a shark caught on the English coast, and brought to London in the winter of 1848.

2. *L. galei*. Female:—The head is oval, depressed, and of a hard horny substance; the thorax is long, rather slender, and somewhat cylindrical, narrow where it is attached to the head, and broadest at its posterior extremity. The arms are slender, and nearly the length of the thorax. At the posterior extremity of the body are two small lobes, between which, on the middle line, is a small tubercle representing the abdomen. Ovarian tubes of moderate length, not quite equal to the length of the thorax.

Length of the whole body, including arms, about three-fourths of an inch.

Male:—Body divided into two portions, of an ovoid form, and nearly of equal size; the upper half represents the head, and carries a pair of antennæ, and two pairs of foot-jaws of considerable magnitude; the lower half, representing the thorax, has at its posterior extremity two sub-globular appendages a little longer than those in the female.

The female was found attached to the cavity posterior to the vent of the *Squalus galeus*.

3. *L. Salmonea*. Linnæus's description of this species, as

far as it goes, is very good:—"Body ovate; thorax obcordate; the two arms linear, approximated." The head is rather small, somewhat bulging out at the back part, broader there, and rather sharp-pointed at the anterior extremity. From the base of the head spring the two arms, which are rounded, and slightly shorter than the body. The thorax is pyriform and short, and at its lower extremity we see two minute eminences. The ovarian tubes are of considerable thickness, cylindrical, and about the same length as the whole animal.

The colour of the animal is white. Length about half an inch.

It is found in the gills of the Salmon, in the London markets.

Family II.—*Anchorelladæ.*

Arm-shaped appendages very short, and united to each other from the base, so as to resemble a single organ.

Genus *Anchorella.*

Female:—Body in general short, and somewhat swollen. Head small, and situated at the extremity of a long neck, which is generally curved backwards. Two pairs of foot-jaws well developed, and a third rudimentary. Antennæ rudimentary. Ovarian tubes of moderate length, and cylindrical.

The male differs in appearance very much from the female, and is very small.

1. *A. uncinata.* Female:—The body of the animal is thick, oblong, of a milk-white colour, smooth, and opaque. Head very small, situated at the extremity of a long slender neck, which has a wrinkled appearance, and is nearly the length of the thorax. The arms spring from the upper portion of the thorax, and are rather short, terminating in a rounded knob or button. At the posterior portion of the thorax there is on the middle line a small protuberance representing the abdomen. The ovarian tubes are cylindrical, straight, smooth, and about the length of the body. Length from 6 to 8 lines.

Male:—Body globular, terminated in front by a small conical eminence, at the extremity of which is the mouth, and having at its base one pair of rudimentary appendages, and a pair of rudimentary foot-jaws. On the middle of the body, on the inferior surface, there are two pairs of large hooked claw-like members. Length, one-fourth of a line.

The female fixes itself to the fins and gill-covers of the Cod and Haddock, and is most probably the most common species of our seas. (Johnston.)

2. *A. rugosa.* Body nearly of a square shape, a little emarginated on each side. Head small; neck slender, and nearly cylindrical. A rounded tubercle on the middle line represents the abdomen. Ovaries rather larger than the thorax, nearly cylindrical, or slightly club-shaped. Length, about 3 lines.

Found in the mouth of the *Gadus cellarius.*

Tribe III.—*Anchoraceracea.*

Females:—Attached to their prey by the anterior extremity of their body only, thrusting the entire head into the tissues of the animal to which they adhere, and being retained there by means of a kind of horns, which are various in form, and spring from the posterior part of the head. No antennæ. Only one pair of foot-jaws, which is simple and hooked. Feet either very small or often wanting altogether.

Males:—Very small. Body globular, and more imperfect than in the preceding tribes, having no distinct thorax, and no rudiments of feet behind the appendages which represent the foot-jaws.

Family I.—*Penelladæ.*

Several pairs of feet situated on the under surface of the body near the head, but very small and rudimentary.

Genus *Lerneonema.*

Body long, slender, narrowed anteriorly in the form of a neck, which is terminated by a swollen head furnished with two or three simple curved horn-shaped appendages. Abdominal portion of the body of inconsiderable length, and simple. Oviferous tubes long and slender.

1. *L. spratta,* the Eye-Sucker. Body slender, considerably larger at the posterior extremity. Head of tolerable size, rounded, and provided with two narrow rather hooked horns at its back part, directed backwards. The head is connected to the body by means of a long and very slender cylindrical neck, which is furnished with about a dozen constrictions, which make this part of the body appear as if it were beset with an equal number of rings or knobs.

A short distance beneath the head it is very narrow, gradually increasing in size as it joins the body. Abdominal portion small, blunt, and obliquely truncate. The ovarian tubes are very long and slender, about as long again as the whole body of the animal. Length of the body about an inch; ovaries one inch and a half.

It is found attached to the eyes of Sprats.

2. *L. encrasicoli.* Body cylindrical, shorter than the preceding, and about the same size at both extremities. The neck is long and slender, quite smooth, and destitute of the constrictions which mark so decidedly the preceding species. The neck is white, and the body is of a brown horny colour.

The abdomen is like that of the preceding, and the ovarian tubes are long and slender, at least twice the length of the body. Turton describes the ovaries as "clear white." Perhaps they may be so in the living animal, but in the specimens preserved in spirits they are of exactly the same colour as the body. In one specimen however one of the tubes is broken, and the ova have escaped, and in this the tube is white. Length of the body about half an inch; ovaries fully one inch.

It is found attached to the bodies of the *Clupea encrasicolus* and *C. sprattus.*

Family II.—*Lerneoceradæ.*

No vestiges of feet on under surface of body, nor any appendages representing them.

Genus 1.—*Lerneocera.*

Body long and slender; head furnished with horn-shaped appendages, which are simple and symmetrical in form. Ovarian tubes straight, and of moderate length. Abdomen very small.

L. cyprinacea. Head furnished with four horn-shaped appendages, which are somewhat long and slender. The two outer or posterior are bifurcated; the anterior simple.

The thorax is very slender anteriorly, forming a long neck, but becomes much broader posteriorly, and when it terminates in the small abdomen appears obliquely truncate. The oviferous tubes are cylindrical, and rather long. The length of the whole animal is about 8 lines.

It is found on the sides of the Carp, Bream, and Roach, in many of our ponds and rivers, in great abundance.

Genus 2.—*Lernea.*

Body more or less twisted, and outré in appearance. Head furnished with horn-shaped appendages, which are irregularly branched. Ovarian tubes twisted into round masses, and placed under the posterior portion of the body. Abdomen of considerable size.

The genus *Lernea* is now restricted within very small limits. Established by Linnæus upon the *L. branchialis,* it is at the present day confined to that species and one or two others.

L. branchialis. Head rounded, and furnished with three horn-shaped appendages, each of which is divided at the tip into three short branches.

The anterior portion of the thorax is long, cylindrical, and very slender, like a long narrow neck, while the body itself is very much swollen in the middle, and abruptly twisted upon itself in the form of the letter S.

The abdominal portion of the body is long, blunt at the extremity, and of considerable size. The ovarian tubes are slender and very much twisted.

The whole animal is about an inch and a half in length, and is of a very firm consistence, being hard and horny.

It is found on the gills of the Cod.

(Baird, *History of British Entomostraca;* Milne-Edwards, *Histoire Naturelle des Crustacés.*)

LERWICK. [SHETLAND.]

LETTERKENNY, county of Donegal, Ireland, a market and post-town, and the seat of a Poor-Law Union, is situated on the side of a steep hill above the left bank of the Swilly, at about a mile above its entrance into Lough Swilly, in 54° 57′ N. lat., 7° 44′ W. long., 15 miles N.W. from Lifford, 140 miles N.N.W. from Dublin. In 1851 the population was 1947, besides 233 inmates of the workhouse. The Poor-Law Union contains 14 electoral divisions, with an area of

101,207 acres and a population of 20,665 in 1851. The town of Letterkenny consists principally of one long straggling street, which however contains some good retail shops. The chief buildings are the parish church, a Roman Catholic chapel, three chapels for Presbyterians, a court-house, fever-hospital, and the Union workhouse. There are also a dispensary, a bridewell, and a loan-fund. Quarter and petty sessions are held in the town, which is the head-quarters of the county police. The creek of Ballyraine, called the Port of Letterkenny, is a mile distant from the town, and admits vessels of 150 tons. The exports are chiefly corn, butter, eggs, and hides; the imports consist of colonial produce, manufactured goods, iron, coal, oak-bark, fish, &c. The scenery of Glen-Swilly above Letterkenny, and of Lough Swilly below, presents much picturesque beauty.

LEUCHTENBERGITE. [MINERALOGY, S. 1.]

LEUCIC ACID. [CHEMISTRY, S. 2.]

LEUCINE. [CHEMISTRY, S. 2.]

LEUCO'JUM, a genus of Plants belonging to the natural order *Amaryllidaceæ*. It has a 6-parted perianth, bell-shaped; the segments all equal, and thickened at their points; the stamens equal.

L. æstivum, the Summer Snow-Flake, has a many-flowered spathe; a style thickened upwards. The height is from 2 to 2½ feet. The flowers are white and drooping; the tips greenish. Leaves broadly linear, keeled; scape 2-edged; spathe usually as long as the flowers. It is found in wet meadows in Great Britain.

LEUCOLINE. [CHEMISTRY, S. 2.]

LEUCOPHANE. [MINERALOGY, S. 1.]

LEYBOURN, or LEYBURN. [YORKSHIRE.]

LIBERIA, Republic of, occupies a considerable extent of the West Coast of Africa. Liberia was originally confined to the tract of country lying west of the Grain Coast, of which the town of Monrovia on Cape Mesurado is the centre; but the republic, though its limits are not accurately defined, now, we believe, claims the entire coast (including the whole of the Grain Coast) from the Cavally River east of Cape Palmas, 4° 20′ N. lat., 7° 30′ W. long., to the Sherboro River, opposite Sherboro Island, 7° 23′ N. lat., 12° 31′ W. long., bordering on the colony of Sierra Leone: a length of about 450 miles, with a breadth at present ranging from 20 to 50 miles, but the settlers are gradually extending farther into the interior. The area may be about 17,000 square miles. We find some difficulty in stating the population. In a semi-official statement published in 1848 by the American Colonisation Society, in which the extent of the territory is made nearly as wide as that given above, the population is said to consist of 4200 colonists (including 700 in Maryland-in-Liberia) and "from 10,000 to 15,000 natives;" while in some popular works recently published in this country we find the colonists variously estimated at from 6000 to 10,000, and the natives at 250,000 to above 300,000. This no doubt is a great exaggeration; and we think the population, including the additions by immigration and extension of territory, cannot exceed 7000 colonists and 50,000 natives: perhaps the native tribes in the interior with whom the Liberians have entered into treaty may number 150,000 to 200,000, but they are not inhabitants of Liberia.

Liberia owes its origin to the efforts of the American Colonisation Society, founded in 1816, for the colonisation of the free coloured people of the United States. The first settlement was made on Sherboro Island, off the coast of West Africa, opposite the present western boundary of Liberia; but several of the settlers having died, and the others experienced much suffering, the settlement was abandoned, and the settlers removed to Sierra Leone. A second party was however sent out, who established themselves, early in 1822, on the site of the present town of Monrovia, on Cape Mesurado, 6° 19′ N. lat., 10° 46′ W. long. At first the settlers encountered many difficulties, owing to the unfriendly disposition of the native tribes; but after a time, as they increased in numbers and were more abundantly provided with fire-arms and some pieces of artillery, they were able not only to keep the natives in check, but to act on the offensive, and to drive them into the interior, or subject them to their authority. In about a dozen years the colony had become sufficiently numerous and energetic to seek the privileges of self-government. In 1839 a constitution was framed and a governor appointed by the Colonisation Society to carry out its provisions. The new constitution appears to have worked very well in home matters, but difficulties occurred in enforcing the laws on foreign traders; and the English government, which had displayed the friendliest feeling and rendered important assistance to the infant community, announced that it could not recognise the right of the Liberian authorities—the colony being neither an independent state nor an acknowledged dependency of the United States—to impose duties on goods imported into the country by British subjects. The Liberian council forwarded a resolution to the Colonisation Society, importing that the existence of the colony was dependent on its possession of complete political jurisdiction: and the Society replied by a resolution admitting that the time had come for the "commonwealth of Liberia to take into their own hands the whole work of self-government, including the management of all their foreign relations." Accordingly, the question was put to the vote of the people whether the settlement should declare itself an independent state, and carried in the affirmative. A convention was then appointed to draw up a constitution, and on the 24th of August, 1847, the flag of the 'Independent Republic of Liberia' was hoisted with much ceremony. The chief events in the history of the settlement have been the numerous encounters with the natives, and since its independence the visits of the president to England and America with a view to the arranging of certain treaties. The republic was recognised by England as an independent state soon after its declaration of independence, and has since been recognised by France, Prussia, Brazil, and some other powers, but not by the United States.

The coast of Liberia has a general direction north-west and south-east, and is broken by several inlets and coves, of which those formed by Cape Mount, Cape Mesurado, and Bassa Cove are of much value as harbours. The greater part of the coast is low and sandy, or marshy; but about Cape Mesurado and Cape Mount (which is 1060 feet above the sea) the shore is considerably elevated. Between those points however there is a low continuous beach of light brown sand, backed by an unbroken tract of forest. Towards the south-eastern extremity the coast is in many parts bold and rocky, the cliffs in many places being from 40 to 60 feet above the sea, with large irregular blocks of granite on the beach, over which the sea breaks heavily, and many rocks lie a short distance off the shore; but between the higher parts everywhere occur long stretches of low sandy beach, in many places bordered by sand-banks: so that nearly all along the coast it is necessary for the mariner to keep a sharp look-out.

From the coast the land rises for the most part gradually towards the interior. About 20 or 30 miles from the shore is a succession of hills covered, like a large part of the lower country, with forests, rising farther inland into mountain ridges, and divided by wide and fertile valleys. The rivers are numerous, and some of them are good-sized streams; but all have their mouths obstructed, and some entirely closed, by sand-bars; and, owing to the prevalence of rapids, none appear to be navigable far inland. The chief river is the St. Paul, which falls into the sea by Cape Mesurado. The sand-banks at its mouth leave only a narrow channel for boats, with 7 feet of water in it at low-tide. It is half a mile wide 40 miles from its mouth, has a considerable body of water, flows through an extremely fertile valley, and has along its banks numerous native villages as well as settlements of the Liberians; but its course is greatly obstructed by rapids; boats of light draught can only ascend it for about 25 miles. The other most important streams are the St. John, which falls into the sea at Bassa Cove; the Junk, which lies between the St. Paul and St. John, and has a very narrow channel through the bar at its mouth; the Cape Mount River, which falls into the sea at Cape Mount, and has its entrance almost closed by a narrow spit of sand; the Grand Cestos, some distance eastward; and the Droo, still farther east, which has about 6 feet of water over its bar, deepening inside to 4 fathoms.

The climate is hot and oppressive. During the dry season, which lasts from May to November, the temperature averages 85°; but in the wet season it falls to 75° or 74°. The extreme heat is alleviated by gentle breezes, which blow daily from the sea. To whites, whether natives of Europe or America, the climate is very prejudicial; but the negro colonists, though the descendants of families long settled in America, experience no inconvenience from it after they have passed through the 'seasoning,' or 'acclimatising fever,' which visits all the newly-arrived alike, but is now comparatively seldom fatal in its attacks. Nothing like an epidemic has ever appeared in Liberia.

The following brief extract from an 'Address of the Citisans of Liberia to the Free Coloured People of the United States" 1847, may serve, with allowance for a little heightening in the colouring, to convey a tolerably clear idea of the character and capabilities of the country:—

"A more fertile soil, and a more productive country, so far as it is cultivated, there is not, we believe, on the face of the earth. Its hills and its plains are covered with a verdure which never fades; the productions of nature keep on in their growth through all seasons of the year. Even the natives of the country, almost without farming tools, without skill, and with very little labour, make more grain and vegetables than they can consume, and often more than they can sell. Cattle, swine, fowl, ducks, goats, and sheep thrive without feeding, requiring no care but to keep them from straying. Cotton, coffee, indigo, and the sugar-cane are all the spontaneous growth of our forests, and may be cultivated at pleasure, to any extent, by such as are disposed. The same may be said of rice, Indian corn, Guinea corn, millet, and too many species of fruit to enumerate. Add to all, we have no dreary winter here. . . . Nature is constantly renewing herself, and is also constantly pouring her treasures all the year round into the laps of the industrious."

It is thought that when labour becomes more abundant, sugar, cotton (which yields two crops in the year), coffee, and indigo will come to be staple products of Liberia. The coffee-tree has already been somewhat extensively planted; at one place there is a plantation of 30,000 trees. At present the chief articles of export, besides fruits, vegetables, and salted meats supplied to ships calling at the ports, are palm oil, which has become an article of great importance, dye-woods, ivory, and rice, with some gold, tortoise-shell, gums, hides, wax, ground-nuts, ginger, and pepper; a good proportion of which is brought by natives from the interior. The exports in the two years ending September, 1843, amounted to 25,767*l.*, the imports to 32,880*l.*: the exports are said now to average upwards of 100,000*l.* annually. The supply of dye-woods, especially cam-wood, appears to be inexhaustible. It is said that from about 30 miles east of Bassa Cove, there "extends a forest-region of unknown extent, where scarcely any tree is seen except cam-wood." Liberia has a considerable coasting-trade, carried on by schooners belonging to the country; and a large trade with the interior. For home consumption as well as export there is a great variety of timber-trees suitable for building purposes; good building-stone abounds; as do also shells for lime, and clay of excellent quality for bricks.

Liberia is divided into the counties of Mesurado, or Montserrado, Bassa, and Sinoe. The chief town is *Monrovia*, the capital, on Cape Mesurado, a busy sea-port town and the principal place of trade. It contains a court-house, a public library, two or three churches and schools; several stores, warehouses, and good wharfs; a fort and a lighthouse; and has about 1500 inhabitants. The other larger towns and settlements along the coast are Marshall at the mouth, and on the right bank of the Junk River; Edina and Grand Bassa at the mouth, but on the opposite banks of the St. John, in Bassa Cove; Bexley, and the new town of Cresson in the same neighbourhood; Greenville on the Sinoe; Trade Town, a populous place 4 miles W. from Young Cestos; and Cestos, or St. George's Point in Cestos Bay. The chief inland towns and settlements are Caldwell on the St. Paul; New Georgia; and Millsburg. Along the coast are several factories, chiefly for the trade in cam-wood, belonging to Liberians, and some to English and American merchants: and both along the coast and inland are numerous native towns and villages, some of them, as Grand Cestos and Great Neefoo, of considerable size.

On Cape Palmas, the south-eastern extremity of Liberia, is established the colony of *Maryland-in-Liberia*, consisting of free-coloured emigrants sent thither from the state of Maryland by the 'State Colonisation Society.' The colony was founded in 1834, and a considerable number of free-coloured persons have since been sent to it by the Society, which is assisted in its operations by an annual grant from the state legislature of 20,000 dollars. The colony, which is independent of Liberia, is governed by an agent, or governor, appointed by the Colonisation Society, and a council and other officers elected by the colonists; and appears to be in a tolerably flourishing condition. *Harper*, the chief town, contains about 700 inhabitants, and carries on a good deal of trade. The Palmas River is about a hundred yards wide towards its mouth, but several rocks lie in the channel; it has a depth of 3 feet over the bar at low water. The colonists have erected a lighthouse on Cape Palmas, which shows a fixed light 100 feet above the sea. There are two or three villages and smaller settlements.

The constitution, adopted at the declaration of the independence of Liberia, and said to have been drawn up by Professor Greenleaf, of Harvard College, Massachusetts, is founded on that of the United States, which it greatly resembles in its leading principles. It proclaims the equality of all men; establishes perfect religious freedom, and the liberty of the press; prohibits slavery; gives the right of every one to be tried by a jury of his peers, of bail, and of habeas corpus; makes nearly all offices elective, and gives the suffrage to every male citizen 21 years of age possessing real estate—citizenship belonging however exclusively to persons of colour; and of such, at present at least, only to the free coloured emigrants from the United States, who immediately on arriving are admitted to full citizenship, and receive a grant of five acres of land, with liberty to purchase more. The executive government is vested in a senate elected from the counties, and a house of representatives elected after the American system, according to a ratio of representative population; and a president who is elected for two years, is to exercise supreme executive power, is the commander-in-chief of the army and navy, and has a qualified veto on the acts of the legislature. The judicature consists of a supreme court, and districts courts: the judges are only removeable by the president on a vote of two-thirds of the houses of legislature. The annual revenue and expenditure average about 7000*l.* a year each. The republic appears to be making steady progress.

There were in 1847 in Liberia (without including the Maryland colony) 23 churches with 1474 communicants, of whom 469 were natives; there are now above 30 churches. Schools are provided for all the children of citizens. In 1847 there were 16 schools with 562 scholars, of whom 192 were the children of native Africans: in 1851 the scholars were said to exceed 2000. Three high-schools are in operation in Monrovia; and an Act has passed the legislature for the establishment of a college. The 'Liberia Herald,' a very respectably conducted newspaper, has now continued to be published for above 20 years: one or two others have been issued within the last few years.

LIBRARIES, PUBLIC. Up to a recent period one of the first things which struck a foreigner with pain when he took up his residence in London, or in any other of our great towns and cities, was the total absence of free libraries. In every large town on the continent there is a public library (often there are two, four, or six), to which every one is admitted at once, without introduction or guarantee. In the whole of the British Islands there was but *one* such institution—Chetham's Library, in Manchester; and even this was so ill-managed in other respects as to be of hardly any use to the inhabitants of the town in which it existed. In 1849 a committee of the House of Commons was appointed, of which Mr. Ewart was chairman, and its report contained a mass of startling facts, and a number of valuable suggestions. It was shown that our public libraries were not only difficult of access compared with foreign libraries—they were wretchedly few in number. One of the most striking things in this report is a map of Europe, shaded so as to exhibit the relative provision of books in libraries accessible to the general public in the various states on the continent, excepting Turkey. The small German states—Baden, Hanover, Dresden, and so on—and England are on the two extreme verges. The minor countries are, in this respect at least, white with the light of science and learning, while the British islands appear to be in utter darkness. The gradations run down the scale thus:—For every 100 of the population, there are in the minor states of Germany 450 books; in Denmark, 412; in Switzerland, 350; in Bavaria, 339; in Norway and Sweden, 309; in Prussia, 200; in the Austrian empire and the kingdom of Hungary, 167; in the states of Italy, 150; in France, 129; in Sardinia, 100; in Spain, 100; in Belgium, 100; in Portugal, 80; in Russia, 75; in Holland, 63 to 53; in Great Britain and Ireland, 63 to 53. Look at it how we will, such a table is calculated to put one to the blush; but still it should not have been sent forth by the reporters without some sort of explanation. Such a statement is very likely to mislead continental writers, not well acquainted with England, into a grievous mistake. It is only too true that the peasant of Devonshire has fewer books accessible to him in public collections than the peasant of Podolia or the Banat has—the citizen of London or Liverpool than the weaver of Catalonia and the vine-dresser of Catania. But it is not true that there are more books in Russia and Hungary, in Spain and Sicily, in proportion to the number of inhabitants, than in Holland and England. It is not even true that there are more books accessible to the working classes in any of the countries named than in England. There are coffee-houses in the bye streets of London which have better libraries than can be found in cities of from five to ten or fifteen thousand inhabitants in Germany or Denmark. There are divans in the Strand where more papers and reviews are taken in than in the Casino of Pesth. In fact, with the exception of the United States of North America, no nation in the world has so many books, so much literature, in proportion to the amount of the population, as England. In Spain, in Italy, and Germany, even in France, very few persons have private libraries in their own houses. In England a house is not considered furnished without a stock of books. Even the cottage of the peasant has its family Bible, and its copy of Shakspere or Milton, a thing having no parallel in some of the countries standing higher in the above list. It is a remark often made by foreigners, that in England there are no pictures. It is much the same with regard to books. But the fact is, both our art and our literature are gathered up in our homes; while in public collections we are lamentably deficient, but only in public collections.

This distribution of books, as of paintings, in small quantities, and in many houses, has its evils as well as its virtues. It induces a certain amount of reading in the classes to whom literature is chiefly a graceful recreation; but the education of the masses, and the higher culture of men of letters, suffers by it most deplorably. Within the recollection of men still living there was no library in London, accessible to the public, even moderately complete in the great departments of inquiry. Gibbon had to purchase all the books necessary for the composition of his great works. Fortunately for us he had the means. Roscoe was unable to obtain from any public library in Liverpool the ordinary Italian authors whom he had to consult on the subject of his two biographies. Still later than this, the historian of North America (Graham) found himself obliged to remove from London to Göttingen, in order to get access to a well-stored library, which was at the same time open to the public. Within a year or two of our own time, Robert Southey was obliged to collect at his own cost all the materials of his voluminous writings, as any other author would have to do again next year, if it were inconvenient for him to reside in London, and to attend at the British Museum in the heart of the day. How disastrously this scarcity of books, publicly accessible, operates upon the current literature of the time, men of letters are alone truly aware. How it operates to prevent the spread of sound and useful information among the masses, is evident to every one who has been in the habit of reading in the libraries of foreign countries. For example, let any one compare the reading rooms, day after day, of the British Museum and the National Library in Paris, he will at once perceive that two distinct classes of persons frequent these rooms. In London he will find only men of letters and artists, the teachers of the people. In Paris he will see that it is the people themselves who come to read. In the British Museum he sees only grave men and women dressed in the customary suits of solemn black, so well befitting the avocation of letters. In the National Library, he observes groups of students from the civil and military colleges, soldiers of the line in their blue-coats, officers, clerks, shopkeepers, porters, and generally speaking specimens of all classes of the population. A peep over the shoulders of the readers in the two rooms will reveal another difference between them. In London, you see the tables covered with old volumes, maps, and manuscripts—the literature of the past. In Paris, you notice that the readers are chiefly poring over the new books and new writers—Thiers, Lamartine, Louis Blanc—the living literature of their own age. In strict truth, the British Museum is only a library of reference; the Parisian institution is a library for reading.

There is nothing in the theory of the two institutions which ought to lead to this variety of result; but practically it is so; and the circumstances in which the rules are founded are sufficient to explain it. The National Library is open to the public—the British Museum is not. Whenever a man finds himself in the heart of Paris with an hour's leisure on his hands, he can at once repair to the Library. No one can do this in London unless he is previously provided with a free card. The Parisian who obtains an unexpected holiday can use the institutions of his country—not so the Londoner; for although it is not difficult to get a pass card to the British Museum, to get it is a work of time. It cannot be done in a day. This is the great advantage which the masses of Paris have over the same classes in London. To the man of letters, Paris offers still greater advantages—as, under proper regulations, he is there allowed to take home with him the books he is using for literary purposes. How far in the opinion of the Committee these provisions might be safely extended to the British Museum readers, will be considered by and bye.

It appears from the evidence tendered to the Committee, that,

In France there are	107	Public Libraries open freely.	
„ Belgium . .	14	„	„
„ the States of Prussia	44	„	„
„ Austria (with Venice and Lombardy)	48	„	„
„ Saxony . . .	6	„	„
„ Bavaria . . .	17	„	„
„ Denmark . .	5	„	„
„ Tuscany . .	9	„	„
„ Great Britain and Ireland .	1	„	„

All the great public libraries on the Continent are like the National Library in Paris; that is, they are open freely to all comers without distinction of person, rank, or country. This is as it should be everywhere; none should be sent back from the temple of knowledge who knock for admission. The following list gives the number of these public libraries in the chief capitals in Europe:—

In Paris there are	7	open Public Libraries.	
„ Brussels . .	2	„	„
„ Berlin . . .	2	„	„
„ Vienna . .	3	„	„
„ Milan . . .	2	„	„
„ Dresden . .	4	„	„
„ Munich . .	2	„	„
„ Copenhagen .	3	„	„
„ Florence . .	6	„	„
„ London .	none	„	„

Compared with the population of these cities thus provided—the whole of them little over-counting London alone—the facilities for mental culture afforded to our masses are not to be named. Indeed all the collections of books which can by any straining of the terms of their acts of foundation be considered as public libraries are wretchedly inadequate to meet the wants of a population pining for a higher class of reading. Besides the British Museum, there are in London—the library of Sion College, in London Wall, founded by Dr. White, in 1636, and now containing nearly 40,000 volumes; the library in Red Cross Street, founded by Dr. Williams in 1716, and now containing about 20,000 volumes; and Archbishop Tenison's library in Westminster, containing about 4000 volumes. This last is now degraded to the purposes of a club-room. These are all public; a card of admission is obtained in much the same way as at the British Museum. Of course there are many other libraries in London to which men of letters obtain access for the objects of their craft—such as the library of the East India House in Leadenhall Street; the libraries of the Inns of Courts; libraries connected with the various professional Colleges; the library of Lambeth Palace; and so on. But from none of these can the books be borrowed. None of them are open to the general public, or to the unknown student. The only decent library in London from which books may be taken home is a subscription library in St. James's Square—and that is necessarily very imperfect in all departments, and is moreover barricaded by a large entrance fee.

Out of London, the Bodleian at Oxford, and the University library at Cambridge, are the best in England. But these are both closed to the public; and not only so, but to the majority of the students themselves. It is the same in the University library in Glasgow. At Trinity College, Dublin, at the University library of Aberdeen, and at that of St. Andrews, there are restrictions which exclude the public. Chetham's library, in Manchester, containing about 20,000 volumes, has the reputation of being the only one in England open to the public after the manner of the Conti-ment. In Dublin, there are four other decent libraries in addition of that of Trinity College—belonging respectively to the Royal Irish Academy, 10,000 volumes; to the Royal Dublin Society, 19,000 volumes; to the Queen's Inns, and Marsh's library, 18,000 volumes. The Advocates' library in Edinburgh is the chief public collection of books in the east of Scotland.

Besides these great collections, which are known but not easily accessible to the general public, there are a considerable number of small libraries, belonging to the public, scattered about the country, which at present are neither known nor accessible—but which may constitute the nuclei of a system of public libraries by and bye. These little-known collections are of two kinds—cathedral libraries and parochial libraries. Of the cathedral collections there are known 34 in England and 6 in Ireland. For the most part they are stocked with works on theology and divinity, but some of them have also works on literature and history—particularly ecclesiastical history. Many of these have incomes settled upon them by pious and munificent founders. In such as have, new books are added yearly; the number of volumes which they contain will average from 7000 to 10,000 in each. In some the books have had little care taken of them, and much loss has thereby accrued to the public. Generally speaking, these church libraries are the closest of corporations. Parochial libraries once prevailed to a considerable extent throughout England and Wales, and Scotland. The Committee have come upon the traces of no less than 163 such institutions in England and Wales, and 16 in Scotland. These parish libraries were founded in the first instance by private benevolence. Many of them owed their origin to the efforts of Dr. Bray and his friends, the founders of the Society for Promoting Christian Knowledge, at the beginning of the 18th century; but others had already been in existence some time, as we learn from the preamble to an Act of Parliament for their better preservation, passed in 1708. Many of these libraries, from sheer neglect, have fallen into a state of decay. It is stated in evidence that "the books lie exposed to chance, and liable to be torn by the children of the village;" as however they were originally formed chiefly with a view to their being useful to the poorer ranks of the clergy, at a time when standard works were dear, and few parsonages could boast of a well-stocked set of shelves, the works which they contain are by no means fit only for children. They are generally of a high class; but there are not very many of them unfortunately.

That the public required greater facilities for consulting better works than they possessed, was proved—first, by the more educated classes continually making our national poverty in this respect the subject of complaint in the press and in society; secondly, by the artisan classes constantly making efforts to create libraries of a better class for themselves. Our lyceums and mechanics' institutes are chiefly supported by the strong desire of the daily worker for a good book, a desire which has already acquired something of the power and regularity of a passion. Nor is it only in the place of education that the hard-working man desires to see himself within the reach of an intellectual companion. Wherever there is a real want, it will sooner or later be supplied. If the workman who has little leisure, and that little only such as may be snatched from brief intervals allowed for rest and refreshment, seriously wishes to devote a part of that leisure to reading, he will soon, as in the London cheap coffee-houses, find them placed about him by those who are anxious to court his custom. Of these coffee-houses there are 2000 in the metropolis, many of which have books as well as magazines and newspapers. Some of these have as many as 2000 volumes, and, what is equally significant, novels, or works belonging to a light class of literature, form only a moderate proportion. Histories, poetry, travels, political works, and so forth, books of solid thinking and high character also find their place. A cursory glance at these places, lyceums and coffee-houses, will show that the race of hard workers is also a race of hard thinkers. Such considerations as these convinced the Committee of Inquiry, that the establishment of public libraries, open and free to all comers, was a national want, expressed in the most practical and convincing manner.

The suggestions offered by the Committee were chiefly for the purpose of rendering the existing libraries more available to the general public, with occasional grants from government for the purpose of extending them. They were not adopted altogether, but the Report produced such a conviction of the necessity for doing something, that in 1850 an Act was passed (13 & 14 Vict., cap. 65) "for enabling town councils to establish public libraries and museums." There had been a previous Act in 1845 for enabling them to form museums in towns or boroughs where the population exceeded 10,000. The town councils were by the present Act empowered, with the consent of a majority of two-thirds of the persons legally entitled to vote in an assembly called for the special purpose, to levy a rate not exceeding a halfpenny in the pound on the annual value of the property assessed to the borough rate, and to hire or purchase land, erect buildings, furnish them fittingly, appoint and pay officers, &c.; the property in buildings, books, maps, specimens of art and science, whether purchased or acquired by donations, to be vested in the council in trust for the inhabitants of the borough and others resorting thereto; the admission to such libraries and museums to be at all times free of charge. This Act was extended to Scotland and Ireland by the 17 & 18 Vict., cap. 74. Numerous towns have availed themselves of the powers of this Act in England; among others, Birkenhead, Bolton, Cambridge, Hertford, Kidderminster, Liverpool, Manchester, Norwich, Oxford, Salford, Sheffield, Warrington, and Winchester. The general results are reported in every case to be satisfactory: in some highly so. At Salford, in the first year, out of 3000 consecutive issues of books, 1931 were works of fiction; in 1855, out of the same number, only 720 were works of fiction. At Oxford it is said 235,000 persons have visited the library in two years (visits, we presume, are meant, and not distinct persons); and, it is added, the public library "has proved of more real benefit, and rendered more solid advantages to the middle and working classes in this city than any other measure which has been adopted." In Liverpool, it is stated, "a marked improvement has been noticed in the habits and manners of the people who frequent the library." The return also mentions that in Birmingham, Cheltenham, Exeter, Islington, and the City of London, the proposal for establishing a public library has been rejected.

One of the suggestions of Mr. Ewart's Committee was that, wherever the public were admitted to libraries, gas should be provided, that the artisan might use them in the evening. In most of the libraries established under this Act the suggestion has been adopted. Another suggestion, that the library of the British Museum should be to a certain extent divided, one division containing those works best adapted for general reading, to which the public might be admitted in the evening, and the other, the great national collection of records, manuscripts, and books of reference, for literary men, has not been attempted. Such a division would certainly be a great benefit to both classes of book-users. The recently constructed large and elegant new reading-room of the British Museum, even under the restriction of obtaining pass-cards, has yet too many readers to be pleasant for a student. If also, as in Paris, books could be had for a limited time to be used at home by the writer who, in fact, makes these boarded treasures profitable for the world at large, it would be an invaluable boon.

LINDE, SAMUEL BOGUMIL, the great lexicographer of Poland, was of immediate Swedish descent. His father was a native of Dalecarlia, who was settled at Thorn in Poland when Linde was born in 1771. After receiving a good education in the schools of Thorn, he was sent, at the age of eighteen, to study in the university of Leipzig, where he attracted the favourable notice of Professor August Wilhelm Ernesti, the editor of Livy and Tacitus. "Ernesti," says Linde, in one of the prefaces to his great work, the Polish Dictionary, "struck out for me, without my knowledge, an opening to a career which he thought would be for my benefit. One day he told me, to my great surprise, that he had written some weeks before to Dresden, to recommend that a chair of the Polish language and literature should be entrusted to me at the university of Leipzig. I told him, with some consternation, that I was not well acquainted with Polish; that all I knew of it was what clung to my memory from the mere intercourse of daily life at Thorn, where I was much neglected; and that if I were made professor I should myself be obliged to begin to learn the language anew from the first rudiments." In the course of 1792, however, Linde received the appointment, and began to do as he had said. Among the books that he procured from Poland was the 'Powrot Posla' ('The Deputy's Return'), a satirical play, directed against the national failings of the Poles, which he found so excellent, that, though many passages were beyond his comprehension, he commenced a translation, with the intention of making use of the original as a book for study with his pupils. It was lying on his table when two Polish gentlemen called on him, whose attention was at once attracted by the book, and he asked them if they could inform him who was the author of that anonymous masterpiece. One of them, Julian Niemcewicz, replied, "I wrote it." "That moment," Linde afterwards said, was "the decisive moment of my life." Niemcewicz became his intimate friend, explained to him the passages that had perplexed him, and introduced him to the society of the other distinguished Poles then living at Leipzig, to which it appears the professor had hitherto had no access. Among them were the Counts Potocki, Kollotaj, and Thaddeus Kosciuszko, some of the most illustrious names of Poland. Linde, who now first heard his native idiom from the lips of gentlemen and scholars, became fired with enthusiasm for the Polish language, and resolved to devote himself to the production of a great Polish dictionary. He took this resolution at the age of twenty-two; he published the last volume of his great work twenty-one years after, having worked at it almost unremittingly during the interval. The Dictionary of the Polish Language, 'Slownik Jezyka Polskiego,' occupies six quarto volumes, of which the first was published at Warsaw in 1807, and the last in 1814. It fills about five thousand quarto pages in closely printed double columns; to every word is appended an explanation in Polish and German, a comparison with the forms which resemble it in the other Slavonic dialects, and a collection of passages from authors in which it occurs, to amass which Linde read through six or seven hundred of the principal works in Polish, of which he gives a list in the first volume. It was the first great dictionary of the Polish language; it has served as the basis for every subsequent one, and though of course susceptible of improvement and augmentations, it is not likely to be ever either superseded or surpassed. In the course of its preparation Linde soon resigned the professorship at Leipzig which had first given rise to it, passed some time at Warsaw, then became librarian to Count Ossolinski at Vienna, and had the congenial employment of travelling in Poland to collect Polish books, by which he enriched the library and his Dictionary together, and lastly established himself at Warsaw to superintend the printing, which was carried on in his own house by compositors and pressmen, some of whom had the privilege of immortalising themselves by affixing their own names at the end. These labours were carried on during a stormy period, but the house in which the Dictionary was printing was repeatedly spared by contending armies, and the author received support from the Prussian and the Austrian governments, and in particular from the Russian, as well as from numerous Polish magnates, one of whom, Count Zamoyski, when the works were on one occasion brought to a stand-still by an absolute want of pecuniary means, sold a favourite horse and sent the proceeds to the lexicographer. Linde held various appointments connected with the educational establishments of Poland, and was enabled to introduce extensive reforms. He continued to reside at Warsaw as rector of the Lyceum and principal librarian of the university, during the long period of comparative tranquillity which preceded the insurrection of 1830; and though he was elected to the revolutionary diet as member for Praga, was averse to that unfortunate movement, which he thought ill-timed and likely to issue in nothing but calamity. Fryxell the Swedish historian, who, in his travels in search of Swedish documents, was surprised to discover that the Polish lexicographer was the son of one of his own countrymen, found him depressed and melancholy in the year 1834. "It was instructive," says Fryxell, in the preface to his 'Handlingar rörande Scandinaviens Historia,' "to hear him trace the true reasons of Poland's fall first and foremost in the national character of the Poles themselves, instructive especially for a Swede, who belongs to a country which has the same powerful and wily neighbour that Poland had, and who hears the same misleading doctrines preached around him which ended in subjecting Poland to the Russian yoke." Linde had at that time been re-appointed by the Russian government to some of the educational posts he formerly held; but he resigned them in 1838, and appears to have lived in retirement till his death on the 8th of August 1847 at Warsaw. In addition to his Dictionary he was the author of a work in Polish on the statutes of Lithuania, and he translated from the Russian Grech's 'History of Russian Literature,' with an appendix of additions. His pen was frequently employed in rendering Polish works into German, the language with which to the last he seems to have been most familiar. The most important of these was his translation (Warsaw, 1822) of the Dissertation on Kadluhek, the old Polish historian, by his friend and patron Count Ossolinski, who it should be mentioned assisted materially in the composition of the Dictionary, and to whom in conjunction with Prince Czartoryski, also a munificent patron, that work is dedicated.

LING. [LOTA, *S.* 2.]

LINGARD, REV. JOHN, D.D. and LL.D., was born February 5, 1771, in the city of Winchester. He belonged to a Roman Catholic family in humble circumstances, and studied at the Roman Catholic College at Douay, in France, whither he was sent by the Roman Catholic Bishop Talbot, and there he remained till the revolutionary troubles obliged the small community to seek shelter in England. After several intermediate removals the college settled at Crookhall, in the county of Durham, and subsequently at Ushaw, near the city of Durham. Mr. Lingard accompanied the college, and performed the duties of some of its offices. He revisited France for a short time during the dangerous period of the revolution, and on one occasion escaped with difficulty from being suspended 'à la lanterne.' In 1805 he wrote for the 'Newcastle Courant' a series of letters, which were collected and published under the title of 'Catholic Loyalty vindicated,' 12mo. He afterwards wrote several controversial pamphlets, which in 1813 were published in a volume having the title of 'Tracts on several Subjects connected with the Civil and Religious Principles of the Catholics;' and he was also the author of 'Catechetical Instructions on the Doctrines and Worship of the Catholic Church,' of which there have been several editions. In 1836 he published anonymously an English translation of the New Testament, which is said to be accurate and faithful in several passages where the Douay translation is faulty. In 1845 he published the 'History and Antiquities of the Anglo-Saxon Church,' 2 vols. 8vo.

Dr. Lingard's great work, the 'History of England from the First Invasion by the Romans to the Accession of William and Mary in 1688,' was first published in 6 vols. 4to, London, 1819-25; second edition in 14 vols. 8vo, 1823-31; fourth edition, in 13 vols. 12mo, 1837; fifth edition, 10 vols. 8vo, 1849-50; and sixth edition, 10 vols. 8vo, 1854-55. Dr. Lingard's 'History of England' is a work of great research, founded on ancient writers and original documents, displaying much erudition and acuteness, and opening fields of inquiry previously unexplored. The narrative is clear, the dates accurately given, and the authorities referred to distinctly. The style is perspicuous, terse, and unostentatious. The work perhaps exhibits too exclusively the great facts and circumstances, military, civil, and ecclesiastical, and enters less than might be desirable into the manners, customs, arts, and condition of the people. In all matters connected with the Church the work is, as might have been expected, coloured by the very decided religious opinions of the author; but these are not offensively set forth.

Dr. Lingard, after the completion of his 'History of England,' paid a visit to Rome, where Pope Leo XII. offered to make him a cardinal, but he refused the dignity. He spent the last forty years of his life at Hornby, near Lancaster, where he died July 13, 1851. He was buried in the cemetery of St. Cuthbert's College, at Ushaw, to which institution he bequeathed his library. His latter years were rendered comfortable by the profits of his 'History,' and a pension of 300*l.* a year from the Queen for his services to literature.

LINOSYRIS, a genus of Plants belonging to the natural order *Compositæ*. The heads are not radiant; florets all perfect and tubular; receptacle naked, pitted; the pits with elevated dentate margins in the British species; phyllus imbricated; pappus pilose; fruit compressed, silky, without a beak.

L. vulgaris is an herbaceous Plant, found in middle and southern Europe and Great Britain. It has linear glabrous leaves, corymbose heads, the involucre lax; the stem from 12 to 18 inches high, simple and leafy; leaves single ribbed, smooth or scabrous, very numerous, more or less dotted: flowers yellow. It grows on limestone cliffs. It is the *Chrysocoma Linosyris* of Smith.

LINSENERZ. [MINERALOGY, *S.* 1.]

LINTON. [CAMBRIDGESHIRE.]

LISTA Y ARAGON, ALBERTO, an eminent Spanish mathematician, poet, and critic, was born at Triana, a suburb of Seville, in 1775, on the 15th of October, the day which, as he delighted to remember, was also the birthday of his favourite poet Virgil. His parents were in humble circumstances, and engaged in silk-weaving, and in his early years Lista was himself obliged to work at the trade, but he soon displayed such talents for mathematics, that by the time he was thirteen he was already enabled to earn his own living by giving lessons to pupils. As he went about from one house to another for this purpose, he filled up the intervals by playing with the other boys in the streets. At fifteen he was made teacher of mathematics in the schools of the society of 'Amigos del Pais,' and at twenty nominated by the king to the same office in the nautical college of San Telmo at Seville. Before that time he had studied philosophy, theology, and canon law at the university, and he had also devoted himself to the priesthood. This however did not prevent him from engaging in private theatricals, and gaining applause in some of the principal characters in Lope and Calderon. At that period there were four young men in Seville enthusiastic in their devotion to literature and intimate personal friends, Arjona, Reynoso, Lista, and Don José Maria Blanco, afterwards so well known in England by the name of Blanco White.

In 1808, soon after Lista's appointment to the professorship of poetry and rhetoric at the University of Seville, the French invasion brought ruin to every literary circle in the peninsula. Lista at first joined with Blanco in continuing the 'Semanario Patriotico,' begun by Quintana, but his firmness appears afterwards to have failed him. When the French entered Seville he remained, and while improvising patriotic odes on the victory of Baylen, he allowed himself to earn the compliments of Soult by the skill with which, under compulsion, he turned the French proclamations into excellent Spanish. The consequence was that when the French armies were driven out of the country in 1813, Lista found himself obliged to keep them company, and spent some years in France as a teacher of Spanish, and also as a curate, occasionally venturing to preach in French, though he could never conquer the Spanish accent. In 1817 he was allowed to re-enter Spain, and after passing a few years in the provinces as a teacher of mathematics, was established in 1820 at Madrid as, in conjunction with Hermosilla and Miñano, editor of the magazine 'El Censor,' one of the best periodicals Spain has ever produced. In 1822 he published his poems, with a dedication to Blanco White, under the name of 'Albino.' They at once placed their author among the first poets of modern Spain. Not long after he established a sort of private college at Madrid, the reputation of which rose singularly high, and had the effect of exposing him to many annoyances on the part of the government. Among the pupils of Lista at different periods of his life are found the names of Duran, Esproncede, Ventura de la Vega, Roca de Togores, and many others of peninsular eminence. He became so dispirited by the obstacles thrown in his way by the authorities, that he finally left the country and established himself at Bayonne, where he published a 'Gaceta de Bayona' in Spanish, which supported him by its circulation in Spain till it was prohibited by the ministry. He then went to reside at Paris, and while there paid a visit of a fortnight to London, for the exclusive purpose of renewing his intercourse with his old friend White, then a minister of the Church of England, resident at Oxford. When the friends met their emotion was so great that both were for some time unable to speak. Soon after, in 1833, the writer whose 'Gaceta de Bayona' had been forbidden to enter Spain, was summoned home to edit the 'Gaceta de Madrid,' where his leading articles were so highly approved, that King Ferdinand offered him in recompense the bishopric of Astorga, which he declined in favour of his friend Torres Amat, the biographer of Catalan authors. From this time his life flowed through a series of honours. When in 1837 he resigned the editorship of the 'Gaceta,' he became professor of Mathematics at Madrid, and helped to establish the Athenæum, or university there. His health suffered by the climate of Madrid, and he removed to Cadiz, where he superintended the new college of St. Philip Neri. In 1840 he gave this up, and returned to his native Seville, on his road to which he was met at two leagues off by a procession of friends and admirers to escort him in. He again accepted in his old age the professorship of mathematics in the city where his early triumphs had been won, and there he died on the 5th of October 1848. The municipality of Seville decreed that one of the streets in which he had often played when a boy should bear henceforth the name of 'Calle de Don Alberto Lista.'

Lista was an author of very various merit, his 'Tratado de Matematicas puras y mixtas' is the standard book on mathematics in Spain, and his amorous and anacreontic poetry is considered little inferior to that of the admired Melendez. His philosophic poems in the style of Horace are peculiarly happy, and his sacred poems are superior to those of any of his contemporaries. As a literary critic his 'Lecciones de Literatura Dramatica Española' (Madrid, 1839), and his 'Ensayos Literarios y Criticos' (2 vols., Seville, 1844), are in high esteem, and contain a fund of valuable information for foreigners; and he has also displayed his intimate acquaintance with the literature of his country in an excellent collection of selected extracts, 'Trozos Escogidos de los mejores Hablistas Españoles en Prosa y Verso.' A translation of Ségur's French work on universal history, which he executed when in France, has a title to be mentioned from the numerous additions it contains, including, among others, a history of Spain to a late period. As a political writer he was distinguished by his advocacy of moderate and cautious reforms; and it should be mentioned that among his poems is one entitled 'The Triumph of Tolerance,' directed against the Inquisition.

LISSOMUS. [ELATERIDÆ.]

LISTERA, a genus of Plants belonging to the natural order *Orchidaceæ*. It has a ringent perianth; a deflexed 2-lobed lip; the stigma transverse; rostellum elongated, entire, acute, with a minute globose appendage at its somewhat reflexed apex; column very short.

L. ovata, Tway-Blade, is found in woods and pastures in Great Britain. It has 2 opposite ovate leaves, the lip bifid, the column with a crest which includes the anther; the stem a foot high; spike elongated, very lax; flowers small, and greenish; leaves large.

L. cordata has 2 opposite cordate leaves, 4-lobed lip, column without a crest. Height 3 to 5 inches. The stem is slender. Flowers very small, in a lax spike, and of a greenish colour; the lip with 2 basal and 2 terminal linear lobes. It is found on turfy mountainous moors in Great Britain.

LITHOMARGE. [MINERALOGY, *S.* 1.]

LITTORELLA, a genus of Plants belonging to the natural order *Plantaginaceæ*. It is monœcious; the male flowers stalked; sepals 4; tube of the corolla cylindrical; limb 4-parted; stamens hypogynous; filaments very long. The female flowers sessile; sepals 3; corolla oblong, narrowed at both ends; styles long; capsules 1-seeded.

L. lacustris, has white flowers; the fertile flowers sessile; stalks of the male flower one or two inches long; leaves all radical, linear, fleshy, somewhat channelled. It is found on the margin of lakes.

LLANFAIR. [MONTGOMERYSHIRE.]

LLANFYLLIN. [MONTGOMERYSHIRE.]

LLANIDLOES. [MONTGOMERYSHIRE.]

LOCH, JAMES, was the eldest son of George Loch, Esq., of Drylaw, near Edinburgh, by a sister of the late Right Honourable William Adam. He was born in 1780, and called to the Scottish Bar in 1801; he was subsequently admitted within the English Bar. He was for many years auditor to the late Earl of Carlisle, and to the trust estates of the late Earl of Dudley, Viscount Keith, and also to the extensive properties of Lord Francis Egerton (afterwards Earl of Ellesmere), and his brother the Duke of Sutherland, which he managed with great ability during the period when the tide of Highland emigration had set in at its strongest. The improvements which were made on the Duke of Sutherland's Highland property were the subject of much controversy; but Mr. Loch, in some able publications, demonstrated that the removal of wretched cottiers, without any means of cultivating the land, to make room for profitable industry, was real benevolence. He was also well known as the author of a 'Statistical and Historical Account of the

County of Sutherland,' and as a member of the council of the University of London. He represented in the Liberal interest the since disfranchised borough of St. German's, Cornwall, during the last unreformed parliament, after which he sat for the Wick district of Burghs from December 1832 to the dissolution in 1852, when he finally retired from parliament. He died in Albemarle-street, London, July 8th, 1855.

LOCHMABEN. [Dumfriesshire.]

LOCHWINNOCH. [Renfrewshire.]

LOCKER, EDWARD HAWKE, was the son of Admiral Locker, to whom Nelson, soon after the battle of the Nile, thus wrote: "You, my old friend, after twenty-seven years' acquaintance, know that nothing can alter my attachment and gratitude to you. I have been your scholar. It is you who taught me to board a French man-of-war by your conduct when in the Experiment. It is you who always said, 'Lay a Frenchman close and you will beat him;' and my only merit in my profession is being a good scholar." The son, Edward Hawke Locker, was born at East Malling, Kent, on the 9th of October 1777. He was educated at Eton, which he left in 1795, and received an appointment in the Navy Pay Office. He remained in government offices till 1800, when he went to India as private secretary to Lord Exmouth. From that time till the peace of 1814, he was associated with that distinguished commander in arduous and confidential duties, especially as secretary to the Mediterranean fleet; duties which he discharged with eminent ability. In his official capacity he visited Napoleon at Elba in May 1814; of which visit he published an interesting narrative after the death of the ex-emperor. In 1815 Mr. Locker married the daughter of an eminent antiquary and philologist, the Rev. Jonathan Boucher, the author of a 'Provincial Glossary,' the publication of which from the posthumous manuscript commenced in 1832, but which has not been continued beyond the letter B. Mr. Locker resided at Windsor from 1815 to 1819, when he was appointed secretary to Greenwich Hospital. During his residence at Windsor his attention was called to an article in 'The Windsor Express,' in which was pointed out the deplorable want of books adapted to the large class who had learnt to read under the new system of education in National and other schools. Mr. Locker sought the acquaintance of the writer of that article, Mr. Charles Knight, then the editor of the Windsor paper; and they together projected and jointly edited 'The Plain Englishman,' almost the first, if not the very first of any literary pretension, of those cheap and popular miscellanies which the growing ability of the great bulk of the people to read imperatively demanded, in the place of mischievous or childish tracts. Some very eminent friends of sound education, such as the present Archbishop of Canterbury, were among its contributors. Mr. Locker's own papers in the miscellany are excellent models of popular writing—plain, energetic, affectionate. His 'Lectures on the Bible and Liturgy,' which have been reprinted in a separate volume; 'Lectures delivered to the Crew of the Caledonia, Lord Exmouth's flagship,' are admirable examples of clear exposition and earnest exhortation. Mr. Locker, after filling for several years the important duties of secretary to Greenwich Hospital, became the Resident Civil Commissioner of that great institution. The improvements which he introduced into its management were results of his active and comprehensive mind. Of these improvements the Naval Schools are striking instances. Himself an accomplished draughtsman and an ardent lover of the arts, he founded the Naval Gallery at Greenwich by his judicious exertions. In 1844 Mr. Locker's health so failed that he gave up his valuable appointment and retired upon a small pension, his fine faculties overclouded beyond the hope of recovery. Mr. Locker was the intimate friend of many distinguished men amongst his contemporaries. To use Mr. Lockhart's expression, he was "an old and dear friend of Scott's." He died on the 15th of October 1849.

LOCKERBIE. [Dumfriesshire.]

LOCKHART, JOHN GIBSON, was born in 1794 at the manse of Cambusnethan, in Lanarkshire, Scotland; his father, who was of an old Lanarkshire family, being then minister of the parish of Cambusnethan, in connection with the Established, or Presbyterian, Church of Scotland. His mother was related to the celebrated family of the Erskines. When Lockhart was two years of age, his father removed from Cambusnethan to become one of the city clergymen of Glasgow; and here Lockhart was educated. His talents were shown during his course at the Glasgow University; at the end of which, while still only in his sixteenth year, he obtained, by the unanimous voice of the professors, the Snell exhibition to Balliol College, Oxford—a college at which, either on the same exhibition or otherwise, many eminent Scotchmen have been trained. In 1813 he took honours as a first-class man in classics; and in 1817 he graduated B. C. L. at the university—a degree exchanged for the higher one of D. C. L. in 1834. After residing some time in Germany, and acquiring the language and seeing much of the literary society there, he settled in Edinburgh as a member of the Scottish bar in 1816. He never had much practice as a lawyer however, but from the first devoted himself to literature, as a member of the little band of young Scotch Tories, who, with Wilson as their chief, were then beginning to dispute the literary supremacy of the Scotch Whigs, as represented by Jeffrey and the 'Edinburgh Review.' When Blackwood started his magazine in 1817, Wilson and Lockhart were its chief supporters; and considerable portions of the famous 'Chaldee Manuscript' and of the earlier 'Noctes Ambrosianæ' papers were written by Lockhart, though Wilson afterwards made the magazine his own. It was in consequence of Lockhart's literary connection with 'Blackwood' and Scottish Toryism that he became acquainted with Scott, who looked with a kindly interest on the efforts of these young men of the same politics as himself. The first meeting of Scott and Lockhart took place in 1818, and from that time they were intimate friends. When Scott, from the pressure of other work, ceased to write the historical parts of the 'Edinburgh Annual Register,' he recommended Lockhart to the Ballantynes as his substitute. In 1819 Lockhart published anonymously his 'Peter's Letters to his Kinsfolk,' which gives such graphic accounts of Scottish men and manners at that time. In 1820 he married Scott's eldest daughter Sophia, and took up his abode at the cottage of Chiefswood, close to Abbotsford. Here perhaps he spent his happiest days; and few passages in Scott's 'Life' are pleasanter than those describing his walking over early in the morning to breakfast with the young couple at Chiefswood, or helping their servants on a summer afternoon, when they had a modest dinner-party, by drawing up the wine from the well into which it had been lowered to cool. This was also a prolific period in Lockhart's literary career. He wrote his translations of 'Spanish Ballads' for 'Blackwood,' afterwards published collectively; in 1821 he published anonymously his 'Valerius, a Roman Story,' in 3 vols.; this was followed in 1822 by 'Adam Blair, a Story of Scottish Life,' in 1 vol.; by 'Reginald Dalton, a Story of English University Life,' in 3 vols., 1823; and 'Matthew Wald,' in 1 vol., 1824, each showing great power in a peculiar vein; and in 1825 he wrote his 'Life of Burns,' and also a less-remembered 'Life of Napoleon,' for 'Constable's Miscellany.'

In 1826 Lockhart removed to London to succeed Gifford in the editorship of the 'Quarterly Review.' He continued to edit the 'Review' till 1853—with what success all the world knows. In his hands the 'Review' maintained and increased its reputation; and not a few of the most powerful articles that appeared in it during the seven-and-twenty years of his editorship, came from his own pen. He was particularly happy in biographical sketches, combined with criticism. One paper of this kind—that on 'Theodore Hook'—has been reprinted by itself.

On Scott's death in 1832, the task of writing his biography naturally devolved on his son-in-law Lockhart. The task was accomplished in 1837-39, when the voluminous 'Life of Scott' was given complete to the world. Those portions of the work which related to the fall of Scott's pecuniary fortunes, provoked some controversy at the time; but the work as a whole has now taken its place as one of the most interesting and admirable biographies in the language. It has been said by those who knew Lockhart, that such was his practical sagacity that, had his illustrious father-in-law had the benefit of his actual assistance in the management of his affairs, the catastrophe which ruined Scott towards the close of his life could certainly never have happened.

In 1843 Lockhart was appointed by Sir Robert Peel to the office of auditor of the Duchy of Cornwall, with a salary of 600*l.* a year; and as in addition to this and his large literary income he had inherited some family property, he was in very easy circumstances. His last years however were embittered by a series of bereavements. His eldest son, the 'Hugh Littlejohn' of the 'Tales of a Grandfather,' had died in early life; his wife died in 1837; his second and only surviving son died at a later period; and there remained only one daughter. This lady, who was also (by the death of Mrs. Lockhart's eldest brother childless in India, that of the younger brother unmarried, and that of her sister) the sole remaining descendant of Sir Walter Scott, married in 1847 James Robert Hope, Esq., barrister-at-law, and is now proprietress of Abbotsford. Along with her husband she embraced the Roman Catholic faith. She usually lives at Abbotsford, and has one child, a daughter, born in 1852. Lockhart, broken in health and spirit, lived to see his own pedigree and that of Scott centred in this child—his grand-daughter and Scott's great-grand-daughter. Gradually becoming more shattered, he resigned the editorship of the 'Review,' and went to Rome in 1853; but he returned in the spring of 1854, and retired to Scotland. He died at Abbotsford, November 25, 1854, in the sixty-first year of his age. To the last he retained something of the handsome aristocratic appearance and bearing which had distinguished him in earlier life. His manners, always reserved, had become chillingly so before his death; but those who knew him intimately, maintain that, beneath his morose and iron demeanour, his scornful smile, and his withering sarcasm, there lay a host of qualities which commanded the thorough respect and affection of those whom he did admit to his friendship, or who were related to him by blood or affinity.

LOGANIACEÆ, *Loganiads*, a natural order of Exogenous Plants, consisting of shrubs, herbaceous plants, or trees. It is characterised by having opposite entire leaves, usually without stipules, which adhere to the leaf-stalks or are combined in the form of interpetiolary sheaths. The flowers are racemose, corymbose, or solitary; the calyx valvate or imbricated, inferior 4- or 5-parted; corolla regular or irregular, 4- 5- or 10-cleft, with valvate or convolute æstivation; stamens arising from the corolla, all placed upon the same line, and not always symmetrical with the divisions of the corolla, pollen with 3 bands; ovary superior, 2-celled; ovules absent or solitary; fruit either capsular, 2-celled, with placentæ finally becoming loose or drupaceous, with 1- or 2-seeded stones, or buried with the seeds immersed in pulp; seeds sometimes winged, usually peltate, albumen fleshy or cartilaginous; embryo small, with the radicle turned towards the hilum or parallel with it. All the species are either tropical or inhabit countries near the tropics, a few in America and Australia forming the only exceptions. It would be difficult to name a more poisonous order than this, of whose qualities the celebrated *Nux vomica* may be taken as the representative. Notwithstanding the active qualities of these formidable plants, some are used in medicine with great advantage. Several of the species of *Strychnos* are used in the East as remedies for various diseases, and the seeds of *Ignatia amara*, St. Ignatius' Beans, are employed in India for cholera. *Spigelia* yields also several species which are employed for useful purposes. The order consists of 22 genera and 162 species. It is related to *Apocynaceæ*, *Gentianaceæ*, *Cinchonaceæ*, and *Rhizophoraceæ*. The uses of the species will be found under their respective heads, SPIGELIA; STRYCHNOS; &c.

LONDON PRIDE. [SAXIFRAGA.]

LONDONDERRY, CHARLES WILLIAM VANE, THIRD MARQUIS OF, K.G., G.C.B., only son of Robert, first Marquis, by his second wife, Frances, daughter of Lord Chancellor Camden, and half-brother of Robert, second Marquis [*S.* 1], was born in Dublin, May 18, 1778. Charles William Stewart was in his fifteenth year when he received his first commission as ensign in a foot regiment, and embarked under the Earl of Moira (afterwards Marquis of Hastings), to relieve the Duke of York from the perilous position in which he found himself after the reduction of Ypres and the capture of Charleroy. Having held for a few months the post of assistant quartermaster-general to a division of the forces under General Doyle, he was attached in the following year to Colonel Crawfurd's mission to the court of Vienna; and while thus occupied he received a severe wound at the battle of Donauwerth. Returning home, he became aide-de-camp to his uncle, Earl Camden, during his Lord Lieutenancy in Ireland; having gained his majority in 1796, he was made in the following year lieutenant-colonel of the 5th Dragoon Guards, and while encamped on the Curragh of Kildare, succeeded in bringing into partial discipline and order "the worst of bad regiments," which he commanded through the trying period of the Rebellion of 1798. The regiment having been subsequently disbanded for insubordination, Charles Stewart was appointed to the command of the 18th Light Dragoons, which he accompanied to Egypt under Sir Ralph Abercrombie; and in this expedition he was again severely wounded. In 1803 he became full colonel, and aide-de-camp to his Majesty, and for a short time occupied the post of under secretary of state for the war department. This post he quitted in order to accept the command of a hussar brigade under Sir John Moore in Portugal, as brigadier-general, and he did good service by covering the march of Sir John Hope's division into Spain, and the retreat of Sir John Moore, during which he successfully repulsed an attack of the French Imperial Guard. On reaching Corunna he was labouring under severe ophthalmia, and Sir John Moore, who had the highest opinion of his abilities, sent him home to report progress. In a few months however he returned to the seat of war as adjutant-general under Sir Arthur Wellesley, which post he held until May 1813. During the pursuit of Marshal Soult's army across the Douro, and again at Talavera, he rendered important services, for which he received the thanks of the House of Commons. During all this time, since the meeting of the first parliament of the United Kingdom in 1801, he had represented the county of Londonderry, and continued to do so until 1814, when he was raised to the peerage as Lord Stewart, and sworn a member of the Privy Council. In the mean time he had risen to the rank of lieutenant-general, and had received the order of the Bath, besides Portuguese, Russian, and Prussian honours, in recognition of his services not only in the field, but also in the capacity of envoy extraordinary and minister plenipotentiary at the court of Berlin, where he acted as commissioner to the allied sovereigns, and was specially charged with the supervision of Bernadotte, the Swedish king, who had armed his troops with English supplies, but was thought to be wavering in his allegiance.

The secret history of the time shows what kind of remonstrances the British envoy found it necessary to employ at so critical a moment as that which immediately preceded the battle of Leipzig. In 1814 he was appointed ambassador to Austria, and in the following year was one of the plenipotentiaries at the Congress of Vienna, together with his brother, Lord Castlereagh, the Duke of Wellington, and Lords Cathcart and Clancarty. Having been left some years a widower, in 1819 Lord Stewart married the only daughter of Sir Harry Vane Tempest, Bart.; and assumed the name and arms of Vane; and having succeeded to the marquisate on the death of his brother in 1822, was soon afterwards created Earl Vane, with remainder to his sons by his second marriage. In right of his wife he became possessed of large estates in the county of Durham, and applied himself actively to the development of their mineral and commercial resources. With this view he constructed the harbour of Seaham, a vast undertaking for private enterprise, and one which will long be regarded as a wondrous achievement of engineering science.

After this time the marquis never accepted any public office or employment, with the exception of the embassy to Russia, which he undertook during Sir Robert Peel's brief tenure of office in 1834-35, but relinquished before proceeding to his destination. In 1837 he obtained the rank of general, and became colonel of the 2nd Life Guards in 1843. In 1852 the Earl of Derby bestowed on him the Garter vacated by the death of the Duke of Wellington. His lordship was the author of a 'History of the Peninsular War,' published in 4to, 1808-13, and he also edited the correspondence of his brother Robert, the second Marquis, which he published in 1850. During upwards of half a century Lord Londonderry advocated in the Upper and Lower House the strongest Tory principles, and not always in the way best calculated to disarm opposition. He died at Holdernesse House, London, March 1, 1854, from an attack of influenza, and was buried at Long Newton, near Wynyard Park, his princely seat in the county of Durham. He was succeeded in the marquisate and the Irish estates by his eldest son William Robert, who represented the county of Down for many years as Viscount Castlereagh; the earldom of Vane and his English property passed to the eldest son of his second marriage, George, Viscount Seaham, M.P. for the northern division of the county of Durham.

LONGNOR. [STAFFORDSHIRE.]

LONGTOWN. [CUMBERLAND.]

LOOSESTRIFE. [LYTHRUM, *S.* 1.]

LOPHINE. [CHEMISTRY, *S.* 2.]

LOTA, a genus of Subbrachial Malacopterygious Fishes belonging to the tribe *Gadidæ*. It is distinguished by having an elongated body, with dorsal fins and one anal fin, a chin with one or more barbules.

L. molva, the Ling, is a very valuable fish, scarcely less so than the Cod. Large quantities are taken among the Western Islands, the Orkneys, on the Yorkshire coast, and the Scilly Islands; and may be traced nearly all round the Irish coast. The fishing for them is by hand-lines and long-lines; and besides a portion that is consumed fresh, the fish are split from head to tail, cleaned, salted in brine, washed, and dried, but the demand generally falls short of the quantity cured, and the hardy fishermen are but poorly requited. The ports of Spain are the markets supplied; and so valuable an article of commerce was Ling considered formerly that an Act for regulating the price of Ling, Cod, &c., was passed as early as the reign of Edward III. The air-bladders, popularly called Sounds, are prepared separately, and with those of the Cod-Fish are sold pickled. The roes, which are of large size, are also used as food, or preserved in brine are sold to be used for attracting fish. The liver produces oil, which is used by the poor to supply the cottage lamp, also as a medicine. In Zetland the principal fishing for Ling is from May to August. On the Yorkshire coast the young are called Drizzles. In Cornwall they are caught in January and February, and their favourite haunts are about the margins of the rocky valleys of the ocean.

The Ling is exceedingly prolific, and has a most voracious appetite, feeding on young fish, not sparing anything that has life, and the prey is swallowed whole, so that no great art is required to catch it. It is tenacious of life, and survives great injury. Mr. Couch says he once saw a Ling that had swallowed the usual large hook, shaft foremost, of which the point had fixed in the stomach, and as the line drew it, it turned round, entered the opposite side of the stomach and fastened the organ together in complicated folds; yet having escaped by breaking the line, it survived to swallow another hook, and was taken several days after.

The most usual length of the Ling is from three to four feet; Pennant mentions having heard of one which measured seven feet; and Mr. Couch has known them weigh 70 lbs.

The body of the Ling is slender, more elongated than that of the Hake; roundish; head flat; gape large, lower jaw shorter than the upper, with a single barbule at its extremity; teeth in the upper jaw small, and very numerous, those in the lower jaw longer and larger, forming but a single row; lateral line straight, scales small, firmly adhering to the skin; two dorsal fins of equal height, the first short, commencing near the head, not pointed as in the Hake, but with most of the rays even; second long, immediately behind the first, reaching nearly to the caudal; the posterior portion the most elevated; vent in a line with the eighth or ninth ray of the second dorsal fin; the fin immediately behind it is long, resembling the second dorsal fin, and terminating on the same line with it; caudal rounded at the extremity. The back and sides are gray, inclining to olive; sometimes cinereous without the olivaceous tint; belly silvery; ventrals white; dorsal and anal edged with white; caudal marked near the end with a transverse black bar; the extreme tip white.

L. vulgaris, the Burbolt, or Eel-Pout, is the only British species of this numerous family of fishes that lives permanently in fresh water, and prefers in this country slow running rivers; but it is neither so generally known, nor so much esteemed and encouraged, as from the goodness of its flesh it deserves. It is said to be found in various parts of the north of Europe, Siberia, Asia, and India. In this country it is rather local. It occurs in the Cam, and in some of the rivers of Norfolk and Lincolnshire. The Trent produces it, and Nottingham market is occasionally supplied with samples for sale. The Burbolt is not unlike the eel in some of its habits, concealing itself under stones, waiting and watching for its prey, which consists of aquatic insects and young fishes, under arches and near eddies, into which such small and weak animals are likely to be brought by the current of the water. It feeds principally during the night, and like the eel, is most frequently caught by trimmers and night-lines. The Burbolt is sometimes called the Coney Fish, from its habit of lurking and hiding itself in holes like a rabbit. It spawns in February and March, is very tenacious of life, and is said to have lived a considerable time in a cold and damp situation, fed on small fishes and raw meat. In this country it has been known to attain the weight of 4½ lbs., but a common weight is about 2 lbs. The flesh is firm, white, and of good flavour, and is by some considered superior to that of the eel. As the Burbolt is extremely hardy, it might be increased in any quantity, while the value of the fish would amply repay the trouble and cost of the experiment. It would thrive well and multiply in large lakes. The length of the fish is from one to two feet; the head depressed, smooth; jaws equal; chin with one barbule; the gape large, with small teeth above and below; eyes of moderate size; gill-opening large; the length of the head as compared to that of the body as one to four; the form of the body cylindrical, compressed posteriorly; the first dorsal fin is small and rounded, the second elongated, reaching nearly to the tail; both dorsal fins nearly uniform in height; ventral fins placed very forward, narrow, and pointed; the pectoral fins large and rounded; the anal fin begins on a line behind the commencement of the second dorsal fin, but ends very nearly on the same plane; the tail oval and slightly pointed; the colour of the body yellowish-brown, clouded and spotted with darker brown, and covered with a mucous secretion; the under parts lighter; the lateral line indistinct and straight; scales small; the fins partaking of the colour of the part of the body from which they emanate, those of the lower surface being much the lightest.

(Yarrell, *British Fishes*.)

LOTUS, a genus of Plants belonging to the natural order *Leguminosæ*. It has a calyx with 5 nearly equal teeth; keel ascending with a narrowed point; the wings are connivent at their upper margin; longer filaments dilated upwards; style kneed at the base, filiform, subulate; pod linear; many-seeded, 2-valved, imperfectly divided by transverse partitions.

L. corniculatus, Common Bird's-Foot Trefoil, is found in pastures and on dry banks in Great Britain. The claw of the standard is obovate, transversely vaulted; calyx-teeth straight in the bud, subulate from a triangular base, the points of the two upper ones converging; heads 5-10-flowered. The plant is glabrous or slightly hairy; stem ascending; leaflets obovate; stipules ovate; angle between the two upper calyx-teeth rounded.

L. major has the claw of the standard linear; calyx-teeth spreading like a star in the bud, subulate from a triangular base, two upper ones diverging; heads 8-12-flowered; leaflets obovate; stipules roundish ovate.

L. angustissimus is found in the south of England, near the sea. It has the claw of the standard linear: calyx-teeth straight in the bud, subulate; pod linear eight times longer than the calyx; beak straight; head about 2-flowered.

L. hispidus is found near the sea in Devonshire and Cornwall. It has the claw of the standard subulate; calyx-teeth straight in the bud, subulate; pod rugose, terete, twice as long as the calyx; beak elongate, setaceous, bent downwards; heads few-flowered; leaflets obovate-lanceolate; stipules half cordate; stem procumbent. There are many other European species of this genus, none of which are of any importance.

LOUGHOR. [GLAMORGANSHIRE.]

LOUIS PHILIPPE, King of the French, Duc d'Orléans and Chartres, and Count de Neuilly, was the eldest son of Louis Philippe Joseph, Duc d'Orléans, the Philippe Egalité of the Convention [ORLEANS, HOUSE OF], and Louise Marie de Bourbon, daughter of the Duc de Penthièvre.

Louis Philippe himself was born at Paris, October 6th, 1773. His youth was marked by many acts of benevolence, and the judicious training of Madame de Genlis was well calculated to draw out the good qualities of those who were brought up under her charge. In his infancy he bore the title of Duc de Valois and afterwards of Chartres. In 1791 the young Duc de Chartres, having been nominated to the colonelcy of the 14th regiment of dragoons, assumed the command of that corps. It is said that almost his first act of authority was the rescue from the fury of the mob of two priests, who had refused to take the oath at that time exacted by the government from all ecclesiastics. On this occasion he showed great tact and presence of mind, and he subsequently received the honour of a civic crown from the municipality of Vendôme for rescuing M. de Siret, an engineer of that place, from drowning. By these means he became popular among the French people. In August 1791 the young duke quitted Vendôme in command of his regiment for Valenciennes. Whilst he was stationed there, war was proclaimed against Austria, and in the April following he entered on his first campaign. He fought his first battle at Valmy on the 20th of September, and on the 6th of November was again engaged under Dumourier at Jenappes. At this period the Revolution was rapidly advancing to a crisis at Paris. A decree of banishment had been passed (October 1792) against the Bourbon race; and though his father, the Duc d'Orléans, had renounced his titles and had been enrolled as a citizen under the name of Philip Égalité, his son in vain attempted to dissuade him from returning to Paris, where, having been made the dupe of the revolutionary party, and having voted for the death of Louis XVI., he was dragged to the scaffold in his turn, January 21, 1793. For seven months after this date the young duke remained at his post with the army; but in the following October the Committee of Public Safety summoned before them both the Duc de Chartres, and his faithful friend Dumourier. Aware of the sanguinary character of the tribunal before which they would have to plead, they fled to the Belgian frontiers, and made their escape into the Netherlands, then in possession of Austria. The Austrian authorities gladly received the fugitives, and even offered to bestow on the duke a commission in their army; but he refused to take up arms against his country, and retired into private life. In April he set out disguised as an English traveller, on a tour through Germany, and journeyed through Liège, Aix-la-Chapelle, Cologne, and Coblenz, towards Switzerland. The resources at his command were small, and he was beset by dangers wherever he went. His sister Adelaide, known in history as Mademoiselle d'Orléans, at the same time fled the country together with Madame de Genlis, and met her brother at Zürich. The authorities of that canton, in fear of the French government, declining to harbour them, the exiles took up their abode in Zug; but being discovered, the duke placed his sister and Madame de Genlis in the convent of St. Claire, near Baumgarten, adopted the disguise of a traveller, and started on a fresh journey of danger and adventure.

His funds were nearly exhausted, when he received from M. de Montesquiou the offer of a post as professor in the college of Reichenau, close by the conflux of the Upper and the Lower Rhine. He at once offered himself for examination, and was accepted, under the assumed name of M. Chabaud, in October 1793. Here he remained eight months, during which he was engaged in lecturing on mathematics and geography. At this time he accepted the friendly offer of M. de Montesquiou of an asylum at Baumgarten, where he remained in concealment till the close of 1794. His retreat being again discovered, he next went to Hamburg, in the hope of being able to procure a passage to America; but being disappointed, he crossed over viâ Copenhagen to Norway, Sweden, and Finland, which he traversed almost entirely on foot, as far as the North Cape. Meantime the course of circumstances at Paris had changed, and the Directory became anxious to compromise matters with the Orléans family, by procuring their voluntary removal to America. For the sake of his two brothers, the Duc de Montpensier and the Comte de Beaujolais, who had been thrown into prison as dangerous subjects, and at the same time in order to procure the restoration of his mother's estates which had been confiscated, Louis Philippe (whom we shall henceforth term the Duc d'Orléans) accepted a passage to the United States, and having left the Elbe in September 1796, reached Philadelphia, where he was joined by his two brothers. The next year the three brothers spent in travelling through the western provinces of America. In the course of this excursion, the duke gained great repute for his medical skill, by lancing a vein in his arm in an attack of fever. He afterwards performed the same operation for an Indian chief; in reward for which he was allowed to pass the night upon the large rug at the feet of the wild sovereign and his relatives. Having made the acquaintance of Washington at Mount Vernon, they returned to Philadelphia, whence they proceeded to New Orleans, and thence to Havanna. Here the Spanish authorities declining to treat them with respect, or even with civility, they went on to the Bahamas, where the Duke of Kent was in command. His Royal Highness entertained them with true British cordiality, though he did not feel at liberty to grant them a passage to England in a man-of-war. Accordingly they took ship to New York, and crossing to England in a sailing packet, they landed at Falmouth in February 1800. The royal exiles were welcomed in London by the King, the Prince of Wales, Lord Grenville, the Marquis of Hastings, and the leaders of the politics and fashion of the day. An Orléans mania prevailed through London, and an invasion of France to effect the restoration of the Bourbons was even talked of. After a short time the brothers settled at Twickenham, in a house formerly occupied by General Pollock, and since known as Orléans Lodge.

The Duc de Montpensier, whose health had long been declining, died at Twickenham in May 1807, and was buried in Westminster Abbey. Soon afterwards the health of the Comte de Beaujolais failed also, and having gone to a warmer climate in obedience to the order of his physicians, accompanied by the duke his brother, he died at Malta in 1808. Being now rejoined by his sister, who for fifteen years had lived in retirement in Hungary, and by his mother, whom he met at Minorca, the Duc d'Orléans took up his residence at Palermo. It so happened that Ferdinand, king of Naples and Sicily, was dwelling in that city under the protection of the British Flag, while Murat occupied his throne in Italy. During his residence there, he gained the affections of the Princess Amelia, the second daughter of the king, to whom he was married November 25, 1809. For upwards of four years the Duc d'Orléans resided at Palermo without taking any part in the public affairs of Europe, if we except a visit which he paid to Spain in 1810, in the illusive idea that negociations commenced by the Spanish and English authorities might eventuate in an offer on their part to entrust to his hands the regency of that country.

In 1814 tidings reached Palermo of the downfall of the emperor Napoleon I., and of the intended restoration of the Bourbons. The duke returned to Paris without delay, and was re-instated in his honours and military rank. The return of Napoleon in the early part of the following year again disturbed the tenor of his life; and having sent away his family to England for safety, the duke took the command of the army in the north in obedience to the orders of Louis XVIII. Rather than endanger the peace of France by family feuds, he resigned his command in the following March, and retired to Twickenham, whence he returned to Paris after the Hundred Days, in obedience to a decree compelling the attendance of princes of the blood in the Chamber of Peers. He conciliated the popular esteem and respect by liquidating the debts of the Orléans estates, and by other politic measures. Louis Philippe, in his place in parliament, publicly protested against the extreme measures proposed by the government against those who had taken part in the revolution, and procured their rejection. Louis XVIII., who regarded him with especial jealousy, in disgust and revenge, forbade princes of the blood royal to appear in the Chamber of Peers. The Duc d'Orléans revenged himself upon the court by entering his son in one of the public colleges as a simple citizen of Paris. He returned to England, and continued to live in privacy at Twickenham during the remainder of that king's life and the first few years of the reign of Charles X. He did not return to France until 1827, when he took up his abode at the palace of Neuilly, where he continued to live in seclusion until the year 1830, when the revolution occurred which ended in his elevation to the throne as King of the French. Charles, whose weakness and duplicity were his ruin, was now in effect discrowned; and the cause of the elder branch of the Bourbons being pronounced hopeless, the struggle of the three days of July was followed by a provisional government, in which Lafitte, Lafayette, Thiers, and other politicians, took the lead. They naturally turned to the Duc d'Orléans, and in the name of the French people offered to him the crown. After a day's deliberation he accepted it, and came to Paris on the 31st of July; and, the preliminary forms having been passed through, on the 9th of August the crown was formally accepted by the Duc d'Orléans, who was proclaimed as Louis Philippe. For seventeen years he sat on his elective throne, and if an increase of the wealth and physical progress of a nation be a test, the results of his reign may be advantageously compared with those of the first empire. Peace was preserved abroad, order was maintained at home, and commerce increased steadily. His foreign policy was in like manner successful: his sons, the Duc de Némours and the Prince de Joinville, carried the French arms into Algeria; Abd-el-Kader was made a prisoner, and the Bey of Constantine forced to sue for peace, after a spirited resistance, and Algiers became a French military colony. Yet the king was not popular at home. He was hated alike by the Legitimist party, in whose eyes he was but a usurper, and by the revolutionists, who sighed for entire emancipation from kingly rule. Besides, there are deep and dark stains upon the reign of the 'Napoleon of Peace,' as Louis Philippe liked to be called. His reign was a period of corruption in high places, of jealousy and illiberal restriction towards his own subjects, of a fraudulent and heartless policy towards the allies of his country, whose goodwill he more especially forfeited by his over-reaching conduct in regard to the marriage of the Duc de Montpensier to a Spanish princess. And thus it came to pass that the heart of the nation became alienated from their king; and when a trifling disturbance in February 1848 was aggravated into a popular riot through the audacity of a few ultra-republicans, Louis Philippe felt that he stood alone and unsupported as a constitutional king, both at home and abroad, and that the soldiery were his only means of defence. He shrunk from employing their bayonets against his people: he fell in consequence, and his house fell with him. The king fled in disguise from Paris to the coast of Normandy, and taking ship again found a safe refuge on the shores of England, to which his family had already made their escape. He landed at Newhaven, March 3rd, 1848. The Queen of England—who, in 1843, had enjoyed the hospitality of Louis Philippe at the Château d'Eu, his royal residence near Dieppe, and who had entertained him in the following year at Windsor, and conferred on him the order of the Garter—immediately assigned Claremont, near Esher, as a residence for himself and his exiled family. From the time of his arrival in England, his health began visibly to decline, and he died on the 26th of August 1850, in the presence of Queen Amelie and his family, having dictated to them the conclusion of his memoirs, and having received the last rites and sacraments of the Church at the hands of his chaplain. He was buried on the following 2nd of September at the Roman Catholic chapel at Weybridge, Surrey, and an inscription was placed upon his coffin, stating that his ashes remain there, "donec Deo adjuvante in patriam avitos inter cineres transferantur."

LOVAGE. [Haloscias, *S.* 2.]

LOWESTOFFE, or LOWESTOFT. [Suffolk.]

LOXOCLASE, a Mineral belonging to the anhydrous silicates of Alumina. It has nearly the form of Felspar, but is distinguished by a cleavage parallel with the longer diagonal. It contains 8 per cent. of soda and 3 per cent. of potash. It is found at Hammond, in the state of New York, in company with Pyroxene, Graphite, and Calcspar.

LOYDIA, or LLOYDIA, a genus of Plants belonging to the natural order *Liliaceæ*. The perianth is persistent and patent; stamens inserted at the base of the perianth; anthers erect; style filiform; stigma trigonous; seeds angular above, flat beneath.

L. serotina is a native of Welsh mountains. It is a rare plant, but is found on Mount Snowdon. The root-leaves are semi-cylindrical; stem-leaves dilated below and sheathing; flowers mostly solitary, nectary a transverse plait. The height of the plant is 5 or 6 inches. Stem and leaves springing separately from the root; stem-leaves several, short; flowers white, with reddish lines internally.

LUCANIA, a province of ancient Italy, bounded N. by the Silarus, the Apennines, and the Bradanus, which separate it from Campania, Samnium, and Apulia respectively; E. by the Gulf of Tarentum, along which it extended to the mouth of the Crathis; S. by Bruttium; and W. by the Tyrrhene Sea, between the mouths of the Laus and Silarus. The territory of Lucania is now comprised chiefly in the modern province of Basilicata; portions of it are included in Calabria and Principato Citra. Under these heads the physical geography of the country is given, and many particulars respecting its ancient towns. The rivers that fall into the Gulf of Tarentum between the Bradanus and the Crathis were—proceeding from the north, the Casuentus, the Acalandrus, the Aciris, the Siris, and the Sybaris. These rivers rise in the mountains that cover all the interior of the province, and run generally in the direction of east by south across a very fertile plain, which skirts the shore of the Tarentine Bay. Along this shore were several celebrated cities founded by early Greek colonies; Metapontum, between the mouths of the Bradanus and the Casuentus; Heracleia, near the mouth of the Aciris and on its right bank; a little higher up the right bank was Pandosia; Siris, near the mouth of the Siris and on its left bank; Sybaris, near the mouth of the Sybaris; and Thurii, a few miles higher up, in the plain between the Crathis and the Sybaris. On the coast of the Tyrrhene Sea were Paestum, a few miles south of the Silarus, and Elea, or Velia, further south, on the Bay of Elea, and a few miles north of the promontory of Palinurus.

Heracleia, founded about B.C. 432 by the inhabitants of Thurii and Siris, was the place of meeting of the Italian Greeks till its capture by Alexander, king of Epirus, who transferred the meetings to Thurii. The city early rose to prosperity, and was in close alliance with Tarentum against the Lucanians and Messapians. The first engagement between Pyrrhus and the Romans took place in the plain between Heracleia and Siris B.C. 280, and ended in the total defeat of the latter. Two years afterwards the Heracleiots entered into alliance with Rome, and it continued to be a flourishing city under Roman sway till the time of the empire. The date of its final extinction is unknown. Its site is marked by mounds of rubbish and the foundations of ancient buildings near the farm of Policoro, which is marked on some maps near the mouth and on the right bank of the Agri. Many coins, bronzes, and other antiquities have been found on the site, and at a short distance were discovered the two very interesting bronze tables called Tabulæ Heraclëenses, which contain a Latin inscription relating to the municipal regulations of the city. On the back is a long Greek inscription of earlier date and of much less interest. The coins of Heracleia are beautiful masterpieces of ancient art. Zeuxis the painter, it is said, was a native of Heracleia.

LUCAS, FREDERICK, was the second son of Samuel H. Lucas, Esq., of Croham, near Croydon, Surrey, a member of the Society of Friends. He was born in 1812, and was educated at the London University, where he gained early distinction as a debater. He was called to the bar in 1838, and in the following year became a member of the Roman Catholic Church. In his new position he took an active part in public matters, and became the founder of the 'Tablet' newspaper, which he conducted as editor for many years. He was also a frequent contributor to the 'Dublin Review.' In 1849 he transferred the 'Tablet' from London to Dublin, and in 1852 was elected M.P. for Meath, mainly through the influence of the Roman Catholic priesthood, whose cause, and that of the poorer classes of the land of his adoption, he warmly espoused. Believing that the Roman Catholic priesthood, under the existing circumstances of the country, were the natural friends and guides of the lower orders, he very warmly and zealously advocated their right to take part in political affairs. In this view be was not supported by the Roman Catholic episcopate in Ireland; and towards the close of 1854 he travelled to Rome, in order to appeal to the pope against the decision of that body. His health, which had long been failing from over exertion of his mental and physical energies, broke down while the matter was under deliberation at Rome, and Mr. Lucas returned to England and died before a formal decision was given. His death occurred on the 22nd of October, 1855. He was a powerful but declamatory writer and speaker; but he succeeded from the first in securing the respect and attention of the House of Commons, and his able and fearless advocacy of Tenant Right, and of the independence of the Roman Catholic Church in Ireland, made his loss much regretted by his party.

LUDGERSHALL. [Wiltshire.]

LUFFA, a genus of Plants belonging to the natural order *Cucurbitaceæ*. The male flowers are panicled and yellow; the tube of the calyx hemispherical, segments longer than the tube; petals distinct, dropping off by the base; stamens 5, distinct; anthers very wavy. The female flowers are solitary; the tube of the calyx oblong, clavate, segments shorter than the tube; stamens abortive; stigmas reniform; gourd ovate, 3-celled, fibrous, internally operculate.

L. amara is found in hedges and dry uncultivated places in the East Indies. It has several stems, slender, running to a great extent, but with few branches, pretty smooth, 5-sided; tendrils 3-cleft: leaves slightly 5-7-lobed, rough; stipules axillary, solitary, cordate, with glandular marks on one side. Male flowers pretty large, yellow, on long erect axillary racemes; the pedicels with a glandular bract near the base, and articulated a little above it. Female flowers rather larger, axillary, solitary, pedunculated; fruit oblong, 3 or 4 inches long, and 1 inch in diameter, tapering equally towards each end, 10-angled; when ripe dry, gray, and filled with dry fibres; the operculum deciduous; seeds blackish-gray, with elevated minute black dots; every part is extremely bitter. The fruit is violently cathartic and emetic; the juice of the roasted young fruit is applied to the temples to cure headache by the natives of India; the ripe seeds are used either in infusion or substance by them to vomit and purge.

L. Bindaal is a native of Hindnstan. It is a climbing diœcious plant; the leaves are toothed and 5-angled. Male flowers in racemes. Female flowers solitary; fruit round, echinate, with long, straight, ciliate bristles. It is considered in northern India a powerful drastic in cases of dropsy. The leaves of *L. acutangula* are a favourite potherb of the natives of India, and are esteemed very wholesome.

LUG-WORM. [ARENICOLA, *S.* 2.]

LUMINOSITY OF ORGANIC BEINGS. Organic bodies under certain circnmstances become luminous, and upon the supposition that this appearance depends on the combustion of phosphorus at a low temperatnre, the phenomenon has been called phosphorescence. This lnminosity is very constantly developed nnder the same circnmstances in both animals and plants. It is observed both dnring the decomposition of the bodies of plants and animals as well as whilst they are still living. The oldest observations on this subject were made on the wood of trees whilst in a state of decay. This however takes place only nnder peculiar circumstances. It generally occnrs when the wood of trees is buried in the earth whilst they are in a green state, and does not take place when wood is allowed to decompose in the usnal way and in free contact with the air. It is also fonnd that the phosphorescence does not take place when the wood is allowed to decompose in a damp place. Wood exhibiting this property will retain it for a long period when kept in a dry place. Albrecht observed lnminosity in a tree dnring the night at a spot where one of its branches had been torn off. Decaying fungi have been often observed to emit this light. Travellers in tropical climates have observed that when plants containing a milky juice are wonnded, the juice frequently becomes lnminons, whilst it is descending the sides of the tree. The cause of this phenomenon in decaying plants is probably owing to a slow decomposition of the tissnes attended with a union of oxygen gas, but what determines the development of light under these more than other circumstances is still nnknown.

In living plants lnminosity has been freqnently observed. It is most constant amongst some forms of fungi, especially of the genns *Rhizomorphæ*. In the coal-mines in the vicinity of Dresden the species of *Rhizomorphæ* are so numerous as to "dazzle the eye by the hrilliant light they afford." [BYSSACEÆ, *S.* 1.] The light from decaying wood, as also from the living *Rhizomorphæ*, continnes although they are immersed in irrespirable gases, linseed oil, phosphoric acid gas, oxygen, &c. The phenomenon in both the living and the dead plants is probably dne to the same cause.

Another class of plants in which light has been observed is the Mosses. Several species of the genus *Schistostega*, which grow in caverns and other damp places, have been observed to give ont light. Mr. Babington and other botanists have observed it in this conntry in the *S. pennata;* whilst Funk, Brandenbnrg, Nees von Esenbeck, Hornschnche, Struve, Unger, Bridel-Briderei, and Agardh, have observed it on the continent of Europe. The two latter attributed this light to a small alga, which Bridel-Briderei called *Catoptridium smaragdinum*, and Agardh called *Protococcus smaragdinus*, which they supposed was parasitic on the moss. Unger however has examined the moss accurately, and finds that at certain seasons the utricles of this moss assnme a globular form, and being partly transparent, the light is refracted and reflected in snch a way as to present a luminosity on the snrface of the vesicles.

Another class of these phenomena is that which is exhibited by the flowers of some plants. The first observation on this subject was recorded hy Linnæns, and made by his danghter Christina Linnè. She was walking in the garden one hot snmmer's evening, when she observed the flowers of *Tropæolum majus* to give forth a stream of light. This was attributed by many to an optical illnsion, bnt the fact has since been repeatedly observed on this as well as other plants. We are not perhaps in a position to say this was not an optical illnsion; but if it was, one would expect that it should be more constant. It has also been seen by several observers at the same time in different positions, and when one has seen it, the others have seen it also. A correspondent of the 'Gardeners' Chronicle,' October, 1843, says, "I have freqnently observed the luminons appearance of garden plants, and have looked for it in each succeeding summer on the donble marigold, and more especially on the *Papaver pilosum*, the hairy red poppy, in my garden in Worcestershire. In the evening after a hot dry day, the flashes of light have afforded much amusement to myself and others." It is to this phenomenon that Coleridge allndes in the following lines:—

> "'Tis said on summer's evening hour
> Flashes the golden-colour'd flower
> A fair electric flame."

Decaying animal bodies freqnently emit a luminous appearance, which has generally been attribnted to the presence of phosphate of lime in their skeletons, which become decomposed and yield phosphorus when exposed to the action of organic compounds in a state of decomposition. It is to this canse that the luminosity of pntrefying fish is attribnted. But the emission of light is a very constant phenomenon of many of the invertebrate animals nnder peculiar circnmstances. Thns dnring warm weather, when a vessel passes throngh the ocean, the waves frequently exhibit a diffused lustre with here and there streaks and stars of a brighter light. This occurs in our own climate, hnt the phosphorescence is mnch more brilliant in tropical seas. Pöppig, in his 'Reise in Chili, Peru, und auf dem Amazonstrome,' describes this phenomenon in an equatorial sea. "Whilst one side of the vessel is still illnminated by the last fading rays of the evening snn, and the opposite side darkened by the shade of the sails, the sea in this direction already becomes brilliant. One spot after another begins to be illnminated, indistinct stripes of light commence glimmering from greater depths, till at last, with the approach of night, a new creation seems to be called into existence. These illnminated beings move in various directions, sometimes appearing like sparks, sometimes like a radiating ball of fire, at others darting throngh the dark surface of the water like a rapid flash of lightning. A great nnmber of these beings are undoubtedly true night-animals which conceal themselves during daylight in the dark depths of the ocean."

These lights in the sea are principally prodnced by various species of the family *Acalephæ*. [ACALEPHÆ; PULMOGRADA.] The light emitted by these animals seems to be due to the secretions on the snrface of their bodies, for when this secretion is removed it retains for some hours its lnminous character, and will even impart it to milk or water. Bnt this property is not confined to the *Acalephæ*. Many species of *Polypifera*, some of the *Echinodermata*, and the lower forms of *Mollusca* also exhibit this appearance. Some few of the *Crustacea* and even Fishes have been observed to possess the same property.

Amongst insects this phenomenon is not uncommon. Those which possess the greatest luminous power belong to the *Coleoptera*, the Beetle-Tribe, and of these the two families represented by the Fire-Fly—the *Elateridæ*, and the Glow-Worm—the *Lampyridæ*, are the most distingnished. [ELATERIDÆ; LAMPYRIDÆ.] Some of the species of the tribes of *Myriapoda* and *Annelida* give out light occasionally, as the Centipede and the common Earth-Worm.

(Meyen, *Pflanzen-Physiologie*, band ii.; Carpenter, *Animal Physiology;* Lankester, in *Gardeners' Chronicle*, 1843.)

LUNACY. The statntes mentioned under this head [LUNACY, *S.* 1, p. 233] have been to some extent repealed, and their administrative provisions have been consolidated and amended by the Lunacy Regulation Act, 1853, 16 & 17 Vict. c. 70, hy which the proceedings of the Conrt of Chancery in the care and cnstody of lunatics are now regulated. The Lords Jnstices of the Conrt of Appeal in Chancery have the same jnrisdiction in matters of lunacy as the Lord Chancellor, and by them indeed are proceedings in such matters now usnally disposed of.

LUNACY (SCOTLAND). The previous statntes regulating the care and treatment of lunatics in Scotland are repealed, and the whole law on this subject consolidated and amended by the statute 20 & 21 Vict. c. 71.

LUNGS. The development of the lungs has been recently investigated, and the following is Kölliker's summary of what is known:—

"In the *Mammalia* the lungs appear a little after the liver, in the form of two hollow protrusions of the anterior wall of the pharynx, which are in close apposition, and soon become furnished with a common peduncle—the rndiment of the larynx and trachea—and in the composition of which the epithelial tube and the fibrous membrane of the intestine take an equal share. In the further conrse of development there springs from the extremities of the original protrusions a continually-increasing nnmber of arborescent processes, which differ entirely in what may be observed in most other glands. From their first formation they are always hollow, and in the sixth month the air-cells are developed from their invariably clavate dilated extremities. During this growth of the glandular elements the interior epithelium extends itself by spontaneous multiplication of its cylindrical cells (probably by division), whilst at the same time the fibrous layer surrounding them also grows, and finally constitutes the fibrous membrane of the bronchiæ and air-cells, together with the vessels and nerves. In the second month in the human embryo, the large pulmonary lobes are already formed; and besides them smaller divisions also, 0·16‴ in size, may be recognised, originating in the dilated extremities of the bronchiæ, which even at this time are considerably ramified. As development proceeds, and the ramifications of the bronchiæ are multiplied, these gland-granules, as they are termed, become more and more numerous, and ultimately, in the fifth month, are aggregated so as to form smaller lobules of 0·24‴—0·48‴ in size, each of which in all probability is produced from a single gland-granule, or bronchial termination, of the second month. Each of the gland-granules of these lobules, which correspond with the secondary lobules of the future lung, by continued budding, finally constitutes a primary lobule, which, with air-cells of 0·025‴—0·03‴ in size, first becomes distinctly visible in the sixth month, although up to the time of birth new alveoli are constantly superadded. In the new-born child the secondary lobules measure 2‴—3‴—4‴; the alveoli, before they are filled with air, 0·03‴, and after the first inspiration, 0·03‴—0·04‴—0·06‴; the latter at this time appear to exist in the same number as in the adult, the further increase of the lungs proceeding only from the expansion of all its parts.

"The investigation of the lungs," continue the translators of Kölliker, "presents no real difficulty, except in one point; that is, with respect to the relation of the pulmonary cells to the terminations of the bronchiæ; but here the difficulties are very considerable. In recent preparations it is obvious that the air-cells communicate in many ways, and in any case that they are not merely terminal on the extremities of the bronchiæ. If it be desired to investigate the whole subject, inflated and dried lungs (it is better in an inflated lung to tie off an end and dry it by itself), or corroded preparations, or lungs injected with uncoloured substances (wax and resin), are most suitable; and with such a definite result will be obtained, after a series of observations. Before the injection of the bronchiæ is proceeded with the air must be exhausted in the air-pump, for which purpose also, though less conveniently, a well-fitting syringe may be employed. The injection of the blood-vessels is readily effected, and the preparation should be kept wet; sometimes when injected with opaque material, sometimes following the processes of Schröder and Harting, with transparent substances (Prussian blue, &c.), dried preparations are to be preferred. The air-cells and bronchiæ, the larynx and trachea, are readily examined. The epithelium of the air-cells is obtained in large quantities in every section through the lung, as well as ciliated cells. If it be wished to study the alveoli, the air must previously be carefully removed. These are best displayed in man, in whom also all other parts, such as cartilage, elastic elements, muscles, and glands, are easily obtainable."

(Kölliker, *Manual of Human Histology*, translated for the Sydenham Society by Busk and Huxley.)

LUTEOLINE. [CHEMISTRY, *S.* 2.]

LYCIUM, a genus of Plants belonging to the natural order *Solanaceæ*. It has an urceolate calyx regularly 5-toothed, or irregularly 3-5-cleft; permanent corolla funnel-shaped or tubular; limb 5- or 10-cleft, or toothed, imbricate in æstivation, sometimes plicate; stamens 5, usually exserted; filaments banded and widened at the base; stigma peltately depressed, or capitate, bisulcate; berry roundish, 2-celled, propped by the permanent calyx; placentas adnate; seeds numerous, reniform. The species are trees or shrubs usually spinose. Corollas white, yellow, rose-coloured, purple, blue, or scarlet.

L. Europæum has erect loose branches; buds spinescent; leaves fascicled, obovate, lanceolate, obtuse, or spathulate, bent obliquely; flowers twin or solitary; corolla funnel-shaped; stamens exserted, but shorter than the limb. It is a native of the south of Europe and the north of Africa: in the Grecian islands common in hedges, but scarcely indigenous. The calyx is 5-cleft, ruptured at the side: the corollas pale violet, reticulated with red veins; tube greenish. Clusius says that the young shoots are eaten in Spain with oil and vinegar.

L. barbarum has dependent branches; buds spiny; leaves lanceolate, flat, glabrous, acute; flowers twin, extra-axillary, pedicellate; corolla funnel-shaped; stamens exserted, about equal in length to the limb. It is a native of the north of Asia, Africa, and south of Europe. There is a variety having pale corollas and yellowish red berries.

There are about 30 species of this genus described, many of which are to be found in our gardens. They are commonly known by the name of Box-Thorn.

LYCOPODIUM, a genus of Plants belonging to the natural order *Lycopodiaceæ*. It has 1-celled 2-valved capsules, containing powder, or 3-valved, containing 1 to 4 granules.

L. clavatum, Common Club-Moss, has scattered leaves, incurved, with a filamentous point; spikes stalked 2 or 3 together, cylindrical; scales ovate, triangular, membranous, finely incised, serrated. The stem is prostrate and long; branches short and ascending; spikes on long stalks, pale-yellow; scales on the stalks irregularly disposed in whorls. The powder contained in the spore-cases is highly inflammable: shaken out and collected it is employed under the name of Lycopode, or Vegetable Brimstone, on the Continent, in the manufacture of fire-works, and in pharmacy to roll up pills, which when coated may be put in water without being moistened. The plant has long been used as an emetic; a decoction of it is said to be serviceable in removing Plica Polonica.

L. annotinum has scattered lanceolate leaves; spikes sessile, solitary, terminal; scales roundish, with an alternated point, membranous, and jagged. The branches are rather long and erect, each year's growth is marked by a spot where the leaves are adpressed. The spikes are cylindrical, greenish-yellow, not persistent. It is found on stony mountains in Cumberland and Caernarvonshire, and is common in the Highlands of Scotland.

L. alpinum, Savin-Leaved Club-Moss, has leaves in four rows, imbricated, acute, keeled, entire; spikes sessile; solitary, terminal; scales ovate-lanceolate, flat; branches erect, clustered, forked, level-topped. The stem is prostrate and long. Fertile branches, usually twice dichotomous, each division ending in a short cylindrical yellowish-green spike, rather thicker than the branch. It is found on elevated mountains in Great Britain.

L. Selago, Fir Club-Moss, has leaves in eight rows, crowded, uniform, linear-lanceolate, acuminate; capsules not spiked, but in the axils of the common leaves; stem erect, forked, level-topped. The stem is short, erect, or slightly decumbent, densely leafy. Occasionally in sheltered positions the stem becomes elongated. In the Highlands of Scotland it is made into an irritating ointment, which is applied with advantage to the neighbourhood of the eyes as a counter irritant. Internally administered it acts as an emetic and cathartic. Linnæus says the Swedes find the decoction serviceable as a detergent lotion, and in destroying the vermin that infest cattle.

L. inundatum and *L. selaginoides* are the other British species, both found in boggy places. The most remarkable species is the *L. rubrum* of Chamisso, *Yatum condenado*, Great Devil. Sir William Hooker, who calls it *L. catharticum*, states that it acts most violently as a purgative, and has been administered successfully in Spanish America in cases of elephantiasis. According to Vastring, Club-Mosses are likely to become of importance in dyeing: he asserts that woollen cloths boiled with Lycopodiums, especially with *L. clavatum*, acquire the property of becoming blue when passed through a bath of Brazil-Wood. *L. phlegmaria* is reputed an aphrodisiac. *L. squamatum* is remarkable for its hygrometrical properties, rolling up into a ball when dry, and expanding when moisture is applied.

(Balfour, *Classbook of Botany*; Babington, *Manual of British Botany*; Lindley, *Vegetable Kingdom*.)

LYCOPSIS, a genus of Plants belonging to the natural order *Boraginaceæ* and the tribe *Anchuseæ*, which have their 4 nuts placed on a hypogynous disc, with an excavated space surmounted by a tumid ring at their base.

Lycopsis has the calyx in 5 deep segments; the tube of the corolla curved; the limb oblique. The species closely resemble those of *Anchusa*, except in the above characters.

L. arvensis, the Bugloss, has lanceolate erose-dentate very hispid leaves; the calyx of the fruit is bell-shaped, erect. The flowers are small and blue. The whole plant is very hispid, with strong hairs, each rising from a scaly tubercule. It is common in the fields and hedges of Great Britain and Europe.

LYCOPUS, a genus of Plants belonging to the natural order *Labiatæ*. It has a 4-fid corolla, scarcely longer than the equal 5-toothed calyx; stamens 2; anther-cells parallel or ultimately divergent; 2 upper stamens wanting, or rudimentary, or rarely perfect.

L. Europæus inhabits wet ditches and sides of ponds, and is known popularly under the name of Gipsey-Wort, because gipsies are said to stain their skins with its juice. It has stalked ovate-oblong leaves, glabrous or pubescent, opposite. Flowers small, in dense whorls. It is found on banks of streams and ditches in Great Britain.

LYDD. [KENT.]

M

MAAS, or MAES, NICOLAS, a celebrated Dutch painter, was born at Dort in 1632. He was a scholar of Rembrandt, whose manner he imitated with so much skill that it was thought difficult to distinguish the works of the pupil from those of the master. But a visit to Antwerp, where he diligently studied the productions of Rubens and Jordaens, led Maas to adopt a new and more independent style; and one in which, while retaining his former neatness and delicacy of touch, and breadth of chiaroscuro, there was more freedom of handling and variety of colour. His early celebrity was acquired by his genre pictures, chiefly domestic interiors, but he eventually devoted himself to portrait painting, especially after his removal to Amsterdam, where he settled in 1678; and where he rose into high reputation as a portrait painter, and acquired a considerable fortune by the practice of that lucrative branch of art. He died at Amsterdam in 1693. Bartsch mentions several plates etched by him. In the National Gallery there are three paintings by him—like most of his genre pictures, of small size, but elaborately finished—'The Cradle,' 'The Dutch Housewife,' and 'The Idle Servant.'

MACDIARMID, JOHN, was born about 1789 in Edinburgh, where he received his early education, partly at the common schools and partly at the university. He began his career as a clerk in a manufacturing establishment, whence he removed to the Commercial Bank, where for a few years he discharged highly responsible duties. While so engaged he ceased not to pay attention to his literary studies, was occasionally amanuensis to Professor Playfair, contributed poetry to the 'Scots Magazine,' and was an active member of a debating society called the 'Forum.' In January 1817 he became editor of the 'Dumfries Courier,' of which he afterwards became the proprietor. It was in this position that Mr. MacDiarmid chiefly distinguished himself. He raised the character of the provincial press by introducing originality and taste into the conduct of it, his newspaper becoming highly successful, and a model for others. Mr. MacDiarmid had a partiality for natural history, and he was accustomed to observe and record the abnormal specimens which occurred; but though a laugh was sometimes raised at his accounts of enormous gooseberries or marvellous turnips, it is not known that he ever wilfully exaggerated. In addition, he drew attention to the antiquities and natural beauties of Dumfriesshire, and the adjacent counties of Kircudbright and Wigton, not only in the newspaper, but by separate publications, 'The History of Dumfries,' the 'Guide to Moffat,' &c. His other works were— a 'Life of Cowper,' published in 1817; a 'Life of William Nicholson, the Galloway Poet;' 'Sketches of Nature,' 'The Scrap-Book,' &c. After conducting the paper with extraordinary vigour and fertility, he died on November 12, 1852.

MACGILLIVRAY, WILLIAM, a distinguished Scotch naturalist. He was born in the Isle of Harris, and early acquired a taste for natural history, and having gone to reside in Edinburgh, became the assistant of Professor Jameson in the Natural History and Geological Museum of the University. He was afterwards appointed to the position of Conservator of the Museum of the Royal College of Surgeons in Edinburgh. In these positions he had extensive opportunities of studying the specimens and preparations which were committed to his charge, and he seems to have neglected none of the rare opportunities which presented themselves for adding to his store of knowledge. He did not however confine himself to the museum, for he was in the strict sense of the word a lover of nature, and studied natural history extensively in the field. Nor did he confine himself to one department—minerals, plants, and animals, all laid claim to his attention, and he possessed a sufficient knowledge of each to make considerable contributions to the branches of science which contemplate their study. On account of his extensive knowledge of natural history the University of Aberdeen bestowed upon him the degree of LL.D., and subsequently he was appointed Professor of Civil and Natural History in Mariscbal College, Aberdeen. Here he cultivated natural history with great ardour, and wrote some of his most valuable works. He died at Aberdeen on the 5th of September, 1852.

Dr. Macgillivray published various papers on natural history subjects in the 'Memoirs of the Wernerian Society,' the 'Edinburgh New Philosophical Journal,' the 'Reports of the British Association,' and the 'Magazine of Zoology and Botany.' He was also the author of several substantive works of great value.

His labours in botany were not so extensive as in other departments of natural history; he nevertheless edited an edition of Withering's 'Arrangement of British Plants,' and published several lists of plants illustrative of the distribution of the British species.

His geological papers were numerous, and he published in 1839 'A Manual of Geology, with a Glossary and Index.'

Of his various works on zoology, his 'History of British Birds,' in three volumes, two of which were published after his death, is undoubtedly the most important. In this work he has displayed great power of observation, with a skill in the description of the habits of birds quite unrivalled. This work is illustrated with sketches drawn by the author, which display very considerable artistic skill. He is also the author of a 'History of British Quadrupeds,' in Jardine's 'Naturalist's Library.' In 1843 he published a 'History of the Molluscous Animals of the counties of Aberdeen, Kincardine, and Banff.' He also produced a 'Conchologist's Text-Book,' which has gone through a large number of editions.

At the time of his death he had prepared for the press a volume on the 'Natural History of Dee-Side,' which consisted of an account of a personal tour up the valley and among the mountains of Dee-Side. It also contained sketches of the geology, botany, and zoology of the district, with lists of the minerals, plants, and animals of Dee-Side. As this work could hardly be expected to meet with a remunerative sale the family declined to publish it, and the existence of the manuscript having been made known to the Queen of England she generously purchased it of the family, and the work has since been published by her Majesty's command. It forms a handsome octavo volume, illustrated with several woodcuts of the scenery of the district, and contains a carefully executed map of the district of the river Dee, in which the geology of the valley and mountains is laid down. This work was printed for private circulation, and was very liberally presented to the naturalists, natural history societies, and public libraries of Great Britain by His Royal Highness Prince Albert.

Dr. Macgillivray left behind him a large family. His eldest son, Mr. John Macgillivray, accompanied Captain Stanley in the voyage of the Rattlesnake, and published an account of the voyage on his return. He has also published several papers on various departments of natural history.

The following estimate of his character appeared in a notice of his 'British Birds' in the 'Athenæum' for 1852:—

"Dr. Macgillivray was a naturalist, and one of no mean order. Had he confined his attention to a few of the subjects of the vast field over which he laboured with unwearied industry through a long life, he would perhaps have attained a yet higher position as a man of science than that which he reached. Whilst in the fields, on the mountains, or by the sea-shore, he had an eye to every natural object that surrounded him, and the interest with which he regarded them is expressed in the numerous papers and works which he has written on botany, geology, and zoology. Though a list of Dr. Macgillivray's works would alone occupy a large space, yet he was not a man of the closet. Though one of the most diligent of compilers, he was a laborious original investigator. Whilst he lived by natural history as a profession, he pursued it as a science, and in return for the scanty means which it afforded towards the necessities of existence, he rendered a large amount of observation made with great labour and self-sacrifice. Although naturally an amiable man, he has frequently in his works—as is often the case with self-educated men of an ardent character—expressed himself strongly on the views of others, and in this way he made many enemies during his life. Now that the grave has closed over him, even those with whom he most differed will look back on his career only to admire."

MACHÆRIUM, a genus of Plants belonging to the natural order *Leguminosæ*. One species, *M. Schomburgkii*, produces the Itaka Wood of Guyana, remarkable for its brown and black streaks, on which account it is employed in cabinet-work.

MACHYNLLETH. [MONTGOMERYSHIRE.]

MACLURA, a genus of Plants belonging to the natural order *Moraceæ*. The fruit of *M. aurantiaca*, the Osage Orange, is as large as the fist, orange-coloured, and filled with a yellow fœtid slime, with which the native tribes smear their faces when going to war. The wood of *M. tinctoria* is the dye-wood called Fustic; it contains Morine, a peculiar colouring substance; its fruit is pleasant; and used in North American medicine for the same purposes as the black mulberry in Europe. According to Martius, both the other species of the genus yield fustic in Brazil. (Lindley, *Vegetable Kingdom*.)

MACROCYSTIS, a genus of plants belonging to the natural order *Fucaceæ*, and the tribe *Laminaridæ*. The enormous fronds produced by *M. pyrifera* have been spoken of by many navigators. They appear to be from 500 to 1500 feet in length; the leaves are long and narrow, and at the base of each is a vesicle filled with air, without which it would be impossible for the plant to support its enormous length in the water, the stem not being thicker than the finger, and the upper branches as slender as common pack-thread. This plant was seen by Dr. Joseph Hooker in 61° S. lat., in large vegetating patches wherever the water was free of icebergs.

MACRODIPTERYX. [NIGHT-JARS.]

MACROGLOSSA. [CHEIROPTERA.]

MACROOM, county of Cork, Ireland, a post and market-town, and the seat of a Poor-Law Union, is situated on the river Sullane, and on the road from Cork to Killarney, in 51° 55′ N. lat., 8° 55′ W. long., distant by road 24½ miles W. from Cork, and 182½ miles S.W. by S. from Dublin. The population in 1851 was 3727, besides 2124 in the workhouse. Macroom Poor-Law Union comprises 25 electoral divisions, with an area of 179,108 acres, and a population in 1851 of 37,394. The town consists principally of one street nearly a mile in length, occupied in great part by cabins and other mean dwellings. Near the centre are some good houses and shops. The parish church, the Roman Catholic chapel, the sessions-house and bridewell, and a market-house, the dispensary, and the Union workhouse are the public edifices. Petty-sessions are held monthly. Fairs are held on the 12th day of May, July, September, and November. There is a large weekly market. Macroom Castle is a fine old structure overhanging the river.

MACROPIPER, a genus of Plants belonging to the natural order *Piperaceæ*. *M. methysticum*, the Ava, is the most celebrated of the narcotic Pepper-Worts. It has cordate acuminate many-nerved leaves; solitary axillary spikes, very short, pedunculated, and spreading. The rhizoma is thick, woody, rugged, and aromatic. It is used in tincture against chronic rheumatism. Macerated in water it forms an intoxicating beverage, of which the Otahetians make use as a medicine; they make themselves drunk, after which very copious perspiration comes on: this lasts three days, at the end of which time the patient is cured.

MACRORHINUS. [SEALS.]

MADATEUS. [CHEIROPTERA.]

MADELEY. [SHROPSHIRE.]

MADISON. [INDIANA.]

MAES. [MAAS, *S.* 2.]

MAGENDIE, FRANÇOIS, a distinguished French physician and physiologist. Although his father practised as a physician in Paris, he was born at Bordeaux on the 15th of October 1783. He was soon after brought to Paris, where he had the misfortune to lose his mother. His father took an active part in the revolutionary movements of the period, was mayor of the 10th arrondissement, a member of the Hospital Council, and of the Commune de Paris. He also married a second time, and the result was an almost entire neglect of his child, who is said not to have been able to read at the age of ten. He was however then sent to school, and at the age of fourteen had achieved such success that he was rewarded with a prize at the annual concours. Through his father he was introduced to the celebrated Boyer, and became his pupil, and afterwards his demonstrator of anatomy. At the age of twenty, after an examination by concours, he was appointed aide d'anatomie (prosector) in the Faculty of Medicine, and shortly afterwards a demonstrator. In this position he devoted himself enthusiastically to the study of surgery, but he was induced by Dupuytren to give up this branch of the medical art, and devote himself to the practice of medicine. He was subsequently appointed physician to the Hotel Dieu. In 1819 he was elected a member of the Academy of Sciences; he was also a member of the Academy of Medicine, and in 1831 he succeeded Professor Recamier, who had resigned on the accession of Louis Philippe to the throne of France, in the chair of anatomy in the College of France.

Professor Magendie was a laborious writer as well as one of the most illustrious physiological experimentalists and discoverers. His larger works are as follows:—1, 'Formulaire pour la Préparation et Emploi de plusieurs nouveaux Medicaments.' This work was published in 1821, and was speedily translated into all the languages of Europe. It contained an account of the action of those potent active principles found in plants, which had at that time been introduced into the practice of medicine, more particularly by the exertions of French chemists and physicians. It included such remedies as morphine, strychnine, prussic acid, and others, on the operation of which on the animal system Magendie had successfully experimented. 2, 'Précis Élémentaire de Physiologie.' This work was originally published in two volumes at Paris in 1816-17. It went through several editions, and was afterwards entitled, 'Elémens de Physiologie.' It was translated into German and English, and for many years it was one of the best manuals of physiology for the use of students. 3, 'Leçons sur les Phénomènes physiques de la Vie.' These were a series of lectures delivered at different times, and collected together by M. J. James, and published in 1836-42. These were also translated, though occupying four volumes, into German. 4, 'Leçons sur les Fonctions et les Maladies du Système nerveux.' These also were lectures delivered in the College of France, and were published in two volumes in 1839. 5, 'Leçons sur le Sang.' These lectures on the blood were also published in Paris in 1839. 6, 'Recherches philosophiques et cliniques sur le liquide cephalo-rachidien, ou cerebro-spinal,' Paris, 1842. In addition to these larger works, Magendie published a large number of papers, which will be found scattered through the 'Comptes Rendus,' and contained in the 'Journal de Physiologie experimentale,' a periodical which he started in 1821, and which he continued to edit for ten years. He was also a contributor to several of the Dictionnaires which appeared in France during the commencement of the present century. He wrote for the 'Dictionnaire de Médécine et de Chirurgie pratique,' the 'Encyclopædie des Gens du Monde,' and the 'Dictionnaire de Médécine usuelle.'

Although Magendie wanted the generalising power which would have placed him at the head of European physiology, he was most industrious in the performance, and ingenious in devising of physiological experiments. It was as an experimenter that he produced a lasting impression on the progress of physiology. In fact so numerous were his experiments at one time on living animals, that the authorities in France thought it necessary to interfere. Some of the results of his physiological enquiries are too important to be passed over in this notice:—

1. Magendie first successfully demonstrated what had been only suspected by previous physiologists, that the veins were organs of absorption. His experiments on this subject have been regarded by physiologists as setting this question at rest, and proving that the veins are the great agents in the absorption of liquids.

2. His numerous experiments on the absorption of poisons led to a more accurate apprehension of the nature of their action on the human system. He first demonstrated that

strychnia acts upon the spinal cord, and destroys by paralysis the nerves of respiration, thus inducing asphyxia.

3. He gave a more accurate account of the act of vomiting, and showed how little it depended on the action of the stomach itself.

4. He investigated with great care the action of hydrocyanic, or prussic acid on the human system, and drew attention to its value as a remedy in certain forms of cough arising from irritation in the lungs.

5. Long before the chemical nature of food was understood, Magendie pointed out that non-nitrogenous foods were innutritious. This conclusion was the result of a long series of experiments on the feeding of the lower animals.

6. He performed a series of experiments on the admission of air into the veins, and showed how likely this was to be a cause of death in operations about the throat.

7. Magendie must share with Sir Charles Bell the honour of having discovered the real functions of the spinal nerves. Walker had demonstrated the existence of two roots to the spinal nerves. Bell showed that the nerves performed two functions, that of sensation and volition, and that these were sometimes separate, but the final demonstration of the two roots of the spinal nerves being devoted to the two separate functions, seems to have been first clearly established by Magendie.

To these more important discoveries and investigations must be added a large number of experimental researches upon the functions of the brain, its parts and nerves. If these did not lead to immediate and decisive results, they have been important facts by means of which others have been since guided to more correct conclusions.

Magendie was made a Commander of the Legion of Honour, and few men gained more of the respect and confidence of the government in matters of public health, whilst amongst the medical profession he was held in the greatest respect on account of his great talent and original genius. He died on the 8th of October 1855.

MAGHERAFELT. [LONDONDERRY.]

MAGONIA, a genus of plants belonging to the natural order *Sapindaceæ*. The flowers are polygamous; the male flowers have a 5-parted unequal reflexed calyx; petals 5, linear, and unequal; disc unequal between the petals and stamens, on one side long and double, in the other short, simple, and rugose; stamens 8, declinate. Hermaphrodite flowers as in the male, but stamens much smaller and not declinate; ovary 3-celled, many-seeded; styles curved; stigma 3-lobed; capsule large, woody, 3-valved, loculicidal; seeds large, flattened, surrounded with a wing; hilum in the edge. The species are trees with a corky bark; leaves alternate, abruptly pinnate, without stipules; flowers panicled.

M. pubescens is a small tree common in the western deserts of the province of Minas Geraes in Brazil. It has downy branches; leaflets 8, ovate or oblong, sessile, deeply emarginated and downy; the flowers in a terminal sessile or stalked panicle from 9 to 16 inches long; calyx downy, yellowish-green; petals linear, obtuse above, in the middle smooth and dark purple, at the edges and point downy and green; fruit a large, woody, globose, 3-cornered, somewhat depressed capsule, with 3 valves, 3 cells, and many seeds. The ashes of this plant are extremely alkaline. The bark is used for subduing the swellings produced in the skin of horses by the stings of insects. The leaves of this species and *M. glabrata* are poisonous to fishes.

MAGPIE-MOTH. [ABRAXIS.]

MAI, ANGELO, CARDINAL, and Prefect of the Vatican Library, Rome, was born at Schilpario, a mountain village of the province of Bergamo, Italy, March 7, 1782. He received his early education in the village school, and his first master in the higher studies was the ex-Jesuit Father, Lewis Mozzi de' Caspitani. In 1799 Mozzi, struck by the taste and capacity for classical learning which Mai displayed, selected him, along with four other youths of the village, to enter the novitiate of the Jesuit society, which, although elsewhere suppressed, the Duke of Parma, with the sanction of Pius VI., was about to re-establish at Colorno, a small city of his duchy. In this community Mai resided till the provisional restoration of the society in Naples (1804), whither he was sent as Professor of Greek and Latin literature. About the end of 1805, he was transferred to Rome for the completion of his theological studies, and soon afterwards was removed to Orvieto, on the invitation of the bishop, Giambattista Lambruschini. He was here admitted to priest's orders; and to the opportunities which he thus enjoyed of intercourse with two learned Spanish fathers of the Society, Montero and Menchaca, he himself used to ascribe not only his familiarity with the Hebrew language, but what much more sensibly influenced his after-career, his accurate knowledge of palæography, and his skill in deciphering ancient manuscripts.

Mai returned to Rome in 1808, just about the time when the contest of Pius VII. with Napoleon was reaching the crisis; and an order issued by the viceroy, commanding all subjects of the kingdom of Italy to return to their respective provinces, compelled him to change his residence once again. Happily for the interests of literature he settled at Milan.

The Ambrosian Library of that city had long been known as rich in manuscripts of the highest interest—the remnant of the treasures of the old monastic libraries, especially those of Bobbio and Lucca, and of some of the suppressed Benedictine convents of the Protestant cantons of Switzerland. Many of its best treasures had been made public by Muratori, Mabillon, and the Benedictine editors; but there yet remained a department entirely unexplored, which Mai soon appropriated to himself, and which has since come to be regarded as exclusively his own—that of palimpsest or re-written manuscripts, in which the original writing has been effaced in order to make room for a later work written over it. Through the influence of Padre Mozzi and the recommendation of his friends, and especially of Count Mellerio of Milan, Mai was admitted an associate and eventually a doctor of this celebrated library; and, from the date of his arrival in Milan till his ultimate translation to the Vatican, he laboured in his novel editorial career with a zeal and success not unworthy of the traditional glories of his country. His first essay as an author was a Latin translation (with a commentary) of Isocrates 'De Permutatione' (1813), the original of which had been published by a Greek named Andrew Mustoxidi in the previous year; but this was only the prelude of his far more remarkable successes in the decipherment and publication of palimpsest manuscripts. Up to this period, with the exception of Kuster and Wetstein's readings of the Old and New Testament from the 'Codex Ephræmi,' Knittel's portions of the Gothic Bible of Ulphilas, Peter Bruns's fragment of the ninety-first book of Livy, and Barrett's palimpsest of the Gospels, palimpsest literature was entirely untried. Within a few years Mai deciphered and published from palimpsest sources two volumes of inedited fragments of Cicero's 'Orations;' a volume of letters and other writings of Fronto, the preceptor of Marcus Aurelius; some fragments of the lost 'Vidularia' of Plautus; a lost work of Porphyrius, the Platonist; some portions of Dionysius of Halicarnassus; two works of Philo Judæus; eight orations of Lysimachus; an oration of Isæus; two books of the Sybilline Verses; and several other works of the same character.

During this time Mai, although a member of the Jesuit Society, had not taken the solemn vows of the order, which indeed was not formally restored by papal authority till 1814. It was then thought, both by his superiors and by the authorities at Rome, that he could render more effective services to literature and to religion by remaining attached to the Ambrosian Library. Accordingly, with the full approval of all the authorities, he withdrew from the Society, and remained, as a simple priest, at Milan till 1819, when he was called to Rome as chief keeper of the Vatican Library, canon of the Church of St. Peter's, and domestic prelate of the Pope Pius VII. Soon after his establishment in the Vatican, he completed what was wanting in those fragments of Fronto which he had already printed at Milan; having happily discovered in the Vatican the missing portion of the manuscript from which the Milanese fragments had been printed, and which had (as well as the Milanese manuscript) originally belonged to the library at Bobbio. In the following year he published the work by which he is best known out of Italy—a large and interesting portion of the long-lost 'De Republicâ' of Cicero, the fragments of which he arranged with consummate skill in their respective order, and interwove with all the known extracts of the work which had been preserved by ancient authors. The whole text he illustrated by a critical commentary of exceeding interest, which at once established his reputation as one of the first scholars of the age.

From these comparatively desultory labours he turned to a project not unworthy of the palmiest days of Italian editorship. Selecting from the vast and till then imperfectly explored manuscript treasures of the Vatican, he prepared his 'Scriptorum veterum Nova Collectio e Vaticanis Codicibus edita;'—a vast series of ten 4to volumes (Rome 1825, and following years), on the plan of the various *Anecdota*, published under different titles by Mabillon, Pez, Montfaucon, Muratori, and others. It is a work of immense labour and research, and of a most miscellaneous character—Greek and Latin, sacred and profane, theological, historical, patristical, and philosophical. One of the volumes, the second, is perhaps the most curious of the entire, containing considerable fragments, recovered from a very early palimpsest manuscript, of almost all the ancient Greek and Roman historians, Polybius, Diodorus Siculus, Dionysius of Halicarnassus, Dion Cassius, Appian, Dexippus, Eunapius, and others.

The 'Vaticana Collectio,' was quickly followed by a similar collection in ten volumes, 8vo, 'Classici Scriptores ex Codicibus Vaticanis editi,' completed in 1838; which included some of the editor's earlier publications (especially the 'De Republicâ'); although, with the exception of about two volumes, its contents are entirely new. While he was engaged in the publication of this series he held the laborious and responsible post of secretary of the Propaganda, to which he had been appointed in 1833; and it was observed with wonder that his extensive literary engagements never were suffered to interfere with the duties of the secretariate. His active and business-like habits, the promptness of his decisions, and the prudence and discretion of his whole administration, are still gratefully remembered by the members of the various missions under the surveillance of the Propaganda.

After five years of service in this laborious office, he was named (1838) cardinal, at the same time with his friend and successor in the Vatican Library, Mezzofanti; and soon afterwards was appointed to several important and confidential offices in the Roman court, chiefly of a literary character. He was named successively Prefect of the Congregation for the Supervision of the Oriental Press; Prefect of the Congregation of the Index; and Prefect of the Congregation of the Council of Trent. In 1853 he was appointed to the still more congenial post of Librarian of the Roman Church.

This elevation did not interrupt in the slightest degree the literary labours in which he had been engaged. Scarcely was the collection of 'Classici Auctores' completed when he commenced a similar one, also in ten volumes, 8vo, 'Spicilegium Romanum' (1839-44), equally interesting and various in its contents, and a fourth collection entitled, 'Nova Patrum Bibliotheca,' published in 1853 in six volumes 4to; thus completing a series unparalleled since the days of Muratori, and indeed far more extraordinary than the older collections, from the circumstance that it was compiled from the mere gleanings which had escaped the research of the earlier generations of editors and collectors. Several years before, he had undertaken to edit the well-known 'Codex Vaticanus' of the Old and New Testament with various readings and prolegomena. The text of this edition was printed many years before his death, but its publication was delayed in order that it might be accompanied by the intended prolegomena. He died however at Albano, September 8, 1854, in his seventy-third year, leaving this great work still unpublished; and it is much to be regretted that since his death no trace has been found among his papers of the long-expected dissertations which he had intended to prefix to the 'Codex Vaticanus.' It is conjectured either that, engrossed by his other manifold editorial occupations, he deferred year after year this anxious and difficult task, or that, dissatisfied with the execution, he in the end destroyed what he had prepared.

Cardinal Mai's abilities as an editor were of the very highest order. While his collections comprise an infinite variety of authors of every age, of every country, of every variety of style, and in every department of literature, in all he appears equally the master. Whether the subject be theology or history, or law, or languages, or general literature, his learning is never at fault, and his critical sagacity never fails. In the many delicate and difficult questions which so often arise;—in assigning an anonymous manuscript to its true author, in collecting fragments of the same work and dovetailing them together into intelligible order, in selecting from a heap of unknown materials all that is unpublished, and deciding upon the question of its genuineness or its intrinsic value; in a word, in all the thousand investigations which fall to the lot of a critical editor treading upon untried ground, he possessed a skill and acuteness which can hardly be described as other than instinctive, and which, taking into account the vast variety of subjects which engaged him, must be regarded as little short of marvellous.

The private character of Cardinal Mai has been well described as the very ideal of a Christian scholar. Earnestly devoted to the duties of his sacred calling, he yet loved literature for its own sake also, and he was ever foremost in every project for its advancement. He was a member of all the leading literary societies of Italy, and not unfrequently read papers in those of Rome and Milan. His charities were at all times liberal and indeed munificent; and at his death (reserving to the Vatican Library the right to purchase it at a moderate price) he bequeathed the proceeds of the sale of his noble library to be applied to the benefit of the poor of his native village of Schilpario. A monument has been erected to his memory in the church of St. Anastasia, from which he derived his title as cardinal.

MAIANTHEMUM, a genus of Plants belonging to the natural order *Asparageæ*. It has a 4-parted perianth; the segments horizontally patent or reflexed, deciduous; stamens 4; style 1; stigma blunt; berry 2-celled; cells 1-seeded.

M. bifolium has a stem with two alternate, stalked, triangular, cordate leaves; the stem is from 6 to 8 inches high; root filiform; leaves very deeply cordate; raceme terminal, resembling a spike; flowers small; segments reflexed; berry yellow with brown spots. It is found in woods in the north of England.

MAIDENHEAD. [BERKSHIRE.]

MAILATH, JANOS NEPOMUK, an ingenious Hungarian poet and historian, was born at Pesth on the 14th of October 1786, and was the fourteenth child of a family of eighteen. He received an excellent education at Erlau and Raab, and his father, Count Joseph Mailath, an Austrian minister of state, introduced him into the same service, which he was compelled to relinquish after ten years, from increasing weakness of eye-sight. For two years he was forbidden to read and write, and it was during this time that he resolved to devote himself to literature. His works of poetry and history are numerous. Many of his poems and one of his histories, that 'Of the Religious Dissensions in Hungary,' are in the Hungarian language; most of the others are in German. He translated with success into German the 'Himfy' of Kisfaludy. His 'History of the Magyars' (5 vols., 1828-31), and his 'History of the Austrian Empire' (5 vols., 1834-50), are the most important of his historical works: the latter contains the result of his investigations during a period of eighteen years. Count Mailath, who returned to the public service and held the office of a counsellor of the Hungarian Chancery and some others at Pesth, was a member of the Hungarian Conservative party, and in his history mentions his own name, along with that of Count Stephen Szechenyi, as those of the only two magnates who opposed what he characterises as the violent and oppressive proceedings of the Magyars in forcing their language on the six million inhabitants of the country, whose languages were entirely different. The whole of his narrative of the conduct of the Kossuth party in Hungary before the outbreak is deserving of attention, as a statement of one side of the question which is little known in England. The results to unfortunate Mailath were most disastrous. Deprived of the posts he held in Hungary by the revolution of 1848, he appears to have been unable to obtain a compensation from the Austrian government. His literary labours did not prove remunerative, and his fortitude gave way under the combined afflictions of poverty, exile, old age, and blindness. The old man, whose productions have earned him a permanent and honourable place in the literature of both Hungary and Germany, was driven by the pressure of extreme destitution to drown himself in the Lake of Starnberg in Upper Bavaria, and with him his daughter, who had for some time acted as his amanuensis. This most painful catastrophe took place in the early part of January 1855.

MAINTENON. [EURE-ET-LOIR.]

MALACANTHUS. [LABRIDÆ.]

MALACHITE. (*Green Malachite, Carbonate of Copper, Monoclinite.*) Usually in incrustations, with a smooth tuberose botryoidal or stalactitic surface. Structure finely and firmly fibrous; also earthy. Colour light green; streak paler. Usually nearly opaque. Crystals translucent. Lustre of crystals adamantine, inclining to vitreous; but fibrous incrustations silky, on a cross fracture. Earthy varieties dull. Hardness, 3·5 to 4. Specific Gravity, 4. Composition :—

Carbonic Acid	18
Oxide of Copper	70·5
Water	11·5

Dissolves with effervescence in nitric acid. Decrepitates and blackens before the blow-pipe, and becomes partly a black scoria. With borax it fuses to a deep green globule, and ultimately affords a bead of copper. It is readily distinguished by its copper-green colour and its association with copper ores. It resembles a siliceous ore of copper, *Chrysocolla*, a common ore in the mines of the Mississipi valley; but it is distinguished by its complete solution and effervescence in nitric acid. The colour also is not the bluish-green of Chrysocolla. Green Malachite usually accompanies other ores of copper, and forms incrustations, which when thick have the colours blended, and extremely delicate in their shades and blending. Perfect crystals are quite rare. The mines of Siberia, at Nischne Tagilsk, have afforded great quantities of this ore. A mass partly disclosed measured at top 9 feet by 18 feet; and the portion uncovered contained at least half a million pounds of pure Malachite. Other noted localities are Chessy in France, Sandlodge in Shetland, Schwartz in the Tyrol, Cornwall, Australia, and the island of Cnba. This mineral receives a high polish, and is used for inlaid work, and also ear-rings, snuff-boxes, and various ornamental articles. It is not mnch prized in jewellery. Very large masses are occasionally obtained in Russia, which are worked into slabs for tables, mantel-pieces, and vases, which are of exquisite beauty, owing to the delicate shadings and radiations of colour. In the Great Exhibition of 1851 there were magnificent specimens of this material in the shape of doors and vases sent thither by the Emperor of Rnssia. At Versailles there is a room furnished entirely with tables, chairs, &c., wronght in Malachite, and the same are to be found in other European palaces. At Nischne Tagilsk, a block of Malachite was obtained weighing 40 tons. Malachite is sometimes passed off in jewellery as turquoise, though easily distinguished by its shade of colour and much inferior hardness. It is a valuable ore when abundant, bnt it is seldom smelted alone, because the metal is liable to escape with the liberated volatile ingredient, carbonic acid.

MALACHIUM, a genns of Plants belonging to the natural order *Caryophyllaceæ*. It has 5 sepals; 5 bifid or entire petals; 10 stamens and 5 styles; the capsules opening with 5 bifid valves.

M. aquaticum, Water Chickweed, has a decnmbent stem, angular, ascending, and covered with glandular hairs; cordate-ovate leaves, acuminate, sessile, the lowest one stalked; flowers scattered, solitary, in the forks of the stem; petals bipartite, rather exceeding the calyx; capsule exceeding the calyx. It is usually found in wet places in Great Britain.

MALICIOUS INJURIES TO PROPERTY. [Law, Criminal, *S.* 2.]

MALLARD. [Ducks.]

MALLOW, MARSH. [Althæa.]

MALTHACITE. [Mineralogy, *S.* 1.]

MAN. In classifying the races of men, it must be remembered that the divisions and subdivisions which are employed do not resemble those which are used in the systematic classification of plants and animals. When the whole of the species of the vegetable or the animal kingdom have to be arranged, then we divide them into various primary and subordinate gronps, which are called Classes, Families, or Orders, Genera, Species, and Varieties. Now Man himself is bnt a species; he belongs to a subordinate group of a large division of the animal kingdom. Zoologically considered, Man is an animal belonging to the class *Vertebrata*, the order *Mammalia*, the sub-order *Hominidæ*, the genus *Homo*, and species *sapiens*. The characters of this species as given by Blumenbach have been stated elsewhere. [Man.]

The following is the arrangement of the races of men, with the definitions given by Dr. Pickering, an American traveller and writer, in his work 'On the Races of Men:'—

a. White.

1. *Arabian.*—The nose prominent, the lips thin, the beard abundant, and the hair straight or flowing.

2. *Abyssinian.*—The complexion hardly becoming florid, the nose prominent, and the hair crisped.

b. Brown.

3. *Mongolian.*—Beardless, with the hair perfectly straight and very long.

4. *Hottentot.*—Negro features, and close woolly hair; and the stature diminutive.

5. *Malay.*—Features not prominent in the profile, the complexion darker than in the preceding races, and the hair straight or flowing.

c. Blackish-Brown.

6. *Papuan.*—Features not prominent in profile, the beard abundant, the skin harsh to the touch, and the hair crisped or frizzled.

7. *Negrillo.*—Apparently beardless, the stature diminntive, the features approaching those of the negro, and the hair woolly.

8. *Indian*, or *Telingan.*—The features approaching those of the Arabian, and the hair, in like manner, straight or flowing.

9.—*Ethiopian.*—The complexion and features intermediate between the Telingan and Negro, and the hair crisped.

d. Black.

10. *Australian.*—Negro features, bnt combined with straight or flowing hair.

11. *Negro.*—Close woolly hair, the nose mnch flattened, and the lips very thick.

The most recent writer and greatest anthority on the races of men is Dr. R. G. Latham, who, in his work on the 'Varieties of Man,' proposes the following arrangement. In the first place, like Cuvier and other previous writers, he adopts but three primary varieties of the human species :—

I. *Mongolidæ.* II. *Atlantidæ.* III. *Japetidæ.*

The termination in 'idæ' employed here seems preferable to the use of terms such as class, order, family, tribe, or other words which have another nse, either in this or other departments of natural history. It must not however, be supposed that by using these terms any of the varieties of man can be traced up to a common ancestry, so that we could say all the *Mongolidæ* originated with this man, or all the *Atlantidæ* with that man. In tracing back races we have no evidence so conclusive that any particular variety originated with a particular pair of human beings, as we have that all the families of mankind have originated in a single pair. The terms *Mongolidæ*, *Atlantidæ*, and *Japetidæ* are not derived from a community of meaning in the things they express. Thus, the first comes from a nation, the Mongols, who occupied a portion of eastern Asia, and were at one time the conquerors of the world, and are regarded as typical of a large portion of the human race. The *Atlantidæ* are entirely found in Africa; hence their name. The *Japetidæ* include the races of men in Europe, who are traditionally descended from Japheth; hence the name selected to express them.

I. Mongolidæ.—The people comprised under this variety have the following physical conformation:—The face is broad and flat, which either arises from the great development of the zygomatic arches, or from the distance between the parietal bones on each side of the head. There is often also a great depression of the nasal bones, which contributes to give a flat appearance to the face. The profile of the forehead is retiring or depressed, seldom found perpendicular. The profile of the jaws is prognathic or projecting, seldom found on a level with the forehead. The eyes frequently present the peculiarity called oblique. The skin is of a mixed character, never truly white, and very rarely of a jet-black; still it often presents what would be called a black or white colour. The eyes are generally of a dark colour. The hair, as a general rule, is straight, long, and black; in some instances it is curly—rarely woolly— and more rarely still light-coloured.

The languages of the people belonging to this variety are either characterised by the absence of cases (aptotic), or having inflections, they can be shown to have arisen out of the union of different words (agglutinate). They are very rarely amalgamate.

The distribution of this variety is very wide over the surface of the earth. It finds its greatest development on the continent of Asia; although even there it is found not to be entire possessor of the earth. The Persians of northern and western Persia, the Kurds, the Beloochi, the Afghans, the Tajiks of Bokhara, and the Siaposh must all be regarded as belonging to the *Japetidæ*. On the other hand, although we shall find the *Japetidæ* the principal occupants of Europe, there seems to be little doubt that the Lapps and Fins of Scandinavia, the Magyars of Hungary, the Turks of Turkey, the Basques or Euskaldunes of Biscay and Navarre, and probably even the Albanians or mountaineers of ancient Illyria and Epirus, all belong to the *Mongolidæ*.

From the analogy of language this variety is made by Dr. Latham to include the whole of the inhabitants of the Polynesian Islands, as well as those of America. Although at first sight the physical differences between the Asiatic *Mongolidæ* and the inhabitants of the islands of the South Seas and the continent of America might look as great as that between many of the *Mongolidæ* and *Japetidæ*, yet it has been found that even physical characters fail to afford a line of demarcation. Thus, the late Dr. Morton, of America, thought that "the squared or rounded head, the flattened and vertical occiput, the high cheek-bones, the ponderous maxillæ, the large quadrangular orbits, and the low receding forehead," were characters that would distinguish the American from all other varieties. When however we examine the languages of the American continent we shall find that the Esquimaux present so strong a relation to that of the other races that we cannot deny their affinity to the American races; and it is amongst the Esquimaux that we find a departure from the physical type of a peculiar American form, and a strong relationship with the Asiatic *Mongolidæ*. It is considerations such as this which have induced recent ethnologists to regard the American Indian as a form of the variety of mankind to which the followers of Genghis-Khan belong.

The influence of the races included under the variety of *Mongolidæ* must be regarded as rather material than moral. They undoubtedly form by far the largest portion of the human race, and occupy a considerable space in the history of the world. They have, by the sword, established some of the largest empires that the world has seen. China is at this moment an example. Their empires have however crumbled to pieces, and left no deep impression on the world. Such is not the history of the *Atlantidæ* and *Japetidæ*, the first of which includes the Jews and the Mohammedans, and the last the Greeks, Romans, and modern European races.

The *Mongolidæ* are divided by Dr. Latham into groups as follows:—

A. Altaic Mongolidæ.—The term Altaic is taken from the Altai Mountains in Central Asia, these being a convenient geographical centre for the different nations and tribes comprising this division. It embraces two stocks, the Seriform, and the Turanian.

The Seriform stock has the physical conformation of the Mongol; and its languages are either wholly aptotic or with only the rudiments of an inflexion. The area inhabited by these people is China, Tibet, and the Indo-Chinese or Trans-Gangetic Peninsula as far as Malaya; the Himalayan and parts of the Sub-Himalayan range of mountains.

In this stock the chief people are Chinese, Tibetans, Anamese, Siamese, Kambogians, Burmese, the Indu; and several unplaced tribes are added by Dr. Latham.

The Turanian stock has the physical conformation of the Mongols; the languages are not monosyllabic. They are found from Kamtchatka to Norway, and from the Arctic Ocean to the frontiers of Tibet and Persia. The countries included are the northern parts of the Chinese empire, the greater part of Siberia, Mongolia, Tartary, Eastern Turkistan, Asia Minor, Turkey, Hungary, Esthonia, and Lapland. They are divided into four groups:—

1. The Mongolian branch, including the Mongols proper, the Buriats, the Kalmuks of Russia, and the Eimak of Persia.

2. The Tungusian branch including the Tshapojirs on the Lena, the Lamuts on the Sea of Okhotsk, and the Mantshu rulers of China.

3. The Turk branch: this includes the Uighurs, the Turks of the Sandy Desert, Turks of Khoten, &c., the Kirghis, Uzbeks, Turkomans, Osmanli, Nogays, Turks of the Russian empire, and the isolated Yakuts of the Lena.

4. The Ugrian branch includes the Voguls, the Permians, Tcheremiss, Finlanders, Esthonians, Laplanders, and Hungarians.

B. Dioscurian Mongolidæ.—The term Dioscurian is taken from the ancient sea-port Dioscurias. The tribes included in it have a modified Mongol organisation, the languages are (paucosyllabic) few-syllabled and agglutinate. Of all the languages not belonging to the Seriform stock of the last section they approach nearest to the aptotic state. They embrace—1, the Georgians; 2, the Lesgians; 3, the Mizjeji; 4, the Irôn; and 5, the Circassians.

Of this group, Dr. Latham observes, "To have used the word 'Caucasian' would have been correct, but inconvenient. It is already misapplied in another sense, that is, for the sake of denoting the so-called Caucasian race, consisting or said to consist of Jews, Greeks, Circassians, Scotchmen, ancient Romans, and other heterogeneous elements. In this sense it has been used in more than one celebrated work of fiction. In such and in such only, it is otherwise than out of place."

C. Oceanic Mongolidæ.—The epithet Oceanic is applied to this group, because, with the exception of the peninsula of Malacca, the tribes belonging to it are the inhabitants of islands exclusively. With the exception of Mauritius, the Isle of Bourbon, Ceylon, the Seychelles, the Maldives, and the Laccadives in the Indian Ocean, and the Japanese empire, with the islands to the north thereof in the Chinese Sea, every inhabited spot of land in the Indian and Pacific Oceans is inhabited by tribes of one and the same race which are embraced by this division. Not only is this race to be found spread over these islands, but apparently nowhere else. "In the peninsula of Malacca," says Dr. Latham, "and on no other part of the mainland of Asia, is an oceanic tribe to be detected." Although united by Dr. Latham, oceanic races exhibit two types. One class is yellow, olive, brunette, or brown, with long, black, and straight hair. Another class is black rather than yellow; the hair is sometimes long and straight, but in other cases crisp, curly, frizzy, or even woolly. The social, moral, and intellectual difference between these two classes is not less than their physical. The black division inhabits New Guinea, Australia, Tasmania, New Ireland, and the islands between it and New Caledonia. The brown division occupies all the rest of the oceanic area, Sumatra, Borneo, Java, the Moluccas, the Philippines, the South Sea Islands, the Carolinas, &c. The names given to these divisions are as follows:—

1. For the lighter-complexioned straight-haired type—Malay.

2. For the type that partakes of the character of the African negro inhabiting New Guinea, Australia, and what may be called the continuous localities for the unmixed black—Negrito.

3. The tribes with any or all of the Negrito characters, dwelling side by side with Malays in Malay localities, or in localities disconnected with the true Negrito area—the blacks of the Malayan area.

D. Hyperborean Mongolidæ.—The physical conformation of this section is that of undersized Mongolians. Their languages are agglutinate, neither monosyllabic, nor paucosyllabic. They are all subject to either Russia or China. Their religion is either Shamanism or an imperfect Christianity. They are found on the coasts of the Arctic Ocean, and the courses of the Yenisei and Kolima. The principal divisions are the Samoides, the Yeniseians, and the Yukahiri.

E. Peninsular Mongolidæ.—This section comprises races very widely distributed. Some of these lie within the arctic circle, others as far south as 26° N. lat. Their physical conformation is Mongol. Their languages are agglutinate, and in some cases excessively monosyllabic. The area occupied by these races are the islands and peninsulas of the north-eastern coast of Asia. The people embraced in it are the Koreans, the Japanese, the Aino, the Koriaks, and the Kamtchatdales.

F. American Mongolidæ.—This section embraces the original inhabitants of the whole continent of America. By most writers on ethnology, the races of America are regarded as a distinct family. Their connection with *Mongolidæ* seems however to be established by the Eskimo, who are physically Mongol and Asiatic, but philologically American. Of the Eskimo Dr. Latham remarks:—

"Unimportant as are the Eskimo in a political and historical view, their peculiar geographical position gives them an importance in all questions of ethnology; since one of the highest problems turns upon the affinities of this family.

"It has long been known that the nation which inhabits Greenland and Labrador is the nation which inhabits the north-western parts of Russian America as well. It is found on the American side of Behring's Straits, and it is found on the Asiatic side also. So that the Eskimo is the only family common to the Old and New World; an important fact in itself, and one made more important still by the Eskimo localities being the only localities where the two continents come into proximity. Now if these facts had stood alone, unmodified by any phenomena that detracted from their significance, the peopling of America would have been no more a mystery than the peopling of Europe. Such however is not the case. They neither stand alone, nor stand unmodified. The reasons that lie against what is at the first blush the common sense answer to the question 'How was America peopled?' are chiefly as follow:—

"1. The distance of the north-eastern parts of Asia from any probable centre of population—cradle of the human race, so called. For these parts to have been the passage, Kamtchatka must have been full to overflowing before the Mississippi had been trodden by the foot of a human being.

"2. The physical differences between the Eskimo and the American Indians.

"3. The difficulties presented by the Eskimo language.

"It is only these two last reasons to which I attribute much validity. The first of the three I put low in the way of an objection; that is, not much higher than I put the systems founded upon the Icelandic and Welsh traditions, the drifting of Japanese junks, and the effects of winds and currents upon Polynesian canoes. Without at present doubting whether the occurrences here alluded to have happened since America was peopled by the present race, I limit myself to an expression of dissent from the doctrine that by any such unsatisfactory processes the original population found its way; in other words, I believe that our only choice lies between the doctrine that makes the American nations to have originated from one or more separate pairs of progenitors, and the doctrine that either Behring's Straits or the line of islands between Kamtchatka and the peninsula of Aliaska, was the highway between the two worlds—from Asia to America, or vice versâ. I say vice versâ, since it by no means follows that because Asia and America shall have been peopled by the same race, the original of that race must necessarily have arisen in Asia; inasmuch as the statement, that the descendants of the same pair peopled two continents, taken alone proves nothing as to the particular continent in which that pair first appeared. Against America, and in favour of Asia, being the birth-place of the human race—its unity being assumed—I know many valid reasons; reasons valid enough and numerous enough to have made the notion of the New World being the older of the two a paradox. Nevertheless I know no absolutely conclusive ones. Omitting however this question, the chief primâ facie objections to the view that America was peopled from north-eastern Asia lie in the—

"1. Physical Differences between the Eskimo and the American Indian.—Stunted as he is in stature, the Eskimo is essentially a Mongol in physiognomy. His nose is flattened, his cheek bones project, his eyes are often oblique, and his skin is more yellow and brown than red or copper-coloured. On the other hand, in his most typical form, the American Indian is not Mongol in physiognomy. With the same black straight hair, he has an aquiline nose, a prominent profile, and a skin more red or copper-coloured than either yellow or brown. Putting this along with other marked characteristics, moral as well as physical, it is not surprising that the American should have been taken as the type and sample of a variety in contrast with the Mongolian.

"2. Philological arguments.—Few languages, equally destitute of literature, have been better or longer known than the Eskimo. For this we have to thank the Danish missionaries of Greenland—Egede more especially. From the grammar of Fabricius the Eskimo was soon known to be a language of long compound words, and of regular though remarkable inflections. It was known too to be very unlike the better-known languages of Europe and Asia. Finally, it has been admitted to be, in respect to its grammatical structure at least, American."

We need not here enumerate the various tribes embraced in this section, as it includes the whole of the original races found on the American continent.

G. Indian Mongolidæ.—The races belonging to this section are found in Hindustan, Cashmere, Ceylon, the Maldives and Laccadives, and part of Beloochistan. They are found mixed or contiguous to the Japetidæ of Beloochistan and Cabul, and various Seriform tribes. They present two extreme forms of physical conformation, one with the skin dark or even black, the other of a brunette colour, with a skin of great delicacy and clearness. The social condition of caste prevails amongst them. The principal religious are Brahminism and Buddhism, with a variety of intermediate creeds. Their ancient literature is in the Sanscrit, and their alphabets are derived from that language. They embrace the following divisions:—1, the Tamul; 2, the Palinda; 3, the Brahúi; 4, the Indo-Gangetic; 5, the Purbutti; 6, the Cashmirian; 7, the Cingalese; and 8, the Maldivian.

II. The Atlantidæ.—In their physical character the face is not so broad and flat as in the *Mongolidæ*. The jaws project, are prognathic, whilst the nose is generally flat; the forehead is retiring; the cranium dolikocephalic, that is, there is less space between the parietal bones of the skull, whilst its length remains the same, than there is in the last variety; the eyes only rarely open obliquely; the skin is mostly jet-black, presenting however lighter shades, and very rarely approaching a pure white; the hair is crisp, woolly, very rarely straight, and still more rarely light-coloured. The languages amongst the Atlantidæ belong to the agglutinate class. They are seldom or never found with a truly amalgamate inflection.

The great district of the development of the natives which are brought together under the above definition, is Africa. Perhaps there is no quarter of the globe that presents a greater diversity of inhabitants than Africa, or races of men who at first sight appear so evidently distinct. All previous ethnologists have placed the Hottentot, the Negro, and the Bushman in a very different position to the Assyrian, the Babylonian, the Mohammedan, and the Jew; but in Dr. Latham's classification we find these brought together under the common variety *Atlantidæ*. The analogy of language has led to this conclusion; and the transition from the lowest to the highest of these races is so gradual that no investigation of their physical structure with which we are at present acquainted, would be sufficient to break down the affinity discovered in their languages. No part of Africa seems to be inhabited by any races but those of the Atlantidæ. The Syro-Arabian or Semitic nations, however, which are now classed amongst the Atlantidæ, are found occupying a considerable area in the south-western part of Asia. The people of these races are far removed from the Negro and the Hottentot, and present great symmetry of form, and considerable cerebral development.

However small may have been the influence of the lower types of this race on the world, there can be no doubt of the vast impression produced by the Semitic nations. We may pass over the early civilisation indicated by the Assyrian and Babylonian empires, and fix attention on the religious history of the Jews. Here, amidst the surrounding Paganism, we find the worship of the one true God maintained by this small race amongst the Semitic nations; and through them the religion of Christ, which is destined to react on all the other races of mankind. It is also among these races that that compound of Judaism and Christianity, Mohammedanism, has sprung up; and however inferior it may be to the Christian religion, there can be little doubt of the beneficial influence it has exerted on the races who have embraced it.

The following is Dr. Latham's division of this group:—

A. Negro Atlantidæ.—The negroes have a black, unctuous, and soft skin; the hair woolly; lips thick; maxillary profile prognathic, frontal profile retiring; nasal depressed. They inhabit the low lands, sea-coasts, and the deltas and courses of rivers, chiefly the Senegal, Gambia, Niger, and Upper Nile. They are nearly limited to the tropic of Cancer. They are divided into Western Negroes, Central Negroes, and Eastern Negroes.

B. Kaffir Atlantidæ.—The language of the Kaffir supplies a broad distinction between them and other African races. They are prefixional and alliterational. Their physical conformation is modified negro. They occupy a district in Africa (east and west) from the north of the equator to the south of the Tropic of Capricorn. The chief divisions are, 1, Western, 2, Southern, 3, Eastern.

C. Hottentot Atlantidæ.—"The Hottentot stock," says Dr. Latham, "has a better claim to be considered as forming a second species of the genus *Homo* than any other section of mankind. It can be shown however that the language is no more different from those of the world in general than they are from each other." The Hottentots occupy the southern extremity of Africa. They are of a low stature; limbs slight; colour more brown or yellow than black; cheek-bones prominent; nasal profile depressed; hair in tufts rather than equally distributed over the head. They are divided into the Hottentots proper and the Saabs. The latter are found between the Roggeveld and the middle portion of the Orange River.

D. Nilotic Atlantidæ—These people have a modified negro conformation, and inhabit the water-system of the Upper and Middle Nile. Their chief divisions are, 1, Gallas; 2, Agous; 3, Nubians; 4, Bishari.

E. Amazirgh Atlantidæ.—Amazirgh is a term eqnivalent to Berber. These people are found on the coasts of the Mediterranean and the whole north-western quarter of Africa. They present modifications of both the negro and Arab types. Their chief divisions are, 1, the Siwahs of the Oasis of Siwah, the ancient Ammonium; 2, Kabyles of the range of Atlas; 3, Tuaricks of the Sahara; 4, Gnanches of the Canary Islands.

F. Ægyptian Atlantidæ.—This section inclndes the ancient Egyptians, the subjects of the Pharaohs and the Ptolemies, and the modern Copts as far as they are of unmixed blood. They dwell in the valley and delta of the Nile, from Essouan to the Mediterranean. The physical conformation of the ancient Egyptians is gathered from their mummies. The modern Copts have the hair black and crisp or curled; the cheek-bones projecting; lips thick; nose depressed; nostrils wide; complexion from a yellowish to a dark-brown; eyes oblique; frame tall and fleshy.

G. Semitic Atlantidæ.—This section embraces the most highly developed forms of the *Atlantidæ*. The Semitic races are found in Abyssinia, Arabia, Palestine, Syria, Mesopotamia, and parts of Knrdistan. They are light-complexioned, and referrible to three types—the Arab, the Jew, and the Kaldani. Their influence on the world has been pre-eminently moral, spiritually as well as intellectually. Their religions are pre-eminently monotheistic in the later parts of their history. Their alphabet is the earliest in the world, and, with the exception of the Ethiopic, is written from right to left. The chief divisions, which are more or less artificial, are Syrians, Assyrians, Babylonians, Phœnicians, Beni-Terah, Arabs, Æthiopians, Solymi Cappadocians, Elamites, Cyprians, Philistines, Canaanites.

With the Beni-Terah (sons of Terah), father of Abraham, are found the Jews, who are remarkable amongst the nations of the earth for their early intellectual culture, and for the moral and religious influence their writings have produced on the world.

III. Japetidæ.—This variety includes most of the nations of modern Europe. Physically, they present characters superior to the two other varieties. Their face is not flat, and is moderately broad. The jaws project but little, the nose is often very prominent, and the frontal profile is not unfrequently nearly vertical. The skull is shaped generally as the last variety; the opening of the eyelids is straight, and very rarely oblique; the skin is white, or brunette: the hair is never woolly, varying mnch in colour, freqnently very light; the eyes are black, blue, or gray.

The languages of the great European races are never aptotic. They are mostly anaptotic, or having amalgamate inflections. In a few instances they are agglutinate.

Although the *Japetidæ* form the principal part of the nations of Europe, they do not exclnsively occupy this district of the earth, nor are they confined to it. We have before mentioned the Lapps and Finns of Scandinavia, the Euskaldunes of the Basque Provinces, the Magyars, and Turks. It appears not to be improbable that the former were the original inhabitants of Europe, and are the remnants of a race driven away successively by the Celts and the Indo-Germanic races that now occupy this part of the world. As also we find evidence of the origin of the *Japetidæ* in the east, so we find traces of their existence in various parts of Asia: as in the Persians, Kurds, Beloochi, Afghans, Tajiks, and Siaposh. It is not improbable, also, that the Armenians ought to be classed with the Japetidæ.

The influence of this variety of mankind on the history of the world, has been much greater than that of the other two. If we are indebted to the Semitic races for the truth of Christianity, its adoption and propagation in a pure form has been mainly due to European nations. It became early identified with the civilisation of Greece and Rome; and passing from the nations where it obtained its early triumphs, it has become, in later times, the religion of the great Anglo-Saxon race, which on both sides of the Atlantic is increasing with extraordinary rapidity.

Dr. Latham divides the *Japetidæ* into two divisions—Occidental and Indo-Germanic.

A. Occidental Japetidæ include the races called Celts or Kelts. The Keltic languages were separated from the common mother-tongue subsequent to the evolution of the persons of verbs, but anterior to the evolution of the cases of nouns. These languages are evidently agglutinate. The present area of this race is Brittany, Wales, the Highlands of Scotland, the Isle of Man, and Ireland. The original area occupied by the Kelts, which have been constantly removed, is the Scottish Lowlands, England, Gaul north of the Loire, and part of Switzerland. It is probable also that they occupied parts of Baden, Bavaria, and northern Italy. The Taurisci of the Tyrol, the Scordisci of Illyria, the Galatians of Asia Minor, the Celt-Iberians of Spain, and the Cimbri of Jntland are generally regarded as Kelts. They have two types of complexion in the British Islands: the Silnrian type having eyes and hair black, complexion dark with a ruddy tinge, and chiefly found in South Wales; the Hibernian type with gray eyes, yellowish, red, or sandy hair, and light complexion; they are found in Ireland. Dr. Latham gives the following as their chief divisions:—

1. Kelts of Gaul, falling into—*a.* the proper Celts; *b.* the Belgæ. Both extinct or incorporate.
2. British Kelts, falling into—*a.* the Cambrians; *b.* the Picts, which are extinct or incorporate.
3. Gaels. *a.* Scotch Gaels; *b.* Irish Gaels; *c.* Manxmen, or Gaelic Kelts of the Isle of Man.
4. The Cisalpine Kelts of northern Italy.
5. The Ligurians, extending from the Etruscan to the Iberian frontier.

Their line of population seems to have been from Calais and Dunkirk to England, from England to Scotland, and from Scotland to Ireland.

B. Indo-Germanic Japetidæ.—The languages of this group were separated from the common mother-tongue subsequent to the evolution of the cases of nouns. They are less evidently agglutinate than the Keltic. This and the previous group are sometimes called Indo-European, and thus embracing all the Japetidæ. The Indo-Germanic *Japetidæ* are divided into two classes:—

I. European Indo-Germans.—These are divided into—1. Gothic; 2. Sarmatian; 3. Mediterranean.

1. The Goths embrace—

- *a.* The Teutons, which are again divided into—
  - *α.* Mesogoths.
  - *β.* High Germans, including Hessians, Thuringians, Franks.
  - *γ.* Low Germans, including—
    1. Batavians.
    2. Saxons, embracing—
       - * Saxons of Hanover, and Anglo-Saxons of England.
       - ** Saxons of Osnaburg and Westphalia.
       - *** Nordalbingians. Extinct.
    3. Frisians.
- *b.* Scandinavians, embracing—
  1. Icelanders.
  2. Faroe Islanders.
  3. Norwegians.
  4. Swedes.
  5. Danes.

2. Sarmatians. This comprises the Lithnanic and Slavonic divisions, and these are its primary sections.

Of the Lithuanians Dr. Latham says—

1. Of all the Japetidæ they preserved their original paganism longest.
2. Of all the Japetidæ they have had the least influence on mankind.

2. Of all the Japetidæ they speak a language nearest in structure to the Sanscrit.

The Slavonic division includes—

α. Russians.
β. Servians.
γ. Illyrians.
δ. Tcheks.
ε. Poles.
ζ. Serbs.
η. Polabic Slavonians.

3. Mediterranean Indo-Germans. These include the Greeks and Romans of antiquity, and their modern descendants.

II. Iranian Indo-Germans.—Dr. Latham says "the whole of this class is hypothetical." It includes the Persians, who embrace the Kurds, the Beloochi, the Afghans, the Siaposh, and other contiguous races in Asia. The unplaced stocks are the Armenians and Iberians.

Latham, *Varieties of Man;* Lawrence, *Lectures on Man;* Dr. Lankester, *On the Physical History of Man*, in *Family Tutor;* Nott and Gliddon, *Types of Mankind;* Dr. Latham, *Ethnology of British Colonies, Ethnology of British Islands, Migrations of Man, Ethnology of Europe;* Dr. Pickering, *Races of Men;* Dr. Prichard, *Physical History of Mankind;* Cuvier, *Règne Animal.*)

MAN, FOSSIL. [ANTHROPOLITES, *S.* 2.]

MANBY, CAPTAIN GEORGE WILLIAM, the author of several inventions applied to the saving of life in shipwreck, was born at Hilgay in Norfolk, on November 28th, 1765, and died at his residence Pedestal House, Southtown, near Great Yarmouth, on November 18, 1854, thus having nearly completed his eighty-ninth year. He adopted the military profession, but appears to have retired from any active duty after he had attained the rank of captain in 1803, when however he was appointed barrack-master at Great Yarmouth. Here in February 1807 occurred the loss of the Snipe gun-brig, when he saw sixty-seven persons drowned within a few yards of the beach; and, in the same gale, so many other disasters occurred that one hundred and forty-seven dead bodies were cast upon a line of coast of about thirty miles in extent. Such calamities induced him to devise means of assistance by throwing a line over the vessel. This was at first proposed to be done by a balista; but a successful experiment with a small mortar, when he threw a line over a church, led him to prefer the use of gunpowder. The great difficulty to be overcome was as to the connection of the shot with the rope. Chains broke on the discharge. At length, after repeated trials, stout strips of raw hide closely platted, were found to answer, and on the 12th of February 1808, when the crew of the brig Elizabeth were in imminent danger, about one hundred and fifty yards from the beach, having lashed themselves to the rigging with the sea breaking over them, and in what would have been a hopeless position, Captain Manby threw a line over the vessel, a boat was hauled off by it, and the crew of seven men were brought to land. In the same severe winter Captain Manby rescued the crews of several vessels by similar means. In 1810 his services were brought before the House of Commons. A committee was then appointed on the subject of the saving of life in shipwreck. The merits of previous inventions for the same object were brought before that committee, especially by the friends of Lieutenant Bell of the Royal Artillery, who in 1792 had communicated to the Society of Arts a plan for throwing a rope from a mortar from the vessel itself, and to whom 50 guineas had been awarded after some experiments at Woolwich. That plan however would have been obviously very difficult of application in the case of a vessel in a raging sea. Captain Manby having been reported of with high approval by the Committee, received a pecuniary recompense from the Exchequer, and was employed to report upon the dangerous parts of the coast from Yarmouth to the Frith of Forth. He advised that mortars, constructed on his principle, should be stationed at various points; in 1814 the House of Commons addressed the Prince Regent on the subject; and within two years afterwards fifty-nine stations were provided with the requisite apparatus. The attention which was thus given to the subject of the preservation of life in cases of shipwreck, was further expressed through associations which were formed throughout the country chiefly by Captain Manby's exertions. He also contrived means of obtaining a sight of a vessel on a dark night, by the use of a description of firework throwing stars to burn at a certain height; and he suggested the use of shells, filled with a burning composition, to allow the crew to discover the flight of the rope. He also devised an improvement in the manufacture of ropes to prevent mildew and rot, disusing vegetable mucilage, and using a solution with sugar of lead and alum in equal parts; and he suggested various improvements in life-boats. Late in life he visited the Northern seas, chiefly in order to test the efficacy of a new form of harpoon which he had invented. For his various inventions, which were the means of saving upwards of a thousand lives, he received at various times 7000*l.* from the British nation, and the thanks of the chief sovereigns of Europe.

MANDAMUS. The Writ of Mandamus, mentioned P. C. v. xiv., p. 347, and which can only be obtained in the Court of Queen's Bench, is now usually termed the Prerogative Writ of Mandamus, in order to distinguish it from the writs of mandamus obtainable in certain cases in all the other Superior Courts of Law.

The proceeding by Prerogative Writ of Mandamus may be resorted to, as has been already pointed out, in cases where a public inconvenience or a private wrong is occasioned by the omission of a public duty, and no sufficient remedy is afforded by an action for damages. This remedy was originally confined in its operation to a limited class of cases affecting the administration of public affairs; such as the election of corporate officers, or compelling inferior courts to proceed in matters within their jurisdiction, or public officers to perform duties imposed upon them, as to make a rate and the like. But in more recent times it has been extended to cases in which the rights of private individuals only are concerned. In every session of Parliament a number of Acts are passed for making railways, docks, bridges, improving towns, &c., &c., and, in almost all of such Acts, there are provisions directing the company obtaining the Act to do certain works for the benefit of individuals; such as substituting new buildings for others necessarily removed, making new communications in lieu of old ones, and other works of a similar nature. In the event of noncompliance with these enactments, the remedy is by mandamus. This mode of proceeding having been found uncertain, tedious, and expensive, the procedure therein has been very materially altered and amended by the Common Law Procedure Act, 1854, the proceedings being now assimilated as much as possible to those in an ordinary action.

The remedy hitherto afforded by this prerogative writ, in cases where the public were interested, has, by the same statute, been extended to cases in which private rights only are concerned. The plaintiff may claim in his writ the performance of any duty in which he is interested, and this claim must be repeated in the declaration, which must set forth sufficient grounds for the claim, and show that the plaintiff is personally interested therein; that he sustains or may sustain damage by the nonperformance of the duty, performance of which is demanded; and that performance thereof has been demanded by him, and refused or neglected by the defendant.

Where judgment is given that a mandamus do issue, the court, if it shall see fit, besides issuing execution in the ordinary way for the costs and damages, may also issue a peremptory writ of mandamus, commanding the defendant forthwith to perform the duty to be enforced, which the defendant must obey; for no return, except that of compliance, will be allowed, although time to return the writ may, upon sufficient grounds, be obtained.

If the defendant fails either to obey or to return the writ, two courses are open to the plaintiff. He may cause the defendant to be attached; or instead of proceeding by attachment, the court may, upon his application, direct the act required to be performed by the writ to be done by the plaintiff himself, or some other person appointed by the court, at the expense of the defendant; and upon the act being done, the amount of such expense may be ascertained by the court, who may order payment of the amount of such expenses and of the costs, and enforce payment thereof by execution.

MANGO-TREE. [MANGIFERA.]

MANIHOT. [JANIPHA, *S.* 2.]

MANIN, DANIELE, a distinguished Italian politician and patriot, was born at Venice in 1804, the son of Pietro Manin, a respectable advocate. His grandfather, Lodovico Manin, bore the same name as the last doge of Venice, whose weak behaviour at the time of the extinction of the ancient republic by Bonaparte (1797) had attached a certain discredit to the name. Young Manin, who from the first showed great abilities, was bred up to his father's profession of the law, and graduated as Doctor of Laws at the University of Padua at a very early age. He married in 1825, and shortly afterwards commenced practice as a lawyer at Mestre, a small town near Venice. Here he led a quiet domestic life, employing his leisure in historical and legal studies, and occasionally in writings of a kindred character. From the first however he shared fervently in the general discontent of his countrymen with Austrian rule, and the general aspiration after restored liberty and independence for Venice. Though not affiliated to any of the revolutionary societies then existing in Italy, he often discussed with several intimate friends—especially Alexandre Zanetti, Leopold Cicognara, Giovanni Minotto, and Francesco degli Antoni—the wrongs of his native country, and the possibility of remedying them by insurrection or other means. Once or twice—as during the time of the excitement caused by the affair of the brothers Bandiera in 1844—these secret communings were on the point of bursting out into open action; but, on the whole, it was felt by the friends that no movement was practicable, and Manin continued in the ordinary exercise of his profession, varying it by occasional contributions on economical topics to journals. As a speaker, he was distinguished for a logical, direct, positive, and incisive manner, different from the ordinary eloquence of his countrymen. As on several important public trials he acted a vigorous part on the liberal side, he came into collision with the Austrian government; and in the early part of 1848 he was imprisoned. But this year was to witness a change in his fortunes, and in those of Italy. On the 18th of March the spirit of insurrection with which the whole peninsula was charged, broke forth in Milan; the news of the expulsion of the Austrians from Milan acted immediately on Venice, and on the 23rd of March the Austrian commander of the city, Count Zichy, was obliged to surrender, and the republic was declared. It was at this time that Manin stepped forth as a man born to lead. The progress of events was for a time complex—the fate of the Venetians being involved in that of the other Italians. "What we *preferred*," Manin afterwards said, "was to be an independent republic, in confederation with the other Italian states; but what we would have *accepted* was, to become a portion of one great kingdom comprising all Italy."

The war of Charles-Albert, the king of Piedmont, against the Austrians in the name of Italy, as a whole seemed for a while to give likelihood to the latter expectation. The Venetians, willing to show their trust in Charles-Albert agreed to the fusion of their little republic with Lombardy and Piedmont, so as to form a united independent kingdom of Northern Italy. But the battle of Custoza having ended that dream, and restored Lombardy to the Austrian dominion, the Venetians again fell back upon their own resources and prepared for a separate defence. The republican standard of St. Mark was again hoisted; a triumvirate was appointed to carry on the executive government, Manin being the chief of the three; and the military command was intrusted to the Neapolitan general Pepé, who had thrown himself into Venice two months before, rather than obey the order that he should return to Naples. Though the Austrians kept up a blockade against Venice, it was not till March 1849, when the second attempt of Charles-Albert was brought to an end by the defeat of Novara, and when the Austrians were thus free to reconquer all that still remained to be reconquered of their lost territories in Italy, that the Venetians endured the full agony of the struggle. By that time the patriotic movement had been completely crushed in every part of Italy besides, with the exception of Rome. The two republics of Rome and Venice were the sole remains of the insurrectionary work of the previous year; and against the one of these the French were mustering their power in conjunction with the Austrians and Neapolitans, while the other was assailed by the Austrians alone. Both republics behaved bravely. What Mazzini was to Rome, Manin was to Venice. From March 1849 he was invested with all the powers of the dictatorship. The defence of Venice conducted by him is one of the most gallant and obstinate in recent history. It was on the 3rd of July that the French entered Rome; but Venice did not surrender till the 24th of August, after it had suffered a dreadful bombardment. With the fall of Venice the subjugation of Italy was complete. The terms of the surrender were such that Manin was able to go safely into exile. He afterwards resided chiefly in Paris, supporting himself honourably. He died September 22, 1857.

MANIOC. [Cassava.]

MANNHEIM. [Manheim.]

MANTELL, GIDEON ALGERNON, a palæontologist and geologist of extensive and varied acquirements, was born at Lewes, in Sussex, about 1790. For several years he practised as a medical man at Lewes, in a district which he rendered classical by his researches into its geological structure. He was a memorable instance of a man of genius, constantly and diligently occupied in discharging the duties of a laborious profession—in which he acquired great provincial reputation, especially for the delicacy of his manipulation in surgical cases, and for the tenderness of his demeanour to his patients—nevertheless reaching great eminence as a man of science, and finding time to pursue his favourite studies with distinguished success. During his residence at Lewes he collected a vast number of interesting fossils, and formed a private museum, such as has rarely, if ever, been equalled. Here also he published his principal separate works, 'The Fossils of the South Downs,' and 'The Illustrations of the Geology of Sussex.' The former appeared in 1822, simultaneously with that of Cuvier and Brongniart upon 'The Geology of the Environs of Paris;' and many of the organic remains of the chalk were described in both works simultaneously, though independently. Whilst at Lewes also he called attention to the interest and beauty of the remains of fishes found in the chalk, and it was there he commenced the series of observations which placed him in a prominent position among British geologists. His attention was early directed to the phenomena exhibited by the assemblage of clays, sands, and subordinate limestones which immediately underlie the cretaceous system in the Weald district, happily designated by his friend Mr. P. J. Martin as the 'Wealden Formation.' His location being exceedingly favourable for researches in that group of rocks, he became the original demonstrator of the fresh-water origin of the mass of Wealden beds, thus making a great step in British geology; and it is remarkable and instructive that this resulted from the direct application of the knowledge of existing causes and phenomena to the investigation of the past. Dr. Mantell's observation of the conditions under which existing fresh-water shells were imbedded in the alluvium of the valley of the Sussex Ouse, and even alternated with marine exuviæ, suggested the probability of the occurrence of similar, but immensely more ancient, phenomena in the clays and sands of the Weald; and careful research fully confirmed his conjecture. His chief and very memorable palæontological discoveries are connected with the Wealden. But the particular circumstances under which researches in fossil osteology have been pursued in England for many years past render it difficult, with a due regard to brevity, to define accurately the character, and to delineate the extent, of Dr. Mantell's labours in that department of science. The following view of the subject is from the impartial pen of Mr. William Hopkins, F.R.S., and forms a part of an obituary notice contained in his 'Anniversary Address' from the chair of the Geological Society, on the 18th of February 1853, on which the present article is founded.

Out of the Wealden, Mr. Hopkins states, Dr. Mantell "procured the most interesting of the relics of prodigious extinct reptiles, which owe to him their scientific appellations, and whose remains will long constitute some of the chief attractions of the great collection originally amassed by him, and now displayed in the galleries of the British Museum. Whether we regard his discovery and demonstration of the *Iguanodon* and its colossal allies in a geological point of view, as characterising distinctly an epoch in time, or, with respect to their zoological value, as filling up great gaps in the series of *Vertebrata*, and elucidating the organisation of a lost order of reptiles, at once highest in its class, and most wonderful, we must, as geologists and naturalists, feel that a large debt of gratitude is due to the indefatigable and enthusiastic man out of whose labours this knowledge arose. In the group of Dinosaurian reptiles were some of the largest of terrestrial animals. In their organisation, whilst truly Reptilian, they approached [by a direct relation of analogy] the Mammalian type. Their characters were so peculiar, that of the value and distinctness of their order there can be no question. Their osteology has been elaborated with skill and care, and has worthily occupied the attention of the most eminent anatomists. They give a feature to the herpetology of the middle portion of the secondary epoch. Now, of the five marked genera constituting this group, as at present known, we owe the discovery and demonstration of four—viz., *Iguanodon*, *Hylæosaurus*, *Pelorosaurus*, and *Regnosaurus*—to Dr. Mantell. Worthily then were the Wollaston Medal and Fund adjudged to our lamented colleague in 1835, 'for his long-continued labours in the comparative anatomy of fossils, especially for the discovery of two genera of fossil reptiles, *Iguanodon* and *Hylæosaurus*.' That he did not rest from his labours, after having received this honourable reward, the discovery of two additional genera mentioned above can testify. Nor did he cease from continually seeking to perfect his knowledge of the wonderful animals brought to light during his earlier career. Thus, whilst the announcement of the *Iguanodon* dates as far back as 1825, his account of the jaw of this reptile was given to the world fifteen years afterwards. His paper on *Pelorosaurus*, in the 'Philosophical Transactions,' was published in 1850."

Dr. Mantell was equally interested in all other branches of palæontology. One of his earliest papers, communicated to the Linnæan Society, and published in its 'Transactions,' vol. xi., related to the bodies called by him and now well-known as *Ventriculites*, found in the chalk, and referred by him to *Alcyonia*. On fossil *Mollusca* and *Radiata* he wrote many valuable papers, especially those that concern the *Belemnites* and their allies. Mr. Henry Deane of Clapham, afterwards president of the Pharmaceutical Society, having detected the soft bodies of *Foraminifera* (*Rotaliæ*) in an extraordinary state of preservation in the chalk of Folkstone, and prepared illustrative specimens of them for the microscope, called Dr. Mantell's attention to them, who devoted much time to their investigation, and, uniting the observations made by Mr. Deane and himself with the results of some of his own previous researches, communicated a paper to the Royal Society on the general subject of the 'Fossil Remains of the soft parts of Foraminifera, discovered in the chalk and flint of the South-east of England,' which was inserted in the 'Philosophical Transactions' for 1846. Among his most recent labours was the account of the remarkable reptile from the Old Red-Sandstone, named by him *Telerpeton Elginense*, an animal of singular interest, regarded, until very recently, as the most ancient unquestionable relic of its class. At the time he died he was occupied with a description of a very singular fish from the chalk, to which he intended to give the name of *Rynchonichthys*.

Dr. Mantell was elected a Fellow of the Royal Society in 1825, shortly after his discovery of the Iguanodon, and in 1849 he received from the Council the royal medal, as an acknowledgment of his palæontological researches. He was also enrolled as a Fellow of the Royal Society of Physicians, London, in recognition of his scientific eminence, he not having been originally connected with the College. In 1835 he removed from Lewes to Brighton, and four years later, after the purchase of his collection of fossils by the trustees of the British Museum for 5000*l.*, to Clapham, near London. Some years having elapsed, he disposed of his medical practice at that place, and removed to Chester-square, London, where he continued to reside and practise for the remainder of his life. For many years he endured severe illness and excruciating pain, owing to a spinal disease, the result of an accident. But no torture could destroy his love for science, or his energetic pursuit of geological research. He died at his residence in Chester-square on the 10th of November 1852, aged sixty-two.

Dr. Mantell's scientific character has two distinct features; those of an original discoverer, and of a public teacher. His influence in science depended less perhaps upon the former, brilliant as it was, than upon the latter. As a popular expounder of geological facts he was unequalled; as a lecturer, within his own particular field, he had no rival; fluent, clear, eloquent, and elegantly discursive, he riveted the attention of his audience, and invariably left them imbued with a love for the science he had taught them. His popular writings, of which the 'Wonders of Geology' and the 'Medals of Creation' are among the most useful, had a wide circulation, and are held in high esteem by general readers. They have a considerable reputation also on the Continent, and have been translated into German. The 'Medals of Creation' is almost the only book in the English language, in which a comprehensive survey of the fossil world, and a perspicuous and satisfactory outline of British palæontology, both adapted to the educated and general reader, can be met with. He was likewise the author of several interesting views of the geological structure and physical geography of Sussex and Surrey, or of portions of those counties, as well as of the adjacent county of Kent (into which his favourite Wealden also extends), which were inserted in topographical works, as introductory to the general history of the districts described. One of these forms a portion of the prefatory matter in the 'County History of Surrey,' by the late Edward Wedlake Brayley, F.S.A. In the 'Bibliographia Zöologiæ et Geologiæ' of Agassiz and Strickland, no fewer than sixty-seven works and memoirs of various degrees of importance and length, are enumerated as having proceeded from Dr. Mantell's pen; to these must be added some antiquarian papers, and several professional disquisitions.

MARMONT, AUGUSTE FREDERIQUE LOUIS VIESSE DE, MARÉCHAL DUC DE RAGUSE, the son of the Chevalier de Marmont, an old officer of distinction, was born at Châtillon-sur-Seine, on the 20th of July 1774. He entered the army as sub-lieutenant of infantry in 1789; but his father wishing him to receive a sound military education, sent him, in 1792, to the Artillery School of Châlons. Towards the end of that year he served in the campaign of the Alps, under General Montesquieu. He was present at the siege of Toulon, December 1793; and having been noticed by Bonaparte for his skill in directing his guns, was chosen as his aide-de-camp, and made a captain in 1794. In this capacity he accompanied his general to the army of Italy, during the campaign of that year. After the great insurrection of the Sections, on the 13th Vendémiare (October 6, 1795), Marmont, having been apppointed chef-d'escadron, went a second time to Italy, in March 1796, as principal aide-de-camp to General Bonaparte. In this famous campaign he was present in almost every field: at Lodi, at Castiglione, and at the battle of Saint-Georges, his intrepidity, his skill, his aptitude and invention were alike conspicuous; he was created colonel, and sent to Paris with 22 colours taken from the enemy. Next, he took part in the expedition to Egypt, and was made a general of brigade for his services during the investment of Malta. During the campaign of Syria, in 1799, he was appointed commander in Alexandria, and defended that city against the English and Turks, in a season of famine and pestilence. When General Bonaparte set sail for France, on his return from Egypt, August 22, 1799, General Marmont was one of the seven officers selected to bear him company in his perilous enterprise.

During the crossing of Mount Saint-Bernard in the spring of 1800, Marmont's plans for the conveyance of the guns having been adopted, he superintended the entire transport, and by his persevering efforts the passage of this important arm was effected. He fought with much distinction at the battle of Marengo, June 14, 1800, and was immediately after raised to a division. After the peace gained by this victory, he was made inspector-general of artillery; he then applied himself zealously to various reforms in the service, especially for the accelerating of the transit of the artillery train. All these improvements were sanctioned by the First Consul, though the young military reformer was only in his twenty-seventh year.

In the campaign of 1805, General Marmont was present at the capture of Ulm, October 20, 1805; and he was next successfully employed in the reduction of the province of Styria. Henceforth he commanded armies. In 1806 he was sent to command the army in Dalmatia, where he acted as general-in-chief for several years. On the 2nd of October, with an army of 6000 men, he defeated an allied corps of 9000 Montenegrins, Greeks, and other troops, sustained by a second corps of 7000 Russians. During his occupation of the duchy, Marmont carried out a beneficial system of public works, including a great line of roadway, 210 miles in length, for which useful improvement he received his title of Duc de Raguse in 1808. When the campaign of Wagram opened in 1809, Napoleon called this general to support his main army. Marmont took the field with a corps of 9500 infantry, only 300 cavalry, and 12 pieces of cannon. With this force he defeated an Austrian army of 20,000 men in several severely contested engagements; and then encountering General Giulay, at the head of 35,000 troops, posted on the Drave, compelled that general to retreat into Hungary. After these successes he joined Napoleon the day before the great battle of Wagram, July 5, 1809, took part in the action, and received his marshal's bâton for his conduct in that arduous engagement. This decisive victory being followed by the treaty of Vienna, the Austrian government made over to France the provinces of Dalmatia, Istria, Ragusa, and Croatia, with other adjacent lands, which Napoleon formed into a single state, under the title of the Illyrian Provinces, and placed them under the direction of Marshal Marmont as governor-general. In this high office he continued nearly sixteen months, giving proofs of superior capacity as an administrator, whilst he was honourably distinguished from other marshals by his integrity and disinterestedness. Towards the close of 1810 he stood so high in the esteem of his master, that he was sent into the peninsula to supersede Marshal Massena in the command of the army of Portugal. Though independent in his command, he hastened to unite his army to that of Soult, placed himself under the orders of that eminent leader, and assisted him in relieving Badajoz. Less fortunate at the battle of Salamanca, July 22, 1812, he displayed however many proofs of skill as a general before he retreated, nor did he leave the field until he and the two generals who succeeded him had been disabled by severe wounds. In the campaign of 1813 the marshal, though scarcely recovered, took the command of the second corps, and was present at Bautzen, May 20, 1813; at Dresden, August 26, and at Leipsic on the 16th, 17th and 18th of October. In this last battle he defended the village of Schönfeld, which was taken and retaken seven times. Eight of his generals were either killed or wounded in the action; four horses sank under him, and he was twice wounded.

His name appears again in almost every battle fought on the French soil, in 1814, for the defence of his country. He terminated this campaign, perhaps the most brilliant in his career, by the battle before the walls of Paris, on the 30th of March 1814. The enemy, consisting of Russians, Prussians, and Austrians, were more than four to one, yet Marmont maintained his post for several hours, not surrendering even when the heights of Montmartre had been taken, and the first Russian guns had begun to sweep the Boulevards within the city; and it was not till some hours after receiving a letter from Joseph Bonaparte authorising them to capitulate, that Marmont and Mortier called a council of general officers at an inn within the suburb of La Villette, when they agreed to the evacuation of Paris.

The army of the allies entered the French capital on the 31st of March, and Marshal Marmont, on the 4th of April, after a short correspondence with Prince Schwartzenberg, stipulating for the retirement of the French troops into Normandy, with arms, baggage, and artillery, entered the allied lines, and thence marched to Versailles. It was this step, taken without the sanction of Napoleon, which afterwards drew down upon him so much odium.

The Duc de Raguse was now wedded to the cause of the restored dynasty. He accompanied Louis XVIII. to Ghent in 1815, returned to Paris with that sovereign after the battle of Waterloo, and was employed repeatedly both by that monarch and Charles X. in offices of great trust. At the outbreak of the July revolution in 1830, he was charged with the invidious duty of quelling the revolt, and having failed, became a second time the mark of almost universal obloquy. To satisfy the popular indignation, he was struck off the list of the French army, and exiled from France. He spent his years of banishment in visiting different countries, and in writing works of considerable merit on the military systems of Russia, Austria, and other states. Nearly twenty-two years after his disgrace, he died at Venice, on the 2nd of March, 1852, in his seventy-eighth year. The publication of the 'Mémoires du Duc de Raguse,' from his original manuscript, in 9 vols. 8vo., Paris, was completed in 1857.

MARRAST, ARMAND, who succeeded Carrel as chief editor of 'Le National,' was born in 1802, in the south of France. After a careful education at the College of Pont-Levoy, he went to Paris in 1827, and immediately commenced his career of politics by writing pamphlets against the government. The pungency and playful humour of these light productions drew notice upon the author, and he at once made for himself a distinct position among the young politicians of the day. When he arrived in the French capital, a vivid contest was being waged between the practical school of philosophy, conducted by Laromiguière, and the eclectic school, presided over by Cousin. Marrast entered the ranks of the former, and month after month amused and excited the public by the light artillery of his pleasant brochures against Cousinisme.

In 1830 Marrast established the newspaper 'La Tribune.' It became the organ of the ultra-liberal party, and as such organ it was constantly quoted by foreign as well as French journals. It contained very bitter articles against the government of Louis Philippe, and the fines to which it was condemned, together with the law-expenses attending its defence, put an end to its publication after a few years. Armand Marrast, on one occasion, was called to the bar of the Chamber of Deputies on account of two articles in 'La Tribune.' On another occasion he was arrested and sent to prison as one of the conspirators concerned in the 'complot d'Avril.' He was soon released, when he published his celebrated pamphlet, 'Vingt Jours de Secret,' which produced a great sensation, and much increased his popularity. Proceedings were taken against him by the ministry. He sought refuge in England, remained several months in London, remitting every week one or more letters of great ability to 'Le National,' and married an English lady during his sojourn in this country. These letters were the origin of that long connection with Armand Carrel and 'Le National,' which afterwards gave to Marrast the influence he possessed over his countrymen. He became sub-editor of 'Le National' in 1834; and on the death of Carrel, July 24th, 1836, he succeeded him as chief editor. From this time until the revolution of February 1848, a period of nearly twelve years, Marrast conducted that journal, and maintained it in the high position it had acquired under Thiers, its first editor, and then under Carrel.

During 1847, a series of exciting incidents rapidly followed one another, highly favourable to Marrast's satirical ability. At one time, it was a course of ministerial prosecutions; at another, rumours of bribery and corruption among men high in office; next, these rumours were succeeded by flagrant exposures or confessions; and lastly, came the scandal of an assassination in the mansion of a great noble. The republican journals made the most of these incidents, and 'Le National' took the lead in denouncing the government and the court. The revolution of February, and the abdication of Louis Philippe followed. Pending the crisis of this event, the office of 'Le National' became for a few days the seat of government; and deputations visited Marrast, and received their instructions from him. His name was now on every tongue; and when Lamartine was placed by the rapid progress of events at the head of the provisional government, Marrast became secretary, afterwards maire de Paris, and finally president of the National Assembly. This last office was limited by a new regulation to one month; but the urbanity of the new president, and his extraordinary influence over the 900 members in consequence of his tact in calling them to order by humorous appeals, caused him to be re-elected several times. To him likewise was committed the task of drawing up the new constitution. But the red republican party soon found that Marrast was not advanced enough for them; they began to stigmatise him as a moderate, and his popularity fast declined. On the 15th of May 1848 the insurgents, headed by Barbès and Blanqui, forced their way into the Hôtel-de-Ville, their first cry being "Where is Marrast? We must make an end of that soft-handed republican!" But he had withdrawn for concealment to a private chamber which was not searched. After the insurrection of June, and the consequent dissolution of the Lamartine cabinet, Marrast retired into private life. We believe that he still contributed to 'Le National' without any longer being its editor, until the paper was suppressed by the government of Louis Napoleon. He died on the 10th of March 1852.

MARRIAGE. Provision is made for the licensing of district churches and chapels for the celebration of marriage, by the stat. 7 & 8 Vict. c. 56. The notice given to the Superintendant Registrar must now be accompanied by a solemn declaration as to the consents required by law having been obtained. This is provided for by the statute 19 & 20 Vict. c. 119, which also enables parties who have entered into the contract of marriage merely before the Superintendant Registrar, to have the ceremonies of the church or of their own persuasion added at any time afterwards. The object of this enactment is to permit the parties to satisfy any religious scruples which, after the merely civil form of the contract has been resorted to, may arise or be suggested to them. (Blackstone's 'Commentaries,' Mr. Kerr's ed., vol. 1, p. 464.)

MARRYAT, FREDERICK, was born in London on the 10th of July, 1792. His father, Joseph Marryat, Esq., of Wimbledon, Surrey, was a wealthy West India merchant, and M.P. for Sandwich, and traced his descent from a French Protestant refugee, who had come over to England in the 16th century. His mother was the daughter of an American loyalist. After being educated at various schools in and near London, young Marryat entered the naval service in September, 1806, as a midshipman on board the Impérieuse, 44 guns, commanded by the cebrated Lord Cochrane. Under this daring commander he was engaged in upwards of fifty actions, of more or less importance, off the French and Mediterranean coasts during the next three years. In one he was left for dead on the deck of a ship which he had boarded, and only recovered when a fellow midshipman, who had a grudge against him, touched his supposed dead body with his foot, and began to moralise in rather uncomplimentary terms on his premature exit from life. The reputation for gallantry and ability which he acquired under Lord Cochrane, was amply sustained by his conduct under other commanders during three additional years of service as a midshipman. On four or five occasions he saved men from drowning by leaping overboard, at the risk of his own life. On one such occasion he saved the life of a son of William Cobbett, then his fellow midshipman. At another time, on jumping overboard in an attempt to save a sailor's life, he fonnd to his horror the man bleeding from the maw of one of three sharks that were following the ahip; and he had given himself over for lost before he was picked up. In 1812 he was appointed to his lieutenancy on board the Espiègle sloop, whence he removed to the Newcastle, sent under Lord George Stuart, to cruise off the American coast. He attained a commander's rank in 1815. In 1820 he commanded the Beacon sloop off St. Helena, whence he exchanged into the Rosario, in which he brought home duplicate despatches announcing the death of Napoleon. After beiug employed for some time in the preventive service, he was appointed in March 1823 to the Larne, 18 guns, and proceeded to the East Indies. He was senior naval officer in the attack on Rangoon, and in December 1824 he accompanied Sir Robert Sale in the expedition up the Bassein River. His good services in the East Indies procured him the thanks of the governor-general and much distinction at home. In June 1825 he received the decoration of C.B., and at the same time the Royal Humane Society awarded him its medal for having saved so many lives from drowning. From November 1828 to November 1830 he commanded the Ariadne in the Channel service; and it was at this time, when he was approaching his fortieth year, that he began his career as a novelist by the publication of his 'Frank Mildmay.' This was followed at brief intervals during the next sixteen years by his other well-known writings, most of them novels of sea-life—'Peter Simple,' 'Jacob Faithful,' 'Japhet in Search of a Father,' 'The King's Own,' 'Mr. Midshipman Easy,' 'Newton Forster,' 'The Pacha of Many Tales,' 'Rattlin the Reefer,' 'Snarly-yow, or the Dog-Fiend,' 'The Children of the New Forest,' 'Olla Podrida,' 'The Pirate and the Three Cutters,' 'The Phantom Ship,' 'Poor Jack,' 'The Poacher,' 'Masterman Ready,' 'Percival Keeue,' 'The Narrative of Monsieur Violet in California, &c.' 'The Settlers in Canada,' 'The Mission, or Scenes in Africa,' 'The Privateer's Man,' and 'Valérie.' The merits of these works as amusing works of adventure and description are universally known. Besides these, he published in 1837 a work of a different class, 'A Code of Signals for the use of vessels employed in the Merchant Service,'—which was adopted by government, and is now in general use by our own and all foreign navies, and which procured him the cross of the Legion of Honour from Louis Philippe. He also published in 1839 in two series of three volumes each, 'A Diary in America, with remarks on its Institutions,' a work which gave great offence to the Americans by its satirical spirit. It is said that the free expression of opinions by Captain Marryat against the practice of impressment was the cause of his not having been raised to higher professional rank. For a year or more before his death he was laid aside from duty and literary labour by an illness arising from the burst ing of several blood-vessels. He died at his residence at Laugham, Norfolk, on the 2nd of August, 1848, aged fifty-six years. By his marriage with Catherine, daughter of Sir Stephen Shairp, once chargé-d'affaires at the court of Russia, he had six children. Of two of his sons who had entered the navy, one perished, before his father's death, in the Avenger steamer; one of his daughters has since appeared as a writer of novels. Captain Marryat was a Fellow of the Royal Society.

MARS, ANNE-FRANÇOISE-HYPPOLITE BOUTET, known as MADEMOISELLE MARS, was born in Paris on the 9th of February, 1778; her father being the actor Monvel of the Théâtre Montansier; her mother a country actress named Mars-Boutet. She appeared before she was ten years old in juvenile parts, and in 1793 she already filled at the Théâtre Feydeau, what on the French stage are called 'les rôles d'ingénues.' She met with a generous patroness in Mademoiselle Contat, then the leading actress in comedy, and received from her the best trainiug for the cast of characters which her early talents pointed out as her own. After she had made herself familiar with these parts of the young girl, she was induced, still directed by Mademoiselle Contat, to attempt 'les jeunes amoureuses;' in which character she succeeded to the first place, after the retirement of Mesdemoiselles Mézéray and Lange in 1798. She was then tweuty. Her fine talent was very gradual in its development, nor did the pnblic at all foresee what she would become. It was not until 1803 that her first marked success had been obtaiued. In that year the part of a deaf and dumb pupil of the Abbé de l'Epée, in the piece of that name, having been assigned to her, she displayed so much feeling, ingennousness, and grace in its performance, that from that night she took rank as one of the great comic actresses. Her talents rapidly increased nnder the influence of cordial encouragement. Her kind instructress, Mademoiselle Contat, took leave of the stage in 1809, leaving the inheritance of her 'répertoire' to be divided between Mademoiselle Mars and Mademoiselle Leverd, which gave rise to a long contest between the rival stars. The former however soon distanced all competitors, and for a space of thirty years stood at the head of all French actresses in genteel comedy, gaining a new success in every new part, down to that of Mademoiselle de Belle-Isle, in Dumas's drama, which she played for the first time on the 2nd of April, 1839, when she had passed the age of three-score.

Yet, although she never refused to take the leading characters in plays of the new school, and in each achieved a new triumph, she was to the last opposed to the modern romancists, and geuerally required extensive changes to be made in her own parts. Victor Hugo and the elder Dumas were sometimes embarrassed by her criticisms and strictures, and the latter, in his 'Mémoires,' has described some piquant disputes of this nature between the actress and the dramatists. But her grandest delineations were in the earlier drama, especially in the comedies of Molière. In the lady of fashion, in the coquette of the beau monde, every spectator felt the collected self-possession, the fulness of attention with which she performed these characters. It was her resolute will and extraordinary ability which alone kept alive a respect for the earlier dramatic literature in the house to which she belonged, when a dozen theatres and fifty modern dramatists were endeavouring to subvert it.

Those who never saw Mademoiselle Mars on the stage, can form no idea of the simplicity, the seeming artlessness, the graceful elegauce of her acting; nor of the music of her voice, so distinct that the very letters seemed printed in it, nor of the exquisite expression of her smile. Her form was very fine, her gait easy yet majestic, her costume remarkably elegant and distinguished. She was one of the shareholders of the Théâtre Français, and her yearly rent from this sonrce amounted to 40,000 francs; and, in 1816, Louis XVIII. settled on her as well as on Talma a pension of 30,000 francs. The hotel in which she lived was open to the most celebrated foreign as well as native artists and literati, some of whom were daily to be seen paying their court to her. She was sedulonsly attentive to the critics and feuilletonists, all of whom vied with each other in describing her performances. On the night of the 7th of March 1841 she appeared for the last time on the boards of the Théâtre Français, in the 'Misanthrope' and the 'Fausses Confidences.' It was of course a benefit night, and for the last time she performed the parts of Célimène and Araminte. She died on the 20th of March 1847, her death having been accelerated, if not caused, by the habit of having her hair dyed every ten days. She left behind her a fortune of 800,000 francs.

MARSHALSEA. The Court of the Marshalsea and the Palace Court were abolished by the statute 12 & 13 Vict., c. 101. Their procedure and the costs of actions therein had for some time before been the object of animadversion by the press, whose remarks, however apparently well founded, amounted to no more than the universal complaint of the costs incident to legal proceedings. The Palace Court had not long before been reputed by Royal Commissioners to be one of the best in the metropolis.

MARSHFIELD. [GLOUCESTERSHIRE.]

MARSILEACEÆ, or RHIZOCARPEÆ, *Pepperworts* or *Rhizocarps*, a natural order of Aquatic Plants, with creeping stems bearing leaves, which are usually divided into three or more cuneate portions, and have a circinate vernation. The fructification is produced at the base of the leaf-stalks, and consists of sporocarps and involucres inclosing clustered organs, which consist of antheridian and pistillidian cells. The germinating body has an oval form, and occasionally a mammilla on one side, whence roots and leaves proceed. The species are all inhabitants of ditches or inundated places. They do not appear to be affected so much by climate as by situation; thus they have been detected in various parts of Europe, Asia, Africa, and America, chiefly however in temperate latitudes. Their position is between *Lycopodiaceæ* and *Jungermanniaceæ*. The species number about 20, the principal of which are—*Pilularia, Marsilea, Azolla* and *Salvinia*. (Balfour, *Class-Book of Botany*.)

MARTAGON. [LILIUM, *S.* 1.]

MARTIN, JOHN. was born at a house called the East-land Ends, Haydon Bridge, near Hexham, Northumberland, on the 19th of July, 1789. His early ambition being to become a painter, his father, as the best way of turning his desire to profitable account, apprenticed him to a coach-maker at Newcastle (whither the family had removed) to learn herald-painting. Here however he only remained a few months; and, his indentures having been cancelled, he was then placed with an Italian painter named Bonifacio Musso, the father of Charles Muss, who acquired some distinction as an enamel painter. With him young Martin removed to London in September, 1806, and soon after, not getting on very pleasantly in his master's family, took lodgings for himself; and, as he relates in some autobiographical notes contributed to the 'Athenæum' (see 'Ath.' for 1854, p. 246, to which we are indebted for the leading facts contained in this notice), "at this time, by close application till two or three o'clock in the morning, in the depth of winter, I obtained that knowledge of perspective and architecture which has since been so valuable to me. I was, at this time, during the day employed by Mr. C. Muss's firm painting on china and glass, by which, and making water-colour drawings and teaching, I supported myself: in fact, mine was a struggling artist's life when I married, which I did at nineteen."

His marriage stimulated him to a bolder course. He determined to paint a large picture, and by a month's application produced in 1812 his first work, 'Sadak in search of the Waters of Oblivion.' Before it left his hands his hopes received a severe blow: he "overheard the men who were to place it in the frame disputing as to which was the top of the picture." It was a mistake easy enough to make; but once in the frame the top of the picture would not be again in danger of being taken for the bottom. It found a place in the Royal Academy Exhibition, and, what was better, a purchaser for 50 guineas, in Mr. Manning, a bank director. He followed up his success by sending to the British Institution an 'Expulsion from Paradise,' and to the Academy in 1814 'Clytie,' a work which was hung in the ante-room, as was also his larger and more ambitious picture, 'Joshua commanding the Sun to stand still.' At the British Institution, where the 'Joshua' was again exhibited the following spring, it was placed in a post of honour, and awarded the prize. Martin was excessively angry with the Academy for this treatment of his "grand work," and the breach was never healed: he removed his name from the Academy's books as a candidate for membership, and as a necessary consequence, according to the laws of the Academy, he never received any academic distinction. With the picture itself, and the success it met with, he was however abundantly satisfied. "The confidence I had in my powers," Martin writes, "was justified, for the success of my 'Joshua' opened a new era to me. In 1818 I removed to a superior house, and had to devote my time mainly to executing some immediately profitable works; but in 1819 I produced the 'Fall of Babylon,' which was second only to the 'Belshazzar' in the attention it excited. The following year came 'Macbeth,' one of my most successful landscapes; then, in 1821, 'Belshazzar's Feast,' an elaborate picture, which occupied a year in executing, and which received the premium of 200*l.* from the British Institution."

These works, and especially the 'Belshazzar's Feast,' were of a kind then quite new, and took the London public by storm. A sturdy opposition was raised; but for the time it was borne down by the swelling tide of popularity. It was loudly declared—and pretty widely believed—that a new era was opened to art, as well as to the painter's self; and the engravings quickly made the artist's "sublime style" familiar from one end of the island to the other. Nor was he slow to follow up his success: 'The Destruction of Herculaneum' appeared in 1822; the 'Seventh Plague' and the 'Paphian Bower;' in 1824, the 'Creation;' in 1826, the 'Deluge;' and in 1828 the 'Fall of Nineveh,' perhaps the most popular of all his pictures after the 'Belshazzar.' He was now, however, so much engrossed with engraving, and with various schemes for the improvement of London, and other engineering projects, that for a while his pencil was somewhat less diligently employed, and when he resumed its exercise he discovered that the spell was broken. His later pictures indeed found admirers, but they were few as compared to those which greeted his earlier works, and infinitely less enthusiastic. Yet he went on to the last painting subjects no less awful than those which had originally captivated the public eye. Thus during the last twelve or fourteen years of his life he painted—'The Death of Moses,' and 'The Death of Jacob,' 1838; 'The Eve of the Deluge,' 'The Assuaging of the Waters,' 1840; 'The Celestial City and River of Bliss,' and 'Pandemonium,' 1841; 'Flight into Egypt,' 1842; 'Christ stilling the Tempest,' and 'Canute the Great rebuking his Courtiers,' 1843; 'Morning,' and 'Evening,' 1844; 'The judgment of Adam and Eve,' and 'The Fall of Adam,' 1845; 'Evening—coming Storm,' 1846; 'Arthur and Ægle in the Happy Valley,' 1849; 'The Last Man,' 1850; 'Valley of the Thames viewed from Richmond Hill,' 1851.

The last picture he exhibited during his life was a 'Scene in a Forest—Twilight' (1852). He was now engaged on a series of three grand paintings, illustrative of the 'Last Judgment,' which he fondly hoped would be his master-work, and he laboured steadily at these till a few weeks before his death. Then suffering under a paralytic attack he set out in the hope of improving his health to Douglas, Isle of Man, where, at the house of Thomas Wilson, Esq., he died February 9th, 1854. His remains were interred in the lonely cemetery of Kirk Bradden, on the Strang Road, a few miles from Douglas. His three pictures, 'The Last Judgment,' 'The Great Day of Wrath,' and 'The Plains of Heaven,' have since his death been exhibited in London and the provinces. As might be expected from the nature of the subjects, and the circumstances under which they were painted, suffering under the infirmities of age, with mind and body both enfeebled, they are comparative failures, having all the worst faults and mannerisms of the painter's earlier pictures, and only few of their redeeming excellences.

Martin was undoubtedly an original painter, and possessed a very considerable share of imagination; and in the expression of material grandeur and terror,—the vastness and might of nature, in contrast with the weakness and littleness of man,—he was eminently successful. At least until by repetition the conception had been rendered common-place and unimpressive, this was unquestionably the case; and the unparalleled popularity of his early pictures, while the manner was new, can be readily understood. But Martin did not perceive that his was a trick of style which would not bear often repeating; and he kept on covering acres of canvas with interminable vistas of buildings, pile upon pile, as buildings never could have existed in reality, and crowding the roads and fields with myriads of little insignificant figures, and clothing the whole in floods of stormy gloom and twilight, with flashes of jagged lightning or streams of dazzling sunshine; never advancing beyond a harsh and niggling touch, or attaining to anything better than a crude and conventional system of colour. Seeing only two, or at most three, of his pictures, he might be pronounced a man of genius; seeing all, while acknowledging his talent, it is difficult not to feel surprise at his deficiencies of taste, observation, and judgment.

It has been said that during many years the subject of the improvement of London occupied much of his time and thought. As early as 1828 his ideas had taken a definite shape, and he gave them to the public in a 'Plan for supplying with pure water the Cities of London and Westminster, and improving the western end of the metropolis;' and he continued to publish new and revised editions almost down to his death. The following is his own account of his labours in this line, contained in his contribution to the 'Athenæum' already referred to: "My attention was first occupied in endeavouring to procure an improved supply of pure water to London, diverting the sewage from the river, and rendering it available as manure; and in 1827 and 1828 I published plans for the purpose. In 1829 I published further plans for accomplishing the same objects by different means, namely, a weir across the Thames, and for draining the marshy lands, &c., &c. In 1832, 1834, 1836, 1838, 1842, 1843, 1845, and 1847, I published and republished additional particulars, being so bent upon my object that I was determined never to abandon it, and though I have reaped no other advantage, I have at least the satisfaction of knowing that the agitation thus kept up constantly, solely by myself, has resulted in a vast alteration in the quantity and quality of the water supplied by the companies, and in the establishment of a Board of Health, which will, in all probability, eventually carry out most of the objects I have been so long urging. Amongst the other proposals which I have advanced is my railway, connecting the river and docks with all the railways that diverge from London, and apparently approved by the Railway Termini Commissioners, as the line they intimate coincides with that submitted by me, and published in their report;—the principle of rail adopted by the Great Western line; the lighthouse for the sands, appropriated by Mr. Walker in his Maplin Sand Lighthouse; the flat anchor and wire cable; mode of ventilating coal mines; floating harbour and pier; iron ship, and various other inventions of comparatively minor importance, but all conducing to the great ends of improving the health of the country, increasing the produce of the land, and furnishing employment for the people in remunerative works." He also took out patents for water and sewer-pipes, &c.

Besides his great pictures, Mr. Martin painted a great number of water-colour landscapes, very elaborately wrought out; he also made some drawings for books, including 'Paradise Lost,' and 'Paradise Regained,' the 'Pilgrim's Progress,' &c., for which he received large sums, but which, though popular in their day, now seem for the most part strangely infelicitous as illustrations. For the Milton illustrations he is said to have received 2000 guineas.

MARTINSITE, a Mineral, which is composed of 91 per cent. of chloride of sodium and 9 per cent. of sulphate of magnesia. It comes from the salines of Hassfurth. (Dana, *Mineralogy*.)

MATHEW, THE REV. THEOBALD, the Apostle of Temperance in Ireland, was born at Thomastown, county of Tipperary, October 10, 1790. His father, an illegitimate member of the family of the earls of Llandaff, died while his children were young, and Theobald was enabled by the kindness of the Countess of Llandaff and Lady Elizabeth Mathew, to proceed to the academy of Kilkenny, and afterwards to St. Patrick's College, Maynooth, where he remained until he was ordained a priest of the Roman Catholic Church in 1814. He was appointed to a missionary charge at Cork, where his influence was great among the rich and the poor alike: on his appointment to this mission he received from the pope, Gregory XVI., the degree of D.D., with a dispensation enabling him to hold property. Among other benefits which Father Mathew conferred upon the inhabitants of Cork was the establishment of a religious society for the purpose of visiting the sick and needy, on the model of the societies of St. Vincent de Paul: this institution obtained the warm approbation of the Irish Poor-Law Commissioners in 1834. About four years later he was requested to lend his aid to a temperance association formed in Cork. He joined the association and became its president; and devoting himself heart and soul to the peaceful agitation, he had the satisfaction to see within a few months no less than 150,000 converts in Cork alone. Extending his sphere of action he commenced a 'progress' through the west of Ireland, where proportionate results were seen; wherever he went the crowds that flocked to 'Father Mathew' to take the pledge of temperance were so numerous, that they could only be kept in control by the military and police. The same results followed in all the towns which he visited in the north of Ireland, and at Dublin, and to a considerable extent in Liverpool, Manchester, and London, where, regardless of creed and country, he went about doing good, and raising the squalid objects of pity and compassion to self-respect, independence, and industry. It ought to be added, that in the execution of his mission Father Mathew did not scruple to sacrifice his temporal prospects; a distillery in the south of Ireland which belonged to his brother, and formerly provided him with almost all his income, being shut up in consequence of his preaching against the use of ardent spirits. His services in the cause of morality and religion having been recognised by statesmen of all shades of opinion, her Majesty granted to Father Mathew out of the civil list an annuity of 300*l.* a year—a sum, which though ample in itself, is understood to have been little more than sufficient to keep up the payments on policies of assurance upon his life obtained for the sake of securing his creditors; and a private subscription was entered upon for his assistance. He died on the 8th of December 1856: having from the state of his health been for some years incapacitated for active labours.

MAYACACEÆ, *Mayacs*, a natural order of Endogenous moss-like Plants, creeping over damp places, with narrow leaves, resembling Spider-Worts, but differing in their 1-celled anthers, carpels opposite the inner divisions of the perianth, 1-celled ovary and capsule, and parietal placentas. The species, four in number, are natives of North America. They are of no known use. (Balfour, *Class-Book of Botany*.)

MAYO, HERBERT, M.D., a distinguished medical writer, whose works on Physiology, although now to some extent superseded, were in considerable advance of his time. The first by which he made himself known was, 'Anatomical and Physical Commentaries,' published in 8vo in 1822; followed by a smaller work in 12mo in 1825, 'A Course of Dissections for the Use of Students.' In 1827 he published in 8vo, 'Outlines of Human Physiology,' of which several editions have been published; and in the same year, in folio, 'A Series of Engravings intended to illustrate the Structure of the Brain and Spinal Cord in Man.' On the establishment of King's College he was appointed Professor of Anatomy and Physiology, which office he held till 1836, when he left in consequence of having become a candidate for a similar office at University College. In 1837 he issued 'The Philosophy of Living,' in 8vo and 12mo; and the 'Management of the Organs of Digestion,' in 12mo; in 1840, in 8vo, 'A treatise on Syphilis;' and in 1842, 'The Nervous System and its Functions.' About this time he became a convert to the theory of mesmerism, and wrote many papers in the 'Medical Gazette,' strongly advocating his newly-adopted opinions. Subsequently he also adopted hydropathy. His practice as a medical man fell off, and he at length removed to Germany, in order to follow his profession as a hydropathist. He settled at Bad-Weilbach, near Mainz, on the Rhine, and there died on August 15, 1852. The product of his later opinions was the 'Cold-Water Cure, its use and misuse examined,' published in 1842; and 'Letters on the Truths contained in Popular Superstitions,' issued at Frankfort in 1849, and re-issued in London in 1851, with 'An Account of Mesmerism.'

MECINUS. [CIONUS.]

MEDICINE. [PHYSIC, PRACTICE OF, *S.* 2.]

MEERUT, the chief town of one of the Regulation Provinces into which the sub-presidency of the North-Western Provinces in Hindustan is divided. The town is situated in 28° 57′ N. lat., 77° 45′ E. long., 38 miles N.E. from the city of Delhi. It is an ancient walled town of considerable size, and is one of the military stations of the British army. The town contains a British Protestant church, which is 150 feet long, 84 feet wide, and has a lofty and handsome spire; it is of brick, covered with stucco, and whitewashed, and is altogether a very striking building. There is also a British free school. Here occurred, May 10, 1857, the first important outbreak of the great mutiny of the

Sepoys in Hindustan. From Meerut the mutineers marched direct to the city of Delhi, where they were joined by others, and where the aged nominal King of Delhi was proclaimed Emperor.

MEHEMET ALI, Pasha of Egypt, was born in the town of Cavalla, in Roum-ili, about the year 1769. He began life as the keeper of a small shop in his native town; but having volunteered into the army, he gained the good opinion of the governor of Candia by his zeal in suppressing a rebellion of the pirates of that island. In 1799 he headed a contingent of 300 Candian soldiers in an expedition to Egypt, where he co-operated with the British forces for the expulsion of the French. Here he laid the foundation of his military renown and of his political ascendancy. On the evacuation of Egypt by the troops of the Emperor Napoleon I., the Sultan nominated, as viceroy of Egypt, Mohammed Khosrew; but the Mamelukes, having risen to assert their ancient rank and influence, of which they had been deprived during the occupation of their country by the French, chose Mehemet Ali as their viceroy. In 1806 he was made Pasha of Cairo, to which in the following year was added the Pashalic of Alexandria, as a reward for his services rendered to the Ottoman Empire. No sooner however had he gained this pitch of power than he turned against his old confederates the Mamelukes—470 of whom he murdered in the citadel of Cairo, while the rest, to the number of 1200, were massacred through the country: an end was thus put to a turbulent and formidable race which had kept Egypt in a state of anarchy and warfare for upwards of 400 years. After the destruction of the Mamelukes, Mehemet Ali made himself master of Upper Egypt. He obtained from the sultan the government of that part of the country, the revenue of which he considerably increased by raising the land-tax and the custom duties on its internal trade. In 1811 he was sent against the Wahabís, a fanatical sect of the Moslems, who had pillaged the holy cities of Mecca and Medina, and whom he subdued after six years of constant warfare, and at a vast sacrifice of men and money. When the Greek insurrection against the Porte broke out, he offered to take part in the reduction of that country: his fleet accordingly sailed for the Morea in the summer of 1824, under Ibrahim Pasha, who however was obliged to retire after the battle of Navarino in 1827. In 1830 the administration of the island of Candia was confided to Mehemet Ali; but he had greater schemes in his view. He aimed at obtaining possession of Syria; and pleading as an excuse his desire to recover possession of some Egyptians who had settled in that country, he invaded Syria, with a large army under Ibrahim Pasha, and soon reduced it to submission. Syria as well as Egypt was an integral part of the Ottoman Empire; but the Viceroy of Egypt could not remain content with his own vice-regal territory; and peace was only made between the viceroy and the sultan [MAHMUD II.] by the interference of the European powers in 1833. Syria was ceded to Mehemet Ali on his acknowledging himself a vassal of the Porte. He remained in quiet possession of Syria as well as Egypt until 1839, when his nominal master, the Sultan, jealous and weary of the sway of so formidable a rival, sent an army and fleet to expel him from Syria; and when he found that this was impossible, he sought and obtained the co-operation of England and the other European powers. In the summer of 1840 the combined fleets appeared before the coast of Syria; in the autumn of the same year the Egyptian army was defeated near Beyrut, and both that city and Acre were captured, and Alexandria itself blockaded. Mehemet Ali was obliged to come to terms, and abandoned his claim to Syria, on condition of the Pashalic of Egypt being made hereditary in his family. He continued to administer the affairs of the country until September 1848, when he resigned the reins of government into the hands of his son Ibrahim Pasha, on whose death they passed to Abbas Pasha his grandson. Mehemet Ali himself lived only a few months after these changes, as he died August 2, 1849, at the age of about eighty years. By his wives and concubines he had sixteen children; two of his sons he sent to Paris for the sake of education. He was buried at Cairo with great pomp and splendour.

Mehemet Ali was tolerant in matters of religion to an extent rarely known among Mohammedans. His constitution was strong, his stature short; his features, though dark and stern, were animated and expressive. He was very ambitious, yet particularly sensitive to the opinions formed by others as to his public policy. His government has been extravagantly praised by some writers; but it certainly was more rational, orderly, and enlightened than that of most of the dominions of the Porte. He administered justice without partiality, established police and law-courts, abolished torture, and encouraged education. He did his best to remove the prejudices felt by his countrymen against the introduction of the arts and sciences of Europe; he even went so far as to establish European manufactures and machinery in his dominions, including a printing office for the publication of a periodical journal. He also formed schools and colleges for teaching the arts and sciences and naval and military tactics. But with all these liberal measures, his government was essentially despotic and absolute; and in order to support the expenditure necessary to maintain the institutions already mentioned as having been introduced by him, he was obliged to have resort to a heavy forced taxation, and for his army to an enormous conscription.

Upon the whole, however, it must be admitted that the Albanian peasant was in his day a great benefactor not only to his country but to society at large. Gifted with an admirable talent for organisation, he introduced into one of the most neglected and disorganised of countries the first conditions of a civilised state, *order* and *security*, to such an extent that it is said that a traveller, laden with gold, "could traverse without fear the immense territories under his sway, from the Taurus to the frontiers of Abyssinia, between sea and Nile and desert." In the administration of justice and the general management of his empire he introduced more of equity and settled principle than exists at the present time in any Oriental state. He did his best to curb the fanaticism of his subjects and to protect the Christian population. He not only encouraged commercial intercourse with Europe, but in a great measure created it; and by various enterprises of a grand and striking character, awakened that beneficial spirit of industry which for many a long century had lain dormant in Egypt. He first called into life the cultivation of cotton, indigo, and sugar, which has since been pursued with increasing success—a large portion of the produce being manufactured in his own dominions, in factories erected for that purpose at his expense. At the same time he gave a great impetus to the cultivation of silk in Syria by the plantation of mulberry-trees on an extensive scale. He founded a system of national education, of which no one for centuries past had conceived the idea in the East, and he devoted immense sums to that purpose. In fact he projected and founded more useful institutions than any Egyptian ruler since the days of Saladin. In addition to this, though at his accession to power he found Egypt without a ship or a drilled and disciplined soldier, he found means to build a fleet and to form an army trained after the European fashion. Such are the means by which the Albanian peasant, who only learnt to read in his thirty-fifth year, and who often, during his eventful life, did not know where to lay down his head in safety, became a powerful prince, who twice made the Ottoman Sultan tremble on his throne at Constantinople, and whose personal energy and public importance gave him a place among the potentates of the earth.

MELAM. [CHEMISTRY, *S.* 1.]

MELAMINE. [CHEMISTRY, *S.* 1.]

MELAMPYRINE. [CHEMISTRY, *S.* 2.]

MELANOSPERMEÆ, or FUCALES (Harvey), the first sub-class of the class *Algæ*. It consists of plants of an olive-green or olive-brown colour. Fructification monœcious or diœcious; spores olive-coloured, either external, or contained singly, or in groups, in proper conceptacles, each spore enveloped in a transparent skin (perispore), simple, or finally separating into several sporules; antheridia, or transparent cells, filled with orange-coloured vivacious corpuscles, moving by means of vibratile cilia. It includes the following orders:—

Fucaceæ.—Spores contained in spherical cavities immersed in the frond. [FUCACEÆ.]

Sporoclinaceæ.—Spores attached to external jointed filaments, which are either free or compacted together in knob-like masses.

Laminariaceæ.—Spores forming indefinite cloud-like patches, or covering the whole surface of the frond.

Dictyotaceæ.—Spores forming definite groups (sori) on the surface of the frond.

Chordariaceæ.—Frond cartilaginous or gelatinous, composed of vertical and horizontal filaments interlaced together. Spores immersed.

Ectocarpaceæ.—Frond filiform, jointed. Spores external. (Harvey, *British Marine Algæ*.)

MELASSIC ACID. [CHEMISTRY, *S.* 2.]

MELBOURNE, the capital of the colony of Victoria, or Port Phillip, Australia, is situated on the Yarra-Yarra River, near the head of Port Phillip Bay, 600 miles distant from Sydney by the overland route, and about 500 miles from Adelaide, the capital of South Australia. Melbourne has sprung into existence within the last 20 years; it increased rapidly after the discovery of gold in the colony in 1851, and is now a large and important city, the seat of an extensive commerce. The streets are spacious and laid out with great regularity. Melbourne contains several fine buildings, among which may be named the cathedral, and several places of worship, including chapels for Episcopalians, Independents, Presbyterians, and Wesleyan Methodists; a court-house, the governor's residence, a post-office, a custom-house, a jail, the government offices, several boarding-houses, hotels, baths, and large commercial establishments. Extensive improvements are being effected, including an ample supply of water which has been brought into the city from a distance of 20 miles. The total revenue of the city of Melbourne amounted in 1853 to 109,636*l.* 6*s.* 5*d.* Of this revenue the corporation expended the principal part in public improvements. Melbourne is the seat of a bishopric; a corporate town with a mayor; the residence of the lieutenant-governor; and the seat of government.

The gold finding in the colony, which appears to continue without much diminution, attracts numerous emigrants to Melbourne, especially from Great Britain. The population of the city is probably now more than 40,000. Vessels of 200 tons can ascend the river to Melbourne, larger vessels lie in Hobson's Bay. *Williamstown*, the port of Melbourne, is a small town built on a low sand-flat at Point Gellibrand, on the west side of Hobson's Bay, about 8 miles S.W. from the city. It contains some good houses. A railway connects Williamstown with Melbourne city. By means of a pier at Williamstown, having a communication with the railway terminus, passengers and goods may be landed and sent on to Melbourne.

MELDRUM. [ABERDEENSHIRE, *S.* 1.]

MELILLA, a sea-port town of Marocco belonging to Spain, is situated 11 miles S. from Cape Ras-ud-Dir, or Tres-Forcas, in 35° 8′ 15″ N. lat., 2° 56′ 2″ W. long., and has about 3000 inhabitants. The town stands on a peninsula about 40 feet above the sea, and united to the mainland by a rocky isthmus. Melilla is one of the Spanish presidios on this coast. It is impregnable on the land side, and towards the sea it is defended by strong ramparts. The fortress has large magazines and cisterns, and small vessels can enter the harbour. The presidios of Peñon-de-Velez and Aluzemas, or Alhucemas, two strongly fortified rocky islands between Cape Tres-Forcas and Ceuta, are also under the governor of Melilla. The Spanish garrison of Melilla numbers about 1000. The rest of the inhabitants are for the most part convicts and exiles. Melilla is said to derive its name from the Spanish word for honey, which is gathered of superior quality on the mountain slopes along this coast.

MELISSIC ACID. [CHEMISTRY, *S.* 2.]

MELISSYLE. [CHEMISTRY, *S.* 2.]

MELITTA (Kirby), a name for a genus of Insects belonging to the order *Hymenoptera*, and to the tribe *Mellifera* of Latreille. The genus as originally constituted by Kirby embraced all the Honey Bees known at that time. This genus is now split up into numerous smaller ones. Leach divides the *Mellifera* into two families, *Andrenidæ* and *Chrysididæ*.

The ANDRENIDÆ include the following genera:—

1. *Colletes.*	15. *Epeolus.*
2. *Prosopis.*	16. *Nomada.*
3. *Sphecodes.*	17. *Cœlioxys.*
4. *Halictus.*	18. *Melecta.*
5. *Andrena.*	19. *Anthidium.*
6. *Cilissa.*	20. *Heriades.*
7. *Macropis.*	21. *Chelostoma.*
8. *Panurgus.*	22. *Eucera.*
9. *Dasypoda.*	23. *Saropoda.*
10. *Megachile.*	24. *Anthophora.*
11. *Osmia.*	25. *Apathus.*
12. *Anthocopa.*	26. *Bombus.*
13. *Stelis.*	27. *Apis.*
14. *Ammobates.*	

The CHRYSIDIDÆ—

1. *Cleptes.*	4. *Hedychrum.*
2. *Chryris.*	5. *Elampus.*
3. *Euchrœus.*	

MELITTIS, a genus of plants belonging to the natural order *Labiatæ*. It has anthers approaching in pairs and forming a cross bursting longitudinally. The upper lip of the corolla flat, entire, straight; lower lip with 3 rounded nearly equal lobes; calyx membranous, bell-shaped, ample, variously lobed.

M. Melissophyllum, Bastard Balm, has oblong, ovate, or slightly cordate leaves. The upper lip of the calyx with 2 or 3 teeth; flowers purple, with a white margin, or variegated in different ways, large. Stem 1 or 2 feet high. *M. grandiflora* (Smith) is only a slight variety. They are both found in woods in the south of England.

MELKSHAM. [WILTSHIRE.]

MELOSIREÆ, a family of *Diatomaceæ*, formed by Kützing. The species are striated, not having a central opening on the secondary side. The striæ are interrupted in the median line. It includes the genera *Gallionella*, *Melosira*, *Podosira*, and others. Meneghini, in his 'Natural History of Diatomeæ,' makes the following critical remarks on this group:—

"The *Melosiræ* in general may be regarded as polypariform associations of *Cyclotellæ*, and the comparison prevails principally in the second sub-genus. The distinction of the two sub-genera is also proposed by Hassall (*Sphærophora, Meloseira*); but it is to Kützing we are indebted for establishing it upon the important character of the carina, which occurs only in the first two species (*M. salina*, *M. nummuloides*), a character on whose organographic value we cannot decide anything, but which merits some consideration in a morphological point of view: for that projecting ring bounds the lateral surfaces; whilst in the other species, with sides more or less convex, these are continuous, as it were, with the primary surfaces. In all the species we may notice the double furrow, which forms a ring connecting the body of each individual laterally to the interstitial ring; this furrow or canal presents apertures disposed in a regular manner. Kützing believes these supposed apertures to be sections of the canals themselves, that is, portions of them seen in projection. This opinion is the only one consistent with the fact that the filament being cylindrical, and therefore presenting itself indifferently on every side, these apparent apertures are always seen arranged near the margin. Ehrenberg's assertion that they are more numerous in some species, does not seem to be confirmed. This appearance is still more complicated, inasmuch as these fine tubular canals project from the internal surface of the shield, and a slight furrow externally corresponds with them. This condition is evident in *Melosira distans*, in which, owing to the greater depth of the furrow, the apparent perforations remain separated from the margin. The interstitial ring presents peculiarities of which we have no instance in the preceding genera. Its tenuity and the great variety of its extension are important characters. But here we must add the very important one of the changes it undergoes during observation. It is not uncommon to see the two halves of the articulation separate themselves slowly, and enlarge at the same time with the ring. This fact is not decisive in respect to the great question of the animal nature of these beings; for it is not subject to a subsequent contraction, and because in plants we have the analogy of *Spirogyræ*, in which, on the rupture of the outer tube, the extremities of the articulation, which were inflected like the finger of a glove, expand themselves as if by elasticity; but many facts controvert this inference. In support of the opposite opinion is the frequent enlargement of a particular articulation, in a manner similar to that of the *Œdogonia*. But Hassall justly observes, 'for this endochrome . . . never becomes condensed into a distinct organ or sporangium.' For this reason, the resemblance is reduced to a mere appearance. As to this supposed endochrome, proofs are certainly wanting that it is an ovary, as Ehrenberg supposes; but they are also wanting to show that it consists of gum, starch, or chlorophyll, which would be necessary were it a gonimic substance, as advanced by Kützing; and analogy even is wanting, for we do not see in any *Alga* a similar disposition of the internal substance. The often-quoted resemblance to the *Confervæ* cannot even be deemed apparent; for in no *Confervæ* are distinct spherules met so regularly, or disposed so symmetrically.

During desiccation it happens in the marine species, as in the *Podosiræ* already described, that the internal substance adheres to the inner wall in the form of oily globules surrounded by a distinct transparent margin, and compressed one against another in the form of regular polygons. Ebrenberg also speaks of diaphanous vesicular spaces, which he regards as stomachs. Kützing enumerates, figures, and describes nineteen species, marine, freshwater, and fossil, besides the four doubtful ones placed at the end, and the famous *Ferruginea* (*M. ochracea*, Ralfs), which he proves not to belong to the class of *Diatomeæ*.

"We shall find, as a character common to them all, the circular figure of the vertical section parallel to the lateral surfaces; a character which, as well as the other, of a radiated disposition of the striæ upon the lateral surfaces, we shall find repeated in the family of *Coscinodisceæ*, which, having the shield of a cellular structure, belong to the tribe of *Areolatæ*. Perhaps we may suspect some *Melosiræ* (*sulcata, decussata, lirata*), to be furnished with the same organic condition, and hence arises a fresh doubt respecting the systematic value that has been ascribed to it.

"In general we may also say, that in the *Melosireæ* the development of the lateral surfaces prevails over that of the primary ones, which we find finally to disappear in certain genera (*Pyxidicula, Podosira*), as well as in some species of *Melosira* (*varians, orichalcea*), the increased length of the articulations involving the corresponding development of the primary surfaces: and it is to be observed, that although in this family the primary surfaces differ precisely as much in form as they do in the three preceding ones, yet we find in these the same organic character as in the greater number of the other genera, namely, the presence of longitudinal furrows or canals. The separation of one lateral surface or valve from the other, with the consequent dilatation of superficies, which the primary surfaces exhibit before the duplication takes places (though verified to some degree in other genera, yet in the *Melosiræ* better than elsewhere), presents an undeniable analogy with the reduplication of *Desmidieæ*, which Brèbisson distinguishes from the deduplication of *Diatomeæ*. The particular disposition of the internal substance, the currents or mucous threads radiating from a centre, the enlargement of some articulations, and the dilatation of the interstitial ring, are isolated facts, which however merit particular attention in the paucity of our knowledge."

MENACCANITE. [Titanium.]

MENÆTHIUS. [Maiidæ.]

MENDELSSOHN. Felix Mendelssohn-Bartholdy, one of the greatest musicians of the present century, was born at Hamburg on the 3rd of February 1809. He was the grandson of the celebrated Moses Mendelssohn. His father, who was the head of a great banking-house, on his marriage adopted the name of his wife's family in addition to his own. He had embraced the Lutheran faith, in which his children were brought up. When Felix was in his infancy, his father removed from Hamburg to Berlin, where he resided till his death, enjoying a distinguished place in the society of the Prussian capital. He bestowed the utmost care upon the education of his son, who showed, at a very early age, singular attainments, not only in the art to which his genius especially directed him, but in various branches of literature and science. While yet a child, he gained the affections of Göthe, who was a friend of the family; and the published letters of that illustrious man contain many touching expressions of his love for the youthful Felix and prognostications of his future greatness. He was even then remarkable for his amiable disposition and simplicity of mind; qualities which he retained unimpaired to the end of his too short life.

As in the case of almost every great musician—of almost every great artist indeed of any description—Mendelssohn's genius showed itself even in infancy. He tried to play almost before he tried to speak. His talents received the best and earliest culture. Zelter, the friend and correspondent of Göthe, was his chief instructor in music, and his progress was almost as marvellous as that of Mozart. Indeed his first works, which were afterwards published, were in advance of anything produced by Mozart at an age equally tender. His three quartets for the pianoforte, violin, and violoncello, written before he was twelve years old, are not merely surprising juvenile compositions, but masterly works, which continue to be constantly performed, and hold their place among the classical music of the age. He was in his sixteenth year when his opera, 'The Wedding of Camacho,' was produced on the Berlin stage, more, it has been said, from the wish of his proud and happy parents than his own, for the most unaffected modesty always formed a part of his character. It was favourably received; but, as it betrayed some inexperience in composition for the stage, it was withdrawn by his friends. It was however published; and, though it is not generally known to the public, many copies of it are in the hands of amateurs. The music is not only charming, but full of the dramatic element. Every personage speaks in his own characteristic language, from the solemn pomp of Don Quixote and the grotesque humour of Sancho, to the passionate tenderness of the young lovers, whose wedding and its crosses form the subject of Cervantes's delightful story. This most interesting piece shows what great things Mendelssohn might have done for the music of the stage, had he not left this branch of his art to tread the highest of all—that in which he followed, and at no great distance, the footsteps of Handel. Another proof of the dramatic character of his genius at that early age was the composition of the overture to 'The Midsummer Night's Dream,' which breathes in every bar Shakspeare's own inspiration. Its popularity has now become unbounded: and no listener can fail to trace in its passages, in which the fanciful, the delicate, and the grotesque are so exquisitely blended, the various conceptions of the poet. The rest of the music for 'The Midsummer Night's Dream' was not written till many years afterwards, for the purpose of accompanying the performance of the play at Berlin. Its effect, thus introduced, was found to be so delightful, that in Germany the play is never represented without it, and the same thing is beginning to be the case in this country.

Mendelssohn had just reached his twentieth year when he made his first visit to England; a visit which deeply influenced the whole course of his life. He arrived in London in April 1829. His reputation was not unknown to our most eminent musicians, by whom he was cordially received. At the first concert after his arrival of the Philharmonic Society, his overture to 'The Midsummer Night's Dream' was performed, and received with enthusiasm by an audience, most of whom could never have heard of his name. It was immediately published. In a little memoir of his life, published a few years ago by Mr. Benedict, the eminent German musician so long resident among us, there are some valuable remarks on his London début. "The effect," says Mr. Benedict, "of the first performance of the overture to 'The Midsummer Night's Dream' in London was electrical. All at once, and perhaps even when least expected, the great gap left by the death of Beethoven seemed likely to be filled up; and I am happy to adduce this success as another proof of the much underrated taste of the English public, and its discernment in appreciating and even discovering new-born musical talent. Not to speak of the Elizabethan era—of Orlando Lasso, Luca Marenzio, the great madrigal writers—did not Handel compose his immortal works almost exclusively in England and for an English audience? Were not Haydn's finest symphonies written to gratify the London amateurs before a note of them was heard or known in Germany or France? Was not Beethoven known and revered by English artists, by English musical societies, when almost forsaken and neglected in Germany? And so it was with Medelssohn. His renown, after the enthusiastic but just reports of his reception in London, both as a composer and pianist, spread like wildfire all over Europe, and gave the young and ardent maestro a new stimulus to proceed on his glorious path."

In the same year Mendelssohn visited Scotland. In Edinburgh he was warmly welcomed by a literary and musical society well able to appreciate his genius and attainments, and his stay in that city was always regarded by him as one of the most agreeable incidents of his life. He afterwards made an extensive tour through the Highlands and the Western Isles; and many reminiscences of the days spent in Scotland are to be found in his compositions. He was deeply impressed with the wild and romantic beauty of the old Caledonian music, even in its rudest and most primitive form, and especially admired the Highland bagpipe and those antique strains, which though harsh and discordant to "ears polite," and scarcely allowed by dainty connoisseurs to deserve the name of music, yet reach the heart of every true Scotsman. Such music Mendelssohn could understand and value. A Scottish friend carried him to witness the "Competition of Pipers," as it is called, a gathering of masters of the national instrument, who are chiefly retainers of great families, and assemble annually in the Edinburgh theatre to contend for the palm of minstrelsy in the presence of the most brilliant company of the metropolis—a relic of Scottish feudalism still preserved. To the surprise of his cicerone, who merely wished to give him half an hour's amusement, Mendelssohn remained to the last, immersed in what he heard, and earnestly comparing the merits of the various pibrochs and the powers of the performers. Many years afterwards, the same friend heard the celebrated symphony in A minor (now called the Scottish symphony) performed for the first time, under the author's own direction, at a concert of the Philharmonic Society. Struck with the strains of Highland melody which characterise that piece—the festive dance, the gathering, the warlike march, the lament—he was about to make some remark to Mendelssohn, when he said with a smile, "You remember the pipers?" His fine orchestral piece too, 'The Isles of Fingal,' is full of the impressions made upon his mind by the wild and stormy shores of the Hebrides.

In the following year he was for some time in Italy; and two years afterwards he visited Paris. From thence he came a second time to London; and from that time, we believe, to the end of his life, there was scarcely a season in which he did not visit England. He began even then to feel that he was more justly appreciated in our country than even in his own; and thenceforth England became, as it were, his adopted country, and was associated with the most important circumstances of his artistic life. His treatment at that time by his own countrymen appears to have inspired him with different feelings, and we have the authority of Mr. Benedict for saying, that "the mean cabals which were always at work against him at Berlin increased his dislike to that city so much as to induce him to leave it, as he then thought, for ever." He left Berlin for Leipzig, where he accepted the directorship of the famous Gewandhaus Concerts, and where he remained till the year 1844, when he was induced, by the pressing request of the King of Prussia, to return to Berlin.

His entrance upon his glorious career as a composer of sacred music may be fairly ascribed to the committee of the Birmingham Festival; for he set about the composition of his first oratorio, 'St. Paul,' under the arrangement that it should be performed under his own direction at the festival of 1837. And it was so performed accordingly, having been previously produced at Düsseldorf and Leipzig.

The performance of this oratorio in the Town-hall of Birmingham on the 20th of September 1837, was an event memorable in the annals of music in England. It was got up with the unrivalled magnificence for which the musical festivals of that town are distinguished. The impression which it made upon an immense assemblage will long be remembered by those who were present. Mendelssohn was again at the Birmingham Festival of 1840, when the 'Lobgesang,' or 'Hymn of Praise,' composed expressly for that festival, was performed under his own direction. This remarkable work, called a 'Sinfonia-Cantata,' in which the powers of vocal and instrumental music are equally employed in developing a grand design, had a great success, and like 'St. Paul,' was speedily reproduced in the metropolis, and at all the great music-meetings in the kingdom.

His third and last oratorio, the greatest of them all—'Elijah,' was also written expressly for Birmingham. Though he undertook it immediately after the production of 'St. Paul' in 1837, it was not performed till 1846: and during these nine years, it occupied a large share of his thoughts and his labours. When the time for its production drew near, he resigned his post at Berlin and gave up every other occupation, in order to devote his whole powers to this work. The poem, in which the principal events in the life of the Hebrew Prophet are related in the language of the Bible, was constructed by Mendelssohn himself; and the English version was executed and adapted to the music with admirable skill by Mr. Bartholomew. The first performance took place on the 26th of August 1846, the performance being conducted by the author. The enthusiasm it excited cannot be described. It was pronounced by the general voice to be not only the masterpiece of the composer, but the greatest oratorio given to the world since 'The Messiah:' and this judgment has ever since been strengthened and confirmed, not merely by the opinions of connoisseurs and critics, but by the united voice of the British nation.

The production of this immortal work was the crowning glory of Mendelssohn's career. He was again in London, in 1847, to superintend its performance at Exeter Hall by the Sacred Harmonic Society. It was four times performed there, and afterwards, under his own direction, at Birmingham and Manchester. Soon afterwards he left England, never to return. His health had for some time been declining. Shortly after his arrival at home, he received a shock in the sudden death of his sister, who strongly resembled him in character and talents, and to whom he was fondly attached. From this blow he never recovered. He was persuaded to visit Switzerland, where, living quietly in the bosom of his family, he regained his strength and returned home to Leipzig, seemingly convalescent. But he soon relapsed, and at length sank under his malady, an affection of the brain, and expired November 4th, 1847, before he had completed his thirty-ninth year. He left many manuscript compositions, which, it is understood, were placed in the hands of several eminent musicians, friends of his family, with a view to selection and publication; but none of them have been given to the world except a fragment of an Oratorio, entitled 'Christus,' and some scenes of a romantic opera. The suppression of all the others, some of which were known to be works of magnitude and importance, has excited much surprise and dissatisfaction.

In a sketch like this, it is impossible to speak in detail of Mendelssohn's works. They are very numerous, and embrace every branch of his art; but it was in sacred music that his highest powers were displayed; and 'St. Paul' and 'Elijah' will descend to posterity along with 'The Messiah' and 'Israel in Egypt.'

Mendelssohn was exposed to none of the cares, struggles, and vicissitudes which genius is too often heir to. Happy in all his domestic relations, in the enjoyments and triumphs of his art, and above all, happy in a pure mind and blameless life, few men have had a more enviable lot than Felix Mendelssohn.

MENDLESHAM. [SUFFOLK.]

MENILITE. [OPAL.]

MENISPERMINE. [CHEMISTRY, *S.* 2.]

MENYANTHINE. [CHEMISTRY, *S.* 2.]

MERCANTILE MARINE. [SHIPS, *S.* 2.]

MERCHANT-SHIPPING. [SHIPS, *S.* 2.]

MERE. [WILTSHIRE.]

MERLANGUS, a genus of Fishes belonging to the family *Gadidæ*. It is distinguished from the genus *Morrhua*, to which the Cod-Fish belongs, by the absence of the barbule at the chin. [MORRHUA.]

M. vulgaris (*Gadus vulgaris*, Linnæus), the Whiting. This fish is well known for the excellence and delicacy of its flesh. The pearly whiteness of its flaky muscles, added to its extreme lightness as an article of food, recommend it particularly to invalids as an article of diet. It is caught in great abundance all round our coast, and may be traced from the Orkneys to Cape Clear. Whitings of several pounds weight have been caught as far north as the Dogger Bank; they have also been taken of nearly equal size on the coast of Cornwall, and on the Nymph Bank along the extended line of the south coast of Ireland. In that country they have also been found on the eastern coast, from Waterford to Antrim, and from thence north and west as far as Lough Foyle. The fishing for Whiting with lines is pursued nearly all the year through, but the fish is most plentiful in the months of January and February, when it comes in large shoals towards shore for the purpose of depositing its spawn, and is taken in abundance within half a mile and seldom exceeding three miles from land. The whiting is a voracious feeder, and seizes indiscriminately *Mollusca*, worms, small *Crustacea*, and young fishes. Though occasionally occurring in the London market of three or four pounds weight, the most usual size is from 12 to 16 inches in length, and weighing about one pound and a half. The body of the Whiting, like the bodies of those belonging to this division, is longer for its depth than that of the Cod-Fish; the scales small, oval, and deciduous; the lateral line dark and straight posteriorly, but rising gradually throughout the anterior half; the head elongated; the mouth and gape large, the tongue white and smooth; the upper part of the head and the back above the lateral line pale reddish-ash brown; sides and belly silvery white; pectoral, caudal, and dorsal fins pale brown; ventral and anal fins almost white, the pectoral fins each with a decided dark patch at the base.

M. albus (*Gadus albus*, Risso), Couch's Whiting. It is mentioned by M. Riss, in his volume on the 'Ichthyology of

Nice,' published in 1810, but was not caught in the British seas until 1840 by Mr. Couch. His description is as follows:—"Length 15 inches; the depth in a straight line 2¼ inches; from the base of the first dorsal fin to the vent along the curve, 3 inches; from the mouth to the edge of the gill-covers 3 inches; from the same to the anterior edge of the eye one inch; the eye large, the form a perpendicular oval; under jaw the longest; the upper maxillary bone terminal, the snout receding from it backward, contrary to the form of the Whiting, in which the upper jaw is under a projection. The general form of the body resembles that of the Whiting, but rather more slender; the back rounded as if the specimen was plump, thus showing its slender form not to be the result of emaciation. The distinctions between this fish and the Whiting are obvious, in the jaws, fins, lateral line, colour, and vertebræ."

M. carbonarius (*Gadus carbonarius*, Linnæus), the Coal-Fish. This is decidedly a northern fish, but being a hardy species, is not without considerable range to the southward. It was the only fish found by Lord Mulgrave on the shores of Spitzbergen, and the fry, only 4 or 5 inches long, were caught with the trawl-net on the west coast of Davis's Strait, during the first voyage of Captain Sir E. Parry. It is found on the coast of the United States. It abounds in all the northern seas, and in the Baltic, and may be said to swarm in the Orkneys, where the fry all the months of summer and autumn are the great support of the poor. As an article of food it is more prized when small than when of large size. The flesh of specimens weighing from 15 to 20 lbs. is usually dried or salted. This fish has more provincial names than any other species, some of which only refer to it when of a particular size. Among the Scotch islands the Coal-Fish is called Sillock, Piltock, Cooth or Ruth, Harbin, Cudden, Sethe, Sey, and Gray Lord. In Edinburgh and about the Forth the young are called Podleys; at Newcastle the fry are called Coalsey, and when 12 inches long Poodlers. The Coal-Fish may be traced on the Irish coast from Waterford along the eastern shore to Belfast. When detained and well-fed in a salt-water pond they attain a large size, and are very bold and voracious. The head and body are elegantly shaped; the scales small and oblong; the lateral line silvery white and nearly straight; the upper part of the head and back above the lateral line almost black, much lighter in colour below the line, becoming grayish-white with golden reflections on the sides and belly; pectoral, caudal, and dorsal fins bluish-black; ventral and anal fins grayish-white; the upper jaw rather the shortest, the lips tinged with purple red, the mouth black, the teeth very small, the irides silvery white, the pupil blue.

M. Pollachius (*Gadus Pollachius*, Linnæus), the Pollack. This fish is much less abundant on some parts of the coast than the Coal-Fish, but like that species is an inhabitant of the seas all round our shores. The fish is called Lythe in Scotland, but whether from its supple pliant activity, or from 'lithos,' a stone, in reference to its living among the rocks, is not decided. The Pollack is caught at Hastings and Weymouth, also in Devonshire, where it is sometimes sold as Whiting. When only 12 or 14 inches long it possesses a considerable portion of the flavour and delicacy of that fish. It is also caught along the Irish coast under the names of Pollack, Laith, and Lythe. The body is elongated; the upper part of the head and back above the lateral line olive brown, the sides dull silvery white mottled with yellow, and in young fish spotted with dull red; the lateral line dusky, curved over the length of the pectoral fin, then descending and passing in a straight line to the tail; the dorsal fins and tail brown; the pectoral and anal fins edged and tinged with reddish-orange.

M. virens (*Gadus virens*, Linnæus), the Green-Cod. This fish was first added to the list of British fishes by Sir Robert Cullum, and if a distinct species, as some doubt it, is not only abundant, but has an extensive range. It is mentioned as an inhabitant of the northern seas by Linnæus and others, and is taken on the coast of Scotland, the Isle of Man, and on the Cornish coast. By some it is thought to be the young of the Coal-Fish, and by others as the young of the Pollack. The northern naturalists, who have opportunities of making constant comparison between this fish and the Coal-Fish from the abundance of both, consider them as distinct species. It seems to combine in itself the colouring of the Pollack, with some of the peculiarities of the Coal-Fish, but appears also to be deeper for its length than either, though if the young of a large species, judging by analogy, that would not be the case. The subject in its present state is open to investigation, and invites the attention of those who are so located as to be able to obtain examples of both.

(Yarrell, *British Fishes*.)

MERTENSIA, a genus of Plants belonging to the natural order *Boraginaceæ*. It has a calyx in 5 deep segments; corolla bell-shaped, with a short thick cylindrical tube with 5 minute protuberances in its throat; stamens protruded beyond the throat; filaments elongate; style simple; nuts smooth, inflated, rather drupaceous, attached laterally near their base by a flat surface; seeds free.

M. maritima has a procumbent branched stem; leaves ovate-acute, rough, with callous dots, glabrous, fleshy, glaucous; nuts smooth; flowers in racemes, purplish-blue; protuberances in throat of the corolla yellow; leaves with a flavour resembling that of oysters; nuts free, forming a pyramid longer than the calyx; pericarp membranous; seed smaller than the cavity. It is found on the northern sea-shores in Great Britain.

MERULA. [BLACKBIRDS.]

MESACONIC ACID. [CHEMISTRY, *S.* 2.]

MESITINE SPAR, *Brünnerite*, a native Carbonate of Iron and Manganese. It occurs in yellowish rhombohedrons. Its hardness is 4·0, and its specific gravity 3·3 to 3·6. It includes much that is called Rhomb-Spar, or Brown Spar, which becomes rusty on exposure to the atmosphere. (Dana.)

MESITYLOLE. [CHEMISTRY, *S.* 2.]

METACETONE. [CHEMISTRY, *S.* 1.]

METEOROLOGY. To the article in the 'Penny Cyclopædia' on this union of sciences applied to the investigation of the atmosphere as the physical medium between the earth and the heavens, may now be added some account of two or three important subjects, our acquaintance with which has recently been greatly improved.

METEOR, METEORITE. The following is a condensed statement of the present condition of knowledge upon these subjects, which are connected in a remarkable manner with cosmical science, and with almost every department of physics and of the study of inorganic nature. It includes also a notice hitherto unpublished of a branch of the history of science to which little attention has yet been given—the explanation and interpretation by means of our present knowledge, of the numerous relations of such phenomena which occur in ancient history, both classical and mediæval, as well as in the popular historical literature of more recent periods.

The spaces through which the bodies of the solar system and the comets revolve about the sun, appear also to be traversed by celestial bodies comparatively minute, but in number incalculable; which, in common with the smaller true planets of the system have received from certain astronomers and physicists the appellation of *Asteröids*, or star-like bodies,—the word *star* being taken in its universal and ancient sense of any luminous object seen in the heavens. These smaller asteröids, when they approach within a certain comparatively small distance from the earth, are, or subsequently become, the objects termed shooting-stars, fire-balls, and igneous meteors; new series of phenomena being successively presented by them as they come nearer to the earth's surface, and especially in many instances, in consequence of their finally passing through a great extent of the atmosphere in an oblique direction, so as to experience the effects of its increasing density, both physical and chemical, throughout a trajectory of great length. But in this general statement it is not pretended to deny that objects and phenomena very different in their origin and nature, as well from each other as from those now under review, may probably be included also under the popular or only half-scientific designations of meteors and shooting-stars.

The appearance of these meteors is in many cases attended or succeeded by the fall of solid bodies, either stones or metallic iron, or in some cases both mingled together in the same block, forming a series of bodies collectively termed *Meteorites* (or AEROLITES, 'Penny Cyclopædia'), consisting, mineralogically, of two principal groups, graduating into each other, namely, *meteoric stones*, and *meteoric iron*.

The visible meteor, when observed at those distances which must be within the atmosphere, and possibly indeed when at much greater, must consist of *flame*, or gaseous matter in an ignited or incandescent state, and undergoing combustion, but arising, as may be inferred from Sir H. Davy's researches on flame, not from the combustion of matter which under ordinary circumstances can exist in a gaseous state at the surface of the earth, but from that of matter which is there solid, consisting, doubtless, of the metallic or other combustible bases which meteorites are found to contain. Among these it may be remarked are sulphur and phosphorus, both which Davy particularised as capable of combustion in air rarefied to a degree equal to that of the regions of the atmosphere in which meteors had been observed to display their phenomena; no particular stress, however, can be laid upon this circumstance, as meteorites contain other combustible bases which very probably have the same property, including the metal magnesium, an element of almost every meteoric stone, in considerable proportion. The extraordinary intensity of light also which attends the combustion of magnesium in oxygen, may be connected with the brilliant phenomena of the meteors.

The luminous extensions in the direction opposite to that of the meteor's motion, ordinarily called *tails*, as observed in many, if not in all igneous meteors, are manifestly referable to the elongation of the mass of flame constituting the visible meteor, by the resistance of the atmosphere to their progress through it with planetary velocity, as well as in some degree by the adhesion of the air to it; the passage from the intense white light of the head or body and proximate portions of the tail, to the red light of the distant and extreme portions of the latter, being attributable to the cooling down of the flame during its course, and in proportion to its distance from the most intensely heated part of the meteor.

It would appear, both from theory and observation, that the figure of the meteors must approach in their course more or less closely to that of the solid of least resistance. The meteorites which fall, or are cast down from them, when unbroken, especially those consisting of metallic iron, retain approximately the form which had thus been imparted to the meteors of which they were the nuclei, by the resistance of the air,—a form resembling that of the more perfect volcanic bombs, and which they have received from the same cause. These effects of the resistance of the atmosphere to the meteor's motion were first pointed out by Mr. Brayley.

The persistent *track* or *trail* of less vivid light often continuing to be seen for several minutes, or for a considerable fraction of an hour, or even for more than an hour, after the disappearance of the meteor itself, must be attributed to the deposition in the atmosphere, in the meteor's path, of a kind of *beam* of finely-divided solid matter,—mingled probably with vapour, and no doubt in part produced by the condensation of vapour,—resulting from the combustion proceeding in the meteor, and the particles of which, being originally deposited at insensible distances from each other, continue to preserve, during their slow and uniform descent in the tranquil regions of the air, where they originate, the aggregate form in which they were deposited; while the low conducting power for heat of the rare atmosphere permits them also to retain their high temperature and consequent luminosity for a comparatively long period of time. The continued action of gravity, and the disturbing agency of currents in the lower regions of the atmosphere, will, however, eventually convert the at first rectilinear beam into a more or less curved and waved figure, and at length produce the *serpent of fire* of the superstitious ages, accurately reproduced in the case of the meteor of the 7th of January, 1856, as witnessed at Tunbridge Wells, and represented by a correspondent of the 'Illustrated London News,' of the 12th. These views are supported by reference to telescopic observations of the trails, particularly by those of the late Professor Pictet, of that left visible for seven or eight minutes by the meteor seen in France and Switzerland on the 15th of May, 1811, the most luminous part of which "did not appear to be continuous, but composed of distinct and separate particles."

The production, continuance, gradual change of form and descent, and final dissolution of these trails, may be familiarly, but correctly, illustrated by comparison with the similar succession of phenomena characterising the trail of smoke and soot issuing from the funnel of a steam-ship during its progress in its course; in which also a rectilinear beam of finely divided solid matter separated from flame and smoke, and often several miles in length, becomes a persistent trail, and gradually changes into a waved or serpentine form. In many cases the trail of a meteor must have been originally a cylindrical beam, constituted as now explained, having a diameter of many hundred yards (equal to or greater than that of the meteor itself), and a length of many miles, deposited, in an inclined direction, at heights of some miles above the earth's surface.*

An objection founded on the assumed solidity of the particles, and the considerable specific gravity which must be attributed to them as results of the combustion going on within the meteors, which, it might be inferred, are inconsistent with their long suspension in the manner supposed, is at once obviated by applying to the subject the results of Professor Stokes's researches on the effects of the internal friction of fluids (noticed in the concluding division of this article) as applied by himself to the suspension of fine powders in a fluid of widely-different specific gravity, and to that of the suspension in the air of the minute globules of water constituting the clouds. The trails of meteors are suspended like the clouds, though, at first, probably, in higher regions of the atmosphere, and like them they consist of excessively minute particles, which, as in all probability their dimensions will be very nearly the same in all directions, may be regarded as spherules also, and will, consequently, be suspended temporarily, like the globules of the clouds, by the resistance to their downward motion arising from the internal friction of the air. The degree in which they partake of the projectile motion of the meteor itself, will also tend to their longer suspension, by converting the perpendicular fall which the mere action of gravity would cause into an oblique curvilinear descent.

The two great causes of all the phenomena now described, are evidently the *motion* and the *heat* of the meteors. The origin of the former is doubtless involved in that of the portions of matter constituting the nuclei of the meteors themselves, a subject noticed below. Dr. Chladni, the earliest philosophical investigator of the subject of meteors and meteorites (as a whole), and in later times Sir H. Davy and Sir John F. W. Herschel, have ascribed the heat to the compression and friction of the air, resulting from the enormous velocity, of from six to thirty miles in a second, or more, of the meteors, supposed to be solid when they enter the atmosphere. Still more recently, in a paper read before the Royal Society on the 19th of June 1856, Mr. Joule and Professor William Thomson have inferred from their own experiments on the thermal effects of fluids in motion, to which those of solids carried through fluids must be equivalent, the great probability that meteors really acquire all the heat they manifest from the friction of the air.

In the present state of cosmical and meteorological science, it is unnecessary to enter upon the question of the origin of meteors and meteorites further than to urge, that, the computed enormous magnitude of the former,—the actual diameter of the visible meteor, however constituted, being often many hundred yards, while in some instances its dimensions must probably be expressed in miles,—their planetary velocity—and the pregnant fact that they give out a more intense light than any objects in nature except the sun,—(an assemblage of characters explicitly claimed by the writer of this article for the particular meteors from which meteorites have been observed to descend, as well as for many, if not all of those from which their fall is not known), must at once disprove nearly all the hypotheses which have been framed specifically to explain the *origin* of meteorites; and especially, among others, that of their projection from lunar volcanos. The cogency of this argument will remain essentially unimpaired if it shall be found, according to recent suggestions, that the actual magnitude of many of the meteors is considerably less than that hitherto ascribed to them. The problem of their origin must, in fact, be regarded as the same with that of the origin of the greater asteroids and planets themselves.

It is right to state that Mr. R. P. Greg, F.G.S., who has given much attention to the subject, is of opinion that there is a distinction between luminous meteors and those from which meteorites have fallen; an opinion which, so far as the (apparently) smaller meteors, called shooting-stars, are con-

* These views of the physical constitution of meteors and their trails were in substance originally stated by Mr. Brayley in a paper read in 1824 before the Meteorological Society, then recently formed, and published in the *Philosophical Magazine*, first series, vol. lxiv. p. 288, &c. With the additions and modifications required by the progress of science, they have been subsequently repeated by him in lectures, together with the views on the historical parts of the subject which are given in the sequel of this article. The latter were explicitly treated and graphically illustrated in a lecture delivered at a Soirée of the London Institution on the 16th of January, 1856; in which also the subject of the persistent trails of the meteors was more definitely explained.

cerned, he shares with the American Professor Olmsted, and others. Mr. Greg is the author of a valuable essay on meteorites, entitled, 'Observations on Meteorolites or Aërolites, considered Geographically, Statistically, and Cosmically; accompanied by a complete Catalogue of meteoric falls.' It was first published in the 'Philosophical Magazine' for November and December, 1854, and in a separate form in November of the following year.

The views of the entire subject which have been enunciated in this article, have resulted from long attention to it by the writer. Others will be found, together with an invaluable assemblage of facts, in Arago's 'Astronomie Populaire,' liv. xxvi., 'Météores Cosmiques;' tome iv. p. 181–322; and also in the reports on meteors annually communicated for some years past to the Reports of the British Association, by Professor the Rev. Baden Powell.

The last recorded fall of meteorites appears to have taken place in 1857, on the 28th of February, when two large stones fell at Parnallee, in the Madura district, Madras, as related by the Rev. H. S. Taylor, in a communication to the Asiatic Society of Bengal.

The purely physical history of the subject having now been generally considered, we may proceed to notice the manner in which the extraordinary relations produced in former times, of the appearance in the sky of blazing torches, sceptres, bundles of rods, fiery swords, trumpets, and other objects, may be rationally interpreted, agreeably to our present knowledge of meteoric phenomena. This subject belongs to a field in the history of science and literature, hitherto but little cultivated. It may be elucidated by examining the figures and accounts of such appearances which are given in the works of old writers, especially in those of Zahn, Conrad Wolfhart, and their contemporaries, and also by Ambrose Parey, and comparing them with similar phenomena as witnessed in more modern times, and depicted by observers whose only object was to represent the actual configuration of the luminous appearances. The circumstance that from the enormous rapidity of the meteors, all the visible phenomena (except the persistent trail) would have been seen and have ceased to appear within the limits of a few seconds of time (so that in all cases the figures must have been produced from memory alone), which must have led to the representation of many appearances as simultaneous that in reality occurred in succession, and the manner in which during the transit of the meteor, impressions on the retina of past phenomena must have been mingled with those actually present, have led to the production of many of the singular representations that are extant. It would not be difficult to trace the mental process by which natural objects, thus witnessed for a few seconds only, would by uninformed observers prepared to regard them with superstition, be supposed to be really preternatural types of the familiar objects to which the outlines of their forms were comparable; the meteors, thus supposed to be torches, swords, and the like would naturally be described and depicted with all the appendages and accompaniments of those objects. These accompaniments, however, were not in all cases merely supposititious, as may be evinced by reference to the great meteor of 1758, which exemplified the ringed sceptre of the mediæval figures, the rings on the shaft being manifestly the smaller meteors, the production of which is the first visible result of the explosion, seen as projected upon the tail of the parent meteor; either because, as is evidently the fact in many instances, they were really enveloped in the flames composing it, or on account of the blending upon the retina of the observer of past and actual appearances. The fiery sword dipped in blood is the meteor in its normal form, at the middle of its visible course, the distant part of the tail shining with red light, being cooled down to the temperature of simple ignition, as already indicated. In a similar manner, the bull's heads, flying-eagles, and other monstrous appearances may be consistently explained, care being taken, when the authorities permit, to identify them with the actual meteor otherwise recorded. The blazing and interlaced serpents, moving in the air may be explained by reference to the actual phenomena of the persistent tracks or trails already described, as witnessed in various cases by Pictet and others, as well as by the published representations of the meteor of January 7, 1856; one instance may be cited, in which a large and beautifully luminous serpentine train continued for some minutes after the disappearance of a meteor which threw down a stone at Angers, in 1822. The ensanguined tresses attached to blazing stars are evidently the trails under another phase, and in their later condition, emitting red light only, but retaining their linear or band-like form.

The *Lampades volantes* and *Dracones volantes* of former ages may be similarly understood, by reference to other characters and phenomena of meteors: one of the contemporary figures of the fire-ball seen in London on November 13, 1803, (described under other phases by Dr. Firminger in the 'Philosophical Magazine' for the following year,) exemplifies the particular configuration of the meteors to which the latter appellation was given. This is contained in Nicholson's 'Philosophical Journal' for 1804.

From the latter division of the subject now summarily reviewed, an inference may be drawn, which—though suggested also by other objects of science and literary history united—arises, it is conceived, in a particular manner out of the ancient history of Igneous Meteors and Meteorites. Many of the prodigious sights and supposed portents of moral or historical events, which are described in old chronicles and other works, may be explained, it has been shown, by our present acquaintance with the true nature of such phenomena. The inference is this,—that the superstitious notions and ideas of preternatural manifestations and their significance, held in former times, were often founded in mere ignorance of certain natural phenomena; and that there may be little either of superstition or intentional misrepresentation even in some of the apparently wildest recitals. It would appear, further, that the marvellous relations on such subjects of classical antiquity, and of the middle and later past ages, are not all to be peremptorily discarded; for the resources of modern science may enable us to divest of exaggeration the really accurate observations they frequently include, and to separate from them the erroneous views with which they have been mingled; and thus to render the observations themselves, in numerous instances, available in the advancement of true knowledge.

Suspension of the Clouds. The most recent view of this subject, apparently a very simple one, but which really involves a variety of physical principles, is that of Sir John F. W. Herschel, stated in the following terms (Ency. Brit. Edit. 8, vol. xiv. p. 656):

"When the sun shines on a cloud, which absorbs its heat, the cloud itself is necessarily partially evaporated, and the vapour by its levity tends to produce an upward current, and thus to counteract the effect of gravity on the globules of which it consists. A globule of water 1-4600ths in. in diameter, in air of five-sixths of the density on the surface, or at the height of about 5000 feet, would have its gravity counteracted by resistance, with a velocity of descent of one foot per second (supposing no friction and no drag); and even if the terminal velocity were reduced to half that quantity by these causes, would still require some such upward action to enable it to maintain its level—a circumstance which sufficiently accounts for the lower level generally observed of cloud during the night. It is more than probable, however, that, when not actually raining, cloud is always in process of generation from below, and dissolution from above, and that the moment this process ceases, rain, in the form of 'mizzle,' commences. In a word, a cloud in general would seem to be merely the visible form of an aërial space in which certain processes are at the moment in equilibrio, and all the particles in a state of upward movement."

To complete this view of the subject nothing seems to be required but an adequate estimate of the effects of the 'friction' and the 'drag,' which are supposed not to exist. But it appears to have escaped the attention of Sir J. Herschel, that Professor Stokes had already shown that the internal friction of the air, together, of course, by implication, with the 'drag' which it occasions, is itself one of the causes—in his opinion, indeed, the main cause,—of the suspension of the clouds. As this particular subject is new, and (as we have seen in the previous division of this article, with respect to one department), of great importance in meteorology, we shall treat it at some comparative length.

Clouds consist of an aggregation of separate minute globules of water; and the resistance to such a globule falling through the air with its terminal velocity depends almost wholly on the cause just stated. "Since the index of friction of air is known from pendulum experiments, we may," Professor Stokes observes, "easily calculate the terminal velocity of a globule of given size, neglecting the part of the resistance which depends upon the square of the velocity. The terminal velocity thus obtained is so small in the case of small globules, such as those of which we may conceive a cloud to be composed, that the apparent suspension of the clouds does not seem to present any difficulty. . . . Since in the case of minute globules falling with their terminal velocity the part of the resistance depending upon the square of the velocity is quite insignificant [as will presently be shown], compared with the part which depends on the internal friction of the air, it follows that were the pressure equal in all directions in air in the state of motion [which according to the common theory of the fundamental assumption in hydrodynamics, it would be], the quantity of water which would remain suspended in the state of cloud would be enormously diminished."

To render this view of the subject complete, and to explain the value of the last observation, it must here be stated that Professor Stokes had before shown that the fundamental assumption of hydrostatics and hydrodynamics, that the pressure of a fluid is equal in all directions, though fully justified by experiment in the case of a fluid at rest, is not true in the case of a fluid in motion. The viscosity attributed to water by Dubuat, and the inherent property "analogous to that of viscidity in liquids," ascribed to elastic fluids by Capt. (now Major-General) Sabine, from their respective pendulum experiments, were generalized by Professor Stokes as consequences of the internal friction of fluids in general, all fluids exerting a resistance to bodies passing through them, independently of their density; and when this is taken into account, it is evident that the pressure cannot be equal in all directions.

The suspension of the globules of water forming the clouds, is only a particular case of the more general fact that fine powders remain nearly suspended in a fluid of widely different specific gravity. Professor Stokes has demonstrated that the resistance of the fluid, whether liquid or gaseous, is proportional, not to the surface, but to the radius of the spherule, and consequently the quotient of the resistance divided by the mass,—in other words, the accelerating force of the resistance,—increases much more rapidly as the radius diminishes, than if the resistance varied as the surface: on which principle the suspension, or proximate suspension, of the particles or globules depends. When the downward motion of a globule is so slow, that the part of the resistance which depends on the square of the velocity may be neglected, the terminal velocity of a globule of water forming part of a cloud may be determined. For a globule the one-thousandth of an inch in diameter, we have the velocity 1·593 inch per second. For a globule the one ten thousandth of an inch in diameter, the terminal velocity would be a hundred times smaller, so as not to amount to the one-sixtieth part of an inch per second.

The amount of that part of the resistance which varies as the square of the velocity, and which is the only kind of resistance that could exist if the pressure were equal in all directions, for the velocity 1·593 inch per second, is not quite the one four hundredth part of the weight; and for a sphere only the one ten thousandth of an inch in diameter, the ratio of the resistance to the weight would be ten times as small. Both these proportions, it is manifest, are quite insignificant.

The conclusion thus arrived at by Professor Stokes as to the cause of the suspension of the clouds, illustrates in a remarkable manner the connection of different branches of science. It is an application by him of the theory of internal friction, as applied to the ball pendulum, and verified by recorded experiments on that instrument; and is contained in his memoir 'On the Effect of the Internal Friction of Fluids on the Motion of Pendulums,' published in the 'Transactions of the Cambridge Philosophical Society,' vol. ix. The erroneous extension of the fundamental law of hydrostatics had been discussed by him in a paper 'On some Cases of Fluid Motion' inserted in the preceding volume of that work.

MEYRICK, SIR SAMUEL RUSH, K.H., LL.D., celebrated for his antiquarian knowledge, particularly in matters relating to ancient armour, was born on the 28th of August, 1783, and was the son of John Meyrick, Esq., of Great George Street, Westminster, and Peterborough House, Fulham, who was descended from the Meyricks of Bôdorgan in Anglesea. Samuel Rush Meyrick took the degree of B.A. at Queen's College, Oxford, but we have little other information of his early life, beyond the statement that he married when about twenty years of age; and thus offended his father, who in consequence so arranged the inheritance of his family property, that it should chiefly pass to the next generation. It thus happened that the large collections of armour which were commenced by the subject of this notice at his residences No. 3, Sloane Terrace, and No. 20, Upper Cadogan Place, were purchased with the money of his son, and were known as those of Llewelyn Meyrick, Esq. The original intention as to property was however frustrated ultimately by the death of that son in 1837.

Samuel Rush Meyrick adopted the branch of the legal profession connected with the Ecclesiastical and Admiralty Courts, in which, as Dr. Meyrick, he practised for many years. Prior to this, in 1810, he had published 'The History and Antiquities of the County of Cardigan.' In 1812, he was engaged upon a history on the plan of that of Dr. Henry, relating to the period of the monarchs of the British blood, before their abdication in 703. The materials, which were collected for a work of great extent, were however not published in the form intended. But in 1814, with Captain Charles Hamilton Smith, he produced a work on the 'Costume of the Original Inhabitants of the British Islands,' which was published in 4to with plates. His great work on Arms and Armour was published in 1824 in three 4to volumes, under the title, 'A Critical Inquiry into Ancient Armour as it existed in Europe, but more particularly in England from the Norman Conquest to the reign of King Charles II., with a Glossary of Military Terms of the Middle Ages.' A new edition of this work appeared in 1843, under the care of Mr. Albert Way, with corrections, much required, in the documents and quotations. Dr. Meyrick assisted the Rev. T. D. Fosbroke in the compilation of his 'Encyclopedia of Antiquities,' of which the first edition appeared in 1825. In 1826, the assistance of Dr. Meyrick was sought in the arrangement of the collection of arms and armour at the Tower of London ('Gentleman's Magazine,' 1826, 1827): and in 1828 he was called on by George IV. to arrange the collection at Windsor. For these services, the Hanoverian order was conferred upon him by William IV. in January 1832, and he was made a knight-bachelor on the 22nd of February following. Meanwhile, about the year 1827, Dr. Meyrick had endeavoured to purchase the ruins of Goodrich Castle, on the Wye; but being then unable to succeed, he commenced in 1828, on the opposite hill, a mansion of which Mr. Blore was the architect, and which is now well known as Goodrich Court. The main part of the plan was arranged specially for the display of the collection of armour,—the whole suite concluding with a chamber, where was represented a grand tournament. The chief scenes in the display are shown in a work published, by Mr. Joseph Skelton, F.S.A., in 2 vols. 4to. in 1830, and entitled 'Engraved Illustrations of Ancient Armour,' &c., to which Dr. Meyrick supplied drawings and descriptions. In 1834, when High Sheriff of Herefordshire, he revived a procession of the javelin-men in armour, and with mediæval pageantry. In 1836 he contributed the descriptive matter to Mr. Henry Shaw's 'Specimens of Ancient Furniture.' Sir Samuel Meyrick's last important work was 'Lewis Dwnn's Heraldic Visitation of Wales' which he completed in 1846. He had continued a frequent contributor to the Proceedings of the Society of Antiquaries (of which body he was elected a Fellow in 1810). Some of his contributions are printed in the 'Archæologia,' and others are referred to in the 'Gentleman's Magazine,' in which work also he wrote many papers from 1822 to 1839 ('Gent. Mag.,' New Series, vol. xxx., p. 94). Latterly he also contributed to 'The Analyst,' the 'Cambrian Quarterly Magazine,' and the 'Cambrian Archæological Journal.' Sir Samuel Meyrick died on the 2nd of April, 1848, in his sixty-fifth year. His collection and his domain in Herefordshire, which last he had largely extended by purchase a few months before his death, devolved upon his second cousin Colonel Meyrick.

MEZZOFANTI, JOSEPH CASPAR, celebrated for his extraordinary powers as a linguist, was born at Bologna, on the 17th of September, 1774. His father, Francis Mezzofanti, was a carpenter; and he himself, being destined for the same humble career, was placed at one of the free schools of the Oratory in his native city. Father Respighi, a priest of that congregation, observed the remarkable talents of the boy, and saved him for literature. He was removed to a higher school—one of the so-called 'Scuole Pie' of Bologna—and eventually to the archiepiscopal seminary, where, after completing the usual course of letters, philosophy, divinity, and canon law in the university, he was admitted to priest's orders in September 1797. Of the details of his progress in the study of languages during these early years no accurate record is preserved; but it is known that, like most eminent linguists, he was gifted, even in childhood, with a very wonderful memory; and that, partly under the various professors in the university, partly by the aid of foreign residents in the city, partly by his own unassisted studies, he had acquired, before the completion of his university career, the Latin, Greek, Hebrew, Arabic, Spanish, French, German, and Swedish languages. In September 1779, at the early age of twenty-two, he was appointed Professor of Arabic in the university, and commenced his labours in the December of that year; but he did not long enjoy what would have been a most congenial office. On the annexation of Bologna, as one of the papal legations, to the newly established Cisalpine Republic, he refused to take the oaths of the new constitution, and was set aside from the professorship. After the conclusion of the concordat between Pius VII. and the first consul, the ancient constitution of the university was restored. In 1803 Mezzofanti was named to the higher professorship of Oriental Languages, and in the same year be became assistant librarian of the public library of the city. The professorship of Oriental Languages, however, being suppressed in 1808, Mezzofanti was for some years reduced to great distress, and became dependent for his own maintenance, and that of the orphan family of his sister, mainly upon the casual income derived from private tuition. The elder brother of the late Archdeacon Hare is said to have been one of his pupils, and a living English countess received lessons in English from him at a later period.

Meanwhile Mezzofanti steadily followed in private what had become his engrossing pursuit—the study of languages. A letter of his, dated in 1804, to the celebrated Orientalist John Bernard de Rossi, whose personal acquaintance he subsequently formed during a short visit to Modena in 1805, inclosed a composition in twelve languages, which he submitted for the judgment of his correspondent; and before 1812 his reputation as a linguist had become thoroughly established. The well-known Pietro Giordani, in several of his letters to his friends, calls him "the divine Mezzofanti," and declares that his skill in living and dead languages entitles him to be regarded as "a man of all ages and all nations." The war of which Northern Italy was so long the theatre had afforded Mezzofanti many opportunities of extending his stock of languages. In the hospital of Bologna, to which he was attached as volunteer chaplain, were to be met—among the invalids of the Austrian, Russian, and French armies—Germans, Hungarians, Bohemians, Wallachians, Servians, Russians, Poles, and Croats. Partly in the desire to offer these sufferers the consolations of religion, partly from his love of the study itself, Mezzofanti laboured assiduously to turn these and all similar opportunities to account; and several instances are recorded in which, without the assistance of a grammar or dictionary, he contrived to establish a mode of communication with a stranger who was utterly ignorant of every language except his own, and eventually to master that language sufficiently for all the purposes of conversation. He has left an account of his mode of study during these years, which is not a little curious and interesting. "The hotel-keepers," he says, "were in the habit of notifying to me the arrival of all strangers at Bologna; and I never hesitated, when anything was to be learnt thereby, to call upon them, to interrogate them, to make notes of their communications, and to take lessons in the pronunciation of their several languages. There were a few learned Jesuits too, and several Spaniards, Portuguese, and Mexicans residing in Bologna, from whom I received valuable assistance, both in their own and in the learned languages. I made it a rule to learn every strange grammar, and to apply myself to every new dictionary that came within my reach. I was constantly filling my head with new words. Whenever a stranger, whether of high or low degree, passed through Bologna, I tried to turn the visit to account, either for the purpose of perfecting my pronunciation, or of learning the familiar words and turns of expression. Nor did all this cost me so much trouble; for, in addition to an excellent memory, God had gifted me with remarkable flexibility of the organs of speech."

In the year 1812 Mezzofanti was appointed assistant-librarian of the university; in 1814 he was reinstated in his professorship; and in 1815 he became chief librarian. From this period, especially after the peace, his reputation rapidly extended. Every visitor of Bologna related fresh marvels regarding his prodigious attainments. Tourists from every nation, whether of Europe or of the East, united in representing him as perfect, each in his own language. Mr. Stewart Rose, in 1817, reported him as reading twenty languages, and speaking eighteen. Baron Zach, in 1820, sets down the number at thirty-two. Lord Byron, about the same time, pronounced him "a walking polyglot, a monster of languages, and a Briareus of parts of speech." When Lady Morgan saw him, in 1822, common report described him as speaking no less than forty languages; but when she inquired from himself the truth of the report, he replied that he had only gone over the outline of that number. M. Molbech, a Danish traveller of the year 1820, reports the number of his languages at "more than thirty," and testifies to his speaking Danish "with almost entire correctness." French, German, Spanish, Polish, Russian, Greek, and Turkish travellers concur in the same report, not only with regard to their own, but also to many other languages.

During all these years—except a short visit to Pisa, Leghorn, Florence, and Rome—he had resided altogether at Bologna, though invited, with many flattering offers, to transfer his residence to Paris, to Vienna, to Florence, and to Rome. At length, having come to Rome, as a member of the deputation sent by the Bolognese to offer their submission to the pope, Gregory XVI., after the revolution in 1831, he was induced by the pope to settle permanently in Rome, and to accept a prebend in the church of St. Mary Major, which was soon after exchanged for a canonry in St. Peter's; and, on the promotion of the celebrated Angelo Mai, then keeper of the Vatican Library, to the secretaryship of the Propaganda, Mezzofanti was appointed to succeed him in the important charge of the Vatican. He held this office till 1838, in which year, conjointly with Mai, he was elevated to the cardinalate.

His residence in a great centre of languages, such as Rome, and especially the facilities of intercourse with the various races represented in the college of the Propaganda, gave a new impulse to Mezzofanti's linguistic studies. The reports of his visitors at Rome are still more marvellous than those of the Bolognese period. An eminent German scholar, Herr Guido Görres, who had much intercourse with him in the year 1841, writes thus: "He is familiar with all the European languages; and by this I understand not only the ancient classical tongues, and the modern ones of the first class, such as the Greek and Latin, or the Italian, French, German, Spanish, Portuguese, and English—his knowledge extends also to the languages of the second class, viz., the Dutch, Danish, and Swedish—to the whole Slavonic family, Russian, Polish, Bohemian, or Czechish—to the Servian, the Hungarian, the Turkish; and even to those of the third and fourth classes, the Irish, the Welsh, the Wallachian, the Albanian, the Bulgarian, and the Illyrian. Even the Romani of the Alps and the Lettish are not unknown to him; nay, he has made himself acquainted with Lappish. He is master of the languages which fall within the Indo-Germanic family, the Sanscrit and Persian, the Koordish, the Georgian, the Armenian; he is familiar with all the members of the Semitic family—the Hebrew, the Arabic, the Syriac, the Samaritan, the Chaldee, the Sabaic—nay, even with the Chinese, which he not only reads, but speaks. Among the Hamitic languages, he knows Coptic, Ethiopic, Abyssinian, Amharic, and Angolese."

What is especially notable in this marvellous gift possessed by Mezzofanti is, that his knowledge of each among this vast variety of languages was almost as perfect as though his attention had been devoted to that language exclusively. The reports of the representatives of all the great families of language concur in describing him as speaking in each always with the precision, and in most cases with the fluency, of a native. His pronunciation, his idiom, his vocabulary, were alike unexceptionable. Even the familiar words of every-day life, and the delicate turns of conversational language, were at his command; and in each language he was master of all the leading dialects, and even of the provincial peculiarities of idiom, of pronunciation, or of expression. In

French, he was equally at home in the pure Parisian of the Faubourg-St.-Germain or in the Provençal of Toulouse. He could accommodate himself in German to the rude jargon of the Black Forest, or to the classic vocabulary of Dresden; and he often amused his English visitors by specimens of the provincialisms of Yorkshire, Lancashire, or Somersetshire. With the literature of these various countries too he was well acquainted. He loved to talk with his visitors of the great authors in their respective languages; and his remarks are described as invariably sound and judicious, and exhibiting careful and various reading, often extending to departments with which it would never be supposed that a foreigner could be familiar. A Dutch traveller, for instance, Dr. Wap, was surprised to find him well acquainted with his own national poets, Vondel and Cats; a Dane, with the philological works of Rask; a Swede, with the poetry of Ochsenstjerna; to a Sicilian he would repeat whole pages of the poetry of Meli; and an English gentleman was astounded to hear him discuss and criticise Hudibras, of all English writers the least attractive as well as the least intelligible to a foreigner. He was in the habit too of amusing himself by metrical compositions in the various languages which he cultivated, and often wrote for his visitors a couplet or two in their native language as a little momento of their interview. Dr. Wap, the Dutch traveller just referred to, speaks in high praise of some extempore lines in Dutch by which Mezzofanti replied to a sonnet which Dr. Wap had addressed to him; and the well-known Orientalist, Dr. Tholuck, having asked Mezzofanti for some memorial of his visit, received from him a Persian couplet after the manner of Hafiz, which he composed (although not without some delay) during Dr. Tholuck's visit.

After his removal to Rome, although he had already passed his fiftieth year, he added largely to his stock of languages. His most notable acquisition during this period was Chinese, which he acquired (partly at the Chinese College at Naples, partly among the Chinese students of the Propaganda) in such perfection as to be able not only to write and converse freely in it, but even to preach to the young Chinese ecclesiastics. During the same period he acquired the Abyssinian, the Californian, some of the North American Indian languages, and even the 'impossible' Basque. And it was in Rome, and especially in the Propaganda, that he displayed in its greatest perfection his singular power of instantaneously passing in conversation from one language to another, without the slightest mixture or confusion, whether of words or of pronunciation.

Mezzofanti, as cardinal, was a member of many ecclesiastical congregations in Rome, but he never held any offices of state. He died on the 15th of March, 1849, and was buried in the church of St. Onofrio, beside the grave of Torquato Tasso.

It is difficult to determine with accuracy the number of languages known by Mezzofanti, and still more so to ascertain how many of these he spoke, and with what degree of fluency in each. During his lifetime, as we have seen, report varied considerably at different times; nor was he himself believed to have made any very precise statement on the subject. To a Russian traveller, who visited him before the year 1846, and who begged of him a list of all the languages and dialects in which he was able to express himself, he sent a paper in his own hand containing the name of God in fifty-six languages. The author of a memoir which appeared soon after the cardinal's death in a Roman journal, the 'Civiltà Catolica' (who is now known to be Father Bresciani, a Roman Jesuit), states that, in the year 1846, Mezzofanti himself informed him that he was able to express himself in seventy-eight languages. Marvellous as these statements may appear, they seem fully borne out by inquiries (with a view to the preparation of a biography) which have been made since the death of the cardinal. Reports have been received from a vast number of individuals, natives of different countries, whose collective testimony, founded on their own personal knowledge of Mezzofanti, places beyond all question the fact of his having spoken fluently considerably more than fifty different languages. There are others among the languages ascribed to him, regarding which it is difficult to institute any direct inquiry; but, judging from analogy, and relying on the well-known modesty and truthfulness of Mezzofanti, we need not hesitate to accept his own statement as reported by F. Bresciani; the more so, as among his papers now in the possession of his family is a list, drawn up from memoranda contained therein, of no less than a hundred and twenty languages with which he possessed some acquaintance, unaccompanied however by any note specifying those among the number which he spoke, or the degree of his knowledge of each.

In general learning Mezzofanti's attainments were highly respectable. He was a well-informed theologian and canonist, and an impressive though not eloquent preacher. M. Libri, the historian of mathematical science in Italy, found him well acquainted with algebra, and reports an interesting conversation which he had with him on the Bija Gannita (the algebra of the Hindoos), as well as on the general subject of Indian history and antiquities. Other travellers describe him as entering freely into the history as well as the literature of their several countries. But as an author he is almost unknown. He occasionally read papers at various literary and scientific societies in Bologna and Rome; but his only known publication is a short memoir of his friend and brother professor, Father Emmanuel Aponte, which was printed at Bologna in 1820; and he leaves no monument for posterity beyond the tradition that he was incomparably the greatest linguist the world has ever seen.

MICA, a Mineral belonging to the extensive series of Silicates of Alumina. It occurs in oblique rhombic prisms of about 120° and 60°. The crystals usually with the acute edge replaced. The cleavage is very decided, yielding easily thin elastic laminæ of extreme tenuity. It is found usually in thinly foliated masses, plates, or scales: sometimes in radiated groups of aggregated scales or small folia. The colour is from white, through green, yellowish, and brownish shades to black. The lustre is more or less pearly. Transparent or translucent. Tough and elastic. Hardness 2·0 to 2·5. Specific gravity 2·8 to 3·0.

The composition of mica is as follows:—

Silica	46·3
Alumina	36·8
Potash	9·2
Peroxide of iron	4·5
Fluoric Acid	0·7
Water	1·8
	99·3

A variety in which the scales are arranged in a plumose form is called Plumose Mica; another in which the plates have a transverse cleavage, has been termed Prismatic Mica.

Mica resembles externally talc, and some forms of gypsum. From talc it differs in affording thinner laminæ, and being elastic. It also has not the greasy feel of talc. The same characters except the last distinguish it from gypsum, besides it does not crumble so readily on heating.

Mica is one of the constituents of granite, gneiss, and mica-slate, and gives to the latter its laminated structure. It also occurs in granular limestone. It is found abundantly in the United States, in Russia, in Great Britain, and other parts of the world. It is not often found in large isolated masses, but filling up the veins and fissures of rocks, into the composition of which it enters. It occurs in the oldest rocks, as well as in those which are new and possess a crystalline character.

In Russia it is used extensively as a substitute for glass, and hence it is called Muscovy Glass. The very thin laminæ are employed for examining objects under the microscope. Haüy states that these laminæ are sometimes not more than the 1-300,000th part of an inch in thickness.

Lepidolite, or *Lithia Mica*, occurs in crystals or laminæ of a purplish colour, and often in masses consisting of aggregated scales. It occurs in the Ural. According to Rosales, as quoted by Dana, it consists of the following analysis:—

Silica	47·7
Alumina	20·3
Lime	6·1
Protoxide of Manganese	4·7
Potash	11·0
Lithia	2·8
Soda	2·3
Fluorine	10·2
Chlorine	1.2
	106·3

Fuchsite is a green Mica from the Zillerthal, containing nearly 4 per cent. of oxide of chromium.

From the crystallisation of Mica two species have been made out of the old species so called. The common Mica has an oblique prism for its primary, but many micas when in perfect crystals have the form of a hexagonal prism. This species has been called hexagonal mica, the dark-coloured micas of Siberia, and the brilliant hexagonal crystals of Vesuvius. There are also hexagonal crystals which have been found by Dové to have two axes of polarisation, indicating that the lateral axes of the primary are unequal, and that the form is a rhombic prism with the acute edges truncated. This species is called *Rhombic Mica*, or *Phlogophite.*

Margarite, or *Pearl Mica*, occurs in hexagonal prisms, having the structure of mica, and also in intersecting laminæ. It has the appearance of talc, but differs from that mineral in being a silicate of alumina instead of magnesia. It is found at Sterzing in the Tyrol, associated with chlorite.

Margarodite, another schistose talc of Zillerthal, is a variety of common mica.

Emerylite and *Euphyllite* are new species, somewhat related to *Margarite.* They are found in Pennsylvania, United States.

Nacrite resembles talc, but contains no magnesia. It is whitish and soft, and has a greasy feel.

Lepidomelane is a black iron mica, occurring in 6-sided scales or tables aggregated together.

Ottrelite is an allied mineral occurring in black scales.

Oderit is probably a black mica. It can be split into thin leaves. It is opaque, black, and has very little lustre. It occurs in Sweden.

MICKIEWICZ, ADAM, the greatest poet that Poland has ever produced, was born in the year 1798 at Nowogrodek, a small town in Lithuania, one of the few in the environs of which the ancient Lithuanian language is still spoken. It is certainly remarkable that a man, the chief effort of whose life was to prevent the language, the nationality, and the religion of Poland from being overpowered by those of Russia, should be the native of a country which had lost its language, its nationality, and its religion by its union with Poland. His father, by birth a noble, was by profession an advocate, and an unsuccessful one, and his brother afterwards became a legal writer of some reputation. Mickiewicz himself had so little respect for the nobility of his family, that in his poem of 'Pan Tadeusz,' in which the scene is laid in Lithuania in the year 1812, he introduces his family name as that of a dissipated and illiterate brawler in a pothouse. It is singular that Pushkin, who acquired the name of the Russian Byron as Mickiewicz did that of the Polish Byron, takes occasion in his play of 'Boris Godunov,' to introduce one of his own ancestors in an odious and contemptible light. The feeling of the two poets in this respect was very different from that of their English prototype.

Mickiewicz after receiving his preliminary education at Nowogrodek and the grammar-school of Minsk, was sent when a youth of seventeen to the University of Wilna, where his uncle, an ex-Jesuit, was one of the professors. The university under the auspices of Sniadecki the mathematician, and the patronage of Prince Czartoryski, then Minister of Public Instruction, was at that time in the full tide of prosperity, the chief seat of learning for eleven millions of the population of Russian Poland, and celebrated for the success with which the exact and natural sciences were taught. Almost the first person whom Mickiewicz saw at Wilna was Thomas Zan, a celebrated Polish patriot, who was occupied with getting up secret societies among the students, of which Mickiewicz at once became a member. The professor of history, Lelewel, was another determined opponent of the Russian government, and to him Mickiewicz addressed the first poem he published. While at Wilna he fell deeply in love with the sister of a fellow student, Maria Wereszczakowna, by whom his addresses were finally rejected for those of a richer suitor. When he left the university, where he had first been noted for his devotion to chemistry and afterwards to poetry, he was appointed professor of classical literature in a college at Kowno, and it was while residing there in 1822 that two small volumes of poems from his pen were published at Wilna. Like those of Burns and Byron, they at one blow made their author famous.

These poems not only at once placed their author at the head of the Polish literature of his own time, but above every other serious poet who had ever appeared in the language. The 'Ballads' they contain, several of which are imitated from the Lithuanian, are of very various degrees of merit, some of them spirited, others pleasing, and others again poor and commonplace. But two poems of the set, 'Grażyna' and 'Dziady,' are of a very high class. In 'Grażyna,' in which the poet takes for his scene the old castle of Nowogrodek, the ruins of which are still remaining near his native town, he tells in a tersely classical and sculpturesque style, which reminds the reader of the happiest effusions of Tennyson, the story of a Lithuanian heroine, who to save the honour of her husband assumes his armour, and meets death on the field of battle. It became the favourite poem of a real Lithuanian heroine, Emilia Plates, who eight years afterwards fought in the Polish ranks in the insurrection of 1830, and to whose memory Mickiewicz devoted a poem. The 'Dziady,' or 'Ancestors,' is a poem of a new kind, an autobiographical drama, in which the poet appears as one of his own characters. In it the poet relates, with this slight veil, the story of his love for 'Maria,' the 'Mary Chaworth' of his life, and except in Byron's 'Dream,' which Mickiewicz afterwards rendered into Polish, it would be difficult to find a love-tale more tenderly and delicately told.

The name of Mickiewicz became at once popular among his countrymen. A valley near Kowno, which he was fond of visiting, and where he wrote some of his verses, received the name, which it still retains, of 'Mickiewicz's Valley.' The enthusiasm of the Poles was heightened by the next intelligence that spread far and wide concerning him, that he was a prisoner in the hands of the Russian government, on suspicion of being concerned in the secret societies which had been found to exist in the University of Wilna. The dedication of the 'Poems,' containing 'Dziady,' had been to Thomas Zan and a few friends, and probably the poet little anticipated the dedication which he was to prefix to another part of the 'Dziady,' published after long years of interval—"To the sacred memory of John Sobolewski, of Cyprian Daszkiewicz, of Felix Kolakowski, my fellow-students, my fellow-prisoners, my fellow-exiles, persecuted for love to their country, who, with a longing for that country in their hearts, died at Archangel, at Moscow, at St. Petersburg, the martyrs of their country's cause." Imprisoned for upwards of a year in the Basilian convent at Wilna, while the examination into the conspiracy went on, under circumstances and incidents which were afterwards delineated with all the force of his genius, Mickiewicz, found guilty of being a member of two secret societies, was condemned, in 1824, to perpetual banishment in the interior of Russia. At the age of twenty-six Mickiewicz left Poland for exile, and he never saw it again.

At St. Petersburg, where he was at first permitted to reside, Mickiewicz found himself, in the latter years of the Emperor Alexander, in the midst of native conspirators against the Russian government. Rnilyeev and Bestuzhev, afterwards so active in the abortive insurrection at the accession of the Emperor Nicolas, were ardent for the Polish cause. In a poem "to his Russian friends," written in after years, Mickiewicz mentions them both by name, as victims of the vengeance of the czar, and alludes apparently to Pushkin, to whom they introduced him, as having deserted the cause of liberty. The 'Russian Byron' and the 'Polish Byron' met at St. Petersburg in the year of the death of the English Byron. Probably the conjunction was not looked upon with favourable eyes by the Russian government, which ordered Mickiewicz to Odessa; there, however, he soon obtained permission for a tour in the Crimea, which gave rise to a series of 'Crimean Sonnets,' the first sonnets in the Polish language. Their subject now gives them an additional interest. One of them is 'On the View of the Mountains from Kozlov,' or Eupatoria; another, 'On the ruined Castle of Balaklava.' These poems have been very popular; and one of them, 'On the Chatuir-Dagh,' has enjoyed the singular distinction of being translated into Persian: but we believe that from no other poems of Mickiewicz could so many instances of false brilliancy and other common-place be selected. They obtained for him an invitation to Moscow from the governor, Prince Golitsuin, and afterwards permission to return to St. Petersburg, where, in 1828, his next great poem, 'Wallenrod,' appeared.

This poem was at once prohibited by the censorship of Warsaw, and to those who have read it, it is an inexplicable problem how it should ever have passed the censorship of St. Petersburg. Under the thin disguise of a story of a Lithuanian of the 14th century, who works his way to the mastership of the order of the Teutonic Knights, the enemies of his country, for the purpose of destroying them in detail, it inculcates the most burning hatred on the part of a crushed nation to its foreign oppressors. Its meaning, which was at once apprehended by every Pole, seems to have escaped every Russian. Two Russian translations were published, and it is even said that the Emperor Nicolas sent a message of compliment to the author. A diplomatic appointment in the Russian service was also, it is said, proffered to him; but the only favour he asked was to be allowed to visit Italy for the benefit of his health, and he obtained it by the intercession of the Russian poet Zhukovsky. He left Russia, as he left Poland, never to return.

After passing through Germany, where he spent some days with Göthe, he resided at Rome, where he became intimate with James Fenimore Cooper. It was at Rome that the news of the Polish insurrection of 1830 reached him, an insurrection which was commenced by a party of the insurgents singing in the streets of Warsaw some lines from his 'Ode to Youth.' The rising was crushed by the time Mickiewicz had reached Posen on his way to join it. He retired to Dresden, and there composed another part of the 'Dziady,' which was first published in 1832 at Paris.

As in the former part of this poem Mickiewicz had told in a dramatic form the tale of his early love, in this he related in a succession of scenes the story of his imprisonment in Wilna before the sentence of banishment. As a lover, he represented himself as having been driven by disappointment to insanity; as a man, he actually delineated himself as possessed by the devil, and the devil as exorcised out of his body by a priest, after the utterance of a proud and presumptuous challenge to Heaven, the impious vanity of which is represented as having called down the chastisement. This strange and repulsive scene is accompanied by others of a less eccentric character, in which the poet's friends and foes are put in action without reserve, and in which the horrors of the Russian sway in Poland are depicted with surprising power and pathos. On the whole, this wild production is one of the most remarkable for poetical power that the literature of the quarter of a century since 1830 has produced.

The last great poem of Mickiewicz, 'Pan Tadeusz,' or 'Sir Thaddeus,' was published in Paris in 1834. It differs as entirely in style and sentiment from the 'Dziady' as 'Waverley' from 'Manfred.' It is a minute delineation of Lithuanian domestic life in the year 1812, the time of the poet's boyhood, in which the somewhat insignificant story of a common-place hero is relieved against the dark background of the approach of Napoleon's invading army on its march to Russia, and the intense excitement it produces amongst the Lithuanians, from the peasant and the publican to the priest and the noble. By some it is regarded as totally unworthy of the powers of Mickiewicz—by many as the finest production of his genius; and there can be no doubt that it is by far the most pleasing and the least objectionable.

Up to this period the career of Mickiewicz had been one to which his Polish admirers had looked with constantly increasing admiration, and he occupied a position in the literature of his country without a rival either in the present or the past. "He is our Byron, our Shakspere," was the verdict of Klementyna Hoffmanowa herself, a staid and decorous writer. None indeed could then have foreseen in what darkness the star of Mickiewicz was to set. In 1832, two years before the appearance of 'Pan Tadeusz,' he had published 'A Book of the Polish Nation and the Polish Pilgrimage,' which presented an unbroken series of dull absurdity and extravagance. It was probably the influence of his name which procured its translation into French by Count Montalembert, and into English by Lach Szyrma, combined with the fact that in it Mickiewicz presented himself to the world in the character of a fervent Roman Catholic, convinced that it was to its toleration of Protestantism that the ruin of Poland was to be ascribed.

Before this period Mickiewicz had fixed his residence at Paris, and it was in that city, in 1834, that he became united to Celina Szymanowska, a Polish lady, to whom he had, in 1828, addressed some verses at St. Petersburg. To Paris and to the French he was strongly attached, but his pecuniary circumstances compelled him to accept, in 1839, an appointment as professor of classical literature at Lausanne. In the next year, when M. Cousin, then minister of public instruction, determined to establish a chair of Slavonic literature and the Slavonic languages at the College of France, it was considered a good fortune for the minister to be able to appoint, for the first professor, the greatest poet of Poland.

The first lectures which he gave were eagerly attended, and were reproduced in the French and German journals; but ere long strange alterations began to develope themselves.

Already in 1841, when Madame Mickiewicz, who was in bad health, had received some benefit from being mesmerised by a Polish fanatic named Towianski, Mickiewicz had allowed himself to become associated with this man as the interpreter of certain dreams, in which Towianski alleged that he was favoured with revelations by the Virgin Mary. In his lectures on Slavonic literature the professor gradually lost sight of Slavonic literature altogether, and preached a series of discourses, in which this Towianski was represented as the new Messiah of a new religion, of which the principal feature was the worship of Napoleon Bonaparte. This Mickiewicz represented as a new and necessary development of improved Christianity. At last, in 1844, the French government interposed, ordered Towianski to quit Paris, and put a stop to the course of lectures which had long excited general scandal and disgust. Mickiewicz's name appeared in the list of professors for some years afterwards, but he lived in obscurity, an object rather of compassion than other feelings. In 1848 the revolution of February again excited his hopes for Poland, and he made a journey to Italy for the purpose of gaining over the pope, and was received with enthusiasm by the insurgents at Florence. In 1851 his name appeared in the French calendars as 'Sub-Librarian of the Library of the Arsenal at Paris,' to which he was appointed by the prince president, who might possibly view as a venial error the inculcation of the worship of Napoleon I.

About 1854 Mickiewicz became a widower, and he afterwards returned in some degree to public life. Soon after the commencement of the war with Russia he headed a deputation to the French emperor, to remind him of the opportunity that presented itself for redressing the wrongs of Poland, and in 1855 he was sent by him on a secret mission to the East, which was destined to prove the last incident in his career. He died at Constantinople on the 27th of November, 1855. His remains were removed to France, where they were interred in the cemetery of Montmartre, and a subscription was opened directly after at Paris and London for the benefit of his children.

One of the most remarkable editions of Mickiewicz's works was published at Paris in 1828 and 1829, in three volumes, at the expense of the Countess Ostrowska, a Lithuanian lady, who presented the money received from its sale to the author, then a captive in Russia. It is generally stated to be the first book printed in France in the Polish language, but it had two predecessors, as its editor, Leonard Chodźko, points out in the preface—one in 1668 and another in 1814. Its successors may be counted by hundreds, many of the best works in Polish being now originally printed at Paris. The best edition of Mickiewicz's works is that in four volumes, issued at that city in 1844, revised by the poet himself, and edited by Alexander Chodźko. A translation of all his works into French, by Christian Ostrowski, was published at Paris in 1841, and again in 1845, with two very different prefaces, the first all enthusiasm for Mickiewicz and his genius, the second full of the disappointment and estrangement his devotion to Towianski had inspired. The English language possesses one only of his larger poems in two translations—the 'Wallenrod,' in prose by Leon Jablonski, Edinburgh, 1841, and in verse by Cattley, London, 1842. An article of some length on Mickiewicz appeared in the London 'Metropolitan,' at the outset of his career, and another in the 'Athenæum' for 1856, on the occasion of his death.

The name of 'the Polish Byron,' which has been generally assigned to Mickiewicz, conveys as correct a notion of the nature and the extent of his genius as any single epithet could possibly do. The most striking point of dissimilarity between the two is the vehement patriotism of the Pole, and the indifference to his country which was professed by the Englishman, but a great deal of this was probably owing to the different position of the two countries, one at the foot of a foreign sovereign, and the other in the most prosperous period of its history. It may be remarked that in 'Pan Tadeusz,' where Mickiewicz has occasion to delineate the character of his countrymen, he depicts them, not consciously perhaps on his own part, as arrogant, ignorant, prejudiced, spiteful, and headstrong, with scarcely any good qualities to balance. There is an obtuseness in Mickiewicz's own moral perceptions which it is often painful to observe. His poem of 'Wallenrod' is devoted, from the first line to the last, to the inculcation of a spirit of systematic treachery, and in one remarkable passage he delineates his young hero in the palace of his foe as descending to the meanest spite—

"I remember how oft in the castle
I secretly sharpened my knife, and with what a rapture of vengeance
I cut the carpets of Winrych, and ruined his glittering mirrors."

It is said that at the time of the appearance of this passage in 'Wallenrod,' the Poles in the palace of the Grand Duke Constantine at Warsaw carried out the idea. The gross anachronism of the carpets and the mirrors in a story of the 14th century is only one of many which abound in the works of Mickiewicz, and it is unsafe to rely on his anthority for facts in literary or other history, where his views and theories were concerned. He tells us, for instance, in one of his Napoleonic lectures that the genius of Byron was undoubtedly kindled by a ray from that of Napoleon, and inquires how such a poet could otherwise have arisen in a literature so decrepit and almost dead as that of England, which had as it were come to a close with Thomson and his followers. This general inaccuracy and untrustworthiness must, in fairness to the Russians, be remembered by the readers of the thrilling delineations of their cruelty which abound in the 'Dziady.' Whatever may be the judgment pronounced on Mickiewicz as a writer, a politician, and an historian, nothing can ever erase from Polish literature the name of the poet of 'Graźyna.'

MICROSCOPE, USES OF THE. There are few instruments that have rendered such important aid in scientific search as the Microscope. The chief advances that have been made in the natural history sciences, embracing physiology, during the latter portion of the first half of the 19th century, have been effected by its agency. The structure of this instrument has been described in the article MICROSCOPE. It has been gradually rendered more perfect as the science of optics advanced; and its nature and arrangement can only be understood by the study of the principles of this science. We purpose here referring to its use as an instrument of natural history and physiological research, and of those general arrangements and applications by which its utility can alone be fully secured. It is not alone sufficient that a man possesses eyes in order to observe accurately, nor is it the possession of a costly microscope that will enable a person to confirm the observations of others or make discoveries of his own. The use of the microscope by uninstructed and incautious observers has given rise to many absurd errors. "The fruit of the mulberry has been mistaken for *Entozoa;* calcareous corpuscles have been regarded by several observers as ova, and the appearance arising from the presence of concentric laminæ has been interpreted to be the coils of an inclosed embryo; similar corpuscles have also been regarded as nucleated cells, and again as blood-corpuscles; minute fossils in chalk have been strung together with portions of vegetable tissue, and (perhaps) the spores of *Algæ,* to constitute different stages of a fungus: minute hairs projecting on the surface of a membrane have been declared to be spiculæ within subjacent cells; and quite recently one writer states, that certain minute bodies which he has examined are either blood-corpuscles or the spores of fungi, but which is doubtful! while another recounts, how, by fortunate accident, he discovered that corpuscles, which he had regarded at first as consisting of fat, were afterwards found accidentally to consist of calcareous salts!

"Again, we read in physiological works of the yolk-cells, and the coloured oil-globules of the yolk; and a beautiful function of assimilation has been attributed to them; but they exist only in the imagination of the authors, who have regarded the one as cells, simply because they are round, and the other as consisting of fat, because they are highly refractive. Since the publication of Schleiden's cell-doctrine, almost everything round has been regarded as a cell; any single body within this, or where there are several, the largest has been regarded as a nucleus, and any spot within the nucleus has been viewed as a nucleolus. Whereas many of the so-called cells are homogeneous spheres, many of the nuclei are vacuoles, and a true nucleolus is very rarely found except in books." ('Micrographic Dictionary.')

Against such errors as these a long-continued and careful use of the microscope can alone preserve the young observer. They are not the result of imperfect or inferior instruments, but the consequences of hasty and imperfect observation. They have been made by persons using the most costly instruments, and their erroneousness has been demonstrated by those who have used the simplest and most economical arrangements.

In microscopic observations two things must be remembered: 1st, That in the microscope, especially with high powers, we see surfaces, not bodies. It frequently happens that in looking upon surfaces, we get a glance into the depths of transparent objects by changing the adjustment, without altering the position of the object; it more often happens however that in looking upon such objects, we are unable to make them out to be bodies until we have changed their position, and ascertained their dimensions in three different directions; this, in many cases, from the nature of the object itself, is a matter of great difficulty. 2nd, That we seldom see the objects under the microscope in their natural condition; that we consequently must take into consideration the changes which we ourselves partly produce, either by the medium in which the object is placed, or by the use of the knife or other influences. Long and thorough practice with the microscope secures the observer from deceptions which arise, not from any fault in the instrument, but from a want of acquaintance with the microscope, and from a forgetfulness of the wide difference between common vision and vision through a microscope. Deceptions also arise from a neglect to distinguish between the natural appearance of the object under observation, and that which it assumes under the microscope.

To these difficulties must be added those originating in the eye itself, through the so-called 'Mouches volantes,' and those also which arise from the observer being unacquainted with the appearance, under the microscope, of the common things which are dispersed throughout the air and water, such as small particles of dust, &c. Lastly, deceptions are also caused by air-bubbles, by molecular motion, and by the currents which arise upon the stage of the microscope from the evaporation of water, or from the intermingling of two fluids. The observer must learn to know and distinguish all these things thoroughly, and then no further deception can arise from these causes.

The proper use of the microscope is always the principal thing to be considered. Hedwig, with the microscope of his time, promoted the advancement of science to a greater extent than many observers with incomparably better instruments have done.

In order to use the microscope properly, the observer must be skilful in handling the instrument and the objects, and above all things, his mode of proceeding must be conducted with accuracy and judgment, and he must be able to give a sufficient reason for every thing that he does. His progress in research will be slow, but sure; he must endeavour to obtain objects from every possible source, and must examine them thoroughly; he must verify his own observations as scrupulously as possible, and so, progressing step by step, he will attain the desired end. Work without method will seldom lead to any result; the finest sections of wood made only in one direction, or in a wrong direction, do not lead to any knowledge of the wood under observation. Single observations (of wood, for instance), irregularly made from time to time, only show the condition of the wood at the time of that particular observation, and throw no light on its condition at an earlier or later period; whilst sections made in a proper manner, and well-preserved specimens of the successive conditions of the wood, furnish irrefragable proofs, the one of the construction, and the other of the development in the growth of the wood under observation. (Schacht 'On the Microscope.')

Before speaking of the methods of examining and preserving bodies for microscopic observation, it will be better to draw attention to the natural objects, to the examination of which it has been applied with so much success. In both the inorganic and organic worlds the microscope is made subservient to observation. To speak first of inorganic substances and materials not under the influence of vital action:—It has been found of great use in determining the forms of minute crystals. In this way it aids the analytical chemist. In the examination of the saline contents of water, if a small quantity of the water is allowed to evaporate upon an ordinary glass slide, its contents may be judged of by the forms which the crystalline matters assume. In fluids obtained from organic bodies this plan of examination has been recently applied with the most interesting results. A series of the most beautiful illustrations of the microscopic characters exhibited by crystals obtained by the evaporation of the blood and other fluids, will be found in Dr. Otto Funke's 'Atlas of Physiological Chemistry,' and also in the 'Micrographic Dictionary,' by Dr. Griffiths and Mr. Henfrey.

Not only are the natural crystalline constituents dissolved up in liquids thus obtained, but new combinations obtained by the addition of re-agents. This mode of inquiry is equally applicable to the excretions of the human body, and is rapidly becoming one of the most important means of diagnosis in the hands of the physician.

Although dealing with the disposition of large masses of matter, of which the earth's surface is composed, important knowledge is obtained by the geologist by examining minute portions of them with the aid of the microscope. It is by the aid of this instrument alone that the question of the manner in which an extensive series of rocks has been deposited can be determined. Many rocks which present a homogeneous surface, when sections are made of them and placed under the microscope, are found to consist of the remains of the minutest forms of organic beings. [DIATOMACEÆ, *S.* 2; INFUSORIA.] Whilst, on the other hand, rocks which, like the Oolites, present to the naked eye the appearance of being composed of various forms of organic beings, on close examination with the microscope are found to present appearances due to purely physical causes. Each of the little egg-like bodies seen in these rocks is found to contain a particle of sand surrounded by carbonate of lime. [OOLITE, *S.* 2.] It frequently happens that the fossilised parts of the higher animals which are left in the solid rock are too small or shapeless to indicate the characters of the family to which they belonged; but by the aid of the microscope this question can be determined in multitudes of instances. It has been found by the recent researches of Dr. Carpenter and others, that the microscopic characters afforded by the structure of shells are frequently so distinct as to afford the means of distinguishing between allied species of *Mollusca*. This is a subject of the highest interest to the geologist; for of all the remains of animal life those of the *Mollusca*, from the hard nature of their shells, are those which are furnished to him in greatest abundance for distinguishing the character of different strata, and determining their relative age. Amongst the vetebrate animals, next to the teeth, the bones are the parts which are most frequently left in rocks. When the form of the bone is no guide, its microscopic structure will determine the family to which it belongs. The forms presented by the lacunæ, or bone-cells, which are only visible by the aid of the microscope, are found to differ so much in fish, reptiles, birds, and mammals, as to afford the means of distinguishing each class. The teeth are only modified bone, and although they present most frequently a very definite external form, and are usually better preserved than any other part of an animal body, they afford still more definite characters by the modifications of the internal portions of their structure. It is thus that the internal structure of the tooth presents a better character than any other part of its structure in the gigantic extinct frog, the *Labyrinthodon*.

Among the earlier fishes which inhabited the seas of the earth were principally those which have a cartilaginous skeleton; but with this perishable skeleton they were endowed with hard scales, which have resisted all decomposing agencies, and these scales, frequently scattered, are the only record of their existence. From microscopic examination of the structure of these scales, Professor Williamson has shown that the species of those fishes can be detected.

Numerous are the forms of *Zoophyta*, *Polyzoa*, and *Echinodermata* that have left remains in the strata of the earth which the naked eye can by no means distinguish, but whose differences are immediately revealed when sections of their fossilised remains are placed under the microscope. Examples of these will be found in the second volume of Professor Quekett's 'Lectures on Histology.'

We pass from this glance at the use of the microscope to the chemist and geologist, to point out its value in researches connected with living organised beings. We begin with plants. It is in the vegetable structure that the ultimate cells, of which all organised beings are composed, are most easily discerned. The earliest microscopic observers were aware of this. It was left however for Schleiden to perceive the full significance of this fact in 1838, when he drew attention to the cytoblast as the source of the growth and life of the cell. [CELLS, *S.* 2.] He was followed by Schwann, who pointed out that the cell was of equal importance in the animal as the vegetable kingdom. The ultimate cell of the plant or animal is only visible by the aid of the microscope; hence whatever importance is attached to the discovery of cells and the formation of tissues by their agency is due to the use of the microscope.

The unceasing labours of microscopic observers during the last quarter of a century have developed a new branch of science called histology [HISTOLOGY, *S.* 2], which embraces a knowledge of the ultimate structure of the tissues of which all parts of plants and animals are composed.

One of the most interesting facts connected with the history of the microscope is the discovery of the existence of minute animals and plants, inhabiting more especially water, and which are perfectly invisible to the naked eye. The earliest observations on these minute beings were made by Leeuwenhoek in the middle of the 17th century; but it was left for Ehrenberg, during the present century, to make known to its full extent the immense variety of forms assumed by these microscopic beings. [DIATOMACEÆ, *S.* 2; DESMIDIEÆ, *S.* 2; INFUSORIA.] Since the publication of the 'Infusionsthierchen,' these minute organisms have been a source of increasing interest to microscopic observers. Representing the entire animal or plant in its simplest form, the observations of their growth, structure, and functions have thrown light on some of the most complicated problems of animal and vegetable physiology. Small as they are, they make up for want of size by the prodigious numbers in which they occur, and the important functions they seem to perform in the universe. The unveiling of this world of life is entirely due to the agency of the microscope.

It is not however alone in revealing the minute structure of plants and animals, as the existence of organic beings of minute size, that the naturalist and physiologist are indebted to the microscope. By its aid they have been enabled to investigate the functions performed by cells. If the tissues of plants and animals are built up of cells it was a natural inference that these cells performed an important part in the functions of these tissues. It was soon found that the animal and plant increased in size by the multiplication of these cells; that the tissues were renewed by their agency; that the function of secretion was performed by them; in short, that it was by the aggregate of their functions that plants and animals lived. Hence the cell theory, or cell doctrine, has been to the explanation of the phenomena of living beings what the law of gravitation was to the phenomena of the physical universe. Till the application of the microscope the mysterious function by which new beings in plants and animals were produced was only imperfectly apprehended; but since its extended employment the laws which regulate this process have become perfectly obvious, and but little remains to complete our knowledge of the subject. [REPRODUCTION IN PLANTS AND ANIMALS, *S.* 2.]

Having pointed out the objects of the use of the microscope, we now proceed to give some general directions for examining them. In giving these directions we shall follow Dr. Schacht, whose work on the microscope has been translated into English by Mr. Currey.

One of the principal requisites for microscopical investigation, besides a good instrument, is a proper supply of light. When the position and nature of the apartment can be selected at pleasure, a room should be chosen having windows facing the west or the north, or, what is better, a room with windows towards both those quarters of the heavens. The windows must be as high as possible, since the light received from the horizon is the most favourable; light reflected from a white wall, or the light of white clouds, is often very advantageous. The light of scudding clouds fatigues the eye by the rapid change in the intensity of light, besides rendering necessary a continual change in the position of the mirror. No ordinary observation is possible in direct sunlight; the light is, in the first place, far too dazzling for the eye to bear; and, in the second place, it causes appearances which give rise to the grossest deceptions. In working with the microscope in the forenoon and in the middle of the day, a room lying to the east or to the south must therefore be avoided: by means of white blinds, or curtains, the inconvenience may, to a certain extent, be avoided.

Many objects are seen very beautifully by lamp-light, but this light is far more glaring than daylight. When the light is made to pass through blue glass before reaching the mirror, it bears a greater resemblance to daylight, and is pleasanter to the eye. A piece of white ground-glass, fastened in a wooden frame, and placed before the lamp, will have the same effect. By regulating the light of the lamp in this manner, objects already prepared may be shown very well by night, but it is hardly possible to make fine preparations with such an illumination; for exact observation, therefore, the daytime only must be selected. In order to intercept the light of the horizon by means of the mirror, the latter is placed at least three feet from the window, the microscope is turned with the mirror towards the light, and the whole instrument, but especially the mirror, is placed in different positions whilst the observer looks through the eye-glass; the light is, in fact, sought after: when the field of view appears clearest and brightest, the object which is to be observed is pushed under the microscope.

When it is wished to examine opaque objects with incident or reflected light, the microscope may often be advantageously brought nearer to the window. Since for this kind of illumination a much larger quantity of light is necessary, direct sunlight is sometimes desirable; in the absence of this, the condensing lens is used, by means of which the greatest possible quantity of light is concentrated upon the object. In this kind of illumination, the access of light from below, which would interfere with the observation, is prevented by closing the diaphragm. For objects which are altogether opaque, a background which is white, but not glittering, is often advantageous.

The table at which microscopical observations are undertaken must be sufficiently large, and very firm; it must be so arranged that all the apparatus which is ever wanted shall be at hand. Much time is spared by attention to this, and in microscopical investigations time passes only too quickly; moreover, in a very confined space, it is impossible to make effectual preparations with the simple microscope. Every object intended for investigation should be examined in the first instance with a low magnifying power, since by that means a far larger portion of the object is seen, and thus a better impression with regard to the whole is obtained. Should the light be too strong, the plane mirror may be used instead of the concave one. When the observer has gained as much information as he can with the low-magnifying power, for instance, one of 50 diameters, or, in some cases, even a less magnifying power, the object-glass is changed for a more powerful one. When the most powerful object-glass has been used, and a still stronger magnifying power is found desirable, then a stronger eye-glass is taken. As a general rule, the eye-glass of lowest power should be used, and, if necessary, the magnifying power should be increased by passing from the object-glasses of lower power to those of higher power; but, nevertheless, for seeing with convenience, and especially for drawing, the use of a powerful eye-glass is often not without advantage. As long as the magnifying power can be increased by means of an object-glass, recourse should never be had to the eye-glass, since both the light and the sharpness of outline of the image are necessarily diminished by the use of a powerful eye-glass, which is not the case in using a more powerful object-glass.

In some cases, it is a good plan to shade with the left hand, the eye which looks into the microscope. When an object is thin enough to be seen with transmitted light, it is first illuminated with light transmitted directly, and is examined with different, and gradually increasing, magnifying powers; should any details of the image remain undefined, obliquely transmitted light is used, which is insinuated into all the different corners of the object. In some microscopes this is attained by turning the stage round its axis; where this arrangement is wanting, the position of the object must be changed by moving it with the hand. Lines always stand out most clearly when oblique light falls upon them at a right angle: where, therefore, a line is suspected to exist, or is only dimly seen, particular attention must be paid to this circumstance. In submitting objects to incident light, the same rule generally holds good, and particular care must be taken, by turning either the stage or the object itself, to concentrate the light in all possible directions upon the object. Object-glasses of very high power cannot be used with incident light, inasmuch as the shortness of their focal length prevents the light from falling on the object; in this case recourse must be had to less powerful object-glasses, and more powerful eye-glasses. As a general rule, low-magnifying powers are sufficient when incident light is used.

Objects are frequently examined by polarised light. In order to effect this an instrument called a polariscope is employed. That most frequently used is the arrangement proposed by Mr. Nichol. It consists of two prisms of Iceland spar, one of which is fitted beneath the stage, the other is attached to the eye-piece. Tourmaline is also used for the same purpose. Large crystals of iodide of quinine have also been shown by Dr. Herapath to be applicable in polarising light for the microscope. ('Quarterly Journal of Microscopical Science,' vol. ii.) By the use of polarised light objects frequently exhibit their structure in a more perfect manner. Various objects, especially crystals of a spherical or oval form, exhibit a beautiful variety of colour in this way. In some cases it may be made the means of testing the nature of an object.

In most instances, objects are examined under water: it is but seldom, as, for instance, in examining pollen or spores, that it is necessary to observe them in different media, and also when dry. In the case of incident light, water often operates injuriously, especially when the object is not quite covered by it: it is therefore advisable, for certain particular objects, as, for instance, the embryoes of grasses, to observe them first without water, and afterwards under water; by placing them under a cover, and adding water with a camel's-hair brush, the object is generally sufficiently and fully immersed. When low-magnifying powers are used, it is not necessary that the objects should be placed under a glass cover, in fact, in many cases where it is wished to have the power of turning the object round, or when it is thought that the object may be improved by any additional cutting or preparation, it is very advantageous not to cover it; when object-glasses of very high power are used, the focal distance is so short, that in order to prevent striking the lens against the object, or dipping it in the fluid upon the object plate, it is necessary to make use of glass covers. When these are used, the fluid in which the object lies frequently becomes lessened by evaporation during the observation, in which case a fresh drop is added at the edge of the glass cover by means of a glass rod, or a clean camel's-hair brush, which may be used when it is wished to add a solution of iodine, or of chloride of zinc and iodine, to objects which are already immersed in water.

When any chemical re-agents are used, whether iodine, caustic potash, or an acid, the object should always be covered with a thin plate of glass; in using volatile acids, such as nitric acid and hydrochloric acid, too much care cannot be taken. The vapour of sulphuretted hydrogen has a very injurious effect upon flint glass, which is used by some opticians for the under side of the object-glass.

When the microscope is in daily use, it is a good plan to keep it under a high bell-glass, or an ornament shade.

The greatest cleanliness and accuracy are indispensable for microscopical investigations: it must be laid down as a rule always to use the cleanest water, in the cleanest vessels, for moistening the slides. Even with this precaution it is impossible entirely to protect the object from becoming soiled with particles of dust. Extraneous things of this kind will not easily deceive a practised observer; a beginner however may be easily misled by them. Water which has been left standing should never be used, since it too frequently contains the inferior sorts of animals and plants; and when different objects are examined one after another, fresh water should be taken for every new object, in order that no particles of the objects which have been previously examined may be mixed with the water upon the slide. Many errors may be traced to a neglect of small precautions of this sort.

In order to be able to recognise extraneous objects as such, it is advisable to gain an acquaintance with those things which, notwithstanding all precautions, cannot always be avoided. To this class of things belong: 1st, Air-bubbles, which, with transmitted light, generally appear in the form of circles of larger or smaller diameter, with a dark, black-looking rim: with incident light, on the contrary, their rim appears of a white colour. When the object is under a glass cover and in contact with it, the large air-bubbles frequently assume a very irregular shape; the above-mentioned optical fact is generally however by far the best proof of the presence of air, and by it the presence of air may be detected both in and between the cells of plants. 2nd, Colourless or coloured fibres of paper, or of linen, woollen, or silk-textures, left behind upon the object-glasses, from the cloths with which they have been cleaned, and also the hairs which have been detached from the brush. 3rd, Granular particles of dust of irregular shape, which are frequently coloured, and are probably produced by the decay of organised bodies. If it is wished to examine plants, or parts of plants, which grow either in or upon the earth, or in water, great attention must be paid to the many organised bodies which are likely to be met with: pains must be taken by careful observation to become acquainted with the lower forms of animals and plants: it is necessary, for instance, to be able to distinguish the common forms of *Infusoria*, both those that are provided with siliceons coatings, and those that are not; also with the yeast plant, the different forms of mould, the *Oscillatoria*, and sucb like things, in order to be able to separate tbem from tbe particnlar object under consideration.

The epithelial cells of the mucous membrane of the mouth are also objects which may deceive the observer. Tbey occur wben the brush is drawn through the month previously to bringing an object upou tbe object-plate. It is advisable never to pass the brush throngh the moutb. When in cutting small objects, the latter are held between the thumb and forefinger, or upon the forefinger alone, it often happens that small fragments of the skin of the finger are cnt off at the same time. Tbe observer must learn to distinguish these fragments, as well as the small pieces of cork which he will meet with in sections made between that substance.

Appearances of motion, either usual or accidental, may also give rise to mistakes, and these must therefore be learnt. Molecnlar motion is peculiar to all very small bodies, contained in a thin fluid medium; it consists of a somewhat trembling motion of these small bodies; it is frequently seen iu the interior of pollen grains; it may be observed still better in certaiu fluids, for instance milk, when a small quantity is mixed with water, aud placed under the microscope, with a magnifying power of from 200 to 400 diameters. When acquaintance is once made with this phenomenon no furtber deception can be caused by it. The same result follows from accidental cnrrents upon the object-plate, which may take place either by evaporation or by tbe mingling of two fluids of uneqnal specific gravity, or by the dissolving of any salt existing in tbe fluid.

Observations are made less frequently with reflected than with transmitted light, but since the latter cau only be used for very thiu objects, the principal point to be attended to in dealing with opaqne objects, is to make such an arrangement of them, as to enable the observer clearly to make out their details. The mauner in which tbe object is divided must be regulated and altered according to tbe nature of tbe object itself, and tbe information which it is wished, by the help of the microscope, to obtaiu respecting it. Firm homogeneous textures, such as wood, must be treated quite differently from delicate objects composed of different organs, such as buds and blossoms; in the case of wood it is sufficient to take as tbin a slice as possible, cnt in a certain fixed direction; iu tbe case of buds and blossoms, attention must be paid not ouly to the direction, but also, particularly, to the point at which the section is made; it is necessary to exhibit an accurate longitudinal section through the middle of the whole bud or blossom, and an equally accurate transverse section made at different heights, in order to ascertain the arrangement of the organs with respect to one anotber; moreover, the different parts of the orgaus must be separated and examined by themselves; in cases like tbis, and especially in inquiries connected with the development of plants, a dissecting microscope is necessary. The same remarks apply to hard and soft animal tissues.

Succulent or spongy tissues have generally large cells; it is not necessary therefore to bave thin sections of such tissues, which are always difficult to make. Delicate animal tissues may advantageously be placed in spirit or pyroligneous acid for some days, provided it is not necessary that the tissues should be examined whilst fresb; but tbere is little advantage to be derived from treatiug botanical objects in tbat mauner. It is a good plan bowever, in many cases, to saturate delicate portions of animals and vegetables with thick gum-mucilage, and to let them dry slowly in the air.

In dissecting, different methods must be adopted, according to the magnitnde of the different objects; objects of large size may be held with the left hand, or with tbe thumb and forefinger of that hand; very small or very thin objects, such as the stems of mosses, thin twigs and roots, leaves, small seeds, and such-like things, may be placed between two pieces of cork, and thin slices of the object cut by means of a sharp knife or razor.

Observations are sometimes disagreeably impeded by the presence of air, which becomes accumulated in the hairy parts of plants, in the intercellular canals, iu the vessels, aud in wood; it is best removed by placiug the object for a few minutes in a small watch-glass filled with alcohol; when taken out of the alcohol it must be put into water, and tben transferred to tbe slide. When it is wisbed to examine the cell contents, in which the changes are generally produced hy the operation of alcobol, the removal of the air may be advantageously effected by the use of the compressorium, wbich is permitted to operate continuously upou tho object, wbilst the observer looks into the microscope. In the absence of a compressorium, the fingers may be lightly pressed against the glass cover.

For transferring objects from one fluid into another a very fine camel's-hair brush sbould be employed; needles and other sharp instruments should never be used for this purpose, since the object may be easily injured by them. When the object is very small it will be more easily found if the watcb-glass is placed upon a dark back-gronnd.

The microscope only affords a view of one surface of an object; when, therefore, bodies are subjected to examination, it is not sufficient for a correct understanding of them to examine one side ouly; a transverse section and a longitudinal section, and, in fact, frequently many longitudinal sections iu different determinate directions, must be carefully examined and compared with one another before the observer can be satisfied tbat be has made out tbe construction of tbe body under observation. That whicb in objects of large size is attained by the help of the knife, is effected, in tbe case of very small opaqne objects, by examiniug them on different sides. In examining small bodies wbich are very transpareut, as, for instance, the ovnles of *Orchideæ*, or grains of pollen or starch, tbe adjustment of the microscope is varied from time to time, by wbich means tbe upper side of tbe object is first brought into the focus, then the middle (which may be called an optical section, transverse or longitudinal, as the case may be), and, lastly, tbe under-side. The more perfect tbe object-glass the more exact is the focal plane, and tbe more sensitive is the instrument to any small alteration of tbe focus, on which account the observer sbould always keep his hand upon tbe fine-adjusted screw whilst he is employed upon observations requiring mnch accuracy. Tbe sensitiveness above mentioned increases, in good instruments, in proportion to the magnifying power, and also with the angle of the aperture of the glass.

Tbe accurate adjustment of an object is judged of by the sharpness of delineation of tbe image. The adjustment is more accurate in proportion to the delicacy and sharpness of the lines seen upon small objects, and also in proportion to the fineness and clearness of the outline, which should be soft, but well-defined. The scales of the *Hipparchia Janira*, a common brown butterfly, are well adapted for enabling a person to jndge of the accuracy of an adjustment; the smallest change of focns causes transverse striæ to disappear.

In examining small round bodies, such as pollen-grains, tbe position of the objects sbould be cbanged, by gently pushiug the glass-cover so as to cause the bodies to roll about; by this means different sides of the objects are seen, and from tbe different images presented to the eye their true form is made out.

Small objects should never be compressed between two glass sides, that being too rougb a method of proceeding. If however it is supposed that anytbing is to he gained by compression, then it is advisable to use the compressorium, wbich is an instrument consisting of a mecbanical arrangement by which the tbin glass covering an object may be compressed at will. When the compressorium is cautiously used, tbe observer, by carefully watching what takes place, can gaiu a knowledge of tbe changes produced by pressure during the time the compressorium is permitted to work. In certain cases, wbere, for instance, the question is whether a particular object is a delicate cell or a drop of some fluid, the compressorium may be of service; since, if a cellular membrane be present, it will burst and discharge its contents as tbe pressure is increased, whereas the drop, whether it be oil, liquid resin, or any other chemical substance upon the slide, will only change its form.

In examining any object, whether animal or vegetable, it is not sufficient to observe the nature, form, and arrangement of the cells; it is necessary also to pay attention to their contents, whicb, iu the case of plants, are different according to the functions assigned to tbem by nature. It is necessary, therefore, to distinguish—1st, Whetber a cell is empty, that is to say, whetber it contains air, as is the case, for instance, with perfect vessels and wood-cells; 2ndly, Whether its contents are fluid with a solid substance contained in the fluid. Another question which arises is as to the nature of the fluid contents, that is, whether they consist of a homogeneous fluid, or of fluids of different consistencies, apparently not intermingling with one anotber; the manner in which these fluids are affected by chemical re-agents has also to be considered. Lastly, the solid ingredients of the cell-contents, and their physical and chemical nature, must also be attended to. There are some substances dissolved in the juices of the cell, such as sugar, for example, for which no certain chemical re-agents are known. Gum and dextrine are coagulated by alcohol; the presence of nitrogenous substances is proved by the use of sugar and sulphuric acid, which produce a red colour, or by a solution of iodine, or of chloride of zinc and iodine, and also by nitric acid, with ammonia subsequently added to it; in these three cases an intense yellow colour, almost brown, is produced. When the presence of oil or resin is suspected, the object should be placed in ether or pure alcohol for some hours, which will dissolve both oil and resin. When the juices of the cell hold any salt in solution, some re-agent must be used which operates upon the salt. Starch is detected by being coloured blue by iodine.

The following is a list of re-agents which it will be found convenient to have close at hand in the examination of either animal or vegetable substances:—

1. Alcohol, which is used principally for removing air from sections of wood and other preparations, and as a means of dissolving certain colouring matters, &c. It coagulates the albuminous textures of animals.

2. Ether, which is principally used for dissolving resins, fatty essential matters, and other oils, &c. This is also useful for removing air.

3. A solution of caustic potash, which is used for the purpose of dissolving fat, is also useful in certain cases from its effects upon the contents of cells, and upon the thickening layers. It dissolves up substances of an albuminous nature. This solution often works better after warming.

4. A solution of iodine (one grain of iodine, three grains of iodide of potassium, one ounce of distilled water) for colouring the cell-membrane, and the contents of the cell.

5. Concentrated sulphuric acid. This is principally used for examining pollen and spores. In the examination of hairs it renders the cells very distinct.

6. Diluted sulphuric acid (three parts of sulphuric acid and one part water), for colouring the cells of plants which have been previously moistened with the solution of iodine. The object is moistened with the solution of iodine, which is then removed with a fine camel's-hair brush, and by means of a glass rod a drop of sulphuric acid is added, and the object is then immediately covered with a covering-glass. The effect of the sulphuric acid and iodine, as well as that of the iodised solution of chloride of zinc, is not always the same over the whole surface of an object. At the points where the mixture is more concentrated, the colouring is more intense; frequently places remain without any colour. The colour changes after some time; in twenty-four hours the blue is often changed into red.

The iodised solution of chloride of zinc produces generally the same blue colour in cellulose as iodine and sulphuric acid: the former is preferable in many cases, inasmuch as its effect is not so rapid, and it is not injurious to the cells. Both re-agents should in many cases be employed, and their effects compared with one another. Besides maceration, it is advisable, in examining woods, to adopt the plan of boiling thin sections for about a minute with a solution of caustic potash; after this boiling, the wood-cells, which were not previously turned blue by iodine and sulphuric acid, become of a violet or blue colour upon the application of the iodised solution of chloride of zinc.

7. A solution of chloride of zinc, iodine, and iodide of potassium. A drop of this solution applied to an object placed in a little water, produces the same colour as iodine and sulphuric acid. This solution was first recommended by Professor Schultz, of Rostock; it is more convenient to use than iodine and sulphuric acid, and produces almost the same results; it is, moreover, not so destructive as sulphuric acid. The exact prescription for this solution is as follows:—Zinc is dissolved in hydrochloric acid; the solution is permitted to evaporate, under contact with metallic zinc, until it attains the thickness of a syrup; and the syrup is then saturated with iodide of potassium. The iodine is then added, and the solution, when it is necessary, is diluted with water.

8. Nitric acid, or, what is better, chlorate of potash and nitric acid. This is used for separating cells. The method of maceration discovered by Professor Schultz, and which is much to be recommended, is as follows:—The object (wood, for instance), is reduced in size to the thickness of a lucifer-match; it is then thrown into a long and tolerably-wide boiling-tube; to this is added, in a little while, an equal volume of chlorate of potash, and as much nitric acid as is at least sufficient to cover the wood and the potash; the tube is then warmed over a spirit-lamp; a brisk development of gas quickly appears; the boiling-tube is withdrawn from the flame, the oxydising mixture is permitted to work for about a minute and a half or three minutes, and the whole is thrown into a saucer with water: the small pieces which adhere slightly to one another are then collected, placed in the boiling-tube, and boiled repeatedly with alcohol, until the latter appears colourless; they are then boiled once more, for the last time, with water. By the help of the simple microscope the cells are now separated from one another with a needle, and selected. The boiling with nitric acid and chlorate of potash should never be carried on in the room where the microscope is kept, because its glasses might be injured by the evaporation which is developed. Thin sections of plants, for instance, of woods or leaves, are warmed for half a minute, or a minute, in a watch-glass; the boiling is unnecessary in this case; the section is taken out with a little rod, and thrown into a small watch-glass with water. Nitric acid is one of the best agents for removing animal or vegetable tissues from silica, as in the case of the *Diatomaceæ*.

9. Oil of lemons, or any other essential oil, for examining pollen and spores.

10. A tolerably strong solution of muriate of lime (one part of dry muriate of lime, and three parts of distilled water) for preserving microscopic objects. This is useful for most things, even for delicate objects, unless they contain starch. If it is wished to preserve an object for a few days without mounting it immediately, it is a very good plan to put a drop of this solution upon the object, and to place it under a bell-glass for protection against dust.

11. Glycerine. This is also well adapted for preserving microscopic objects, and especially for cells which contain starch, which latter substance continues unchanged by it. In granules which exhibit lamination, for instance in the potato starch, the lamination is apt to continue invisible for the first few hours; after 24 hours, however, it appears more clearly.

12. Copal varnish, or Canada balsam, also for the preparation of microscopic objects; these are only to be recommended for a few thin sections of wood, such as fossil woods. They both make the object more transparent than the solution of muriate of lime.

13. A tolerably strong solution of carbonate of soda for digesting peat-wood, as well as hydrochloric acid for digesting fossil woods which have been converted into carbonate of lime. It is also recommended for examining the sweat-ducts in the skin.

14. Acetic acid. This is very useful in examining animal tissues. It has the power of making the cell-wall clearer, whilst the nucleus becomes darker and more distinct. It also distinguishes phosphate or carbonate of lime from oxalate of lime, by dissolving the two former, whilst it has no action on the latter.

15. Very dilute chromic acid. It is used for the purposes of hardening tissues. It is especially useful in examining the structure of the retina.

16. Ammonia will be found useful in the same cases where caustic potash and soda are employed.

17. Nitrate of baryta is used as a test for sulphuric and phosphoric acids. Sulphate of baryta is insoluble in acids and alkalies, while phosphate of baryta is readily soluble in acids, but insoluble in ammonia.

18. Nitrate of silver in solution is used as a test for chlorides and phosphates. The white chloride of silver is soluble in ammonia, but insoluble in nitric acid. The yellow phosphate of silver is soluble in excess of ammonia and nitric acid.

19. Oxalate of ammonia is employed as a test for lime, an insoluble oxalate being formed wherever lime is present.

This list of re-agents might be increased, as there is scarcely an operation performed in the laboratory that may not be repeated on a small scale under the microscope. The above list, however, comprises those which will be found most useful.

In addition to the ordinary optical arrangements of the microscope, certain forms of accessory apparatus will be found very useful. Some of these have been already alluded to, and the following will also be found convenient.

1. A spirit lamp, which may be made of brass, tin, or

glass, fitted with a gronnd glass cap. It may be fitted with a stand, and will be found nseful for submitting objects to heat. The objection to the employment of candles, or lamps, is the black smoke they produce.

2. A small warm bath. This will be found of nse for drying objects previons to being mounted in Canada balsam.

3. Watch-glasses are nseful for examining snbstances in flnids with low powers, as by this means a considerable depth of fluid is obtained for observation.

4. Plate glass slides, 3 inches long and 1 inch broad, are useful for mounting and examining all kinds of bodies.

5. Thin glass, called cyliuder-glass, of different degrees of thickness, is indispensable for placing over objects, especially those which are soft or fluid when placed npon a slide.

6. Needles of various sizes are nsed for making minute dissections. Small handles may be attached to them, rendering them more easy to work. Needles or pins may be employed for fastening down minnte organic bodies which are about to be snbmitted to dissection.

7. Scissors of varions sizes will be fonnd serviceable. These may be obtained of the surgeon's instrument makers.

8. Kuives, scalpels, and razors, for cntting soft or hard objects, shonld be kept at hand.

9. A pair of thin brass forceps will be found convenient for placing thin glass on the slides, as well as for placing or removing objects from the slides.

10. A glass-cutter's diamond is nseful for cntting slips of glass, in the making of cells, and in writing the names of preserved objects on the glass slides.

Cements of various kinds are necessary to the microscopic observer who wishes to preserve the objects he examines. They are nsed for making glass cells to contain objects, on the glass slide, and for fixing the cover after the preparation has been placed in the cell, and for other purposes. The principal cements nsed are gold-size, sealing-wax varnish, solution of shell-lac, gum, a French cement composed of lime and India-rubber, Brunswick-black, marine-glue, and Canada balsam. These cements are most of them sold at the optician's, and directions for making them are fonnd in some books on chemistry and the microscope.

In order to preserve preparations for a length of time, it is necessary to place them in an air-tight vessel. These vessels are called cells, and are best made of glass. They are also sold where microscopes are procured. With a little practice, however, the microscopist may make his own cells.

Thin cells may be made of various substances. Even paper answers exceedingly well in some cases, and is well adapted for dry preparations. A thin layer of white lead, which has been allowed to dry, has also been employed for the same purpose. White lead, made into a thick liquid with linseed oil and turpentine, has been recommended by some observers. Varions varnishes have likewise been used; but where it is required to keep the specimen in some preservative solution, glass is the substance which in all cases forms the best material for makiug cells.

Sometimes preparations are of snch extreme tennity that it is only necessary to place them on the slide with a drop of some preservative solution, and then to cover them with a square of thin glass, the edges of which have been anointed with gold size or other appropriate cement. The snperfluons fluid is next absorbed with bibulons paper, and the slide allowed to dry for a few minutes. A layer of gold-size or other cement is then applied round the edges of the thin glass in order to fix it to the slide. In this way an excessively thin cell may be formed; but preparations mounted in cells made in this manner can seldom be kept for any length of time withont the entrance of air-bubbles. This arises from the onter layers of the gold-size drying more rapidly than the more internal layers. By the contraction thus produced the edges of the cement are drawn off from the glass, to which however it does not adhere with great tenacity in conseqnence of the surface being highly polished. It is therefore always better to make very thin cells of glass or other material, which can be cemented to the glass slides with marine glue or other cement; or else to make the cell by painting the slide with a ring of varnish, marine glue, or Brunswick black, and allowing this to dry thoroughly before the preparation is placed in it. In this manner the thinnest cells which can be required are readily made.

Perhaps Brunswick black is, for the purpose just mentioned, the best. It is painted upon a glass slide with a fine camel's-hair brush, and allowed to dry perfectly, when, if the cell is not sufliciently thick, another layer may be applied. If the cell be required immediately, it is better to warm the slide slightly before applying the varnish. If too great a degree of heat however be employed, the varnish becomes brittle and the cell nnfit for nse.

Very thin cells may be made of tin-foil. This may be easily accomplished by cutting with a pair of scissors a piece of thin tin-foil the size of the cell which it is desired to make. A hole is cnt in the centre of the tin-foil sufficiently large to hold the preparation which is to be preserved, and the tin-foil is then attached to the glass slide with marine glue. When cold the cell may be filed perfectly flat with a very fine file, or rubbed with a little emery upon a piece of plate glass, and the marine glne should be afterwards removed from the centre with a little solntion of potash. The cover may be fixed on with gold-size or varnish, as in other cases. Thin cells have also been made of gutta percha, but there is great difficnlty in fixing the cell firmly npon the glass slide. This however has been effected by some observers; bnt in consequence of the difficulty it is a method not generally employed. Preparations however mounted in cells composed entirely of gutta percha keep very well for a length of time.

Cells composed of very thin glass are perhaps the most convenient, and will be fonnd useful for preserving many preparations. They may be obtained of different degrees of thickness, and are made usually by perforating the thin cylinder glass which is used for covering the cells, or by grinding sections of a thick glass bottle to the required tenuity. Ronnd cells of thin glass are made as follows:—A great number of sqnares of thin glass are cemented firmly together with marine glue, and when cold a hole of the reqnired size is drilled through them all. They are next separated from each other by heat, and, after being cleaned with potash, may be fixed on the glass slides with marine glue in the usual way, and kept ready for nse. It is a good plan to roughen the surface of these cells, which renders the subseqnent entry of air less likely, as the gold-size adheres much more firmly to a gronnd than to a polished snrface. This is readily effected by rubbing the cell, after it has been fixed npon the glass slide, np and down a narrow hone or strip of plate glass on which some moistened emery powder has been placed. In this way also the thickness of the cell may be reduced if required. (Beale.)

Cells of any thickness or depth may be made for larger objects, bnt those described will be found most convenient.

If it is only reqnired to examine the character of a specimen in a dry state, it may simply be laid npon a glass slide and placed in the field of the microscope; if however the substance be of a very delicate structure, or in a minnte state of division, it is better to place a piece of thin glass over it in the nsual manner in order to protect it.

Dry objects may be mounted in a thiu glass cell, or in a paper cell, or if of extreme tenuity they may simply be placed on a glass slide and covered with thin glass, which shonld be fixed to the former by a small piece of gummed paper (rather larger than the glass cover) in the centre of which a hole has been cnt of sufficient size to permit the entire object being seen. The paper may of course be of any colour, or oruamented according to the taste of the operator.

When objects are to be examined by reflected light they may be placed in little glass or card-board cells, or in pillboxes, or they may be put np in glass cells. The preparation should be placed upon a dark ground, which may be effected either by cutting a piece of dark blue or black glazed paper of the exact size of the cell and placing it within; or the black paper may be fixed on the posterior surface of the slide; or this surface may be covered with black paint or black varnish.

There are varions methods by which preparations may be subjected to examination, and preserved as permanent objects in a moist state, and the different value of the various preservative solntions which are in use entirely depends upon the natnre of the substance to be mounted. Distilled water forms a very good fluid for some objects, while for the preservation of most it is necessary to immerse them in water impregnated with some antiseptic agent, which is not volatile at ordinary temperatnres. Many again are best preserved in spirit, or in a solution of some salt. It is very difficult to lay down rules which will enable the observer to choose a preservative fluid for any particular specimen. A little experience however will soon enable him to judge which solution is best adapted for the purpose.

We take the following account of several preservative solutions from Dr. Beale's valuable work on 'The Microscope':—

Spirit and Water.—Mixtures of spirit and water of various strengths are required for preserving different preparations. In diluting spirit distilled water only should be employed; for if common water be treated with spirit, a precipitation of some of the salts dissolved in it not unfrequently takes place, rendering the mixture turbid and unfit for use. Proof spirit will be strong enough for all general purposes, except for hardening portions of the brain or nervous system, when stronger spirit must be used. Two parts of rectified spirit, about specific gravity ·837, mixed with one part of pure water, makes a mixture of sp. gr. ·915-·920, which contains about 49 per cent. of real alcohol, and will therefore be about the strength of proof spirit. One part of alcohol, 60 over-proof, to five parts of water, forms a mixture of a sufficient strength for the preservation of many substances.

Glycerine.—A solution of glycerine adapted for preserving many structures is prepared by mixing equal parts of glycerine with camphor water. The latter prevents the tendency to mildew. It may be used as other preservative solutions.

Glycerine is obtained by boiling oil with litharge. The oleate of lead remains as an insoluble plaster, while the glycerine is dissolved. It may be rendered free from lead by passing a current of sulphuretted hydrogen through it; and the clear solution, after filtration, may then be evaporated to the consistence of a syrup.

Thwaites's Fluid.—This fluid has been much employed by Mr. Thwaites for preserving specimens of *Desmidieæ;* but it is also applicable to the preservation of animal substances.

Water	16 ounces.
Spirits of Wine	1 ounce
Creasote sufficient to saturate the spirit.	
Chalk, as much as may be necessary.	

Mix the creasote and spirit, stir in the chalk with the aid of a pestle and mortar, and let the water be added gradually. Next add an equal quantity of water saturated with camphor. Allow the mixture to stand for a few days, and filter. In attempting to preserve large preparations in this fluid, I found it always became turbid, and therefore tried several modifications of it. The solution next to be described was found to answer very satisfactorily. Water may also be impregnated with creasote by distillation. It should be remarked that M. Straus-Dürckheim has succeeded in preserving preparations in camphor-water only.

Solution of Naphtha and Creasote.—

Creasote	3 drachms.
Wood Naphtha	6 ounces.
Distilled Water	64 ounces.
Chalk, as much as may be necessary.	

Mix first the naphtha and creasote, then add as much prepared chalk as may be sufficient to form a smooth thick paste; afterwards add, very gradually, a small quantity of the water, which must be well mixed in a mortar. Add two or three small lumps of camphor, and allow the mixture to stand in a lightly-covered vessel for a fortnight or three weeks, with occasional stirring. Pour off the almost-clear supernatant fluid, and filter it if necessary. Preserve it in well-corked or stoppered bottles.

I have some large preparations which have been preserved in upwards of a pint of this fluid, for more than five years, and the fluid is now perfectly clear and colourless. Some dissections of the nervous systems of insects have kept excellently—the nerves keeping their colour well, and not becoming at all brittle. Two or three morbid specimens are also in an excellent state of preservation; the colour being to a great extent preserved, and the soft character of the texture remaining. I have one preparation mounted in a large gutta percha cell, containing nearly a gallon of this fluid.

Solution of Chromic Acid.—A solution of chromic acid will be found well adapted for preserving many microscopical specimens. It is particularly useful for hardening portions of the nervous system previous to cutting thin sections. The solution is prepared by dissolving sufficient of the crystallised acid in distilled water, to render the liquid of a pale straw colour.

The crystallised acid may be prepared by decomposing 100 measures of a saturated solution of bichromate of potassa, by the addition of 120 to 150 measures of pure concentrated sulphuric acid. As the mixture becomes cool, crystals of chromic acid are deposited, which should be dried and well pressed on a porous tile, by which means the greater part of the sulphuric acid is removed, and the crystals obtained nearly pure.

Preservative Gelatine.—

Gelatine	1 ounce.
Honey	4 ounces.
Spirits of Wine	½ ounce.
Creasote	6 drops.

Soak the gelatine in water until soft, and to it add the honey, which has been previously raised to the boiling-point in another vessel. Next let the mixture be boiled, and after it has cooled somewhat the creasote dissolved in the spirits of wine is to be added. Lastly, filter through thick flannel to clarify it. When required for use, the bottle containing the mixture must be slightly warmed, and a drop placed on the preparation upon the glass slide, which should also be warmed slightly. Next, the glass cover, after having been breathed upon, is to be laid on with the usual precautions, and the edges covered with a coating of the Brunswick black varnish. Care must be taken that the surface of the drop does not become dry before the application of the glass cover; and the inclusion of air-bubbles must be carefully avoided.

Goadby's Solution.—

Bay salt	4 ounces.
Alum	2 ounces.
Corrosive Sublimate . . .	4 grains.
Boiling Water	4 pints.

Mix and filter. This solution may for most purposes be diluted with an equal bulk of water. For preserving delicate preparations it should be even still more dilute.

Burnett's Solution.—This fluid has been patented. Its preservative properties appear to depend upon the chloride of zinc. A strong solution of chloride of zinc forms a very powerful antiseptic, and also possesses the property of absorbing noxious odours, &c.

Other saline solutions.—Many other saline solutions have been employed by different observers. Of these, a saturated aqueous solution of chloride of calcium, free from iron, has been much recommended for preserving specimens of bone, hair, teeth, and other hard structures, as well as many vegetable tissues (Schacht). A solution of alum in the proportion of 1 part of alum to 16 parts of water has been found to answer pretty well for some substances. Gannal's solution, which consists of 1 part of acetate of alumina dissolved in 10 parts of water; solutions of common salt (1 part to 5 parts of water, with a little camphor), corrosive sublimate, persulphate of iron, arsenious acid, sulphate of zinc, and solutions of several other salts, have been recommended as preservative solutions, but their employment has not been always attended with the most satisfactory results.

Arseniuretted hydrogen gas has also been recommended for the preservation of animal substances, but it is not adapted for microscopical preparations.

Canada Balsam forms a most useful agent for mounting various substances; and the structure of many can only be clearly made out when they are examined in this menstruum.

In this method of mounting objects no cells whatever are requisite. The balsam should be pale and old. The glass slides must be warmed before the balsam is put on, and for this purpose the glasses may be held in a pair of wooden forceps, or in a pair of common forceps, the legs of which are covered with cork, and heated over a spirit-lamp or upon a brass-plate. The latter plan is the most convenient when several preparations are to be mounted at the same time, because they may be arranged in a row along the plate, and the balsam placed upon each slide as it becomes hot.

The Canada balsam may be heated after it is placed upon the slide, in order to allow the air-bubbles entangled in it to rise to the surface before it is applied.

The slide being warm, and the small quantity of Canada balsam sufficient to contain the preparation having been placed upon it, it must be gently moved about while the balsam is hot and quite fluid, until all the air-bubbles have floated to the surface and collected together towards one spot. A pointed wire or needle should then be taken, and all the bubbles either drawn out upon the end of it, which may be readily effected, or broken by the wire after it has been heated. In those cases in which the preparation is not detached from the glass slide npon which it has been allowed to dry, it is only necessary to place the drop of balsam npon it and gently warm it, following tho usnal precautions; afterwards the thin glass cover may be applied. When the preparation has been dried separately over the water-bath and cleaned, it may be taken in a fine pair of forceps, gently warmed, and carefnlly placed in the hot and perfectly fluid balsam. After it has been thoroughly wetted by the balsam, and all adhering air-bubbles removed, it may be placed in the position it is intended to occnpy. The thin glass cover, adapted to the size of the preparation having been previously cleaned and warmed, may then be taken in a pair of forceps, and, after being held over the warm balsam for a minnte, allowed to fall gradually npon the preparation (beginning at one side), nntil it becomes perfectly wetted with the balsam. The glass may now be slightly pressed in order to force ont the snperfluons balsam, and the preparation allowed to cool.

We now proceed to give a few directions for the examination of particular objects, more especially animal tissues, as these of all others are the most difficult to manage. In the examination of tissues containing blood-vessels, ducts, or other tnbnlar organs, it is freqnently most desirable that injections shonld be made before they are submitted to the microscope. This operation requires great delicacy. A very small syringe, or small syringes according to the delicacy of the structnre, mnst be employed. The flnid injected consists of size or gelatine, colonred with varions substances, as vermilion, snlphuret, and iodide of mercury, chromate of lead, indigo, Prussian blne, white lead, &c., according to the colonr wished for.

The following general rules for injection are given by Dr. Beale:—Great attention should be paid to the cleanliness of all the instruments to be nsed in injecting. The syringe shonld always be kept scrupulously clean and in good order, and the injecting-cans should be carefnlly covered, to prevent the ingress of dnst. Before commencing the operation, plenty of warm water shonld be at hand; and the subject should be allowed to soak for some time in a basin of hot water, before it is attempted to inject it, in order that it may be thoroughly warmed through. The temperatnre of the water must vary according to the degree to which the injection is reqnired to be heated: if size and vermilion be nsed, the water need only be warm; bnt if melted wax be employed, the water must be so hot that the hand can scarcely be borne on it. The length of time which the preparation is allowed to soak mnst depend upon its bulk; and the water shonld be changed as soon as it becomes at all cool. With respect to the length of time after death that is more favonrable for this operation, no absolute rules can be given. Generally, it may be remarked that we should not attempt to inject while the *rigor mortis* lasts. Many days may in some cases with advantage be allowed to elapse, particularly if the weather is cold, while in warm weather we are compelled to inject soon after death. As a general rule, the more delicate the tissue, and the thinner the vessels, the sooner shonld the injection be performed. Many of the lower animals, annelids, mollusca, &c., and fishes, shonld be injected soon after death. In making minute injections of the brain, only a short time shonld be allowed to elapse after the death of the animal, before the injection is commenced. Injections of the alimentary canal of the higher animals should be performed early—not more than a day or two after death.

When the preparation is warmed through, the injection properly strained, and the pipe fixed in the vessel, we may proceed carefnlly to inject, taking care that the injection is kept at a proper temperature, by allowing it to remain in the warm water-bath during the operation.

The air should be first withdrawn from the upper part of the vessel by means of the syringe, after which the stop-cock is turned off and left attached to the pipe. The syringe is then disconnected, and after being washed ont once or twice with warm water, is nearly filled with injection, which must be well stirred np immediately before it is taken. The syringe shonld not be quite filled, in order that the air in the pipe may be made to rise into the syringe through the injection, by the ascent of the piston, before any of the latter is forced into the vessel. The end of the syringe is then to be pressed firmly into the npper part of the stop-cock, with a slightly screwing movement.

The piston is now very gently forced down by the thnmb nntil the syringe has been nearly emptied, when the stop-cock mnst be turned off, and the syringe refilled with warm injection as before.

Care must always be taken to keep the syringe in an inclined position, so that any air which may be in it may remain in the npper part; and, for the same reason, all the injection shonld not be forced out, for fear of the inclosed air entering the vessels, in which case all chance of obtaining a snccessful injection would be destroyed.

After a certain qnantity of fluid has been injected, it will be necessary to use a greater amount of force, which, however, mnst be increased very gradually, and should only be snfficient to depress the piston very slowly. If too great force be employed, extravasation will be prodnced before the capillaries are half filled. Gentle and very gradually increased pressure, kept np for a considerable time, will cause the minute vessels to become slowly distended withont giving way to any great extent. At the same time it must be borne in mind that extravasation freqnently occurs at varions points in a successful injection; but the longer this event can be kept off, the more likely are we to sncceed.

In order to examine the structnre of many tissues, it is necessary to obtain a section sufficiently thin to permit the transmission of the light readily, and so evenly cut, that the minute structure of the tissne may be submitted to examination in every part of the section. The difficulty of making thin sections of many textures is often very great, and, to effect this object satisfactorily, a knowledge of certain mechanical operations becomes necessary. Sometimes we reqnire to cnt a thin section of a soft pnlpy textnre, which can scarcely be touched without injnring its delicate structnre, and altering the position of its constitnents; while, in other instances, we mnst obtain a very thin transparent section of a snbstance so hard that steel tools will scarcely scratch it, snch as the enamel of teeth, fossil teeth, &c.

Previons to the examination of a tissne, boiling is freqnently of service.

For instance, the fibres of which the crystalline lens is composed are best shown after boiling the lens in water. The branched mnscular fibres in the tongue of the frog, and in other situations may be made ont very readily by boiling the organ in water for a few moments, and then tearing np small portions with fine needles. Beautiful sections of mnscular fibre can often be obtained after the texture has been boiled in water. Various glands and other textnres often require to be boiled some time in water, in order to harden them sufficiently to enable us to cut thin sections; bnt in all cases the microscopical characters of the recent texture should be examined, as well as that which has been hardened by boiling. Small portions of tissne can be readily boiled in a test-tnbe over the spirit-lamp.

Not nnfreqnently we wish to get rid of the soft and more pulpy part of a tissue, in order to subject the more dense and fibrous portion to examination. This object is usually effected by soaking the tissue in water for some little time, and then placing it nnder a running stream of water, by which means the softer portions are gradually washed away. Soaking in water freqnently enables us to tear np a tissne very readily with the aid of needles, and thus to demonstrate its structnre. Occasionally it is found necessary to press the tissue, and rub parts of it together, before the soft pulpy portions can be got rid of. In this way we may demonstrate the supporting or trabecnlar tissue of the spleen, and the areolar and vascular tissue of the liver, &c. Thin sections of kidney, liver, and other glandular organs, may be thus treated when the matrix is to be subjected to examination separately.

Thin sections of various tissues can frequently be obtained only by first drying the substance thoroughly, and then cutting off a thin shaving with a sharp knife. In this way specimens of skin, mncous membrane, and many other tissues, are often most advantageonsly prepared. The tissue is stretched on a board with pins and then allowed to dry, when a very thin section can be cut off and examined in Canada balsam; or it may be placed in water for a short time, in which case, when snbject to examination, it will often be found to have regained its first appearance. Portions of muscnlar fibre, the tongue, skin, and many other tissues, may be allowed to dry in this manner, and then we may with a sharp knife readily obtain exceedingly thin sections, which conld not be procured in any other manner. The drying may be effected in a warm room, or in a current of air. A high degree of artificial heat should be avoided.

When the inorganic portion of a tissue which we wish to examine is not altered by exposure to a red-heat, recourse may be had to ignition, in order to get rid of the animal matter. In this way crystals of carbonate and phosphate of lime, and granules of siliceous matter, may be separated from the organic material with which they were combined. The beautiful siliceous shells of the *Diatomaceæ* may be separated from organic matter by a similar process. The ignition should be performed in a small platinum capsule, or upon a small piece of platinum foil. The carbonaceous residue must be exposed to the dull red-heat of a spirit-lamp for some time, until only a pure white ash remains, which will be found to contain the objects of our search in a very perfect state. If the siliceous matter only is wanted, the ash should be treated with strong nitric acid, which will dissolve any carbonate or phosphate. The insoluble residue may then be washed and dried, and subjected to microscopic examination whilst immersed in turpentine or Canada balsam. In many cases this method is superior to that of boiling in nitric acid in order to remove the organic matter. Both processes may however be employed where only the siliceous residue is wanted, but if we require the salts of lime, ignition at a dull red-heat is alone applicable.

In order to subject a portion of tissue or other substance to examination by transmitted light, the following plan is adopted:—One of the glass slides is carefully cleaned, and the thin section of tissue which has been removed by the aid of forceps and scissors, or a scalpel, placed in the centre; a drop of clean water is then added, and the whole covered with a square of thin glass, also perfectly clean. If the under surface of the thin glass be gently breathed upon, it becomes wetted more easily. The substance may be unravelled with needles, or, if necessary, any other operation performed before covering it with the thin glass. If the substance be covered with too much soft pulpy matter, it may be slightly washed in water before being placed upon the slide, or a jet of water from the wash-bottle may be forced upon it. Thin sections will require to be laid flat upon the slide, with the assistance of needles and forceps.

Hard tissues require a different treatment. Here the great object is to make sections thin enough for the object to be seen by transmitted light.

Many hard substances, such as nail, horn, and dried animal textures, may be cut with a strong sharp knife, or with a razor; an operation which is easily performed by placing the substance upon a piece of soft deal board, and, after cutting a smooth edge, removing a thin shaving, which may be examined dry or in fluid, or may be placed in Canada balsam, as occasion may require.

Such substances as bone, ivory, and fossilised rocks, should be first cut into very thin sections with the aid of a sharp saw. These sections should then be pared down to the necessary fineness upon a hone or smooth stone. This may be effected in the following manner:—The section, after having been cut off with the saw, requires to be ground thin before it can be subjected to examination. It may perhaps be as much as the tenth of an inch in thickness when the grinding is commenced, but by rubbing it for a short time upon a smooth stone it may be reduced to the proper degree of tenuity. Stones which are well adapted for this purpose are the 'Charley Forest' stones, the Turkey stones, or the Water of Ayr stones, about an inch or more in width, and six inches in length. Each of the four sides should be perfectly smooth. Other stones, or even a piece of slate, answer also very well, and may be procured at much less cost. The stone is wetted with a little water, and the section rubbed up and down with the finger, or with a piece of cork or leather.

A very good plan also is to imbed the section slightly in a piece of warm gutta percha, which should extend only a very short distance beyond the edges. This is to be rubbed up and down on the wet hone, water being added as required, till the surface is perfectly smooth, when the section is to be taken off, turned round, and ground down on the opposite side until it is sufficiently thin. The section may also be ground down expeditiously by rubbing it between two hones. If very thick, it will be better to reduce it somewhat with the aid of a flat file before commencing the grinding. After being ground to what is considered the proper thinness, the section may be placed in the microscope, when numerous dark lines will be found all over the surfaces; these must be removed by polishing. The deepest of the scratches may be obliterated by rubbing the specimen upon a very smooth part of the bone quite dry.

Teeth require a little more attention than other hard substances. They should be first ground down upon a lapidary's wheel, or upon a dentist's emery wheel. Sections can also be readily cut with a diamond saw (an iron wheel, the edge of which is covered with diamond dust).

The thin section is now to be soaked for a short time in ether to remove the fatty matter, and then allowed to dry.

It is to be subjected to examination in the dry way, moistened with water, turpentine, or Canada balsam, and the different appearances in each case should be carefully observed.

The cartilaginous basis is to be examined also in thin sections, which may be cut either before macerating in acid, or subsequently. A whole tooth placed in moderately strong acid will become soft in four or five days, when thin sections of different parts may readily be cut with a sharp knife.

The dentinal tubes may be isolated from each other by longer maceration in acid, and afterwards by soaking for a few hours in dilute caustic soda or potash. It is better in this investigation to cut the thin section before maceration in acid, or to macerate the tooth until moderately soft, and then remove a thin section, which is to be further exposed to the action of the strong acid. A mixture of sulphuric and hydrochloric acids has also been recommended.

The examination of fluids does not require so much art as that of solid matters. Where it is wished to examine the whole of the contents of a fluid, all that is necessary is to place a drop upon a glass slide and to cover it with a piece of thin glass. It frequently happens however that it is the matter suspended in a fluid that it is desirable to examine. Under these circumstances the fluid should be placed in an ordinary test-tube, and after allowing the deposit to settle, the supernatant liquor should be poured off, and a drop of the deposit conveyed to the glass slide. In other cases a pipette may be made use of to draw up the deposit from the bottom of the test-tube or other vessel in which it may be held. In examining water for living animalcules a small muslin-bag or net may be employed, through which the water may be poured, and the contents of the bag placed on the slide. In this way the *Desmidieæ* and some of the larger forms of *Infusoria* are best procured for examination.

When the quantity of deposit is very small, the following plan will be found of practical utility. After allowing the lower part of the fluid which has been standing to flow into the pipette as above described, and removing it in the usual manner, the finger is applied to the orifice, in order to prevent the escape of fluid when the upper orifice is opened by the removal of the finger. The upper opening is then carefully closed with a piece of cork. Upon now removing the finger from the lower orifice, the fluid will not run out. A glass slide is placed under the pipette, which is allowed to rest upon it for a short time. It may be suspended with a piece of string, or supported by a small retort-stand. Any traces of deposit will subside to the lower part of the fluid, and must of necessity be collected in a small drop upon the glass slide, which may be removed and examined in the usual way.

Another plan is to place the fluid with the deposit removed by the pipette in a narrow tube, closed at one end, the bore of which is rather less than a quarter of an inch in diameter. This may be inverted on a glass slide, and kept in this position with a broad elastic India-rubber band. The deposit, with a drop or two of fluid, will fall upon the slide, but the escape of a further quantity is prevented by the nature of the arrangement.

Amongst the fluids of the human body which may with advantage be submitted to examination with the microscope, there is none of more importance than the urine. This fluid being the great means which nature employs to rid the system of the used-up and effete matter of the body, becomes an index by which the completeness, redundancy, or inefficiency of this function may be examined. The following hints for the examination of this fluid will be found useful.

The urine which is to be examined should be collected in sufficient quantity, in order to obtain sufficient of the deposit for examination.

In all cases the urine should, if possible, be examined within a few hours after its secretion, and, in many instances, it is important to institute a second examination after it has been allowed to stand for 24 hours. Some specimens of urine pass into decomposition within a very short time after they have escaped from the bladder; or the urine may even be drawn from the bladder actually decomposed.

In other instances, the urine does not appear to undergo decomposition for a considerable period, and may be found clear, and without any deposit a day or two, or even longer, after it has been passed.

In those cases in which lithic acid or oxalate of lime are present, we shall find that the deposit increases in quantity after the urine has stood some time. The latter salt is frequently not discoverable in urine immediately after it is passed, but makes its appearance in the course of a few hours; depending upon a kind of acid fermentation, which has been the subject of some beautiful investigations by Scherer.

In order to obtain sufficient of the deposit from a specimen of urine for microscopical examination, we must place a certain quantity of the fluid in a conical glass, in which it must be permitted to remain for a sufficient time to allow the deposit to subside into the lower part.

Urinary deposits often require to be examined with different magnifying powers, those which are most frequently used being the inch and the quarter of an inch. Large crystals of lithic acid are often readily distinguished by the former, but crystals of this substance are sometimes so minute that it is absolutely necessary to use high powers. Octohedra of oxalate of lime are frequently found so small that they cannot be seen with any power lower than a quarter; and, in order to bring out the form of the crystals, higher magnifying powers than this are sometimes necessary. *Spermatozoa* may be seen with a quarter, but they then appear very minute. In these cases, an eighth of an inch object-glass will be of advantage. The casts of the tubes, epithelium, and the great majority of urinary deposits can, however, be very satisfactorily demonstrated with a quarter of an inch object-glass.

In the investigation of those deposits which are prone to assume very various and widely-different forms, such as lithic acid, it will sometimes be found necessary to apply some simple chemical tests, before the nature of the substance under examination can be positively ascertained.

The urine is very liable to the introduction of foreign substances. A paper on this subject by Dr. Beale will be found in the first volume of the 'Quarterly Journal of Microscopical Science.' The following is a list of these substances occasionally found by Dr. Beale:—Fragments of human hair; cat's hair; hair from blankets; portions of feathers; fibres of worsted of various colours; fibres of cotton of various colours; fibres of flax; potato starch; rice starch; wheat starch, bread-crumbs; fragments of tea-leaves, or separated spiral vessels and cellular tissue; fibres of coniferous or other wood swept off the floor; particles of sand; oily matter—in distinct globules arising from the use of an oiled catheter, or from the accidental presence of milk or butter.

Besides the above, there are many other substances, met with less frequently, as, for instance, fragments of silk, mustard, flower, cheese, small fragments of the skin of potato, or of different kinds of fruit, and many others which will occur to the mind of every one. With the microscopical characters of these bodies the student should be perfectly familiar as soon as possible; and, as they may be obtained without the slightest difficulty, this is easily effected.

For the nature of the deposits found in the urine, see the article URINE.

The examination of the other fluids of the animal body presents little difficulty. Next to the urine the blood is of most importance. In order to examine the blood, a small drop is placed upon a glass slide, and covered with thin glass, which is to be pressed down until a very thin, transparent, and almost colourless stratum only remains. If in this manner the individual globules cannot be seen distinctly, a little syrup or serum must be added; but it is better to avoid the addition of any fluid, if possible. Upon carefully focussing, the red globules will appear to present a dark centre and light circumference, or the reverse, according as the focus is altered, and here and there a white corpuscle may be observed.

If a little strong syrup be added to a drop of blood, the corpuscles will be found to have become flatter from exosmosis of a part of their contents; while, on the other hand, if placed in water, they become spherical from endosmosis, and ultimately burst. It is not difficult to make a solution of similar density to that in the interior of the corpuscle; and in this manner, as Dr. Rees expresses it, we may take the specific gravity of a blood-corpuscle, if we ascertain the specific gravity of the solution which has been added to the blood.

Acetic acid causes the membrane of the corpuscle to become more transparent and clear, and to swell up from endosmosis. After the application of this re-agent the blood-corpuscle may be scarcely visible, but the membrane is not dissolved by it. Strong hydrochloric and nitric acids do not dissolve the globules; with the latter re-agent the outline is often rendered darker and thicker, while the entire globule becomes smaller. The corpuscles are entirely soluble in ammonia and alkalies. They are rendered darker, and the walls corrugated, by the acid of the gastric juice, and after remaining in acid urine for some time a similar change occurs; hence the black colour of blood which has been effused into the stomach, and the dark smoky hue of acid urine containing blood.

We have before spoken of the crystals to be obtained from the blood. These crystals are very readily obtained by diluting blood with water. A drop of blood may be placed upon a glass slide, and after the addition of a drop of water, alcohol, or ether, the whole should be lightly covered with thin glass. A hair, or a small piece of thin paper or wood, may be placed between the glasses, in order that a stratum of fluid of sufficient thickness may be retained. Whenever it is possible, it is preferable to use defibrinated blood. Often the corpuscles and a little serum may be removed from the clot by firm pressure, and from this very perfect crystals may frequently be obtained. The blood-corpuscles become ruptured by endosmosis, their contents escape, and crystallise as the solution gradually becomes concentrated. The time which elapses before crystallisation takes place varies from an hour to several hours or days in different specimens of blood. Crystals may also be obtained in a similar manner from the coagulum of blood.

The form of the crystal often varies slightly in the same specimen, but the blood of different animals yields crystals of very different forms. The prismatic form is that most commonly obtained from the blood of man, the *Carnivora*, and fishes. Tetrahedral crystals appear most common in some of the *Rodentia*, as the guinea-pig, while six-sided tables are formed in the blood of the squirrel, mouse, and some others. Teichmann has succeeded in obtaining crystals from frog's blood by the addition of a very large quantity of water at a very low temperature.

The crystals form more readily in daylight than in the dark, but most rapidly when the slide is exposed in the light of the sun.

Guinea-pig's blood crystallises in the course of half an hour, or even sooner if it be diluted with a little water or alcohol. Dog's blood also crystallises in the course of a short time upon the addition of a little alcohol. Human blood crystallises after the addition of water, slowly if only just removed from the body, but more quickly if the blood has been drawn a few hours.

It is obvious from what has been said above that the microscope is one of the most important instruments of research that has been placed in the hands of man. Its practical value has not however been yet fully recognised. It is employed by the medical man in the diagnosis of diseases, but in medico-legal investigations, in the detection of adulterations in food, in ascertaining the value of fibrous materials in the arts, and in many departments of industry, it has yet to find its way. Dr. Beale gives the following instances of its utility as a means of diagnosis:—

"Diseases of the Kidney.—There is no class of diseases in which its powers have been more advantageously brought to bear by the practical physician than in those of the kidney. By a microscopical examination of the urine we are frequently enabled to ascertain the nature of certain morbid changes which are going on in the kidney, and even to distinguish during life the existence of certain well-defined pathological conditions of that organ. The laborious researches of Dr. Johnson have shown us how, by the peculiar character of the casts of the uriniferous tubes, which are found in the urine, we can ascertain whether the epithelium be desquamating, or, on the other hand, whether it presents no such tendency, but remains firmly attached to the basement membrane of the tube. If the epithelium be undergoing that peculiar change termed fatty degeneration, we shall often be able to ascertain the fact by examining a specimen of the deposit from the urine by the microscope. So again, by the presence of certain other deposits, and a knowledge of the symptoms usually associated with them, the physician is enabled to direct his attention, as the case may be, to the existence of local changes affecting some part of the genito-urinary mucous membrane, or to more general disturbance in the changes which take place in primary and secondary assimilation.

"Fatty Degeneration.—Of late years the remarkable changes which take place, and which have been described under the name of Fatty Degeneration, in some of the highly complex textures of the body, in consequence of which their properties become changed, and their functions impaired, or altogether destroyed, have been undergoing careful investigation by a vast number of highly-talented investigators.

"The recent discovery of a state of fatty degeneration affecting the arteries of the brain, in the majority of cases of apoplexy, by which the strength of their coats becomes deteriorated, and their elasticity entirely destroyed, would tend to lead us to infer that this disease is dependent rather upon complicated changes affecting nutrition, than upon the presence of a condition of plethora or hyperæmia, as was formerly supposed and acted upon.

"The connection between fatty degeneration of the margin of the cornea (arcus senilis), and similar changes taking place in the muscular tissue of the heart (a subject which has been carefully investigated by Mr. Canton), or in the cerebral vessels, must be regarded with great interest by every practitioner.

"The microscopical examination of the matters vomited in certain cases has proved to us that the presence of minute fungi, originally discovered by Professor Goodsir, and named by him *Sarcina Ventriculi*, occurs in connexion with certain morbid conditions of the stomach. These remarkable cases are much more frequently met with than was formerly supposed, and form an exceedingly interesting class of diseases. [ENTOPHYTA, *S.* 2.]

"Tumours and Morbid Growths.—The microscope has many times afforded important aid in the diagnosis of tumours, although it has certainly failed in many instances; which circumstance has been brought forward by some, as an argument against its employment altogether. After careful microscopical examination, the best observers have failed in deciding as to the nature of a particular tumour submitted to examination; and they have been unable to pronounce as to its malignant or non-malignant character.

"On the other hand, not unfrequently this question has been positively and correctly answered in the affirmative or negative, and therefore it would surely not be right altogether to discard the use of an instrument which, although eminently useful in many instances, is not infallible; for it would appear to be the opinion of some, that the use of the microscope ought to be altogether abandoned in the diagnosis of tumours."

"For the discovery of Imposition the microscope is invaluable, as it almost necessarily follows that, in consequence of the frequency with which urine is subjected to minute investigation, patients often resort to various expedients to deceive the practitioner. Perhaps flour, starch, sand, and milk are more frequently employed for this purpose than any other substances. The microscope will obviously enable any one to detect the first three. If milk be added to urine, the mixture may very readily be mistaken for a specimen of the so-called chylous urine. Although a considerable quantity of fatty matter is present, in either case this fatty matter exists in a very different state. In milk we find the oil-globules, so characteristic of this fluid, while in true chylous urine not a single oil-globule can be found, although the specimen may contain a large quantity of fatty matter in a molecular state.

"Larvæ of the Blow-Fly in Urine.—A specimen of urine containing several bodies of about half an inch in length, and of a rounded form, was once sent to Dr. Todd for examination. The bodies in question looked not unlike the larvæ of some large fly, but, as it was confidently affirmed that they were passed by the urethra of a gentleman, the accuracy of this view of their nature was doubtful.

"Upon placing a portion of one of them under the microscope, tracheæ—(the air-vessels characteristic of the class of insects) were observed in considerable numbers; and this circumstance alone enabled me to say positively that they were not *Entozoa*, and that they could not have been passed in the manner stated. They were afterwards proved to be the larvæ of a fly.

"The claws of *Echinococci* and portions of hydatid cysts have on several occasions been discovered in the urine, sputa, &c., upon submitting portions of these fluids to microscopical examination, proving beyond a doubt the existence of hydatids. [ENTOZOA.]

"Substances passed by the Bowels.—If the practitioner have a good knowledge of the use of the microscope, he can often ascertain the nature of substances passed from the alimentary canal; and by the aid of this instrument he can often at once decide as to the nature and origin of substances, which, to the unaided eye, only present most doubtful characters. Considerable perplexity has arisen from the presence of bodies in the stools of patients, which afterwards proved to be portions of almonds, gooseberry-skins, portions of potato, the testa of the tamarind, husks of wheat, &c.; not many years ago the uredo of wheat was mistaken for, and described as, a peculiar fungus, to which it was supposed the phenomena observed in cases of cholera were due.

"Portions of vessels which, unlike the other constituents of the food, have resisted the process of digestion, have been met with in the fæces, and mistaken for small intestinal worms, which they much resemble when examined by the unaided eye. Upon being subjected to microscopical examination their true nature was readily discovered.

"In Medico-Legal Inquiries the microscope has often afforded valuable aid. The distinction between blood-spots and red stains produced by fluids resembling blood in colour—between human hair and that of animals—and the detection of spermatozoa in cases of rape, need only be adduced as examples of the importance of the microscope in such investigations.

"For Detecting Impurities in Food and Drugs the microscope has afforded important aid, and there are several other purposes to which it may be applied."

In preparing this article we have been greatly indebted to Dr. Beale's most useful work on 'The Microscope, and its Application to Clinical Medicine,' also to the translation of Dr. Schacht's work on 'The Microscope in its Special Application to Vegetable Anatomy and Physiology,' translated by Mr. Currey, and to Professor Quekett's admirable 'Treatise on the Microscope.' For those who would wish to refer to the subject further, we give a list of the principal works devoted to this instrument:—Robert Hooke, 'Micrographia,' 1667. Leeuwenhoek, 'Papers in Philosophical Transactions,' from 1673. Baker, 'Employment for the Microscope,' 1744. Adams, 'Micrographia Illustrated; or, the Knowledge of the Microscope Explained,' 1746. Adams, jun. 'Microscopical Essays,' 1787. Pritchard, 'Microscopic Cabinet.' Chevalier, 'Des Microscopes et de leur Usage.' Sir David Brewster, 'Treatise on the Microscope.' Joseph Jackson Lister, 'Philosophical Transactions,' 1829. Ross, article 'Microscope,' in 'Penny Cyclopædia,' 1839. Carpenter, article 'Microscope,' in 'Cyclopædia of Anatomy and Physiology.' MIDDLEHAM. [YORKSHIRE.]

MIDDLESBOROUGH. [YORKSHIRE.]

MIDDLETON. [DURHAM; LANCASHIRE.]

MIDDLETONITE. [MINERALOGY, *S.* 1.]

MIDDLETOWN. [CONNECTICUT.]

MIDHURST. [SUSSEX.]

MIDLETON, county of Cork, Ireland, a post- and market-town, and the seat of a Poor-Law Union, is situated near the head of the north-eastern branch of Cork Harbour, in 51° 55′ N. lat., 8° 10′ W. long., 13½ miles E. from Cork by road, and 173¼ miles S.W. by S. from Dublin. The population in 1851 was 3676, besides 2334 inmates of the workhouse. Midleton Poor-Law Union comprises 19 electoral divisions, with an area of 109,266 acres, and a population in 1851 of 44,049.

Midleton consists mainly of a spacious and well-built street between the Avanachora and Roxborough rivers, terminating at each end in a bridge. In the town are a neat parish church, a Roman Catholic chapel and nunnery, a Free school, or college, founded in 1696, which had 30 scholars in 1852, two National schools, a court-house, a market-house, a bridewell, a fever hospital, and a district dispensary. There are also distilleries, breweries, corn-stores, and flour-mills. Vessels of 300 tons ascend to Baillick, within half a mile of Midleton; and at the port of Ballincurra, about a mile below the town, large shipments are made of corn and other provisions. Quarter and petty sessions are held in Midleton. Fairs are held on May 14th, July 5th, October 10th, and November 22nd. The town and neighbourhood are the property of Viscount Midleton.

MILBORNE. [SOMERSETSHIRE.]

MILDENHALL. [SUFFOLK.]

MILITARY AND NAVAL FORCES. Under 'Great Britain,' in Penny Cyclopædia, vol. xi., p. 420, the state of the army and navy of the United Kingdom, in 1838, was given. Since that period, partly in consequence of the deficiencies made apparent during the war against Russia, several important regulations have been introduced into the army. To the branches of the Artillery and the corps of Engineers, commissions were thrown open to competitive examination, with a marked success. After a certain time, not yet fixed (April, 1858), the first entrance to these corps is to be made at Sandhurst Military College, but it would appear that, with very slight restrictions, these corps, as well as staff appointments, will still be open to public competition. The competitors must not be less than 16, nor more than 18, years of age, they must have testimonials of respectability, and they will have to be nominated by the Commander-in-chief, before they can be received for examination.

To the main body of the army facilities have been afforded for rewarding extraordinary merit by promotion from the ranks. The use of the Minié and Enfield rifles have been generally adopted throughout the army, and prizes have been instituted for the encouragement of skill in their use. Some alterations also have been made in the clothing and equipment of the soldier, which as far as they have gone have been improvements, but which might be judiciously extended. A permanent camp was also formed at Aldershott, near Bagshot, in 1855, where field operations could be effectively performed; and another in Ireland. Also, in consequence of a medical report showing the fearful mortality in the army arising from sickness, an investigation was ordered, which resulted in showing that the main cause of a mortality which considerably more than doubled the average rate, and greatly exceeded even that of the most deleterious and dangerous trades, was the ill-constructed and crowded state of the barracks. In March, 1858, General Peel, the Secretary for War, announced that surveyors had been appointed to examine the barracks, and that prompt means would be taken to remedy these evils.

The number of officers, non-commissioned officers, and rank and file, voted for the effective service of the United Kingdom for the year ending March 31, 1857, the close of the Russian war, was 244,716, exclusive of the troops in the East Indies, who amounted to 26,363; the number of the non-effective service was 2,000; the estimated charge was 34,998,504*l.*; an increase of 30,378 men, and of 6,328,007*l.* of charge, over the preceding year. The revised estimate was subsequently reduced to £20,249,084.

For the year ending March 31, 1858, there were voted 126,756 men, with 11,786 horses, a decrease of 119,920 men from the preceding year. The troops in the East Indies had been increased to 30,197, with 2,812 horses.

For the year ending March 31, 1859, the estimate was as follows:—

	1858-9.				
	Officers.	Non-Com. Officers.	Rank and File.	Total Men.	Horses.
Life Guards and Horse Guards 3 regs.	99	162	1053	1814	825
Royal Horse Artillery	44	90	1426	1560	1200
Cavalry of the Line	476	687	8078	9241	5993
Royal Artillery	658	1272	15,203	17,133	2606
Royal Engineers	367	301	8,000	8668	120
Military Train	112	184	1196	1492	1000
Foot Guards	261	439	5600	6300	—
Infantry of the Line	3331	5913	69,350	78,594	—
Medical Staff Corps	2	70	928	1000	—
West India Regiments	180	239	3000	3419	—
Colonial Corps	243	395	5140	5778	900
General Staff	122	—	—	122	—
Commissariat Staff	179	—	—	179	—
Medical Staff	335	—	—	335	—
	6409	9752	113,974	130,135	12,644

There are three regiments of Life Guards and Horse Guards, one battalion of Horse Artillery, 7 regiments of Dragoon Guards, and 16 regiments of Dragoons according to the Army List (1 to 17, the 5th having been disembodied), but the estimates provide for 18 regiments, the 5th being restored; one regiment of Royal Artillery, one of Royal Engineers, a Military Train, a Medical Staff, and a Commissariat Staff. The Infantry of the Line consist of three regiments of Guards, 99 foot regiments, and a Rifle Brigade. There are three West India Regiments, and seven Colonial Corps. In Jan. 1858, according to the Army List, there were 4 Field-Marshals, 67 Generals, 89 Lieutenant-Generals, and 220 Major-Generals.

At the beginning of 1857 the army of the East India Company, independent of the Queen's troops, amounted to about 320,000 men, of which 34,630 were cavalry, and 7420 artillery, horse and foot, with 516 pieces of cannon. The European officers of this force numbered 6215.

This was, of course, before the breaking out of the Indian mutiny. The Bengal army mutinied almost to a man, and what remains of that force is now (April, 1858) in arms against us. Some disaffection has also probably decreased the numbers of the Madras and Bombay armies. On the other hand, the number of royal troops has been greatly increased; but so many are still on their passage, or under orders to proceed thither, that it is not possible to state the precise numbers. On the whole an addition, from home and from some of our colonies, of more than 50,000 has been forwarded to India, though incessant fatigue, the climate, and frequent fighting, has no doubt materially thinned their ranks. The Queen's troops in India for 1858-9 are estimated as follows:—

	Officers.	Non.-Com. Officers.	Rank and File.	Total.	Horses.
Royal Horse Artillery	26	56	728	810	680
Cavalry of the Line	440	649	7128	8217	7815
Royal Artillery	153	323	4230	4706	1768
Royal Engineers	19	32	448	499	—
Military Train	16	32	230	278	—
Infantry of the Line	2434	4514	58,000	64,948	—
Medical Staff Corps	—	6	30	36	—
Depôts of regiments in India — stationed in the United Kingdom	382	955	11,908	13,245	418
	3470	6567	82,702	92,739	10,181

The amount voted for the year ending March 31, 1857-8, was 11,443,235*l.*; for 1858-9 it was 11,750,000*l.* Of this in the first year 4,388,017*l.*, and in the last 4,361,027*l.* were expended on regimental and staff payments and allowances, but 680,000*l.* in the last year was to be paid by the East India Company on account of the excess of number of men sent to India.

The amount voted for the Embodied Militia for the year ending March 31, 1859, was 650,000*l.*, and for Volunteer Corps, 80,000*l.*; for 1858 the amount had been 50,282*l.*

The sum expended on the effective service of the army in 1857-8 was 9,221,360*l.*; the estimate for 1858-9 was 9,298,319*l.*; on the non-effective (pensions, rewards, and allowances,) 2,221,875*l.* and 2,240,068*l.*

In the *Navy* much attention has been given to instructing the seamen in the working of great guns. This has been eminently successful, and the precision and rapidity with which they can now be directed and discharged has added materially to their efficiency for destructive purposes.

In 1857 the total navy consisted of 260 sailing vessels, carrying 8722 guns, and 202 steam vessels carrying 5050 guns, besides 160 gun-boats. These were manned by 40,776 men, including officers, and there were in addition 15,000 marines.

In Jan. 1858 there were in commission 548 vessels of various sizes, sailing and steam-propelled vessels, mounting 15,716 guns, and 136 steam gun-boats. Of the ships of war, 5 mounted 131 guns each, and 22 others mounted from 101 to 120 guns each. The arming of vessels has however undergone considerable modification, the chief objects aimed at now are facility of motion in the ships, and weight of metal and length of range in the guns.

The flag officers in active service in January 1858 numbered 21 admirals, 27 vice-admirals, 51 rear-admirals, 356 captains, 517 commanders, 1106 lieutenants, 345 masters, 159 mates, 105 second masters, 127 engineers, 327 surgeons, 255 assistant-surgeons.

Of the Royal Marines there are 104 companies, of which the total strength is estimated at 15,000. They are commanded by 3 generals, 3 lieutenant-generals, 5 major-generals, 4 colonels commandant, 5 colonels and second commandants, 19 lieutenant-colonels, 120 captains, 176 lieutenants, and 88 second lieutenants. There are also 14 companies of Royal Marine Artillery, with 1 colonel and second commandant, 2 lieutenant-colonels, 14 captains, 37 first lieutenants, and 9 second lieutenants.

The total expenditure on the navy for the year ending March 31, 1857, was 14,664,514*l.*, an amount less by 1,904,100*l.* than that of the estimate of the gross sum. The vote for 1858-9 was for 44,380 seamen, including coast-guards, &c., and 15,000 marines; the estimate of the expenditure was 9,860,000*l.*, including the effective and non-effective services.

The military and naval forces of the principal foreign countries for 1857 (where not stated to the contrary), are given as follows in the 'Gotha Almanac' for 1858.

Austria had 64 regiments of infantry of the line, numbering, on the war footing, 425,878 men; 14 frontier regiments, with 55,200 men: 25 battalions of light infantry, numbering 32,534 men; with a division or depôt of light infantry, numbering 6,684 men. The cavalry consisted of 8 regiments of cuirassiers, 8 of dragoons, 12 of hussars, and 12 of uhlans, amounting in the whole to 70,376 men, with 60,784 horses. The artillery numbered 58,614 men, with 1,344 pieces of cannon; the engineers and staff corps amounted to 11,116 men; there were 5 battalions of pioneers, numbering 9,217 men, with 3,880 horses; and 20,000 gendarmerie (these are the armed police), in 12 regiments. There are also many other military establishments, such as the military schools, with 7,640 students, sanitary corps consisting of 3,457 men, 21 depôts, with garrison and frontier battalions, &c. The Austrian navy numbered 101 vessels, including 52 gun-boats, and 9 transports, the whole carrying 950 guns. It contains one vessel of 100 guns, 5 frigates, carrying together 165 guns, 3 screw-steamer frigates, carrying 129 guns; the remainder are corvettes, brigs, and smaller craft. The population, at the end of 1854, was 39,411,309, exclusive of the military.

Bavaria had 134,626 infantry; 22,879 cavalry; 24,700 artillery, with 112 pieces of cannon; 2,554 engineers; together with a landwehr, active on the east of the Rhine, of 54,000 infantry and 2,500 cavalry. The population was 4,541,556.

Belgium possessed an army of 16 regiments of infantry, numbering 56,550 men; 7 regiments of cavalry and gendarmerie, numbering 8,202 men, with 7,585 horses; 4 regiments of artillery, numbering 6,700 men, with 152 pieces of cannon; one regiment of engineers, numbering 1,690 men; and a corps of pontoneers, numbering 576 men. This is the peace establishment, and forms in effect a total force of 100,000 men when on a war footing. The population was 4,530,228.

For Denmark the number of men is not stated, but in time of peace it has a general staff, a corps of engineers, 2 regiments of artillery, with 96 pieces of cannon, 25 squadrons of cavalry, and 23 battalions of infantry. There is besides a corps of reserve, composed of cavalry, infantry, and artillery. The navy numbered 119 vessels, mounting 913 guns, of which 4 are ships of the line, and 11 are steam-vessels, carrying 153 guns; of the remainder, 67 are gun-boats, 17 transports, and other small vessels. In 1856 the total population of Denmark, together with Schleswig Holstein, and other dependencies, was 2,600,000.

In France, the infantry of various sorts numbered 220,268 men, the cavalry 62,988, the artillery 34,282, the gendarmerie 22,712, the engineers 9068, the staff 4345, the military train 4971, the veterans 1135, military intendants 6295, the foreign legion (Algeria) 6110; riflemen and indigenous cavalry (Algeria) 6737; a total of 378,911 men. In 1856 the total number had amounted to 577,536 men, of whom there were in France 310,347, in Africa 64,235, engaged in the war in the East 197,597, and in Italy 5357. The navy in 1857 consisted of 353 vessels, of which 10 were of 120 guns each, 10 of 100, 15 of 90, 5 of 80; there were 50 frigates of from 60 to 40 guns each; the rest were smaller vessels, corvettes, brigs, and a few steam-propelled vessels of war. The population was 36,039,364.

Hanover had a total land force of 26,938 men, of which 20,464 were infantry, 3078 cavalry, 257 engineers, 2666 artillery, 441 gendarmerie, and 32 staff officers. The population was 1,819,777.

Naples in 1855 possessed an army amounting in the whole to 143,586 men. Of these 74,814 were infantry, 6736 were cavalry, with 6000 horses; 6322 were artillery, with 1347 horses; 2880 were engineers. These formed the active army, and there were in reserve 48,000 infantry, and 3000 cavalry. The navy contained 98 vessels, mounting altogether 832 guns; there were 2 ships of the line, 5 sailing and 14 steam frigates; there were 50 mortar and gun-boats, and other small vessels. The total population of the Two Sicilies was 9,117,050 in 1856.

The army of the Netherlands amounted to 58,495 men, of whom the infantry, including the staff, number 43,858 men; the cavalry 4490; the engineers 695; the artillery 8867; a corps of pontoniers, numbering 213; and 2 companies of gendarmerie. The navy comprises 82 sail; of which 5 are of the line; 16 frigates, some of them screw-steamers; 16 smaller war steamers; 58 gun-boats; the remainder are smaller craft. The whole carried 1934 guns. The population of the Netherlands, exclusive of the colonies, was 3,487,617.

In Portugal the military force comprised 15,984 infantry; 2,410 cavalry, with 1,362 horses; 1,524 artillery, with 199 horses, and 240 pieces of cannon; and 290 engineers; these, with the staff, sanitary corps, &c., make a total of 20,520 men in active service; and there are also municipal guards, veterans in retreat, and others, with a reserve of 4,996, making a total of 31,845 men. These were independent of 17,353 men, forming the armed force of its foreign possessions. The navy consisted of 39 vessels, of which 5 were disarmed, and 2 being built; the whole carried 362 guns, and were manned by 2181 men. One vessel carried 80 guns, there was one frigate of 50 guns, 6 steam-vessels carried each 26 guns; the rest were small. The continental population of Portugal in 1854 was 3,499,121.

Prussia had an army on the peace establishment amounting to 161,000 men. It comprised 98 regiments or battalions of infantry of the line, 80 regiments of cavalry, 9 regiments of artillery, with 864 pieces of cannon; a corps of pioneers, &c. The navy consisted of 55 vessels, carrying 265 guns, and 3,500 men. There were 2 sailing frigates carrying 86 guns, 2 steam-frigates carrying 21 guns, 36 gun-boats with two guns each; the rest small vessels, some of which were steamers. The population in 1855 was 17,202,831, in which year the military force was 211,731.

The military force of Russia comprises 96 regiments of infantry; 40 regiments of cavalry, with 12 in reserve; and 33 brigades of artillery, with 2,988 pieces of cannon, and 12 regiments of engineers. The total of the active force consists of 655,000 men, with 141,691 horses, and 1,584 pieces of cannon; the local corps amount to 294,741 men, with 33,325 horses, and 422 pieces of cannon; and a reserve estimated at 70,000 men, with 10,000 horses. The irregular army, consisting chiefly of Cossaks, and forming a principal part of the light cavalry, numbered 127,200 men. The navy was divided into four divisions: the Baltic fleet, the White Sea fleet, the Black Sea fleet, and the fleet of the Pacific Ocean. The first consisted of 6 sail of the line, 3 frigates, and 2 corvettes, mounting in the whole 740 guns, with 3 steam-frigates, of which the number of guns is not stated; the second division consisted of 6 sail of the line, mounting 496 guns, and 8 frigates, of which the armament is not given; the third division consisted of 9 sail, but of these the force is not given; and the fourth division consisted of 8 sail of the line, mounting 660 guns, 5 frigates, and 2 steam-vessels. There were also a considerable number of gun-boats, both rowing-boats and steam-boats. The total population of the empire of Russia in 1851 was 65,237,437.

In Sardinia the infantry formed 20 regiments, numbering 26,410 men; 10 battalions of riflemen (Bersaglieri), with 3627 men; 9 regiments of cavalry, with 5175 men, and 4352 horses; 3 regiments of artillery, with 4300 men, and 1279 horses; 2 corps of engineers, with 1505 men and 252 horses; and 3901 men of the gendarmerie. There are other military bodies, such as guards of the palace, invalids, &c., bringing up the total to 48,273 men. The marine force consisted of 4 sailing and 4 steam frigates, 4 corvettes, 3 brigantines, 1 brig, 10 steam-boats, &c., in all 40 vessels of war, with 900 guns. The population, including the continental possessions, with Sardinia and Capres, was, in 1848, 4,916,084.

Saxony had 15,748 men of infantry of the line; 4005 of light infantry; 3208 cavalry, and 2420 in the artillery, a total of 25,396 men, not including the reserve. The population in 1855 was 2,039,075.

Spain had 75,317 infantry troops; 12,894 cavalry, with 7998 horses; 10,585 artillerymen, with 1670 horses; 2786 engineers; 10,717 gendarmerie, with 2000 horses; and

303 provincial guards in the Canaries; a total of 112,602 men, with 11,980 horses. There is also a corps of carabineers consisting of 75 companies, of which 11 are cavalry, which form the frontier guard. There are likewise a considerable number of forces in Cuba, and other foreign possessions. The navy consists of 51 sailing ships, and 42 steam-vessels; there were 3 ships of the line, 10 frigates, ranging from 42 guns to 2 guns; 5 corvettes, 11 brigantines, &c., the whole mounting 1100 guns. There are also a large number of gun-boats, &c. The total number of men on board the whole was 15,177. The population of Spain in 1856-7 was nearly 17,000,000.

In Sweden the military force is somewhat peculiar. A part consists of enrolled troops enlisted for six years; another part (called Indelta) are cantoned in different places, and are paid by the owners of estates, and partly by the crown; having also a house and some ground furnished to each man; during war they are paid wholly by the crown, and in peace they are assembled once a year for four weeks to be exercised and reviewed; a third part consists of the militia of Gothland, who are only available for home service; and the fourth part consists of the troops raised by conscription, to which every Swede between 20 and 25 years of age is liable. The total force thus composed amounts to 144,013 men. The enrolled troops form 3 regiments of infantry, 2 of cavalry, and 3 of artillery, and number altogether 7692 men, exclusive of officers; the cantoned troops number 33,405 men; the Gothland militia numbers 7621 men; and the troops raised by conscription number 95,295 men. Norway had a military force of 11,924 infantry, 1070 cavalry, 1330 artillery, with 9160 of the landwehr. The navy possessed 897 vessels of various sizes; it had 10 vessels of the line, 6 frigates, 3 corvettes; but its greatest strength consisted of a swarm of gun-boats and vessels of a similar character, there being 594 row-boats, besides 77 shallops, and 122 yawls carrying guns. The navy of Norway consisted of 142 vessels, mounting 450 cannon; of these 3 were frigates, 4 corvettes, 125 gun-boats, &c. The maritime conscription amounted to 46,000 men. The united population of Sweden and Norway in 1855 was 5,076,088.

Of Switzerland the army consisted of 108,000 men, of whom 76,000 formed the regular army, and 32,000 the reserve. The regular army comprised 74 battalions of infantry, 45 companies of riflemen, 29 companies of cavalry, 40 companies of artillery, and 9 companies of engineers. The population of Switzerland in 1850 was 1,417,754.

Turkey had an army comprising 100,800 infantry, 17,280 cavalry, 7800 artillery, with 5200 additional in fortresses, 1600 engineers, 16,000 detached troops in Candia, Tripoli, and Tunis, and 30,000 gendarmerie; a total of 178,680 men, with a reserve of 125,880 men. The navy in 1853 comprised 70 vessels, manned with 34,000 seamen, and 4000 marines. The population of Turkey in 1844 (the latest taken) was 36,600,000.

Würtemberg had on the peace establishment, 6149 infantry troops, 1972 cavalry, and 1562 artillery, [engineers, &c., making a total of 9683 men; on a war establishment these can be raised to 22,016. The population of Wurtemberg in 1855 was 1,669,729.

The United States of America possessed an army composed of 1 corps of engineers, 5 regiments of cavalry, 4 regiments of artillery, and 10 regiments of infantry. The whole effective force was 15,562 men; but in addition, the militia numbered 51,067 officers, and 1,885,662 men. The navy consisted of 74 vessels, mounting 2244 guns. There were 10 sail of the line ranging from 120 to 84 guns; 13 frigates ranging from 56 to 50 guns, most of the guns of large calibre, and many of the vessels propelled by steam of most excellent construction. The population of the United States in 1856 was 27,601,708.

MILITARY PUNISHMENTS. The policy which has been pursued of late years in modifying the punishments prescribed by law for offences which are cognisable in criminal courts, has been extended to those which may be inflicted by courts martial for military offences. One material alteration consists in the limiting of corporal punishments; the utmost extent to which flogging can now be carried being fifty lashes. See Annual Mutiny Acts.

MILITIA. The qualifications of the officers of this constitutional force are now regulated by the Statute 15 & 16 Vict. c. 50. There have been of late years several statutes, modifying in other details the law relating to the militia, which, it would appear, cannot serve out of the kingdom except with the consent of Parliament (18 & 19 Vict. c. 1).

MILLER, HUGH, an eminent geologist. He was born at Cromarty, in the north of Scotland, on the 12th of October, 1802. He was descended from a humble family, who had been long known in the parish of Cromarty as sailors. His father became eventually possessed of a small vessel of his own, in which he was lost, whilst Hugh Miller was yet a child. In a work entitled 'My Schools and Schoolmasters, or the Story of my Education,' he has given not only an interesting account of his own life, but that of his father, and many of the members of his family. He received his first education at the parish school, where he was early distinguished for his fondness for poetry and poetical composition. At this time he was a large reader, and placed under contribution the libraries of the parish. In this way he laid the foundation of an extended knowledge of literature, which availed him in after life. But the most important part of his education consisted in the natural history instruotion he received from an uncle who had acquired a taste for the observation of natural phenomena. Whatever might have been his aspirations, he was obliged to content himself with learning the trade of a mason. This occupation however unexpectedly fostered the taste he had acquired for the study of natural history; and whilst hewing blocks of stone in the quarry, he was diligently studying the traces they exhibited of their past history. It was in this way that he prepared himself to become the historian of the Old Red-Sandstone, amongst the rocks of which he principally worked. His first literary efforts were not however directed to geology. He was early devoted to the muses, and was induced, by the refusal of a newspaper to print one of his poetical effusions, to publish a book of poetry. This work, though it failed to give him a position as a poet, drew towards him the attention of friends, which resulted in his giving up his mason's employment and becoming accountant in a bank in his native town. This appointment gave him more leisure for literature. He became a frequent contributor to newspapers, more especially the 'Inverness Courier;' but his first distinct prose publication was entitled 'Scenes and Legends of the North of Scotland.' Although the subject of this work was only of local interest, the purity of its style and the thought and feeling thrown into the subject discussed, made it a popular work, and several editions have been printed.

With naturally strong feelings, and a power of writing rapidly and impressively, it might be expected that a man in Mr. Miller's position would enter into the great discussion which terminated in a rupture of the Scotch church. His first publication on the subject was entitled 'Letter from one of the Scotch people to the Right Hon. Lord Brougham and Vaux, on the opinions expressed by his lordship in the Auchterarder case.' This letter, which was referred to by Mr. Gladstone in his 'Church Principles,' as the "elegant and masculine production of Hugh Miller," drew at once upon the author the attention of the Free Church party. They had long felt the need of an organ, and the man had at length appeared who was capable of undertaking its conduct. The 'Witness' newspaper was started, and Mr. Miller was invited to accept its editorship. This paper was published twice a week, and conducted with great ability by Mr. Miller to the day of his death. Although never failing in the polemical and political departments, he found time to arrange his geological experience, which he first published in a series of papers in the 'Witness.' These papers excited the surprise and admiration of the geologists who assembled at the first meeting of the British Association in Glasgow in 1840. Sir Charles Lyell, Sir Roderick Murchison, and Dr. Buckland, were amongst the first to express their astonishment at the amount of new matter which was thus for the first time brought before them. Professor Agassiz, who was also present at this meeting, named one of the fishes which had been described by Mr. Miller *Pterichthys Milleri*, after its discoverer. These papers were afterwards published in a volume, 'The Old Red Sandstone, or New Walks in an Old Field.' This work is written in a style remarkably pleasing, and treats of the great facts of geology in a peculiarly attractive manner. It has had a very large sale, and still remains one of the most popular works on geology in the English language. Its scientific merit consists in the description of a number of new fossil forms of animals belonging to a formation which had, up to the time of its publication, been regarded as almost destitnte of the remains of animal life.

Hitherto Mr. Miller had never visited England. He now made a jonrney to London, and with pen in hand made notes of what he saw and felt. These notes he published on his return nnder the title of 'First Impressions of England and its People.' This work has also had a very considerable circulation. An anonymous work entitled, 'Vestiges of the Natnral History of Creation,' was published in 1844, which excited mnch attention, and not least in the religions world. The discovery of a fish and a plant in the old red sandstone furnished Mr. Miller with arguments against the views of the author of the 'Vestiges.' These he embodied in a work entitled 'Footprints of the Creator, or the Asterolepis of Stromness.' It embraced a general view of the natnral history of creation, and is regarded as an able exposition of the views of geologists on the interesting points to which it is devoted. Like the anthor's other works it hss had a large circulation.

Mr. Miller also published other works and papers on geology. In 1848 he published 'The Geology of the Bass.' At the meeting of the British Association at Edinburgh in 1850 he read a paper on 'certain pecnliarities of structnre in some ancient Ganoids' (Fishes). At the meeting of the Association at Glasgow in 1855 he gave an elaborate account of the Fossil Flora of Scotland. He also lectnred in Edinbnrgh and London on geological snbjects. Mr. Miller's death was sndden and very startling. On the morning of the 24th of December, 1856, he was found dead in his room, shot through the body, and under circumstances which left no doubt that he died by his own hand. He had been latterly engaged, in addition to his editorial labonrs, at a work called 'The Testimony of the Rocks,' and his brain, already diseased, had become strongly excited. An old habit, that of sleep-walking, bad returned upon him. He had, through fear of robbers, kept a loaded pistol in his room; and with this pistol, in a paroxysm of his disease, he pnt an end to his life. The work which he had thus completed on the day preceding his death, was shortly afterwards pnblished, and had a large sale.

His death cansed a most painfnl excitement. Few men have occnpied a higher position in the estimation of his countrymen. He was a noble example of what self-edncation can do for a man, and whether regarded as the fearless and independent writer, or the man of literatnre and science, his character mnst claim the respect and admiration of posterity.

MILLER'S THUMB. [COTTUS.]

MILLTHORPE, OR MILNTHORPE. [WESTMORELAND.]

MILNE, JOSHUA, an eminent actuary, was born in 1776. He received a good education, became particnlarly skilful in mathematics, and acqnired an extensive knowledge of laoguages. When about forty years of age he was appointed actuary of the Sun Life Assurance Office, a sitnation which he held for upwards of thirty years. His 'Treatise on Annuities,' published in 1815 in 2 vols. 8vo, is one of the the nniversally-acknowledged authorities on the snbject of life assurance, for the calculations of which he invented and described a new system of notation. Mr. Milne had also paid some attention to botany, and was said to have possessed one of the best botanical libraries in London. His uniform courtesy gained him general esteem, and his information and assistance were readily given wherever they might serve a nseful purpose. He died Jan. 4, 1851, having nnfortunately become mentally incapacitated for fulfilling his official dnties a few years earlier.

MILTON ABBAS. [DORSETSHIRE.]

MILVERTON. [SOMERSETSHIRE.]

MIMOSA, a genus of Plants belonging to the natural order *Leguminosæ*. It has polygamous flowers; petals 4 or 5, connected together into a 4-or-5-cleft fnnnel-shaped corolla; stamens inserted in the base of the corolla, or in the stipe of the ovary, eqnal in number to the lobes of the corolla, or double or triple that number; legumecompressed, flat, 1- or many-jointed; joints one-seeded; ribs permanent; stipules petiolar; leaves bipinnate, with one or more pairs of pinnæ, each pinna bearing two or many pairs of leaflets; flowers rose-coloured or white, disposed in heads. The leaves are frequently sensible to tonch, as in the Sensitive Plant. The species are very numerous.

M. sensitiva, the Sensitive Plant, has prickly stems and petioles; leaflets ovate-acute, dotted, with adpressed pili beneath, but glabrous above. It is a native of Brazil. The flowers are rose-colonred and tetrandrous. The leaflets are sensitive to touch, but not so mnch so as the following species.

M. pudica has a prickly herbaceons stem, with the petioles and peduncles more or less beset with stiff hairs or bristles; leaves somewhat digitately pinnate, with 4 pinnæ, each pinna bearing many pairs of linear leaflets. It is a native of Brazil, and is commonly grown in our gardens under the name of Sensitive Plant, the leaves falling on the slightest tonch. The roots of this plant and its allies emit a most offensive smell, resembling the odonr of a sewer at the time of impending rain. The legumes of *M. saponaria*, according to Royle, form a considerable article of commerce in India on acconnt of their saponaceons qnalities. [SENSITIVE PLANTS.]

MIMOTAMIC ACID. [CHEMISTRY, *S.* 2.]

MIMULUS, a genus of Plants belonging to the natural order *Scorphulariaceæ*. It has a tubular calyx, 5-aogled and 5-toothed; corolla ringent, upper lip 2-lobed, lower one trifid, usually bigibbous at the base, segments all flat; stamens 4, didynamous, inclosed; cells of anthers diverging or divaricate, at length subconflnent; stigma bilamellate; capsule hardly furrowed, 2-valved, valves entire with flat margins, dissepiment at length free; placentas adnate. The species are erect or procumbent, glabrons, rarely villous herbs, with usually tetragonal stems; leaves opposite, usually toothed, rarely quite entire; flowers axillary, solitary, pedicellate, snperior ones sometimes racemose.

M. luteus, Yellow-Flowered Monkey Flower, has leaves closely toothed, lower ones on long petioles, ovate or somewhat lyrate, superior ones rounded cordately, stem clasping; calyx ovate, bnt campannlate in the fructiferous state, with ovate-acute teeth, the upper tooth larger. It is a native of Chili. Babington says it has become naturalised in Great Britain. The corolla is yellow, with a dark mark io the month.

M. moschatus, Mnsk-Scented Monkey-Flower, has diffuse stems clothed with woolly villi; leaves petiolate, ovate, or ovate-lanceolate, a little toothed, rounded at the base, rather pilose, and somewhat clammy; calyx tubular, bnt oblong in the fruit-bearing state, with lanceolate nnequal teeth. It is a native abont the Columbia River, on the north-west coast of America. The plant exhales a strong scent of musk. The flowers are small and yellow. The plant is diffuse, rooting at the base.

MIMUS. [MOCKING BIRD.]

MIMUSOPS, a genns of Plants belonging to the natural order *Sapotaceæ*. It has a calyx 6- to 8-parted; segments disposed in a twin order; corolla with a double row of segments, the outer row containing from 6 to 16 in nnmber, which are either entire or divided, the inner row containing 6 or 8 entire segments; antheriferous stamens 6 or 8, opposite the inner segments of the corolla, alternating with as many sterile ones; ovarium 6-8-celled; berry 1- or few-seeded from abortion. The species are trees with alternate quite-entire glabrous coriaceous leaves, and axillary fascicles of 1-flowered pedicels. The flowers are small and white; the fruit edible.

M. Elengi has oval-lanceolate or oblong leaves, acumioated, glabrous; pedicels many together, shorter than the petioles, which are glabrous. It is a native of the East Indies, where it is mnch planted on account of its fragrant flowers, which come ont chiefly in the hot season. A fragrant water is distilled from the flowers. The seeds yield an abnndance of oil in reqnest for painters. The leaves are said to produce an extraordinary noise when bnrnt.

M. Kaki has obovate leaves, very blunt, silvery or hoary beneath, hardly three times as long as the petioles, crowded at the ends of the branches; flowers fascicled, hexandrous. It is a native of the East Indies and Anstralia within the tropic. The tree yields a gum, and the fruit has a sweetish taste, and is much eaten by the natives of India.

MINCHINHAMPTON. [GLOUCESTERSHIRE.]

MINEHEAD. [SOMERSETSHIRE.]

MINERALOGY, according to the definition given by Kirwan, is the art of distinguishing mineral substances from each other. It may be regarded both as a science and an art: as a science, in reference to the knowledge requisite for supplying accurate descriptions of minerals, and forming what may be termed a natnral classification; and an art, in reference to the arrangement of the descriptive characters for the pnrpose of afterwards distinguishing minerals from each other.

Mineralogy then mnst be considered as including the chemical composition of bodies, and an acconnt of their external or physical properties. Both are reqnisite, for substances occur which agree in their chemical composition, and exhibit differences in their external characters; while there are other bodies which differ in their chemical constitution, bnt agree in their external properties.

Various methods of arrangement of minerals have been proposed by different authors. According to Werner, minerals were divided into the four classes of earthy minerals, saline minerals, inflammables, and metals; Karsten classed them under the heads of earths, salts, combustihles, and metals; Haüy divided minerals into acidiferons earthy substances, earthy suhstauces, non-metallic combnstible bodies, metallic bodies, substances not sufficiently known to admit of classification, rocks, and volcauic products. In Phillips's 'Elements of Mineralogy,' the classes are earthy miuerals, alkaline-earthy minerals, acids, acidiferous earthy minerals, acidiferous alkaline minerals, native metals, metalliferous minerals, and combustihle minerals. Berzelius attempted a strictly chemical classification of minerals: he has, however, candidly admitted that considerable difficulties attend this method, owing, in part, at least, to the uncertainty which exists as to what are the essential and what the accidental constituents of a mineral.

The following is the arrangement of Dufrenoy, as given in Professor Ansted's 'Elementary Conrse of Geology,' &c:—

Class I.—Simple bodies, or Binary Compounds never bases, generally essential ingredients in combinations, and serving as proximate elements.

Gronp 1. Hydrogen.
2. Carbon.
3. Silicon.
4. Sulphnr.
5. Selenium.

Class II.—Alkaline Salts.

Group 1. Salts of Ammonia.
2. Salts of Potash.
3. Salts of Soda.

Class III.—Alkaline Earths, and Earths.

Group 1. Salts of Barytes.
2. Salts of Strontia.
3. Salts of Lime.
4. Salts of Magnesia.
5. Salts of Yttria.
6. Salts of Alumina.

Class IV.—Silicates.

Group 1. Anhydrons Aluminous Silicates.
2. Hydrous Alnminous Silicates.
3. Silicates of Alumina and Lime, or their isomorphs.
4. Alumiuous and Alkaline Silicates, and their isomorphs.
5. Hydrous Alnminous Silicates with Alkaline and Lime bases, and their isomorphs.
6. Non-aluminous Silicates.
a. With Lime as a hase.
b. With Zircon as a hase.
c. With several bases.
7. Silico-Aluminates.
8. Silico-Fluates.
9. Silico-Borates.
10. Silico-Titanates.
11. Silico-Sulphurets.
12. Aluminates.

Class V.—Metals.

Gronp 1. Cerium.
2. Manganese.
3. Iron.
4. Chromium.
5. Cobalt.
6. Nickel.
7. Zinc.
8. Tellurium.
9. Cadmium.
10. Antimony.
11. Arseuic.
12. Mercury.
13. Titanium.
14. Tantalium.
15. Niobium.
16. Pelopium.
17. Ilmenium.
18. Lead.
19. Tin.
20. Bismuth.
21. Iranium.
22. Tungsten.
23. Molybdeum.
24. Vanadium.
25. Copper.
26. Silica.
27. Gold.
28. Platinum.
29. Iridium.
30. Osmium.
31. Rhodium.
32. Palladium.

Dana, in his nseful 'Manual of Mineralogy,' adopts the following classification:—

Class I.—Gases; consisting of or containing Nitrogen or Hydrogen.

Class II.—Water.

Class III.—Carbou, and Compounds of Carhon.

Class IV.—Sulphnr.

Class V.—Haloid Minerals: Compounds of the Alkalies and Earths with the Soluhle Acids, or of their Metals with Chlorine or Flnorine.

1. Salts of Ammonia.
2. Salts of Potash.
3. Salts of Soda.
4. Salts of Barytes.
5. Salts of Strontia.
6. Salts of Lime.
7. Salts of Magnesia.
8. Salts of Alumina.

Class VI.—Earthy Miuerals: Silica and Siliceons or Aluminous Compounds of the Alkalies and Earths.

1. Silica.
2. Lime.
3. Magnesia.
4. Alumina.
5. Glucina.
6. Zirconia.
7. Thoria.

Class VII.—Metals and Metallic Ores.

1. Metals easily oxidisable: Iron, Lead, Copper, Mercury, &c.
2. Noble Metals: Gold, Silver, Platinum.

We have already observed that Mineralogy includes a knowledge of the chemical composition and of the external and physical properties of minerals, and they are all divisible into two great classes of crystallised and uncrystallised. With respect to regularly crystallised minerals, we refer for an account of their forms to what is stated under CRYSTALLOGRAPHY. There are some substances which do not assume regular forms, but have an imperfect crystalline structure; while those bodies which are not either crystallised or crystalline, unless they are pulverulent, are described as massive, and these are subdivided into such as possess particular forms, as botryoidal, mammellated, nodular, stalactitic, reniform, globular, aud amorphous, or without any particular form.

The structure of minerals is an important feature. It may he Columnar, Lamellar, or Granular. Tho following are explanations of the terms used in describing the different kinds of columnar structure:—

Fibrous: when the columns are minnte and lie in the same direction, as gypsum and asbestus. Fibrous minerals very commonly have a silky lustre; a fihrous variety of gypsum, and one of calc-spar have this lustre very strongly, and each is often called satiu-spar.

Reticulated: when the fibres, or columns, cross in various directions, and produce an appearance having some resemblance to a net.

Stellated: when they radiate from a centre in all directions, and produce a star-like appearauce. Stilbite aud gypsum are examples.

Radiated divergent: when the crystals radiate from a centre without producing stellar forms. Examples, quartz, gray antimony.

In the Lamellar Structure the laminæ or leaves may be thick, or very thin; they sometimes separate easily, aud sometimes with great difficulty. When the laminæ are thiu and separate easily, the structure is said to be Foliaceous. Mica is a striking example, and the term Micaceous is often used to describe this structure. When the lamiuæ are thick, the term Tahular is often applied; quartz and heavy spar afford examples. The laminæ may he elastic, as in mica, flexible, as in talc, or graphite, or brittle, as in diallage. Small laminæ are sometimes arranged in stellar shapes; this occurs in mica.

When the grains in the texture of a mineral are coarse, it is said to be Coarsely Granular, as in granular marhle; when fine, Finely Granular, as in granular quartz; and if no grains can he detected with the eye, the structure is described as Impalpable, as in chalcedouy. Granular minerals, when easily crumbled by the fiuger, are said to be Friable.

Massivo miuerals also take certain imitative shapes, not peculiar to either of these varieties of structure. The following terms are used in describiug imitative forms:

Globular: when the shape is spherical or nearly so: the structure may be Columnar and Radiatiug, or it may be Concentric, consistiug of coats like an onion. When they are attached, they are called Implanted Globules.

Reniform: kidney-shaped. In structure, they are like globular shapes.

Botryoidal: when a surface consists of a group of rounded prominences. The prominences or globules usually consist of fibres radiating from the centre.

Mammillary: resembling the botryoidal, but consisting of larger prominences.

Filiform: like a thread.

Acicular: slender like a needle.

Stalactitic: having the form of a cylindor or cone hanging from the roofs of cavities or caves. The term stalactite is usually restricted to the cylinders of carbonate of lime hanging from the roofs of caverns; but other minerals are said to have a stalactitic form when resembliug these in their general shape und origin. Chalcedony and brown iron-ore are often stalactitic.

Reticulated: net-like.

Drusy: a surface is said to be drusy when covered with minute crystals.

Amorphous—shapeless: having no regular structure or form, either crystalline or imitative.

Crystals are also called Pseudomorphous. A pseudomorphous crystal is one that has a form which is foreign to the species to which the substance belongs.

Crystals sometimes undergo a change of composition from aqueous or some other agency, without losing their form; for example, octahedrons of spinel change to steatite, still retaining the octahedral form. Cubes of pyrites are changed to red or brown iron-ore.

Again, crystals are sometimes removed entirely, and at the same time and with equal progress, another mineral is substituted; for example, when cubes of fluor-spar are transformed to quartz. The petrifaction of wood is of the same kind.

Again, cavities left empty by a decomposed crystal are refilled by another species by infiltration, and the new mineral takes on the external form of the original mineral, as a fused metal the form of the mould into which it is cast.

Again, crystals are sometimes incrusted over by other minerals, as cubes of fluor by quartz; and when the fluor is afterwards dissolved away, as sometimes happens, hollow cubes of quartz are left.

The first kind of Pseudomorphs are Pseudomorphs by Alteration; the second, Pseudomorphs by Replacement; the third, Pseudomorphs by Infiltration; the fourth, Pseudomorphs by Incrustation.

Pseudomorphous crystals are distinguished by having a different structure and cleavage from that of the mineral imitated in form, and a different hardness, and usually little lustre.

A large number of minerals have been met with as pseudomorphs. The causes of such changes have operated very widely and produced important geological results.

The characters of minerals depending on light are also arranged. They are of five kinds, and arise from the power of minerals to reflect, transmit, or emit light. They are as follows:—1, Lustre; 2, Colour; 3, Diaphaneity; 4, Refraction; 5, Phosphorescence.

The lustre of minerals depends on the nature of their surfaces, which causes more or less light to be reflected. There are different degrees of intensity of lustre, and also different kinds of lustre.

The kinds of lustre are six, and are named from some familiar object or class of objects:—

Metallic: the usual lustre of metals. Imperfect metallic lustre is expressed by the term Sub-Metallic.

Vitreous: the lustre of broken glass. An imperfect vitreous lustre is termed Sub-Vitreous. Both the vitreous and sub-vitreous lustres are common. Quartz possesses the former in an eminent degree; calcareous spar often the latter. This lustre may be exhibited by minerals of any colour.

Resinous: lustre of the yellow resins. Opal and zinc-blende are examples.

Pearly: like pearl. Talc, native magnesia, stilbite, &c., are examples. When united with sub-metallic lustre, the term Metallic-Pearly is applied.

Silky: like silk; it is the result of a fibrous structure. Fibrous carbonate of lime, fibrous gypsum, und many fibrous minerals, more especially those which in other forms have a pearly lustre, are examples.

Adamantine: the lustre of the diamond. When sub-metallic, it is termed Metallic-Adamantine. Varieties of white lead-ore are examples.

The degrees of intensity are denominated as follows:—

Splendent: when the surface reflects light with great brilliancy, and gives well defined images. Elba iron-ore, tin-ore, some specimens of quartz and pyrites are examples.

Shining: when an image is produced, but not a well-defined image. Calcareous spar and celestine are examples.

Glistening: when there is a general reflection from the surface, but no image. Talc and copper-pyrites are examples.

Glimmering: when the reflection is very imperfect, and apparently from points scattered over the surface. Flint and chalcedony are examples.

A mineral is said to be Dull when there is a total absence of lustre, as chalk.

In distinguishing minerals, both the external colour and the colour of a surface that has been rubbed or scratched, are observed. The latter is called the Streak, and the powder abraded, the Streak-Powder.

The colours are either metallic or non-metallic.

The Metallic are named after some familiar metal, as copper-red, bronze-yellow, brass-yellow, gold-yellow, steel-gray, lead-gray, iron-gray.

The Non-Metallic colours used in characterising minerals, are various shades of white, gray, black, blue, green, yellow, red, and brown.

There are thus snow-white, reddish-white, greenish-white, milk-white, yellowish-white; bluish-gray, smoke-gray, greenish-gray, pearl-gray, ash-gray; velvet-black, greenish-black, bluish-black; azure-blue, violet-blue, sky-blue, indigo-blue; emerald-green, olive-green, oil-green, grass-green, apple-green, blackish-green, pistachio-green (yellowish); sulphur-yellow, straw-yellow, wax-yellow, ochre-yellow, honey-yellow, orange-yellow; scarlet-red, blood-red, flesh-red, brick-red, hyacinth-red, rose-red, cherry-red; hair-brown, reddish-brown, chestnut-brown, yellowish-brown, pinchbeck-brown, wood-brown.

The expression a Play of Colours is used when several prismatic colours appear in rapid succession on turning the mineral. The diamond is a striking example; also precious opal.

Change of Colours: when the colours change slowly on turning in different positions, as in labradorite.

Opalescence: when there is a milky or pearly reflection from the interior of a specimen, as in some opals, and in cat's eye.

Iridescence: when prismatic colours are seen within a crystal; it is the effect of fracture, and is common in quartz.

Tarnish: when the surface-colours differ from the interior; it is the result of exposure. The tarnish is described as Irised, when it has the hues of the rainbow.

Polychroism: the property, belonging to some prismatic crystals, of presenting a different colour in different directions. The term Dichroism has been generally used, and implies different colours in two directions, as in the mineral iolite, which has been named dichroite because of the different colours presented by the bases and sides of the prism. Mica is another example of the same. The more general term has been introduced, because a different shade of colour has been observed in more than two different directions.

These different colours are observed only in crystals with unequal axes. The colours are the same in the direction of equal axes, and often unlike in the direction of unequal axes. This is the general principle at the basis of polychroism.

Diaphaneity: the property which many objects possess of transmitting light; or in other words, of permitting more or less light to pass through them. This property is often called transparency, but it is properly one of the degrees of diaphaneity. The following terms are used to express the different degrees of this property:—

Transparent: a mineral is said to be transparent when the outlines of objects, viewed through it, are distinct. Glass and crystals of quartz are examples.

Sub-Transparent, or Semi-Transparent: when objects are seen, but their outlines are indistinct.

Translucent: when light is transmitted, but objects are not seen. Loaf-sugar is a good example; also Carrara marble.

Sub-Translucent: when merely the edges transmit light faintly. When no light is transmitted, the mineral is described as opaque.

Those minerals whose faces emit light exhibit two sets of phenomena, Refraction and Polarisation.

The index of refraction has been obtained for many minerals, of which the following are a few:—

Air	1·000	Calc-Spar	1·654
Tabasheer	1·211	Spinel	1·764
Ice	1·308	Sapphire	1·794
Cryolite	1·349	Garnet	1·815
Water	1·335	Zircon	1·961
Fluor-Spar	1·434	Blende	2·260
Rock-Salt	1·557	Diamond	2·439
Quartz	1·548	Chromate of Lead	2·974

Many crystals possess the property of refracting light in two directions instead of one, and objects seen througb them consequently appear double. This is called Double Refraction. It is most conveniently exhibited with a crystal of calc-spar, and was first noticed in a pellucid variety of this mineral from Iceland, called from the locality Iceland-Spar. On drawing a line on paper and placing the crystal over it, two lines are seen instead of one—one by ordinary refraction, the other by an extraordinary refraction. If the crystal, as it lies over tbe line, be turned around, when it is in one position the two lines will come together. Instead of a line make a dot on the paper, and place the crystal over the dot: the two dots seen will not come together on revolving the crystal, but will seem to revolve one around the other. The dot will in fact appear double through the crystal in every direction except that of the vertical axis, and this direction is called the Axis of Donble Refraction. To view it in this direction the ends mnst be ground and polished. The divergence increases on passing from a view in the direction of the axis to one at right angles with it, wbere it is greatest. In some substances the refraction of the extraordinary ray is greater in the latter direction than that of the ordinary ray, and in others it is less. In calc-spar it is less, it diminishing from 1·654 to 1·483. In quartz it is greater, it increasing from 1·5484 to 1·5582. The former is said to have a Negative Axis, the latter a Positive.

Tbis property of double refraction belongs to such of the fundamental forms as have unequal axes; that is, to all except those of the monometric system. Those forms in which the lateral axes are equal (the dimetrio and hexagonal systems) have one axis of donble refraction; and those in wbich they are unequal (the trimetric, monoclinate and triclinate systems), have two axes of double refraction.

Both rays in the latter are rays of extraordinary refraction. In nitre the two axes are inclined about 5° to eacb otber; in arragonite 18° 18′; in topaz 65°. The positions of the axes thus vary widely in different minerals.

The extraordinary ray exhibits a peculiar property of light, termed Polarisation. Viewed by means of another doubly-refracting crystal, or crystalline plate (called from this nse of it an analysing plate), the ray of light becomes alternately visible and invisible as the latter plate is revolved. If the polarised ligbt be made to pass through a crystal possessed of double refraction, and then be viewed in the manner stated, rings of prismatic colonrs are developed, and on revolving the analysing plate the coloured rings and intervening dark ring successively change places.

Several minerals give ont light either by friction or when gently heated. This property of emitting light is called Pbosphorescence.

Two pieces of white sugar struck against one another give a feeble light, which may be seen in a dark place. The same effect is obtained on striking together fragments of quartz, and even the passing of a feather rapidly over some specimens of zinc-blende is sufficient to elicit light.

Fluor-spar is the most convenient mineral for showing Phosphorescence by Heat. On powdering it, and throwing it on a shovel heated nearly to redness, the whole takes on a brigbt glow. In some varieties the ligbt is emerald-green; in others pnrple, rose, or orange. A massive fluor from Huntington, Connecticut, shows beautifnlly the emerald-green phosphorescence.

Some kinds of white marble, treated in the same way, give out a bright yellow light.

After being beated for a while the mineral loses its phosphorescence; but a few electric shocks will in many cases to some degree restore it again.

Many minerals become electrified on being rubbed, so that they will attract cotton and other light substances: and when electrified some exhibit positive and others negative electricity when brought near a delicately suspended magnetic needle. The diamond, whether polished or not, always exhibits positive electricity, while other gems become negatively electric in the rough state, and positive only in the polished state. Friction with a feather is sufficient to excite electricity in some varieties of blende. Some minerals thus electrified retain the power of electric attraction for many hours, as topaz, while others lose it in a few minutes.

Many minerals become electrio when heated, and such species are said to be Pyro-Electric.

If a prism of tourmaline, after being heated, be placed on a delicate frame, which turns on a pivot like a magnetic needle, on bringing a magnet near it, one extremity will be attracted, the other repelled, thus indicating the polarity alluded to. Several other minerals exhibit electrical phenomena, especially boracite and topaz, which, like tourmaline, are bemihedral in their modifications.

Magnetism is exhibited more especially in the ores of iron. The loadstone, as the magnetic oxide of iron is called, is common where the ores of iron are found. Wben monnted like a horse-shoe magnet, a good loadstone will lift a weight of many pounds. Tbis is the only mineral that has decided magnetic attraction; but several ores containing iron are attracted by the magnet, or, when brought near a magnetic needle, will cause it to vibrate; and moreover, the metals nickel, cobalt, manganese, palladium, platinnm, and osmium, have been fonnd to be sligbtly magnetic.

Minerals vary in their specific gravity. This must he ascertained as for any other substance. [Specific Gravity.]

The Hardness of minerals differs much, and is the point first attended to by tbe mineralogist. In order to ascertain the hardness of a mineral it is only necessary to draw a file across the specimen, or to make trials of scratching one with another. As standards of comparison, the following minerals have been selected, increasing gradually in hardness from talo, which is very soft and easily cut with a knife, to the diamond which nothing will cut; this table is called the Scale of Hardness:

1. Talo, common foliated variety.
2. Rock-Salt.
3. Calc-Spar, transparent variety.
4. Fluor-Spar, crystallised variety.
5. Apatite, transparent crystal.
6. Felspar, cleavable variety.
7. Quartz, transparent variety.
8. Topaz, transparent crystal.
9. Sapphire, cleavable variety.
10. Diamond.

If on drawing a file across a mineral it is impressed as easily as fluor-spar, the hardness is said to be 4; if as easily as felspar, the hardness is said to be 6; if more easily than felspar, bnt with more difficulty than apatite, its hardness is described as $5\frac{1}{2}$ or 5·5.

The file should be run across the mineral three or four times, and care should be taken to make the trial on angles equally blunt, and on parts of the specimen not altered by exposure. Trials shonld also be made by scratcbing the specimen nnder examination with tbe minerals in the above scale, as sometimes, owing to a loose aggregation of particles, tbe file wears down the specimen rapidly, although the particles are very hard.

Minerals differ in tbeir state of aggregation. Solid minerals may be—

Brittle: when parts of the mineral separate in powder on attempting to cut it.

Sectile: when thin pieces may be cut off with a knife, but the mineral pnlverises nnder a hammer.

Malleable: when slices may be cut off, and these slices will flatten out under the hammer, as native gold and silver.

Flexible: when the mineral will bend, and remain bent after the bending force is removed, as talc.

Elastic: when after being bent it will spring back to its original position, as mica.

A liquid is said to be Viscous when on pouring it the drops lengthen and appear ropy, as petroleum.

When a mineral is broken its cut surface presents different aspects. The following are the several kinds of fracture in minerals:—

Conchoidal: when the mineral breaks with a curved or concave and convex surface of fracture. Flint is a good example.

Even: when the surface of fracture is nearly or quite flat.

Uneven: when the surface of fracture is rough with numerous small elevations and depressions.

Hackly: when the elevations are sharp or jagged, as in broken iron.

Soluble minerals may have taste: the kinds are—

Astringent: the taste of vitriol.

Sweetish-astringent: the taste of alum.

Saline: taste of common salt.

Alkaline: taste of soda.

Cooling: taste of saltpetre.

Bitter: taste of Epsom salts.

Sour: taste of sulphuric acid.

Excepting a few gases and soluble minerals, minerals in the dry unchanged state do not give off odour. By friction, moistening with the breath, the action of acids, and the blow-pipe, odours are sometimes obtained, which are thus designated:—

Alliaceous: the odour of garlic. It is the odour of burning arsenic, and is obtained by friction and more distinctly by means of the blow-pipe from several arsenical ores.

Horse-Radish odour: the odour of decaying horse-radish. It is the odour of burning selenium, and is strongly perceived when ores of this metal are heated before the blow-pipe.

Sulphureous: odour of burning sulphur. Friction will elicit this odour from pyrites, and heat from many sulphurets.

Fetid: the odour of rotten eggs or sulphuretted hydrogen. It is elicited by friction from some varieties of quartz and limestone.

Argillaceous, the odour of moistened clay. It is given off by serpentine and some allied minerals when breathed upon. Others, as pyrargillite, afford it when heated.

Without submitting the mineral to a regular analysis, advantage is often taken of the effects of heat by means of the blow-pipe, with or without the aid of certain fluxes, as soda, phosphoric salt, &c.; and the mineral is stated to be either fusible alone, or with the assistance of the different fluxes, and the nature of the resulting compound is described; sometimes it is a colourless glass, at other times coloured, transparent, or opaque, &c. [Blow-Pipe.]

MINNESOTA, a Territory of the United States of North America, lies between 43° 30′ and 49° 22′ N. lat., 90° 0′ and 102° 30′ W. long. It is bounded E. by the State of Wisconsin, N.E. by Lake Superior, N. by British North America, W. by the Territory of Nebraska, and S. by the State of Iowa. The area is 141,839 square miles. The population in 1856 was estimated at 160,000.

The surface of this Territory has generally the character of an immense high 'rolling prairie land,' but there are considerable exceptions. Towards the eastern side it runs into a ridge of lofty hills, which traverses a large portion of it in a north-east and south-west direction. From a short distance above the Falls of St. Anthony, on the Mississippi, there extends southward a vast forest region for 120 miles, with a breadth ranging from 15 to 40 miles. The northern and north-eastern portion of the Territory is sometimes termed the 'region of lakes,' from the great number of lakes of various sizes which here lie along the upper course of the Mississippi and its tributaries; and for some distance below this region the Mississippi traverses a swampy country.

The Territory is in every part abundantly watered. The Mississippi rises within its boundaries, in Lake Itasca; and belongs wholly to it down to the confluence of the St. Croix, after which, to the southern boundary of the territory, it belongs equally to Minnesota and Wisconsin. This part of its course is described under Mississippi River. The principal tributaries which join it in this territory are the St. Croix, which separates Minnesota from Wisconsin, and the Minnesota, a large and broad stream, which rises near the centre of the Territory, flows through Big Stone Lake, and after a course including its windings of some 500 miles, first south-east, then south, and finally north-east, falls into the Mississippi at Fort Snelling. The Mississippi is navigable in Minnesota by steam-boats during seven months of the year; the other five months it is, with its tributaries, closed by ice. The Missouri, with its tributary, the White Earth River, forms the western boundary of Minnesota: it is navigable by steam-boats throughout Minnesota. It is joined by several small feeders, but by none of any consequence in this Territory. The Red River, which flows northward to Winnipeg Lake in British America, has its source in, and belongs for a very considerable distance to Minnesota, and has numerous tributaries in this part of its course. The Big Sioux and several other rivers have also their upper courses in this Territory. The Mississippi, Missouri, Minnesota, and St. Croix rivers, with Lake Superior, afford great commercial facilities: while the numerous smaller streams and lakes afford like facilities for agricultural and manufacturing operations. The principal lakes are the Itasca, Cass, Red, Leech, Devil, Ottertail, Big Stone, and Pepin lakes, which range from about 5 to 20 miles long.

As regards its geological character, the larger half of the country, including the centre and north-eastern portions, appears to belong to the igneous and metamorphic formations. In the northern and south-eastern districts are extensive tracts of Lower Silurian rocks. Extending from the centre eastward to Lake Superior is a narrow band of New Red-Sandstone, with dykes of copper trap. The Missouri through its whole course in Minnesota appears to flow through cretaceous rocks, which are bordered on the east by tertiary formations. Copper- and lead-ores are said to have been found.

The climate, though severe, is not subject to rapid or extreme variations. The winters are long, but owing to the stillness of the air during winter, the coldest weather is endurable. A great quantity of snow falls in the winter, but generally there is not much moisture. The soil over a country so vast in extent, and having such different lithological features, is of course greatly varied; but in the settled parts it is found to be remarkably fertile, and the mould is of unusual depth. Most of the cereals appear to flourish: maize, oats, and wheat are the crops most cultivated, but rye, barley, and buckwheat are also grown. Potatoes, peas, and beans are raised to some extent. The broad prairies appear well adapted for raising stock. There are at present no manufactures in the Territory. The chief occupation is the cutting and preparing of pine lumber, much of which is retained for home consumption, but the larger portion is sent to St. Louis.

At the census of 1850 Minnesota was divided into nine counties. The political capital is St. Paul, the only place which can as yet fairly take rank as a town; but Pembina, on the right bank of the Red River, at the northern boundary of the territory—Fort Snelling, at the confluence of the Minnesota with the Mississippi—and Stillwater, on the west side of St. Croix Lake, are places of growing local importance.

St. Paul, the capital, occupies a commanding position on the left bank of the Mississippi, 15 miles below the Falls of St. Anthony, in 44° 52′ N. lat., 93° 4′ W. long. The first trading house was built here in 1842, it having previously been merely the station of a Roman Catholic mission. It now contains a state-house 139 feet long, a court-house, jail, nine churches, schools, numerous hotels, stores, an iron-foundry, agricultural implement factories, flour-mills, &c. The streets are traversed by coaches and omnibuses; and, whilst the river is free from ice, steam-vessels arrive and sail daily, although the vicinity of the town is still a wilderness. In 1850 St. Paul had 1135 inhabitants; in the spring of 1853 it is said to have had above 2500.

Minnesota has a legislature, consisting of a Council and House of Representatives. By the constitution, as framed by the territorial legislature, citizenship is not limited to whites, but extended to "all persons of a mixture of white and Indian blood who shall have adopted the habits and customs of civilized men." Minnesota was erected into a Territory by Act of Congress in March 1849; that portion of it west of the Mississipi having previously formed a part of the Territory of Iowa, and that part east of the Mississipi having belonged to the Territory of Wisconsin.

On the 26th of February, 1857, an Act was passed by Congress, authorising Minnesota to form a State government. This Act makes an alteration in the area of Minnesota, and consequently in the population. The Convention for forming the State assembled in November, 1857; but the particulars have not yet (April 1, 1858), reached us.

MIRAMICHI. [New Brunswick.]

MIRBEL, BRISSEAU- C.F., a French naturalist, more especially distinguished for his knowledge of botany. He was born on the 27th of March 1776. He was appointed professor of botany in Paris in 1801, and one of his earliest published works was the lecture introductory to his course. The subject was the influence of the study of natural history on the civilisation of man. He was associated with others in the production of the volumes on the general and special history of plants, in the series of works in continuation of the natural history of Buffon. In this work, which extended to eighteen volumes, the first, second, fourth, fifth, and sixth, were written by Mirbel. In 1802 he published his treatise 'On Vegetable Physiology.' He was also associated with Lamarck in the publication of a great work on the 'Natural History of Plants,' which was published in 1803. He subsequently, in answer to views put forth by Link, wrote an 'Exposition of the Theory of Vegetable Organization,' and also a defence of this work in 1808. In 1815 he published his 'Elements of Vegetable Physiology and Botany.' This work was published in three volumes, and was an admirable exposition of the state of vegetable physiology at the time it was published, and contained the result of numerous observations on the structure, functions, and development of plants. In 1835 he published a paper on the nature and origin of the bark on dicotyledonous trees, in which he gave an admirable account of the structure of the bark in exogenous plants. After this he published his celebrated paper on the 'Anatomy and Physiology of Marchantia Polymorpha,' in which he not only described the general structure of the plant, but the history of the development of its embryo. In his general theoretical views and numerous exact observations, Mirbel exercised a great influence on the progress of the science of botany during the first half of the 19th century. He died September 12, 1854.

MITCHELL, SIR THOMAS LIVINGSTONE, Knight, was born in 1792, at the residence of his father, John Mitchell, Esq., of Craigend, in Stirlingshire, Scotland. The name of Livingstone was assumed by the family on a marriage with the heiress of J. Livingstone, Esq., of Halning, brother to Lord Viscount Kilsyth, who was attainted in 1716. Thomas Livingstone Mitchell entered the British army in Portugal in 1808, and served on the staff till the termination of the Peninsular War, when he had attained the rank of major. In the course of this service he had distinguished himself so much as to attract the attention of the late Sir George Murray, upon whose recommendation he was sent back to the Peninsula to make surveys of the great battle-fields. The series of military maps which he constructed from these surveys are preserved in the Ordnance-office, and are unsurpassed for accuracy and skilful execution. A model which he formed of the Lower Pyrenees is in the Museum of the United Service, Whitehall. He married in 1818 the daughter of Lieutenant-General Blunt.

In 1827 Major Mitchell published 'Outlines of a System of Surveying for Geographical and Military Purposes,' 8vo, London. In the same year he received the appointment of deputy surveyor-general of New South Wales under Mr. Oxley, whom he succeeded as surveyor-general—an office which he retained till his death. Besides performing the ordinary duties of this important situation, he conducted four expeditions into the interior, and was one of the most successful of the explorers of the Australian continent. Three of these expeditions were performed in the years 1831-32, 1835, and 1836. The first was in search of an imaginary river called the Kindur, which a runaway convict, who had resided among the aborigines, described as having a north-west course, and entering the sea; and the result of the journey was the discovery of the Peel River and the Nammoy. The second expedition was for the purpose of exploring the course of the river Darling, and was continued in the third expedition, when the Darling was traced to its junction with the river Murray. Australia Felix was also discovered, and the Glenelg was explored to its entrance into the sea. These journeys were attended with great danger from the occasional hostility of the native tribes, and required continual vigilance, combined with the steadiness and resolution of an experienced leader. Major Mitchell published in 1838 his account of these journeys, under the title of 'Three Expeditions into the Interior of Eastern Australia, with Descriptions of the recently-explored Region of Australia Felix, and of the present Colony of New South Wales,' 2 vols. 8vo, London, illustrated with lithographic drawings and woodcuts. He had a short time previously published his 'Map of the Colony of New South Wales, compiled from actual Measurements with the Chain and Circumferenter, and according to a Trigonometrical Survey, in Three Sheets.' Major Mitchell came to England for the purpose of superintending these publications, and, before his return, received, in 1839, the honour of knighthood from the queen, and the title of D.C.L. from the University of Oxford. He was also elected a Fellow of the Royal Society and of the Geographical Society.

Sir Thomas Mitchell's fourth and last expedition was commenced in December 1845, and terminated in December 1846. His account of it was published in 1848, under the title of a 'Journal of an Expedition into the Interior of Tropical Australia, in Search of a Route from Sydney to the Gulf of Carpentaria, by Lieut.-Colonel Sir T. L. Mitchell,' 8vo, illustrated with lithographic engravings and maps. This expedition did not reach the Gulf of Carpentaria, having been compelled to return in consequence of the loss of the cattle and horses from drought and want of pasturage; but advanced as far as 21° 30′ S. lat. Sir Thomas Mitchell himself was the first to discover the important river which he named the Victoria, and saw it taking a north-western course, in a direction towards the Gulf of Carpentaria. Mr. Kennedy, however, Sir T. Mitchell's assistant-surveyor, in a subsequent journey in 1847, found that the river makes a great bend to the south-west, and he traced its course in that direction as far as 26° 14′ S. lat. The channels were in many places quite dry, and he was compelled to return from want of water and pasturage for his horses. In 1850 Sir Thomas Mitchell published an admirable manual of geography for the schools of New South Wales, entitled 'Australian Geography, with the Shores of the Pacific and those of the Indian Ocean, designed for the Use of Schools in New South Wales,' 12mo, Sydney. In 1853 he again visited England. Having invented a new propeller for steam-vessels on the principle of the curious instrument used by the natives of Australia, he delivered a lecture on the subject which excited much interest. It was published under the title of 'Origin, History, and Description of the Boomerang Propeller, a Lecture delivered at the United Service Institution,' 8vo, London.

Sir Thomas Mitchell was advanced to the rank of colonel in 1854. He died October 5, 1855, at his residence near Sydney, and his remains received the honour of a public funeral.

MITCHELSTOWN, county of Cork, Ireland, a market- and post-town, and the seat of a Poor-Law Union, is pleasantly situated near the river Funcheon on a small tributary, in 52° 17′ N. lat., 8° 17′ W. long., 30 miles N.N.E. from Cork, 129 miles S.W. by S. from Dublin. The population in 1851 was 3091. Mitchelstown Poor-Law Union comprises 18 electoral divisions, with an area of 86,957 acres, and a population in 1851 of 27,269. The town consists of an extensive square, containing some well-built houses, and of two principal streets with several smaller streets intersecting these at right angles. It contains the parish church—a handsome building, enlarged in 1830, a spacious Roman Catholic chapel, a National school, and a town library. There are also a court-house, fever hospital, dispensary, bridewell, and Union workhouse. Mitchelstown College, a group of neat buildings with a chapel attached, was founded by the Earl of Kingstown for the support of 12 males and 16 females of his decayed Protestant tenantry. Each receives 40*l.* a year, besides a house and garden. On one side of the square is the gateway to the extensive demesne of Mitchelstown, the seat of the Earl of Kingstown, proprietor of the town. The mansion with its towers and battlements forms a striking object. It was erected in 1823, and is the largest and finest of the modern castles in Ireland. Petty sessions are held monthly. Fairs are held January 10, March 25, May 23, July 30, November 12, and December 2.

Mitchelstown and Kingstown caves are two series of beautiful stalactite caverns, under small limestone hills about 8 miles from Mitchelstown on the Dublin road. One series, discovered in 1833, is 870 feet in extreme length by 572 feet in breadth.

MITFORD, MARY RUSSELL, one of the most delightful of our female authors, was born on the 16th of December 1786, at Alresford, Hampshire. Her father was a physician, and a man of very considerable attainments and ability, but of unthrifty and somewhat eccentric habits, and consequently unsuccessful alike in his professional pursuits and in his pecuniary affairs. By his general want of management and injudicious speculations he wasted his wife's property as well as his own, and when a characteristic present made—when his own fortunes were at the lowest ebb—to his daughter on her tenth birthday, of a ticket in the Dublin Lottery, turned up a prize of 20,000*l.*, that too was as thoroughly, though somewhat more slowly, dissipated as his previous wealth had been. Yet he was a man of the kindliest and most cheerful, as well as sanguine temper, and Mary Mitford, his only child, without a murmur dedicated her life to the promotion of his comfort and happiness, and almost before arriving at womanhood devoted herself to literature as a means of ekeing out his diminished income.

At ten years of age she was sent to a boarding-school at Chelsea; and in addition placed under the special guidance of a governess, who, as Miss Mitford mentions in the introduction to her dramatic works, was not only herself addicted to verse-writing, but seemed to have the faculty of making her pupils write verses also; and among her pupils she at different times numbered, besides Miss Mitford, Miss Landon (L. E. L.), Fanny Kemble, and Lady Caroline Lamb. Miss Mitford took the poetic fit strongly; and before she was twenty she had published three volumes of poetry, one of which was a romance in verse after the manner of Sir Walter Scott. They were not of much worth, but they met with rougher treatment at the hands of the 'Quarterly,' than their juvenile demerits justified. But though pained she was not disheartened, and she profited by the somewhat rough lesson. Another volume of verse—'Watlington Hill; a Poem,' was published in 1812. She had by this time deliberately adopted literature as a profession, and was busy in writing short tales and sketches for the magazines. She had acquired facility and confidence by these exercises, when the early celebrity probably of the 'Sketch-Book of Geoffry Crayon,' turned her thoughts to the writing of some descriptive sketches of English rural scenery and rustic life. A pleasant little village on the borders of Berkshire and Hampshire—Three Mile Cross, near Reading—had long been her residence; every lane and field, and almost every nook and corner of it, every house and cottage, and almost every person in them, was familiar to her; and it occurred to her that faithful delineations of the country scenery and country manners as they existed in that small southern village would not be unwelcome to the world of readers.

But she met in the first instance with serious discouragement. Thomas Campbell was then editor of the 'New Monthly Magazine,' and the earlier essays of what ultimately formed 'Our Village' were offered to him, but peremptorily rejected. They were beneath the dignity of his magazine. After other rebuffs they were fain to take shelter in the 'Lady's Magazine.' There their freshness, geniality, and faithfulness were recognised, and Miss Mitford, nothing loth, was called upon to publish them in a collected form. By the general public 'Our Village' was warmly welcomed, and each series has been several times reprinted. They have found many imitators too, but hitherto no rivals. She wrote in the Preface when they were first collected:—"Her descriptions have always been written on the spot and at the moment, and in nearly every instance with the closest and most resolute fidelity to the place and the people. If she be accused of having given a brighter aspect to her villagers than is usually met with in books, she cannot help it, and would not if she could. She has painted, as they appeared to her, their little frailties and their many virtues, under an intense and thankful conviction, that in every condition of life goodness and happiness may be found by those who seek them, and never more surely than in the fresh air, the shade, and the sunshine of nature." This is a fair account of them, and fairly represents, moreover, the genial and hearty spirit of their authoress. 'Our Village' is in all respects a work that more than almost any other represents in literature that phase of English taste and feeling, which is so characteristically exhibited in our best water-colour landscapes and scenes of country life—so redolent of the open air and sunshine. 'Our Village' altogether extended in its original collected form to five volumes, or series, the last of which was published in 1832. Of some of the sketches in the last volume or volumes it must however be admitted that there is a little want of the primal freshness, and in them, and in some of her later essays, there is too much yielding to the besetting sin of those who depict character—the tendency to exaggeration or caricature. 'Belford Regis; or Sketches of a Country Town,' in which the neighbouring town of Reading, instead of the pretty country hamlet, supplied the materials, was her most important subsequent work in a similar style. Her later sketches and essays furnished to various periodicals have not, we believe, been collected. Among her other works may be mentioned her 'Stories of Country Life.' She also for some years edited Finden's 'Tableaux;' and three volumes of 'Stories of American Life by American Authors.'

Whilst at the Chelsea school Miss Mitford's dramatic tastes had been as carefully nurtured as her poetic tastes. The consequence was that in early life her most ardent aspirations as an authoress were directed towards the stage. She wrote altogether a large number of dramatic pieces of various kinds. Four of these were works of considerable importance. The first, 'Julian,' was performed in 1823, with Macready for the hero, and met with decided success. The 'Foscari' appeared with equal good fortune in 1826; and 'Rienzi,' which had a run, in 1828. 'Charles the First' was not so fortunate as its predecessors; Colman, then licenser of plays, having refused to sanction its performance on the ground of the impropriety and danger of permitting the trial of an English king to be represented on the stage. Driven from the legitimate houses, Charles I. was at length brought out at a minor theatre, the Coburg, and it has not apparently been repeated elsewhere. Besides these an opera, 'Sadak and Kalasrade,' written by her, was produced at the Lyceum, but was unsuccessful. One of Miss Mitford's last literary appearances was in an edition of her 'Dramatic Works' (2 vols. 8vo, 1854), which, besides the pieces above named, included a tragedy—printed for the first time—'Otto of Wittelsbach;' 'Inez di Castro,' another five-act piece, twice rehearsed for performance, and twice withdrawn; a melodrama, 'Gaston de Blondeville;' and several 'Dramatic Scenes.'

In looking at Miss Mitford's works, it should be borne in mind that, though they seem almost invariably the reflex of a mind full of happy images, and surrounded by pleasant circumstances, they were often really written under the pressure of pecuniary discomfort and during much ill-health. As long as her father lived her attention to him was unremitted, and her own health suffered from her filial devotion: shortly after his death it gave way entirely. Yet she lived and laboured on in her pretty Berkshire cottage, beloved by every friend, and cheered often by finding that her books had made her friends innumerable. About three years before her death she was hurt by the accidental overturning of her pony-chaise, and thenceforth she was pretty much confined to her house; but through her prolonged and hopeless suffering, she retained her wonted cheerfulness, and even her old industry was continued. Besides revising the work on which her fame is chiefly founded—'Our Village'—for a new edition, which appeared in 1852, she compiled a sort of literary patch-work, 'Recollections of My Literary Life; or Books, Places, and People,' which is in fact a sort of gossiping commentary on the "books, places, and people" that had, she fancied, most influenced her mental career, with a somewhat large addition of extracts from her favourite authors. She also prepared the collected edition of her 'Dramatic Works,' already noticed—to which works she prefixed various autobiographic introductions; and in 1854 she published 'Atherton; a novel,' in 3 vols. She died at her residence, Swallowfield Cottage, near Reading, on the 10th of January 1855.

MOA. [DINORNIS, *S.* 2.]

MOCHA-STONE. [AGATE.]

MOIR, DAVID MACBETH, was born at Musselburgh, in the county of Edinburgh, on the 5th of January 1798. He was educated at the grammar-school there, and when only thirteen was apprenticed to Dr. Stewart, a medical practitioner in that town. He was a diligent and attentive student in his profession, but became very early inclined to literary pursuits. In 1812 he produced some poems, which, though neat, had little originality; shortly afterwards he appeared in print with two brief essays in prose, in a small local magazine. During the last year of his apprenticeship, which was for four years, he attended the University of Edinburgh, which he continued to do after his apprenticeship terminated, and obtained his diploma as surgeon in the spring of 1816. It had been his intention to enter the army, but the peace offering few hopes of advancement in that direction, he abandoned his purpose, returned home, and for awhile devoted himself to literature, writing occasionally for the 'Scots Magazine,' and published an anonymous volume, entitled 'The Bombardment of Algiers and other Poems,' which brought him little profit or fame. He was also a member of 'The Musselburgh Forum,' a debating society, in which he favourably distinguished himself. In 1817 he entered into business as a partner, in his native town, with Dr. Brown, who had an extensive but laborious practice. Moir worked hard at his professional duties, but, when the toils of the day were ended, he employed a great part of the night in his literary pursuits. He was at this time a frequent contributor in prose and verse to Constable's 'Edinburgh Magazine.' When 'Blackwood's Magazine' was started, he became a still more constant contributor to its pages. He wrote for it both prose and poetry, both comic and serious. Among his comic effusions were 'The Eve of St. Jerry,' and 'The Auncient Waggonere,' and at the time some of them were supposed to be from the pen of Dr. Maginn. His serious poems were marked as by Δ, a signature which he retained in that magazine until his death. In 1823 he formed a strong friendship with John Galt, who, when he departed for America, left his novel, 'The Last of the Lairds,' unfinished, and Moir wrote the concluding chapters for him. In 1824 he published 'The Legend of Genevieve, with other Tales and Poems,' consisting of selections from his magazine contributions, with some original additions. In the same year he commenced, in 'Blackwood's Magazine,' his novel of 'The Autobiography of Mansie Wauch,' which was continued for nearly three years, and afterwards published separately. It had great success, and the character of its hero is a clever embodiment of some of the peculiarities of Scottish character. During all these literary labours he continued to attend to his professional duties with indefatigable assiduity and extreme kindness. Between 1817 and 1828 he is stated never to have slept a night out of Musselburgh. He was now recommended to remove to Edinburgh, where he might have readily attained a more lucrative practice, but his attachment to his old haunts and his old patients and neighbours caused him to refuse. In 1829 he married. In 1831 he published his 'Outlines of the Ancient History of Medicine, being a View of the Healing Art among the Egyptians, Greeks, Romans, and Arabians.' In 1832, after having exerted himself in a most energetic manner when the cholera was raging in his district, he published as a pamphlet 'Practical Observations on Malignant Cholera,' which had a very extensive circulation; and this was followed by 'Proofs of the Contagion of Malignant Cholera;' both works being allowed to possess great merit, even by those who differed from the author's conclusions. In 1832 Mr. Moir attended the meeting of the British Association for the Advancement of Science at Oxford, and afterwards visited London, where he extended his acquaintance among the literary celebrities. In 1843 he published 'Domestic Verses,' in which, among other things, he records, with much tenderness, the loss of two of his sons, who died young. In 1845 he contributed the account of the civil history and antiquities of the parish of Inveresk, of which Musselburgh is the chief town, to the 'New Statistical Account of Scotland.' In 1846 he met with an accident, being thrown from a carriage, by which he was rendered lame for life. In the spring of 1851 he delivered a series of lectures 'On the Poetical Literature of the Past Century,' at the Edinburgh Philosophical Institution. In the same year, 'Selim,' his last contribution to 'Blackwood's Magazine,' appeared, and on the 6th of July he died. His activity had continued unabated during his whole life. He had, besides paying a sedulous and benevolent attention to his patients, filled various municipal offices, and had been a member of the General Assembly. His contributions to 'Blackwood' alone number 370. His serious poetry, by which he will be chiefly remembered, is sweetly pensive and tender, without any remarkable original poetic power, but it possesses a charm in its natural imagery and its appeals to our feelings that can never fail to please. In 1852 his 'Poetical Works,' which, however, are only a selection, were published, with a memoir of his life, by T. Aird.

MOLÉ, COMTE DE, was born in 1781, and was descended from an illustrious family in France. He was the son of the President Molé, who fell a victim to the violence of the first French Revolution. Enough property however appears to have been saved from the wreck of his family fortunes to enable the father to send his son to the Central School of Public Works, afterwards called the Polytechnique, where he pursued his studies with industry and vigour. In 1806 he published 'Essais de Morale et de Politique,' which attracted the attention of the Emperor Napoleon I., and secured for him the post of auditor of the Council of State. These essays, as may be supposed, were of a highly absolutist cast; and though their author continued to the last a staunch adherent of the Bonaparte dynasty, he remained in office under the Bourbons after their restoration, who created him a peer of France. To the policy and measures of Prince Polignac he offered the most determined opposition. After the revolution of July 1830 he was appointed by Louis Philippe to the portfolio of Foreign Affairs, and shortly afterwards was advanced to the post of Prime Minister of France, which he eventually was obliged to resign by the opposition of M. Guizot and M. Thiers. Upon this he retired into private life, and though he was elected a member of the Legislative Assembly, he took little or no part in its proceedings. The family of Count Molé was of that rank which is known as the 'nobility of the robe,' and his ancestors were of gentle blood as long ago as the days of Henri IV. Talents and administrative capacity seem to have been hereditary in the family, as well as the love of legal order, monarchy, and constitutional government. Count Molé was almost the last remaining link between his countrymen of the old and of the new régime, as combining the high-bred tone and monarchical principles of the former with a proportion of the liberal principles which are the distinctive mark of the latter class. But while Count Molé accepted each successive change in the governing system of France as the result of political necessity, it cannot be said that he ever swerved in principle from the opinions which he had originally professed. At the close of his long career, under various successive changes of government, he renewed his relations with the ancient dynasty, and departed life as he entered upon it, a supporter of the old monarchy. In his theological opinions he inclined to the Ultramontane party, and from his high character, great abilities, and illustrious position, he was one of the strongest supporters of the Roman Catholic Church in France. His memoirs, which naturally include reminiscences of all the great men and notables of France during the first half of the 19th century, were announced as in preparation, but have not yet (April 1858), been published. He died suddenly at his family seat at Champalatrux, November 23rd 1855.

MOLESWORTH, RIGHT HON. SIR WILLIAM, eighth Baronet of that name, was born in 1810. He was the lineal representative of an old Cornish family of large landed possessions, originally of Irish extraction. The first baronet was governor of Jamaica in the reign of Charles II. Sir William's father died in 1823. It is uncertain at what school Sir William Molesworth was first educated, but it is certain that having spent some time at Cambridge, he was sent to Edinburgh, where he was taught classics, mathematics, and metaphysical science, by an Italian refugee, and afterwards passed to a German university. In this latter soil his mind took deep root; he acquired the German language, and followed at will the bent of his own vigorous talents. Having left England with an average acquirement of general and classical knowledge, he concentrated his powers in Germany upon the study of philology and history. His mind however revolted against the mysticism of the German school, and as soon as he was released from collegiate study he made the usual tour of Europe. On his return to England in 1831 he was still in his minority. His first public appearance in this country was at a meeting convened in his native county in that year for the purpose of supporting parliamentary reform, and his maiden speech on that occasion gave considerable promise of future eminence. He was little more than of age when he was returned to parliament unopposed in December 1832, for East Cornwall, by which constituency he was re-elected in December 1834, but withdrew from the contest in July 1837, when he was returned for Leeds. At the dissolution of 1841, being convinced that his chance of success at Leeds was hopeless, he declined a contest, and remained out of parliament for four years. During this interval he read and thought much on politics and social economy, gave himself a sounder political education, and accumulated capital for his future senatorial life. In 1850, however, on the death of Mr. Wood, he offered himself as a candidate for the representation of Southwark, and though strenuously assailed for his support of the grant to Maynooth College, he was successful, and he continued to represent the same constituency to his death. In January 1853 he accepted the office of First Commissioner of Public Works on the formation of Lord Aberdeen's administration, and was re-elected without opposition; and again on his subsequent translation to the Colonial Office.

As a 'Commons' debater' Sir William Molesworth was not of first-rate eminence. His speeches in parliament were few, but always valuable, though of too philosophical a cast to be generally popular. Those on the colonies, delivered in 1838; in 1840 on the state of the nation and the condition of the people; on transportation, in 1837-38; and on many important social and economic questions about the same period, were of great merit and immense practical utility. They were carefully prepared beforehand, and were the results of reading, labour, and reflection. In July 1855 Sir William Molesworth found a sphere far more congenial to his tastes, and a larger scope for his administrative ability, on being appointed to the secretaryship of the colonies, but he held that office only for the brief space of four months, when his career of public usefulness was cut short by death, which occurred on the 22nd of October 1855. The colonial and domestic press were all but unanimous in expressing their satisfaction at his appointment; it was not forgotten that he had taken the deepest interest in the affairs of Canada and Australia, and had studied the problem and mastered the theory of colonisation to a greater extent than perhaps any contemporary. Neither was it forgotten that he was the first person who, in this country, succeeded in calling public attention to the manifold abuses connected with the transportation of criminals, though eighteen years had elapsed since the parliamentary committee, of which he was chairman, brought to light all the horrors of our penal system. In the words of a writer in the 'Times,' "Sir William Molesworth found our colonial empire disorganised and distracted by the mal-administration of the Colonial Office, wedded as it then was to a system of ignorant and impertinent interference. He first aroused the attention of parliament to the importance of our remote dependencies, and explained with incomparable clearness and force the principles of colonial self-government. With untiring diligence and great constructive power he prepared draught constitutions, and investigated the relations between the imperial government and its dependencies. Starting from a small minority, he brought the public and parliament over to his side, till principles once considered as paradoxes came to be regarded as axioms. By such means he fairly won the position of Secretary of State for the Colonies; but he did not live to enjoy the prize which he had grasped. Before we had time to hear of the satisfaction with which his appointment was sure to be hailed by our remote dependencies, the sceptre was snatched from his hand by death, and the post became again vacant. In the full vigour of life and intellect, in the possession of what must have been to him the highest and noblest prize of ambition, in the enjoyment of the confidence of his sovereign and the esteem of his fellow-subjects, he was taken away suddenly and prematurely, yet not so soon as to deprive his friends of the consolation of thinking that he has left behind him durable memorials which will link his name with the destinies of every British community planted on the face of the earth. The best monument that could be raised to him would be a complete collection of his parliamentary speeches; the noblest epitaph that could be inscribed on his tomb would be the title of the 'Liberator and Regenerator of the Colonial Empire of Great Britain.'"

Though he had not avowedly appeared before the public as an author, Sir William Molesworth was favourably known in the world of letters and science. Having purchased the 'Westminster Review,' he for some years conducted it either alone or in conjunction with his friend, Mr. John Stuart Mill, the eminent political economist, and during that time he was a not unfrequent contributor to its pages; he likewise wrote at different times many articles in other periodicals and newspapers. He also edited and published at his own expense a complete edition of the English works of the philosopher Hobbes, in 16 volumes. [HOBBES, THOMAS.] In science Sir William Molesworth had obtained some reputation as a botanist; but his acquirements extended over a large range of subjects. In private life few men have been more highly esteemed.

MOLLUSCA. Referring to the articles CONCHIFERA, GASTEROPODA, CEPHALOPODA, and MALACOLOGY, for information as to the zoological arrangement and subdivision of the various families of the *Mollusca*, we shall in the present article consider the animals which constitute this great group in a purely anatomical and morphological point of view; that is, we shall endeavour to show—firstly, what Common Plan or Archetype is discoverable among the varieties of Molluscan forms; secondly, in what way the Common Plan is more specially modified in the leading sub-typical groups of this great division of the animal kingdom; thirdly, the various modes in which the organs are arranged being thus comprehended—what peculiar characters are presented by these organs themselves; and fourthly, the development of the *Mollusca*, so far as it bears upon the idea of a Common Plan, will be discussed.

1. *The Common Plan or Archetype of the Mollusca.*—By the Common Plan or Archetype of a group of animals we understand nothing more than a diagram, embodying all the organs and parts which are found in the group, in such a relative position as they would have, if none had attained an excessive development. It is, in fact, simply a contrivance for rendering more distinctly comprehensible the most general propositions which can be enunciated with regard to the group, and has the same relation to such propositions as the diagrams of a work on mechanics have to actual machinery, or those of a geometrical work to actual lines and figures. We are particularly desirous to indicate the sense in which such phrases as Archetype and Common Plan are here used; as a very injurious realism—a sort of notion that an Archetype is itself an entity—appears to have made its way into more than one valuable anatomical work. It is for this reason that if the term Archetype had not so high authority for its use, we should prefer the phrase 'Common Plan' as less likely to mislead.

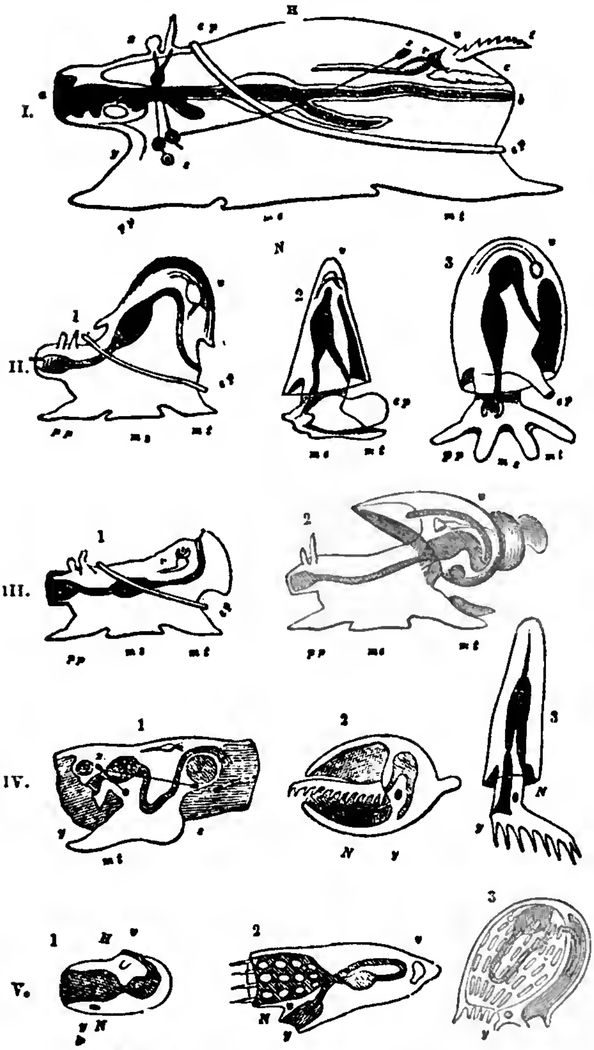
There are two modes in which the Archetype or Common Plan of any group of animals may be set forth. In the first, the community of plan among the members of each group would be demonstrated; and then, the minor plans thus obtained being compared together, the general Common Plan would be deducible. But this analytical method (which has been carried out to a certain extent for the *Mollusca* by the writer in a Memoir in the 'Philosophical Transactions' for 1852), would require more space and more illustration than can here be devoted to it; we must, therefore, take the opposite course, and, assuming a Common Plan, trace out its modifications in the subordinate plans, and explain the laws by whose operation they are affected.

The assumed Common Plan or Archetype of the *Mollusca* may be represented by *fig.* 1, I.:—

This figure is supposed to be bilaterally symmetrical, and the following parts and regions are to be distinguished in it: —(*H*). The Hæmal Region, or that upon which the heart is situated, and which corresponds with what is commonly termed the dorsal region. The word dorsal, however, is vague, being used in different senses in various divisions of the animal kingdom, and should therefore be abandoned in philosophical anatomy. For the same reason, the opposite region (*N*) is termed, not ventral, but Neural, inasmuch as it is the region in which the great centres of the nervous system are placed. The termination (*a*) is the anterior or oral; the end (*b*), the posterior, or anal. Between these extremities the intestine takes a straight course. The neural surface is that upon which the majority of Molluscs move, and by which they are supported; and it is commonly modified to subserve these purposes into a muscular expansion or disc called the Foot. Three regions again, often very distinctly divided from one another, may be distinguished in this foot:—an anterior, the Propodium (*pp*); a middle, the Mesopodium (*ms*); and a posterior, the Metapodium (*mt*). In addition to these, the upper part of the foot or middle portion of the body may be prolonged into a muscular enlargement on each side, just below the junction of the hæmal with the neural region—the Epipodium (*ep*). The mass of the body between the foot proper and the abdomen, or post-abdomen, which bears the Epipodium, and whose limits cannot very well be defined, though it would be very convenient to have a name for it, may be termed the Mesosoma (mid-body); and for what is loosely called the head the name Prosoma might advantageously be adopted. On the upper part of the sides of the head or Prosoma are two pairs of organs of sense: the Eyes (which may be supported on pedicles—Ommatophores), and the Tentacles. In the hæmal region the integument may be peculiarly modified and raised up at its edges into a free fold, either in front of or behind the anus, and when so modified it is called a Mantle (Pallium). In front of the anus again the Branchiæ (*t*) project, as processes of the hæmal region. Among the internal organs we need only point out the position of the Heart (*u*, *v*), which lies in front of the branchiæ in the hæmal region; and the

Nervons Ganglia (x, y, z), of which there are three principal pairs arranged around the alimentary canal, which they encircle by means of their commissures.

Fig. 1.



I. The Ideal Archetype or Common Plan of the *Mollusca*.

II. Its modifications in consequence of the development of an abdomen and consequent neural flexure of the intestine. 1, Hypothetical; 2, Pteropod; 3, Cephalopod.

III. Modifications resulting from the development of a post abdomen and consequent hæmal flexure. 1, Hypothetical; 2, Pectinibranchiate Gasteropod.

IV. Primarily neural flexure modified by subsequent changes. 1, Lamellibranchiate Mollusc; Neural *Molluscoida*. 2, Brachiopod; 3, Polyzoon.

V. Hæmal *Molluscoida* (Ascidians). 1, simple hæmal flexure, as in *Appendicularia*; 2, after hæmal flexure the intestine is bent back, and an atrium is formed; the branchial sac remains comparatively small; 3, the branchial sac comparatively large.

a, oral aperture; *b*, anal aperture, or extremity of the intestines; *c*, renal organ; *pp*, propodium; *ms*, mesopodium; *mt*, metapodium; *ep*, epipodium; *t*, branchiæ; *u*, auricle; *v*, ventricle; *x*, cerebral ganglia; *y*, pedal ganglia; *H*, hæmal region; *N*, neural region.

[The letters have the same signification in these and all the other figures, with the exception of figure 10.]

Such is the Common Plan of which all Molluscs whatsoever may be regarded as modifications; the next question is, to consider the laws according to which the plans of the great snb-classes of the *Mollusca* may be derived from it.

2. *Modifications of the Common Plan.*—The structural peculiarities of all known Mollnscs may he very simply accounted for by the excessive or defective relative development of certain regions in the Archetype, more particularly of one or other parts of the Hæmal Region. Of this region the portion which lies in front of the anus may be conveniently termed the Abdomen, while to that which lies behind it the term Post-Abdomen may be applied. Now, if it be snpposed that the Ahdomen grows out of proportion to the rest of the body, constituting a kind of prominence, and that the intestine passes into the outgrowth so as to form a sort of loop (II.), it is clear that the open angle of this loop will be turned towards the Neural snrface; and the intestine may be appropriately said to have a Neural flexure. On the other hand, if it be snpposed that the Post-Abdomen grow out in the same way, and draws into itself a loop of the intestine, then the open angle of the loop will he in the opposite direction, that is, it will be directed towards the Hæmal surface; the intestine therefore may in this case be said to have a Hæmal flexnre (III.). It will be readily nnderstood that either Abdomen or Post-Abdomen may develop a mantle or not, and that the existence or absence of this mantle has nothing to do with the essence of the change in qnestion, however mnch it may affect the external appearance of the resnlting form.

Again, the extent to which the Abdomen or Post-Abdomen is developed, may have a great influence on the relative position of certain organs of the Mollusc. Thus, in the first place, the position of the anns may hecome greatly altered. When there is a neural flexnre it will acqnire a direction towards the nenral surface and backwards, the final approximation to the oral end depending on the amount of the development of the abdomen on the one hand, and that of the neural region on the other. Again, if the outgrowth of the abdomen take place, not symmetrically, hut more or less on one side of the median line, the final position of the anus will be towards the opposite side and to the right or left, as the case may be.

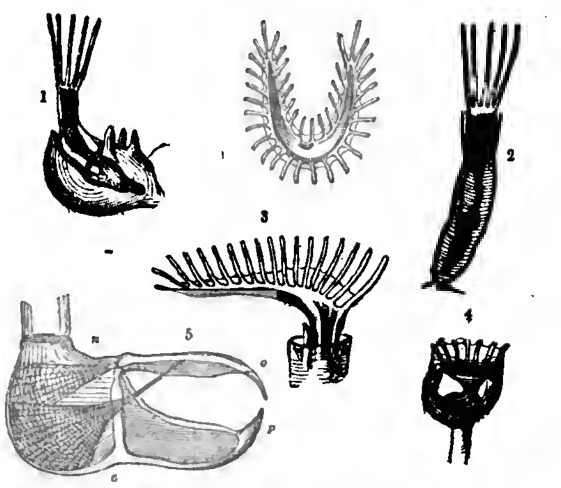
It is even conceivable (this amount of modification indeed actnally obtains in natnre) that by an exceedingly one-sided development of the abdomen, the anns may be thrust quite ronnd on to the hæmal side. Its final position therefore must not be regarded as certainly indicative of the direction of the flexnre by which it ohtained this position. Where there is a hæmal flexnre again, the direction of the anns will be normally towards the hæmal (that is, dorsal) side, and forwards; its approximation to the head, its asymmetrical position, and the amonnt to which it may be thrust backwards and towards the nenral side, depending npon conditions of the same order.

It is not merely the anns which is affected by these changes however; the branchiæ (and the heart which follows them) nndergo similar transpositions, whose nature and origin it is very necessary to nnderstand, in order to appreciate their value as organic characters. M. Milne-Edwards long since pointed out the singular fact that, in certain Molluscs, the branchiæ are in front of the heart, while in others they are behind it. The latter he termed *Opisthobranchiata*, the former, *Prosobranchiata*. It will be seen that our Archetype is Opisthobranchiate. Now, it is easy to understand that if an Ahdomen were developed in front of the heart, without involving the cardiac region, the Mollusc would remain opisthobranchiate; if however it were more extensively developed, so as to involve the heart and branchiæ, the heart, from having been in front, wonld eventually take a position posterior to the branchiæ, and the Mollusc wonld thns hecome prosobranchiate. So, with regard to the development of a Post-Abdomen; its effect on the position of the heart and hranchiæ would depend wholly on the extent of hæmal surface which it involved. It follows, therefore, that Opisthobranchism may co-exist with either a hæmal or a neural flexnre, or with none; while Prosohranchism indicates one or the other, bnt not which; and that these organic characters, however valuahle, are secondary to and therefore of less importance than the neural and hæmal flexures (that is, development of an abdomen or post-abdomen), on which they depend. Dealing with the facts furnished by adult structure alone then, there are two primary modifications of the Molluscan Archetype, which may he shortly termed the Neural and Hæmal Plans. The *Cephalopoda*, *Pulmonata*, *Pteropoda*, *Lamellibranchiata*, *Brachiopoda*, and *Polyzoa*, are the molluscs which present modifications of the Neural Plan. The *Heteropoda*, *Gasteropoda*, *Tectibranchiata*, *Inferobranchiata*, *Cyclobranchiata*, *Tubulibranchiata*, *Nudibranchiata*, and *Ascidioida*, are those which present modifications of the Hæmal Plan.

3. *The Neural Plan and its Principal Modifications.*—Milne-Edwards has proposed a division of the *Mollusca* into the *Mollusca* proper, and the *Molluscoida* (*Mollus-coides*), including under the latter class those Polype-like forms, the *Polyzoa* and the *Ascidioida*. Believing that the *Molluscoida* are as truly and wholly Molluscan as any other *Mollusca*, we nevertheless consider the distinction drawn by the eminent French naturalist to be very important, and that it should be retained as a primary snhdivision of the great Hæmal and Neural Divisions. In the hæmal division the limits of the *Molluscoida* are the same for us, as for M.

Milne-Edwards; but in the neural we include somewhat more. In fact, if the most fitting definition for this sub-division be those Molluscs which have the neural region comparatively little developed, and the nervous system reduced to a single or at the most a pair of ganglia, while the mouth is usually surrounded by a more or less modified circlet of tentacles, then we shall find that, in the neural division we must include the *Brachiopoda* with the *Polyzoa*. Commencing our study of the morphology of the special groups of the *Mollusca* with the Neural Division; and with the *Molluscoid* sub-division of the neural forms, we have to consider first, the *Polyzoa* and the *Brachiopoda*;—

Fig. 2.



Polyzoa.—1, *Membranipo* . 2, *Bowerbankia*. 3, *Plumatella*. 4, *Pedicellina*. 5, *Avicularium*.

The *Polyzoa*.—Conceive the abdomen of the Archetype to be greatly prolonged, the neural region with its appendages, the organs of sense and the heart remaining undeveloped; so that the anus comes into close apposition with the oral extremity, while the edges of the latter are produced into long ciliated tentacles, and the result will be a Polyzoon, which needs only the power of gemmation to give rise to those composite aggregations which are so characteristic of the group.

The Polyzoic type itself presents five subordinate modifications in the five principal orders of the group:—the *Cyclostomata, Ctenostomata, Cheilostomata, Hippocrepia*, and *Pedicillinida*.

In the first three, the body of the Polyzoon when fully expanded is completely straightened, there being no permanent fold or inversion of the integument. In the last two there is such a permanent inversion.

In the *Cyclostomata* the horny or calcareous deposit in the integument of the abdomen joins the soft parts by an even level edge, and there is nothing which serves as a cover or operculum for the retracted Polyzoon.

In the *Ctenostomata* (*fig.* 2, 2) the margins of that portion of the abdomen which is inverted in the retracted state are produced into a toothed horny sheath, which can be retracted by special muscles, and which serves as an operculum.

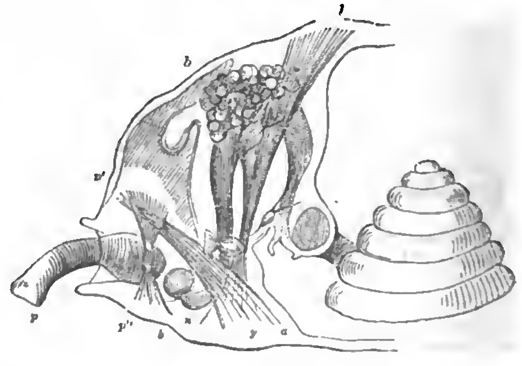
In the *Cheilostomata* (*fig.* 2, 1) the horny or calcareous deposit takes place in such a manner that the hardened integuments of the front portion of the hæmal region constitutes a sort of lid, regularly articulated upon the hinder portion, and provided with proper occlusor (and perhaps levator?) muscles. It should be noted that the anal aperture is directed away from this lid or operculum.

In each of the previous divisions the tentacles are arranged on a circular disc, or lophophore, of whose edges they are prolongations; but in the great majority of the *Hippocrepia* (*fig.* 2, 3), which are all fresh-water forms, the lophophore is so produced into two arms on the anal side as to assume a horse-shoe shape. It is important to consider this in connection with the peculiar features presented by the *Brachiopoda*.

Thirdly, we venture to regard the peculiar genus *Pedicellina* (*fig.* 2, 4) as constituting an order by itself. Essentially a Polyzoon, it is nevertheless distinguished from all other *Polyzoa* by the circumstance that its tentacles are united together by a membrane into a cup, which cup is never protruded far beyond the general boundary of the body.

The *Cheilostomata* are remarkable for possessing two kinds of moveable appendages—*Flabellaria*, whip-like processes, articulated to a bulb containing muscles by which they are moved; and *Avicularia* or bird's-head processes (*fig.* 2, 5). The structure of the latter is of great interest in a morphological point of view, and demands particular attention. They consist of a larger piece, or valve (*p*), shaped like a bird's head, and produced into a longer or shorter process of attachment, to which a smaller valve (*o*), representing the bird's lower jaw, is articulated. Stalked or sessile, these avicularia present during life an incessant snapping action, produced by the alternate contraction of two sets of muscles, which arise from the concavity of the 'skull' of the bird's head by wide fan-shaped origins, and seem to be inserted by narrow tendons into the smaller articulated valve. The one tendon (*e*) is inserted into the smaller valve in front of the line of articulation, and the other (*n*) behind it, and therefore by their alternate action they raise and depress the lesser valve upon the larger.

Fig. 3.



Rhynchonella psittacea.

a, oral aperture; *b*, anal aperture, or extremity of the intestine; *l*, adductor muscles of *Brachiopoda*; *n*, cardinal muscles of *Brachiopoda*; *p*, pedicle; *p' p''*, pedicle muscles; *y*, pedal ganglion.

The *Brachiopoda*.—Now, if we compare the relative positions and mode of articulation of the operculum and cell of a Cheilostomatous Polyzoon, or of the two valves of an avicularium, with those which obtain in the shells of the typical *Brachiopoda*, such as the *Terebratulidæ* and *Rhynchonellidæ*, the resemblance will be found to be very striking; and still more so, if in addition the arrangement of the muscles be taken into consideration. In such a Brachiopod, in fact (*fig.* 3), the shell is composed of two valves—one large, excavated, and produced into a canal or tube, through which a pedicle of attachment passes; while the other is smaller and more or less flattened. The two valves are articulated together by means of a socket in the smaller valve and a tooth in the larger, on each side, the intermediate space being free, just as the operculum of the Polyzoon is united with its cell, or as the lesser valve of an avicularium is articulated with the larger. So likewise the anal extremity of the Brachiopod is turned from the smaller valve. Then the arms of the Brachiopod are essentially comparable to those of the lophophore of a Hippocrepian Polyzoon, except that their direction is different; the calcified supports to which they are fixed in many *Brachiopoda*, are so variable in form and so extensively absent in others, that their existence can in nowise affect the homology of the parts. Again, if we leave out of consideration the pedicle muscles (which are however, in all probability, as Mr. Hancock has shown, the homologues of the retractors of the *Polyzoa*), the arrangement of the other muscles is precisely what we have seen to obtain in the avicularium: the adductors which pass from the larger valve to be inserted into the smaller, in front of its point of support, corresponding precisely with the occlusor muscles of the avicularium; while the cardinal muscles, which arise from the larger valve, and pass to be inserted into the cardinal process of the smaller, behind the point of support, are identical with the divaricator muscles of the avicularium.

The existence of distinct muscles for the purpose of separating the valves of the shell is characteristic of the *Polyzoa* and *Brachiopoda*, the only approximation to such an arrangement at present known among the *Lamellibranchiata* being presented by the *Pholades*.

Finally, if the great proportional size of the *Brachiopoda*, their pedunculated attachment, their thick and solid shells, and their simple forms, be brought forward as arguments against the view we take of their essentially polyzoic nature, we would remind the objector of the like opposition in such features between *Boltenia* and *Botryllus*, or *Aplidium*, among the Ascidians.

Two principal modifications of the common Brachiopod plan are to be observed. In the *Terebratulidæ* and *Rhynchonellidæ*, and in all probability in their extinct allies the *Spiriferidæ*, *Orthidæ*, and *Productidæ*, the muscles are always arranged in three sets—Adductor, Cardinal, and Peduncular. At the same time the mantle (whose homology with the produced edges of the non-retractile part of the abdomen of a Polyzoon is at once appreciable), though divided into two distinct lobes in front, is continuous and entire behind, that is, towards the peduncle. A still more remarkable feature in their organisation is that, at least in *Waldheimia* and *Rhynchonella*, there is no anal aperture, the intestine terminating in a cæcum, directed towards the middle of the large valve.

In the *Craniadæ*, *Discinidæ*, and *Lingulidæ* the muscles have a very different arrangement, which could only be rendered intelligible by detailed descriptions and illustrations, as the homologies of these muscles with those of the other division are not yet determined. The lobes of the mantle again are completely separated (*Discina*, *Lingula*, *Crania ?*), and the intestine opens upon one side of the body between these lobes. There are no teeth, and the articulation of one valve with the other and the modes of attachment vary remarkably; *Lingula* having a long peduncle; *Crania* being attached by the surface of its lower valve; and *Discina* having an aperture in the corresponding valve through which a portion of the adductor passes, and spreading out at its extremity into a sort of plug, acts as a pedicle.

Neural Mollusca.—The *Lamellibranchiata*. In all *Mollusca* proper the neural region is developed to a much greater extent than in the *Molluscoida*, and there are always three pairs of ganglia, two Cerebral, two Pedal, and two Parieto-Splanchnic (or branchial). The especial characters of the *Lamellibranchiata*, as modifications of the Archetype, are the following:—The hæmal region is well developed in its abdominal portion, but forms no prominent sac-like abdomen, into which the viscera enter in the adult condition. Its edges are produced into extensive pallial lobes, which are arranged on each side of a longitudinal plane, and not above and below a horizontal one (or more properly before and behind a transverse one), as in the *Brachiopoda*. The mouth is surrounded by a fringe, representing the tentacles in the *Molluscoida* (as may be well seen in *Pecten*, *fig.* 4, 4) which is produced laterally into elongated 'palps,' but is totally unprovided with any manducatory apparatus. The intestine passing from the stomach either forms a simple loop with a second open angle directed hæmally, or this loop may be much coiled and convoluted: the intestine finally passing over the great posterior adductor and terminating between the lobes of the mantle behind it.

The foot may be more or less largely developed, but never presents any clear distinction into pro- meso- and metapodium, unless indeed, as we are inclined to suspect, the whole free portion of the foot of the *Lamellibranchiata* ought to be regarded as a modified metapodium. Besides the pedal muscles, the Lamellibranchs possess one or two characteristic muscles—the adductors, which approximate the valves of the shell, and whose greater or less development seriously affects the ultimate form of the animal.

The gills deviate but little from their archetypal form and position in some Lamellibranchs, such as *Trigonia* and *Pecten*, being merely thrown downwards by the development of the mantle. In *Nucula* (*fig.* 4, 3), their inner edges are united posteriorly, but they remain comparatively small. In the majority of Lamellibranchs, however, the gills are exceedingly large in proportion to the rest of the body, and consist of two double plates, which are united with the mantle and with one another, in such a manner as to divide the pallial cavity into two chambers, a supra- and infra-branchial, which communicate only by the passage between the anterior edge of the branchiæ and the foot, and by the multitudinous perforations in the branchial plates themselves.

It is in the absence of external organs of sense or of any buccal masticatory apparatus, and in the peculiar arrangement of the gills, that the main difference between the *Lamellibranchiata* and the *Gasteropoda* lies; and hence the great resemblance which the ideal section of a typical Lamelli-

branch bears to a typical Gasteropod. Compare (*fig.* 4) 4 with 1, 3, and 2.

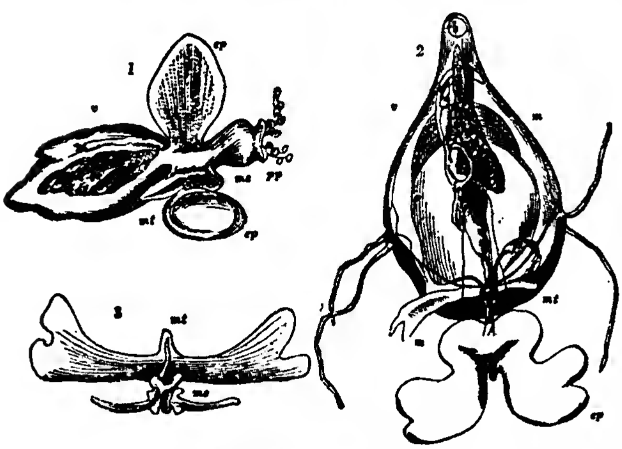
It may seem at first sight inconsistent with our own principles to consider as neural molluscs these Lamellibranchs, which confessedly have the principal loop in the intestine open to the hæmal side. But the position of the largely-developed mantle, completely in front of the anal aperture, and the direction of the aortic end of the heart, unchanged from what is observable in the Archetype, are sufficient, apart from developmental considerations, which will be adduced by and bye, to prove that the second flexure of the intestine in this case is to be considered accidental, the result of the great development of the mesosoma, to serve as a chamber for the viscera, and of the enlargement of the great posterior adductor, thrusting up the rectum which passes over it.

As for the leading varieties of form of the Lamellibranchs, there are none which, in reality, depart very widely from the Common Plan. Perhaps *Teredo* or *Pholas*, on the one hand, and *Ostræa*, on the other, may be regarded as the extreme forms, the former being as much as possible elongated longitudinally, the latter attaining the extreme of concentration about a centre. At the same time there is a reduction of parts to a minimum, as shown in the absence of a second adductor, and of any foot in the adult state. The differences between these forms are, however, decidedly less than those which may be observed between the extreme forms among the *Cephalopoda* or *Gasteropoda*.

The *Pteropoda* and *Pulmonata*.—The Lamellibranchs are, as we have said, curiously exceptional in presenting the general features of the *Mollusca* proper, without that singular buccal apparatus which we meet with in all other members of the subdivision, whether neural or hæmal, and whose peculiar nature is described below. Again, they are exceptional in the vast development and symmetrical longitudinal division of their mantle, and in the corresponding division of their pallial shell into two pieces or valves—characters we shall not meet with again in any modification of the Common Plan.

In the *Pteropoda* and *Pulmonata* the mantle is never developed into such lateral lobes, and the shell to which it gives rise never consists of two pieces, but is constituted by a single mass, which either has the form of a flat plate or presents some modification of a cone. Again, the foot (or some part of it) is always well developed, presenting no obvious distinction into regions in the *Pulmonata ;* but in the *Pteropoda* often exhibiting a well-marked meso- and metapodium, and always presenting a characteristically large epipodium—an organ which in these Molluscs constitutes the so-called 'wings,' from which their name is derived.

Fig. 5.



Pteropoda.—1, *Pneumodermon*. 2, *Cleodora*. 3, *Psyche* (foot and head only). Letters as in figure 1.

There is usually a well-developed mantle in the *Pteropoda* and *Pulmonata*, and its walls act as a branchial surface without being produced into true gills—(*Hyalæa ?*)—the sea-water in the marine *Pteropoda* and the air in the terrestrial and aquatic *Pulmonata* being inspired and expired into its cavity.

In the *Pteropoda* in general, the aperture of the pallial cavity and that of the anus, are situated upon the posterior surface of the body, in accordance with the neural flexure of the intestine. The anal aperture however is usually thrust to one side of this surface, and, in *Limacina* and *Spirialis*, this lateral thrust has taken place to such an extent, that not only the anal aperture, but that of the mantle cavity, is thrown up completely on to the dorsal surface. This laterodorsal, or dorsal position of the anal and respiratory apertures, is as regular in the *Pulmonata* as it is exceptional in the *Pteropoda*.

In the *Pteropoda* and *Pulmonata* some most important modifications of form are produced by the greater or less development of the mesosoma on the one hand and of the mantle on the other. The predominance of the latter is to be observed in such forms as *Criseis*, *Cleodora*, *Hyalæa*, and *Helix ;* while the former may be seen in *Pneumodermon* and in *Limax*. In the latter the mantle is very small, and in the former it is almost if not entirely absent; what is ordinarily considered as the mantle in this mollusc being in fact nothing more than the mesosoma. The like confounding together of parts so essentially different has taken place, we shall find, in the *Nudibranchiata* and in the *Heteropoda*.

The *Cephalopoda*.—In the Pteropod forms, *Pneumodermon* and *Clió*, a hood, giving off long processes covered with suckers from its inner surface, surrounds the oral aperture, and there is every reason to believe corresponds with the propodium, whose lateral halves have united over the mouth. If the like process were to take place in a *Criseis*, but to a greater extent, so that the mouth were thrust back between the halves of the mesopodium, and the propodium and mesopodium formed one continuous tentaculigerous sheath around the oral aperture; and if at the same time the two halves of the epipodium united posteriorly into a funnel-shaped tube, the *Criseis*, so far as its external organisation goes, would no longer be a Pteropod, but would have become a Cephalopod. In fact, the Cephalopod may be derived from the Archetype by supposing these modifications. The mantle is always well developed, and its cavity incloses one or two pair of gills. The two halves of the epipodium are united behind into what is called the funnel, a peculiar apparatus, of great importance in the economy of many Cephalopods; and in the majority of the group the sides of the foot, having united in front of, and forming a complete sheath for, the head, are produced into eight or ten processes, the so-called arms, on which are set the acetabula, or suckers.

Fig. 6.

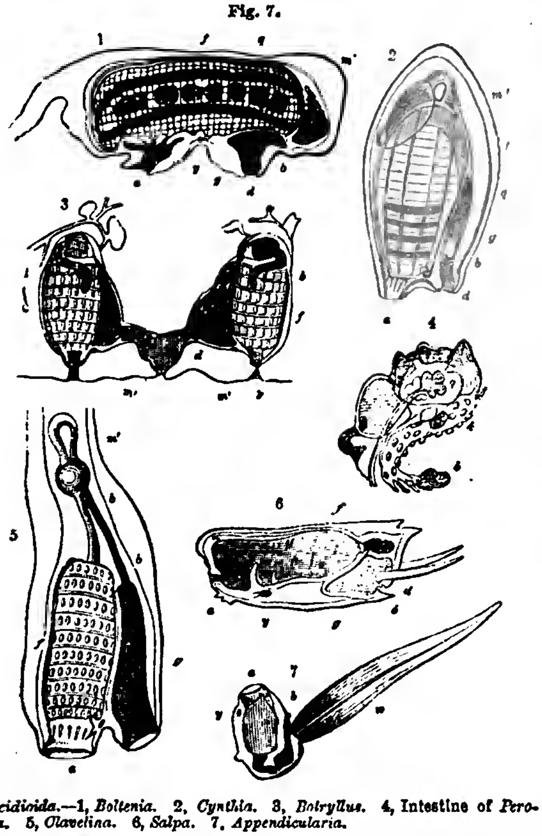
a, oral aperture; *b*, anal aperture, or extremity of the intestine; *m*, mantle; *m'*, shell; *x*, cerebral ganglia; *y*, pedal ganglia; *z*, parieto-splanchnic ganglia; *ep*, funnel.

Beyond this peculiar arrangement and development of the external organs, we are not aware that any characters exist by which the *Cephalopoda*, as a class, can be distinguished from the other *Mollusca*. Among themselves they present a remarkable harmony, differing chiefly in the number of their branchiæ, in the internal or external position of their shell, and in the nature of the appendages into which the edges of the foot are modified—characters which do not attain to ordinal importance in other divisions of the *Mollusca.*

Having thus glanced at all the leading modifications of the Neural Plan, we may next turn to the Hæmal Plan, commencing with its Molluscoid modification constituted by the *Ascidioida* alone.

The *Ascidioida.*—As a Molluscoid group, the Ascidians are characterised, in the first place, by the rudimentary condition of their whole neural region, and by the reduction of their nervous system to a single infra-œsophageal ganglion. Besides these, however, their organisation presents certain characters which appear at first sight very remote from such a Common Plan as has been described, and hardly deducible from it. An Ascidian, in fact, is usually fixed by one extremity of its body, and presents at the other two apertures. One of these leads into a wide cavity, whose entrance is fringed with a circlet of tentacles, and whose walls (except along the middle line anteriorly and posteriorly) are perforated by innumerable ciliated apertures, and often thrown into folds, by which their surface is greatly increased. At the bottom of this cavity—the branchial sac—a second wide aperture leads into the alimentary canal, which invariably presents a hæmal flexure, and then almost always bends backwards neurally to terminate in a second wide cavity. This, the *atrium,* whose more external portion is usually termed the *cloaca,* opens externally by the second or cloacal aperture, and extends along each side of the branchial sac up to its median line of attachment—communicating freely with its cavity by means of the small ciliated apertures which have been mentioned. The single ganglion lies between the oral and cloacal apertures.

Fig. 7.



Ascidioida.—1, *Boltenia.* 2, *Cynthia.* 3, *Botryllus.* 4, Intestine of *Perophora.* 5, *Clavelina.* 6, *Salpa.* 7, *Appendicularia.*

a, oral aperture; *b,* anal aperture, or the extremity of the intestine; *d,* cloacal aperture and atrium; *f,* branchial sac; *g,* hypo-pharyngeal band; *m',* test; *q,* genitalia; *y,* pedal ganglia.

Now, in what manner is this form derivable from the Archetype? It is to be remarked, in the first place, that the pharynx, large in the *Polyzoa,* becomes comparatively enormous in the Ascidians; while the tentacles, which were very large in the *Polyzoa,* are in the Ascidians comparatively small. Next, with the development of a post-abdomen, the intestine acquires a hæmal flexure; but instead of the anal aperture remaining on the hæmal side, it is bent round, by the same process as in *Spirialis* and *Limacina,* but in the inverse direction. Suppose with all this that a mantle has been developed, and that its free margin remaining small and narrow, has followed the anus to the neural side, while its cavity has extended up on each side of the pharynx to the middle line of the hæmal surface of the latter, carrying to a great extent a process of which the outline may be seen in *Cymbulia,* and giving rise to the atrium;—imagine also that the sac thus constituted externally by the inner surface of the mantle (third tunic), and internally by the pharynx, becomes perforated by minute apertures—and the result would be an Ascidian.

Such is the manner in which the Ascidian type is derivable from the Common Plan. Of this type the group presents three subordinate modifications. The first is that presented by the extraordinary and instructive genus *Appendicularia* (*fig.* 7, 7), which in a manner represents permanently the larval state of the more perfect members of the group—swimming by means of a long rapidly-vibrating tail, like that of a tadpole. In *Appendicularia* there is no cloacal aperture or atrium. The mouth opens into a wide pharynx representing the branchial sac of other Ascidians; from this a gullet leads into the stomach. The narrower intestine passes from the stomach, forwards and to the hæmal surface, where it terminates without bending downwards, and without being surrounded by any special cavity. *Appendicularia* therefore might be said to be a form in which the process of modification of the Molluscan Archetype into the Ascidian Type is arrested half way.

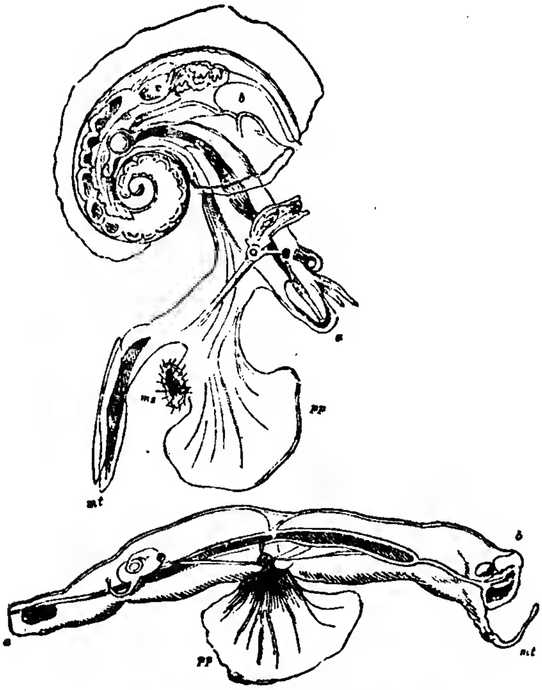
In all other Ascidians this process is complete, and there is a distinct cloacal aperture and atrium; but these forms again may be arranged under two great sub-typical modifications, according to the development of the branchial sac relatively to that of the post-abdomen. In such forms as *Cynthia, Boltenia, Perophora, Botryllus,* the branchial sac attains so great a proportional size as to occupy the whole, or nearly the whole, length of the body, the intestine lying on one side of it: these might therefore be well denominated *Ascidiæ Branchiales,* Branchial Ascidians. On the other hand, in *Clavelina, Aplidium, Polyclinum, Salpa,* the alimentary canal lies completely behind the branchial sac, which is proportionally small, and these might therefore be termed *Ascidiæ Intestinales,* Intestinal Ascidians. A very complete mutual representation will be found to obtain between the members of these two groups.

Hæmal Mollusca.—In passing from the Hæmal *Molluscoida* to the Hæmal *Mollusca,* we find the same new features presenting themselves as in the Neural Division, the transition being even more abrupt, from the absence of any representative of the *Lamellibranchiata.* In all these *Mollusca,* in fact, there is a more or less well developed foot; a distinct head, with its organs of sense and buccal armature; and three pairs of ganglia—cerebral, pedal, and parieto-splanchnic.

The modification of the Common Plan is carried to a less extent in this than in the Neural Division, the chief varieties of its forms depending on the changes in the shape of the shell with which the majority are provided; on the greater or less development of the different regions of the foot; but most of all in the relative proportions of the mesosoma and mantle.

If we divide the Hæmal *Mollusca* into two great groups—the one consisting of the *Heteropoda, Scutibranchiata, Tubulibranchiata, Pectinibranchiata,* and *Cyclobranchiata,* families, which are most intimately allied, and which are connected as a group by the diœcious arrangement of their reproductive organs; and the other of the *Nudibranchiata, Inferobranchiata,* and *Tectibranchiata,* families in like manner united, among other characters, by their common hermaphrodism, then we shall find in each such group two extremes of form—the one resulting from the great development of the pallial region, the other from that of the mesosoma. In the Diœcious Division, *Dentalium, Vermetus, Atlanta,* and the ordinary *Pectinibranchiata* may be regarded as examples of the former case; and in the Monœcious Division the *Inferobranchiata* and *Tectibranchiata;* while the mantle becomes rudimentary or absent altogether in the Diœcious *Firoloides,* in the Monœcious *Phyllirhoë,* and the *Nudibranchiata* in general, where the region from which the so-called branchial processes arise, and which is commonly called the mantle, is not the homologue of the mantle of *Atlanta* for example, but of its mesosoma, which here, as in *Firoloides*, constitutes the main portion of the body.

Fig. 8.

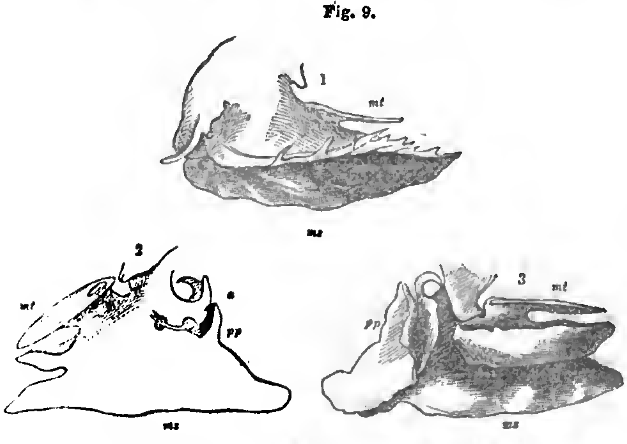


Heteropoda.—8, *Atlanta*; 9, *Firoloides*.

a, oral aperture; *b*, anal aperture, or the extremity of the intestine; *mt*, mantle; *ms*, mesopodium; *pp*, propodium; *v*, ventricle.

The foot in the Monœcious Hæmal *Mollusca* rarely presents any special development of its different regions, except that in certain forms—namely, *Aplysia* and *Gasteropteron*—the epipodium is as well marked as in the *Pteropoda*, and serves the same end in locomotion. This is well known in *Gasteropteron*, and we have seen a tropical *Aplysia* 'fly' through the water in precisely the same way as a Pteropod would do. These epipodial lobes have been frequently called mantle, although the true mantle is a most distinct and obvious structure.

Fig. 9.



Foot of *Pectinibranchiata*.—1, *Trochus*; 2, 3, *Natica*.

a, oral aperture; *mt*, metapodium; *ms*, mesopodium; *pp*, propodium.

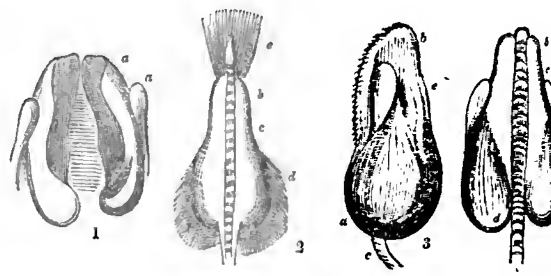
In the Diœcious group the epipodium is never well developed, presenting itself at most under the form of little lobes and processes—at least it would seem probable that the neck-lappets and head-lappets of the *Trochidæ* are rudiments of the epipodium. On the other hand, it is in this group that the propodium, mesopodium, and metapodium attain their most complete and distinct form; as in *Atlanta*, where the propodium constitutes the anterior flattened fin, the mesopodium the rounded sucking disc, and the metapodium extends backwards, as the tail-like lobe which carries the operculum. In *Firoloides* we find that the mesopodium has vanished, and the metapodium has taken the form of a mere filament, while the propodium constitutes the great swimming fin.

In the ordinary *Pectinibranchiata*, on the other hand, the foot may not be differentiated into its subdivisions at all, the metapodium being marked only by the position of the operculum, when this exists, as in *Buccinum*. In other cases, as in *Oliva* and *Sigaretus*, a deep cleft marks off a very distinct propodium from the conjoined mesopodium and metapodium; in others, as in *Pteroceras*, the metapodium is as specialised as in *Atlanta*; while again, in such forms as *Natica*, the three constituent parts are distinguishable—the propodium constituting the hood in front of the head; the mesopodium the creeping disc; and the metapodium the operculigerous lobe. (*Fig.* 9.—2 and 3.)

Having thus passed in review those modes of arrangement of the various organs of the *Mollusca* which constitute the Common Plan of the group and the subordinate plans of its leading subdivisions, we have next to consider the peculiarities presented by these organs themselves, or, in other words, those more striking features in which the organs of the *Mollusca* differ from those of the *Vertebrata*, *Annulosa*, and *Radiata*. The most important organs, in this point of view, are those of—1, the Alimentary; 2, the Circulatory; 3, the Respiratory; 4, the Renal; and 5, the Nervous System.*

1. The Alimentary Organs, in certain *Mollusca*, present two kinds of apparatus which are met with in no other division of the Animal Kingdom. The first of these is that peculiar manducatory instrument usually called the 'tongue,' which is possessed by all the *Mollusca* proper, except the *Lamellibranchiata*; and for the first description of whose true structure and mode of action we are, we believe, indebted to Mr. Thompson (see article 'Tongue,' in the 'Cyclopædia of Anatomy and Physiology'), although the organ itself had been more or less an object of attention ever since the time of Cuvier.

Fig. 10



Tongue of *Patella*.

1. *a a*, the cartilaginous plates which constitute the pulley over which the elastic plate 2, *b*, supporting the series of teeth *c*, plays; *d* and *e* are the anterior and posterior insertions of the intrinsic muscles of the tongue. 3 is a side view, and 4 a view from above, of the entire apparatus.

The tongue is essentially composed of a cartilaginous mass, with a pulley-shaped upper and anterior surface, which projects from the bottom of the oral cavity. An elastic plate plays over the pulley, and is attached at each end to muscles which arise from the upper and lower surfaces of the cartilaginous mass. Along the middle line of this elastic plate successive transverse series of strong recorved teeth are set—new ones being continually formed behind as the old are worn away—in a sort of persistent dental sac.

When the tongue is brought into play it is protruded by appropriate muscles from the cavity of the mouth, and its extremity is firmly applied against the body to be rasped. The superior and inferior sets of muscles, which are inserted into the corresponding ends of the elastic plate, now contract alternately, and the resulting action is precisely that of a circular saw. It is by means of this apparatus that the Carnivorous *Mollusca* bore through the shells of the animals upon which they prey; and perforated shells, which have been thus emptied, abound on every coast.

The other appendage of the alimentary canal peculiar, so far as we at present know, to the *Mollusca*, is what is termed the Crystalline Style, a transparent, usually elongated body, which projects by one end into the stomach, and is lodged for the rest of its extent in a sac formed by a diverticulum of

* Our limits preclude the consideration of the tegumentary and genital systems, whose peculiarities, however, are less exclusively Molluscan.

that organ. The Crystalline Style is found in a great number of Lamellibranchs (to which group it has erroneously been supposed to be confined), but has hitherto been observed in only a few Pectinibranch *Mollusca*, such as *Pteroceras*, *Strombus*, *Trochus*, and *Murex*. Its function is wholly unknown.

Among the alimentary appendages, the Liver in one group, the Ascidians, departs sufficiently from the ordinary plan to deserve particular notice. In these animals (*fig.* 7, No. 4, *k*) it always consists of a series of narrower or wider anastomosing tubules, commencing in cæca upon the outer surface of the intestine, which they envelop in a close network, and terminating by a narrow duct in the stomach. In the *Botryllidæ* the hepatic tubules are remarkably wide.

2. The nature of the Circulatory System in the *Mollusca* is at present in some respects a vexed question, more especially as regards the important point whether they possess a true closed system of vessels or not. Without entering into any discussion of the various arguments used on both sides of a dispute which is in some respects verbal, we may be permitted shortly to state our own conclusions on the subject.

In the *Polyzoa* there are no special circulating organs, if we except the cilia with which the perivisceral cavity is often lined, and which keep up a continual current in the perivisceral fluid; nor do we imagine that any one will insist that in them the perivisceral cavity is not a sinus, but has a truly venous lining membrane.

In the *Ascidians* there is a heart, but it is a simple muscular sac, open at each end, and possessing the extraordinary power of reversing the direction of its contractions, and thus circulating its blood first in one way and then in the opposite. The blood thus poured out is driven through channels in which assuredly no separate lining membrane is demonstrable. Indeed it is difficult to comprehend how any one with a living Ascidian under his microscope can question that here, at any rate, the circulation takes place through lacunæ, and not through vessels with distinct walls.

In the *Brachiopoda* a very remarkable vascular system has been said to exist, consisting of two hearts (in *Rhynchonella* of four), each composed of an auricle and a ventricle; the former being in free communication with the perivisceral venous sinuses (perivisceral cavity, *nobis*), while the latter ends in an aorta, whose branches undergo a regular distribution. Such is the circulatory system in the *Brachiopoda* according to Professor Owen; but our own inquiries have tended to strengthen very greatly the doubts first raised by Mr. Hancock as to the true nature of this so-called circulatory system. It fact these inquiries lead us to doubt whether the so-called 'hearts' of the *Brachiopoda* have anything at all to do with the circulating system; inasmuch as, in the first place, we are pretty confident that no 'arteries' are given off from the apices of the 'ventricles,' as has been said, and think it more than probable that they open externally. Secondly, there is no evidence at present, either indirectly from structure or directly from observation during life, that the so-called 'hearts' of any Brachiopod are contractile. Thirdly, the multiplication of these hearts to four in *Rhynchonella* seems not a little to militate against their cardiac nature.

We may fairly conclude then that, for the present, the nature of the circulatory system in the *Brachiopoda* must be regarded as an open question.

Mollusca Proper.—The doctrine first advocated by M. Milne-Edwards that in these Molluscs the circulating system is always more or less incomplete, has met with a wide acceptance, but also with no small opposition. So far as the minute transparent Molluscs, which can be submitted to direct microscopical observation during life, are concerned, we do not understand how the truth of M. Milne-Edwards's doctrine can be questioned. If the term 'venous lining' is to have any meaning but a non-natural one, assuredly it cannot be said with truth that anything of the kind exists in the sinuses of *Firoloides*, or of *Atlanta*, or in those of the *Pteropoda*.

In the larger *Mollusca*, on the other hand, much depends on the verbal question—what is the definition of a 'vein,' or 'venous membrane?' If a lamina of connective tissue separable from the surrounding parts be a venous wall, then doubtless the venous blood-channels of many Lamellibranchs and Gasteropods, and perhaps of all Cephalopods, are veins. If on the other hand a greater histological differentiation corresponding to that which exists in the *Vertebrata* be required to constitute a vein, evidence of the existence of anything of the kind in the greater proportion of the venous blood-channels of these creatures is at present wanting.

As regards the grosser structure of the circulatory apparatus in the *Mollusca* proper, it may be observed that, in the *Lamellibranchiata* there is either a single auricle and a single ventricle (*Ostrœa*), a single ventricle and a double auricle (most Lamellibranchs), or two auricles and two ventricles (*Arca*). In all other *Mollusca*, except the *Cephalopoda*, there is a single auricle and a single ventricle. In the *Cephalopoda* the heart is essentially similar to that of the Lamellibranchs, inasmuch as it consists (in the *Dibranchiata*) of a single ventricle and of two contractile, so-called 'Branchio-Cardiac Veins,' which represent the two auricles of the Lamellibranchs. The circulation in these creatures is assisted (at least in *Loligo media*, in which we lately had opportunities of convincing ourselves of the fact), not only by the regular contraction of the so-called 'branchial hearts,' which are dilatations of the afferent branchial veins, but by that of the gills themselves.

The nature of the so-called Pericardium in the *Mollusca* has been much misunderstood. It is most important to recollect that in no case is there evidence of its being a closed serous sac, comparable to the pericardium of the higher animals. On the contrary, wherever it has been examined with sufficient care (*Lamellibranchiata, Pteropoda, Heteropoda, Nudibranchiata,* and *Cephalopoda*), it has been found to be a blood-sinus, which in some cases (*Pteropoda, Cephalopoda* (?), *Lamellibranchiata* (?), and *Heteropoda*) communicates with the exterior by the mediation of the renal organ.

3. The Respiratory Function is performed by modifications of several distinct parts in the *Mollusca*.—1. By the general surface of the pallial cavity, which may be more or less adaptively modified: this kind of respiratory organ is to be found in the *Brachiopoda*, *Pteropoda*, and *Pulmonata*. 2. By specially modified parts of the walls of the pallial cavity into true gills: the whole tendency of the modification of form which these gills undergo is to increase their surface, and this end, generally speaking, is effected in one of three ways:—*a.* By the development of simple processes, as in *Patella* or *Atlanta*. *b.* The simple processes become ramified, so that the gill eventually consists of a stem with lateral branches, and these again may be subdivided into smaller and smaller branchlets—*Pectinibranchiata* and *Cephalopoda*. *c.* In the *Lamellibranchiata* each gill essentially consists of a stem with lateral undivided branches, and in such forms as *Trigonia* and *Nucula* (*fig.* 4, No. 3, *t*); the branchiæ have precisely this structure. In *Nucula* the lateral branches are comparatively short, but in *Trigonia* they are much longer. In *Pecten* they turn up at their free ends upon themselves and form a close loop, so that the free end takes a position near the fixed extremity; at the same time lateral processes are given off from the branches which unite and connect them together by a very loose and open vascular network. Each gill has thus become a flattened pouch, completely open, both laterally and superiorly; the sides of the pouches are very open, and are constituted superficially by the parallel produced and reflected portions of the gill-branches, and more deeply by the very loose network formed by the anastomosing lateral processes. Now, if we suppose that the reflected portion of the outer gill-pouch adheres to the mantle, while the reflected portion of the inner gill-pouch remains free on each side of the foot, but adheres to its fellow behind the foot, thus forming a complete partition across the pallial cavity, the deep vascular network becoming very close, and giving off vertical septa, by which the pouch becomes divided into successive antero-posterior chambers; then the result will be such a gill as we meet with in the Oyster, the *Unio*, and the great majority of *Lamellibranchiata*. The minute structure of these branchiæ strikingly resembles that of the branchial sac of the Ascidians, as has been long since pointed out by Siebold and others, and has given rise to the prevalent idea that the two organs are homologous. Structural resemblance, however, is in itself no true basis for the establishment of homologies, and here there are abundant means of demonstrating the resemblance to be simply analogical. 3. The 'branchiæ' of the *Nudibranchiata* again doubtless subserve respiration, but they are developed from the mesosoma, and contain the gastro-hepatic processes of the alimentary canal—features by which they are essentially distinguished from true gills. 4. The branchial sac of the Ascidians is, as we have shown, a modification of their pharyngial sac, resembling

the gills of fishes (especially *Amphioxus*) more than any structure to be found in other *Invertebrata* (the nearest approximation perhaps is in the cloacal branchiæ of Neuropterous Larvæ and of some Annelids). Like the wall of the gill-pouch of *Lamellibranchiata*, that of the branchial sac of the Ascidians is fundamentally composed of two elements—a superficial strong framework of branchial bars corresponding with the 'gill-branches,' and a deeper vascular network connecting these. The more obvious peculiarities in the structure of the branchial sac of Ascidians are produced by the plaiting of its wall into the so-called branchial folds, which may vary in number from four (*Cynthia*) to a number so great that the wall of the sac appears crimped (*Phallusia*).

4. The Renal Organs.—The existence of a special organ for the urinary secretion has now been demonstrated in all the great divisions of the *Mollusca* except the *Polyzoa* and *Brachiopoda*. The essential feature of the molluscan kidney is the deposition of a quantity of urinary excretion beneath a free surface, which in all aquatic *Mollusca* is, by some means or other, freely bathed with water. In *Phallusia*, for instance, minute rounded sacs, each clothed with a delicate epithelium, and containing one or many concretions, are scattered over the intestine immediately beneath the lining of the atrial cavity. It is probable that the constant current setting through this cavity carries away some portion of the secretion; but the greater part seems to remain, and eventually coats the whole parietal surface of the atrium. Here the secreting part of the apparatus appears to be out of proportion to the excretory. In the *Pteropoda* and *Heteropoda* the reverse relation would appear to obtain. In these animals, in fact, the concretions have not yet been detected; but the excretory apparatus is an elongated sac, which opens at one end by the side of the anus, and at the other communicates with the pericardial blood-sinus. The sac contracts rhythmically and with great rapidity, so that the blood in contact with its delicate walls must be very effectually washed. How far the internal communication with the blood-sinuses is available for the same end, is not at present understood. In the *Lamellibranchiata* (at least in *Unio*) the pericardial sinus is connected anteriorly with the internal cavities of two spongy bodies—the glands of Bojanus—in which a great quantity of concretionary matter may be detected; on the other hand, the outer surfaces of these glands lie in a cavity which admits the water freely by an opening placed anteriorly close to the genital aperture. This cavity clearly corresponds with the contractile sac of the *Pteropoda* and *Heteropoda*, but no evidence of contractility has yet been observed in it, or in the renal organ itself. Keber also denies that any direct communication exists between the interior of the kidneys and pericardial sinus and the outer sac, but it is somewhat difficult to make sure of this. However this may be, the arrangement of the kidney in *Unio* is very interesting, from its close analogy with what obtains in the *Cephalopoda*, where the 'serous cavities,' which open at the base of the gills and contain the peculiar spongy venous appendages attached to one of their walls, correspond exactly with the excretory sacs of the *Lamellibranchiata*, while the spongy appendages themselves are but the glands of Bojanus in another form. Our limits will not permit of the description of the structure of the renal organ in *Nudibranchiata* and *Pectinibranchiata*, but it might readily be shown to resemble in all essential points that of the *Lamellibranchiata* and *Cephalopoda*.

5. The nervous system of the *Mollusca*.—The *Molluscoida* and the *Mollusca* respectively present a remarkable agreement in the general arrangement of their nervous apparatus, which consists in the *Polyzoa* and *Ascidioida* of a single ganglion placed in the midst of the neural region of the body; in the former case between the oral and anal apertures, in the latter between the oral and cloacal apertures. In the *Brachiopoda* the nature of the nervous system is only known with certainty in the *Terebratulidæ*, where it consists of a single elongated ganglion having the same position as in the *Polyzoa*, sending on each side a commissural branch to surround the mouth, and giving off numerous branches to the mantle. In the *Brachiopoda* no distinct organs of sense have yet been observed, but in the Hippocrepian *Polyzoa* a little tongue-shaped organ projecting from the lophophore close to the ganglion, probably represents the 'languet' of the Ascidians, an organ whose function is not known, but which probably performs, in conjunction with the ciliated sac, the part of an organ of sense. The 'ciliated sac' is, as its name implies, essentially a small ciliated pouch placed between the oral end of the hypopharyngeal band and the

The circles with central dots represent the auditory vesicles.

cs, ciliated sac; *x*, cerebral ganglia; *y*, pedal ganglia; *z*, parieto-splanchnic ganglia.

circlet of tentacles. In the *Cynthiæ*, *Phallusiæ*, &c., it becomes enlarged and twisted upon itself, so that its margin frequently presents a very elegantly convoluted pattern, *fig.* 11, 2, c s. In this form it was described by Savigny as the 'Tubercule Antérieure.' In *Appendicularia* and in the *Salpæ* an otolithic sac is also attached to the ganglion.

In all the *Mollusca* proper the nervous system presents a remarkable uniformity as to its central elements, and remarkable differences in their arrangement. There are essentially three pair of ganglia:—

1. The Cerebral, which supply the eyes and olfactory organ, and give off the nerves to the buccal ganglia where they exist.

2. The Pedal Ganglia, which supply the foot with nerves, and always, save in *Heteropoda* and perhaps some Nudibranchs (where the exception is very possibly only apparent), give off the nerves to the auditory vesicles.

3. The Parieto-Splanchnic Ganglia, which supply the hæmal region of the body and many of the viscera.

There are never more than two pedal and two cerebral ganglia, but the parieto-splanchnic centres would seem to be capable of almost indefinite multiplication. These multiplied centres however may be reduced to two classes—Parietal Ganglia, which give nerves to the sides of the body, and Visceral Ganglia, which supply the heart, branchiæ, &c.

The accompanying diagramatic figures of the nervous systems of Molluscs of all classes, in which the Cerebral Ganglia are marked *x*, the Pedal *y*, and the Parieto-Splanchnic *z*, will render the great changes of position, while the essential parts remain the same, obvious without further description.

For the organs of sense of the *Mollusca* proper we must refer to the articles CONCHIFERA, GASTEROPODA, &c.

4. *The Development of the Mollusca.*—Those conceptions which the philosophical anatomist comprehends under the name of Archetypes, or Common Plans of Animal Forms, must always present a certain value and interest to all who regard anatomy as something more than an exercise of the

memory; but the amount of the value of such conceptions, and of their beneficial influence on the forward progress of science, depends entirely on the extent to which they embrace the whole anatomical peculiarities of a group of animals. Now animals, like all living beings, not only are, but become; and their anatomy, in the widest sense of the term, is to be obtained, not merely by the study of their structure (which is their final anatomy), but also by that of their development, which is the anatomy of the successive states through which they pass in attaining their final condition. Now the Archetype or Common Plan professing to be the embodiment of the most general propositions which can be enunciated with regard to the anatomy of the group, its validity will depend upon its embracing both structural and developmental facts. If it neglect either of these, it will be theoretically imperfect, and will run the risk, at any rate, of being practically erroneous. Before the publication of Von Bär's great work, and unfortunately too often since then, the extant notions of archetypes, unity of organization, &c., were open to precisely this objection, their authors having contented themselves with devising hypotheses to fit the facts of adult structure, without concerning themselves whether their hypotheses would or would not also fit the facts of development. Hence the infinite variety of baseless speculations of the 'Nature-philosophie' school; in botany, the unlimited and quite gratuitous demands upon 'abortion and fusion' of parts which Schleiden has so justly ridiculed; in zoology such notions as that a Cephalopod is a vertebrate animal doubled upon itself, that an Insect is a vertebrate animal with free ribs, &c.

It is precisely on this footing however that at present our Common Plan or Archetype of the *Mollusca* stands. We have before us the evidence which might perhaps have satisfied Geoffroy and Oken. Given our plan and certain laws of modification, and all known molluscan forms may be derived from it; but it remains to be seen how far the evidence which would alone have satisfied Von Bär, the evidence of development, justifies the view which has been taken; how far, in fact, our hypothesis is capable of being elevated to the dignity of a theory.

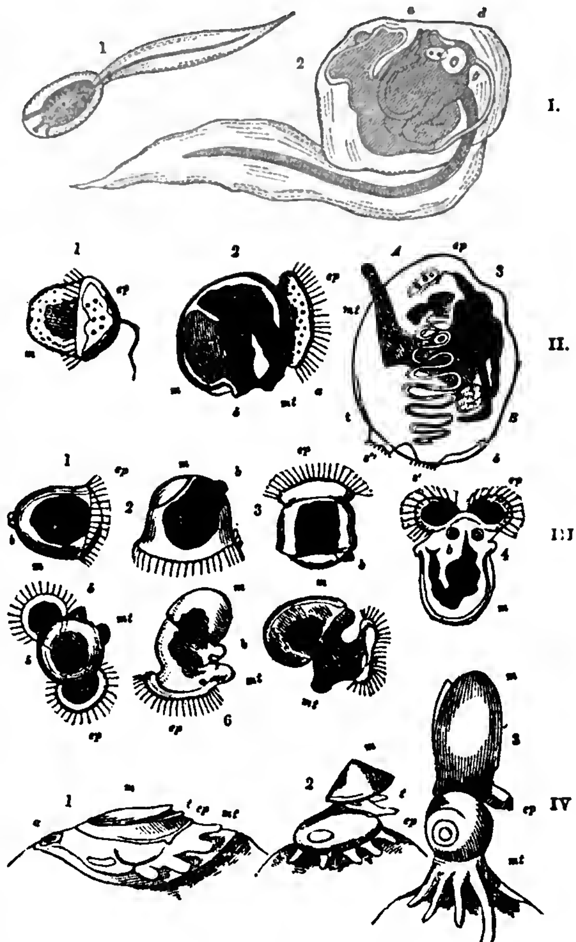
To this end it is by no means requisite to show that every Mollusc has at one time the archetypal form, and is subsequently modified into its persistent condition; to maintain such a proposition it would be necessary greatly to simplify (though not essentially to alter) the archetype, and thus to do away with a great part of its utility in exhibiting the tendencies of every Mollusc. All that appears to be really necessary is to show:—first, that no molluscan form presents features in its development which cannot be reconciled with the archetype; and secondly, that the kind of modifications which have been supposed to take place in the conversion of the archetype into the special types are such as actually occur.

The first stage of development of the *Mollusca* resembles that of other animals. The yelk, at first a homogeneous mass, undergoes the process of division to a greater or less extent, its outermost layers eventually becoming converted into a blastodermic layer, the plastic material out of which the future animal is modelled.

In the *Molluscoida* the rounded or oval embryo thus formed either becomes covered with cilia and swims away as a free form (*Polyzoa Brachiopoda?*), or it gives rise from one portion of its surface to a long fin-like muscular process (*fig.* 12, I. 1.), by whose rapid vibration it is propelled (*Ascidioida*, in great part). With what organ of the *Mollusca* is this 'tail' or 'fin' of the Ascidian larva homologous? This is a very difficult point to ascertain, as the tail arises before the regions of the animal are differentiated. At first sight one might be tempted to consider it as a modification of the velum of the embryos of the *Mollusca* proper; but its relation to the middle of the neural surface, and its insertion close behind the ganglion, which may be readily observed in later stages, appear rather to indicate that it is the homologue of the foot proper, and probably of the metapodium, as this is the portion of the foot which in the *Mollusca* appears first.

In the further development of the *Molluscoida* there can be no question that, as regards the *Polyzoa*, the neural region soon almost ceases to grow, the further increase of the body taking place by the disproportionate development of the hæmal region, which constitutes almost the whole of the body of the adult animal, and presents the surface by which it becomes fixed. Again, simple inspection is sufficient to show that the intestine extends into the great abdomen thus developed; that it acquires herewith a neural flexure; that the tentacles are produced from the margins of its oral aperture; and that the pharynx acquires a large proportionate size.

Fig. 12.



Development of—I. *Clavelina*. II. *Lamellibranch* (Lovèn). III. *Antiopa*. IV. *Sepia* (Kölliker).

a, oral aperture; *b*, anal aperture, or extremity of the intestine; *d*, cloacal aperture and atrium (Ascidians); *ep*, epipodium; *mt*, metapodium; *g*, hypopharyngeal band (Ascidians); *m*, mantle: *s'*, *s''*, anal and branchial siphons (*Lamellibranchiata*); *t*, branchiæ; *A*, anterior adductor (*Lamellibranchiata*); *B*, posterior adductor.

In the *Ascidioida* the neural region remains in a like rudimentary condition, the hæmal region undergoing a similar disproportionate growth; but it is next to impossible to ascertain from the study of development whether this hæmal outgrowth is formed behind the anus or before it, inasmuch as the intestine has acquired its complete hæmal flexure when its parts are first distinguishable.

In the youngest state in which the different organs are distinguishable, the intestine is almost entirely bent up on to the hæmal side of the body; the pharynx is a wide cavity (not wider proportionally however than that of a Polyzoon); the tentacles spring from its margin in exactly the same relative position as in a Polyzoon, and there is no atrial cavity. By degrees the pharyngeal cavity enlarges still more, the tentacles remaining comparatively rudimentary (*fig.* 12, I. 2). Contemporaneously with these changes, the end of the intestine becomes more and more bent down towards the neural surface, and a cavity, which in another Mollusc would be the mantle-cavity, appears around its extremity; a single or two lateral apertures (subsequently uniting into one) are soon formed, and allow this cloacal portion of the atrial cavity to communicate with the exterior. At the same time the atrium extends on each side of the enlarged pharynx, detaching it from the side of the body, and enveloping it just as a serous sac invests the surface of a viscus. Ciliated apertures (at first one or two only on each side) now pierce the wall of the enlarged pharynx, and increase in nnmber until it assumes the structure of the perfect branchial sac. Finally, it depends upon the proportional development of the branchial sac, and of the post-abdomen, whether the adult Ascidian shall belong to the Branchial or to the Intestinal subtype.

We unfortnnately know hardly anything of the development of the *Brachiopoda;* bnt so far as the *Polyzoa* and *Ascidioida* are concerned, it is obvions that the hypothetical modifications of the Archetype do in fact faithfully represent the actnal course of development. (See however the remarks, further on, as to the nature of the post-abdominal ontgrowth in hæmal *Molluscoida* and *Mollusca.*)

Development of the Neural Mollusca.—The *Lamellibranchiata.*—The first step towards the production of the organs from the blastodermic layer in this group is the development of one portion of its snrface into a disc with mixed edges, provided with very long cilia (*fig.* 12, II. 1). Next in the inner snbstance of the germ the intestine appears as a solid mass, bent upon itself, towards what the eventnal development of the foot proves to be the nenral surface; its oral portion being placed immediately behind the ciliated disc (2). Finally, the hæmal surface behind the ciliated disc gradnally gives rise to the two lobes of the mantle, npon each of which a thin transparent pellicle, the first rudiment of one valve of the shell, eventually appears. As development goes on (3), the neural snrface between the primarily approximated oral and anal apertures becomes converted into the large foot and mesosoma of the Lamellibranchs, which serve to lodge the principal mass of the viscera, the abdomen never becoming developed into a great process as in Gasteropods. The great posterior adductor makes its appearance on the nenral side of the intestine, and by its development the latter is thrown up so as almost to appear to have a hæmal flexure. The gills next appear as processes of the body within the mantle-cavity, and therefore have not the remotest homology with the pharyngeal branchial sac of Ascidians, any more than the two siphonal apertures which are essentially dependent upon the union of the two lobes of the mantle with the gills and with one another have anything to do with the oral and cloacal apertnres of the Ascidians.

Finally, it is said that the ciliated disc becomes metamorphosed into the labial palpi. This is a point well worthy of further investigation; for the arrangement and form of the appendages in *Pecten* leads us strongly to believe, as we have said, that they are the homologues of the tentacles in the *Ascidioida* and *Polyzoa.* On the other hand, there can be no doubt that the ciliated disc of Lamellibranchs is homologous with the ciliated lobes of the Gasteropod embryos; and these, there is every reason to believe, are nothing bnt the specially modified anterior portion of the epipodium. The tentacles of the *Polyzoa* would thns come to be the homologues of the epipodium; bnt the validity of the whole chain of reasoning obvionsly depends upon whether the ciliated disc does or does not become metamorphosed into the palpi—a position which the more requires confirmation as in the *Gasteropoda* the ciliated lobes are now known entirely to disappear. However this may be, what has been stated with regard to the main steps in the development of the *Lamellibranchiata* fully confirms the hypothetical derivation of the type from the Common Plan.

Pteropoda and *Pulmonata.*—In the primary stages of their development no important distinction is to be drawn between the members of this division and those of the last, except that in the *Pteropoda* the ciliated disc is replaced by two ciliated lobes, one on each side; and in the Pulmonate embryos by a contractile expansion—their so-called 'yelk-sac.' The primarily neural flexure of the intestine in the *Pulmonata,* and the development of their mantle in front of the anus (that is, the development of an abdomen), are fnlly demonstrated by late observations npon their embryogeny. It is important to remark, that in the *Pteropoda* the ciliated lobes of the embryo do not become the lateral alæ of the adnlt form, but are a production of the anterior part of the epipodium, which usnally disappears in the adult.

Cephalopoda.—In this group the embryo attains a much higher development before leaving the egg, and the modifications which its primary form undergoes are extremely instructive. The first organs of the Cephalopod which appear on the germ-disc are (*fig.* 12, IV. 1) the mantle, which is simply a thickening in the middle of the hæmal surface with somewhat raised edges; around this is a surface representing the mesosoma and foot, at ono end of which is the mouth, and at the other or anal extremity are placed two little processes, the rudiments of the gills. Again, on each side of the mantle the mesosoma is produced into a longitudinal ridge occupying the precise position of the epipodium. As development goes on, the hæmal surface occupied by the mantle grows ont, and becomes a prominent sac, whose free edges detaching themselves more and more for only a short distance anteriorly, but for almost the whole length of the sac posteriorly, give rise to the mantle cavity (IV. 2). The intestine passing into the abdomen thus formed becomes more and more bent upon itself, until at last it makes a complete loop, open towards the nenral side. With all this the epipodium, remaining rudimentary in its anterior region, becomes a free process on each side posteriorly (representing for a time the alæ of a Pteropod), but after a while these processes unite, and form a hollow canal, the Funnel. The changes nndergone by the margins of the foot are not less remarkable; they are produced from behind forwards into four or five digitations on each side, the anterior pair of which stretch in front of the mouth and unite over it; the digitations elongate more and more, and the mouth is in consequence at last placed in the centre of a sort of inverted cone, formed by the foot and its prolongations—the acetabuliferous arms (IV. 3).

Such may be taken as a very short abstract of Professor Kölliker's most valuable 'Entwickelungs-Geschichte der Cephalopoden,' and it is needless to point ont that it is onr hypothetical process of modification of the Archetype into the Cephalopod type, in other words.

The Hæmal Mollusca.—It is unnecessary to consider the development of the separate families of these Molluscs, as the process, as far as we know, is the same in all. We will take that of a Nudibranch (*Antiopa cristata*) as a type, having recently had occasion to go over it with especial reference to the points here under consideration.

The end of the process of yelk-division (which, we may remark in passing, results, not in the formation of 'nucleated cells,' but simply in that of smaller and smaller packets of yelk-granules) in this Mollusc, is the formation of a blastodermic layer investing the remainder of the yelk. The whole embryo next becomes more or less bell-shaped, a sort of rim, with very long cilia, appearing at the broader end, while a minnte prominence is seen at the opposite extremity (III. 1). A straight line drawn from this prominence to the centre of the surface, surrounded by the rim, would have the body of the creature symmetrically disposed around it. On the one surface is a deep pit, formed by the edges of the blastodermic layer; on the opposite a delicate transparent cup, the rudiment of the future shell, and the indicator of the position of the hæmal surface and mantle appears (III. 3). By degrees the hæmal surface becomes more and more prominent, and the shell larger. With this the prominence above referred to is thrust more and more towards the right side, so that its position becomes quite asymmetrical (II. 3, 5). At the same time the ciliated rim from being circular is produced laterally into a lobe on each side—the ciliated lobes; the metapodium makes its appearance behind these as a small prominence; and a delicate operculum is formed npon the metapodinm. The aperture of the mouth may now be observed behind the ciliated lobes and between them and the metapodium; and the internal substance of the germ is seen to present the outlines of an alimentary canal, consisting of a rounded gastro-hepatic mass and a narrower intestine, which turns abruptly forwards and upwards, to end on the right side more or less hæmally in the before-mentioned prominence, whose position has become thus extensively altered. The mantle cavity has begun to appear as a sort of pushing-in of the integument around the anal prominence.

Two things are obvious in this series of developmental changes. In the first place, the primary symmetricality of the embryo; secondly, the gradual asymmetry brought about by the development of that portion of the body which bears the shell, and which is a portion of the hæmal surface.

Now this is perfectly in accordance with our hypothetical derivation of the Hæmal *Mollusca* from the Archetype, and the only point which remains to be proved is, that this over-developed hæmal surface is to be considered as a post-abdomen, that is, as a post-anal portion of the hæmal surface.

This view has been taken in deriving these forms from the Archetype, because it is much the more readily comprehensible, and has many structural facts in its favour; but we are by no means prepared to assert that the post-anal position of the hæmal outgrowth in the Hæmal *Mollusca* may not be a secondary production, the result of a gradual twisting to one side and backwards of a primarily pre-anal outgrowth of the hæmal surface. The facts just detailed with regard to the development of *Antiopa* would favour this view; but, on the other hand, sufficient attention has not been paid to the process of development of other *Gasteropoda* to decide whether it is in these respects identical with that of the Nudibranchs or not. The anatomy of adult Pectinibranchs and Pteropods would lead one to believe that in these forms, at any rate, the hæmal flexure has been direct and primary; and it may be that a careful comparative study of development of the Pectinibranchs and Nudibranchs will lead to the translation of the Nudibranchs to the Neural division, the final hæmal flexure turning out to be a secondary modification. In the absence of sufficiently conclusive studies of this kind, however, we prefer to be guided by structural considerations, and thence to retain the Nudibranchs provisionally among the Molluscs with a hæmal flexure. It will probably be granted that the doctrine of a Common Plan among the *Mollusca*, which has been advanced, will have its value as a guide through the mazes of their varying organisation—even although the details of this first sketch should turn out to be even in many points erroneous.

MOLOSSUS. [CHEIROPTERA.]

MONASITE, or MONAZITE, a mineral with the following composition:—

Oxide of Cerium	26·00
Oxide of Lanthanum	23·40
Thoria	17·95
Phosphoric Acid	28·50
Oxide of Tin	2·10
Protoxide of Manganese	1·90
Lime	1·70
	101·55

It occurs in modified oblique prisms. It has a perfect and brilliant basal cleavage. It is only found in small imbedded crystals. It has a brown or brownish-red colour; subtransparent, or nearly opaque. The lustre vitreous, inclining to resinous. It is found near Platoust in Russia.

MONK, DR. JAMES HENRY, Bishop of Gloucester and Bristol, was born in 1784, and received his early education at Norwich Grammar School and the Charter House. He subsequently entered at Trinity College, Cambridge, of which he became Fellow and Tutor. In 1808 he was chosen to succeed the celebrated Richard Porson as Regius Professor of Greek in the University. It was mainly owing to his efforts that the present system of classical honours at Cambridge was established, and the Pitt Press founded. As a scholar of Porson's school he is best known for his editions of the 'Alcestis' and 'Hippolytus' of Euripides, and in the literary world for his 'Life of Bentley,' and the 'Adversaria' of Porson. He was appointed Dean of Peterborough in 1824, and consecrated Bishop of Gloucester in 1830; the see of Bristol was added to his charge in 1836. He died June 6, 1856.

MONKEY-FLOWER. [MIMULUS, *S.* 2.]

MONRADITE. [MINERALOGY, *S.* 1.]

MONSTROSITY, a term applied to those individuals amongst plants and animals which present any irregularity in their general form or the form of the organs of which they are composed.

The term Monstrosity is often applied to those anomalies only which are apparent externally, and which produce more or less deformity; but, in a scientific point of view, it includes every variation, either external or internal, in any organ, from its most general or natural conformation; and it is in the latter sense that we shall here treat of it.

Monsters were formerly regarded as sports or prodigies of nature, and these ignorant notions, with respect to their true character, continued prevalent among all classes of people until the commencement of the last century, and are even now held by the uninformed. By the physiologist however the study of the various anomalies of organisation in plants, animals, and man, are now viewed as a branch of natural science. An accurate anatomical examination of monstrosities and a minute acquaintance with embryology and structure, have shown that the formation of these different imperfect beings is governed by the same laws which preside over the formation of perfect individuals; the only difference being, that the process of development in the former cases has been perverted, or arrested, or increased in its course during the growth of the embryo or germ.

Monstrosities in the animal kingdom are treated of under the head MONSTER. We shall here treat of monstrous growths in plants. The study of such growths is not a mere matter of curiosity, as their structure tends to throw light on the true laws of development amongst plants. Although direct observations are more easily made on plants than on animals for the purpose of ascertaining the facts of their history during growth, it is nevertheless interesting to obtain a confirmation of these facts from the forms which monsters assume, these forms in the majority of cases being permanent conditions of the stages of growth through which plants pass. In these forms nature presents us with as it were experiments to test the truth of the general laws of morphology.

This subject can perhaps be best illustrated by reference to special instances. To begin with the Leaves. [LEAF.] In the history of the normal development of the leaves, it is found that they are always arranged in an alternate manner, one leaf above the other, but subsequently in many plants, and even whole families, the leaves become opposite or whorled. In the case however of individuals it not unfrequently happens that the leaves of opposite or whorled-leaved families of plants become alternate. Thus an instance is recorded of *Hippuris vulgaris* (Mare's-Tail), which in its normal complete development has whorled leaves, presenting its leaves arranged alternately in a spiral upon the stem. (Lankester in the 'Report of British Association,' 18th meeting, p. 85.)

In the conversion of the leaf-bud into the flower, one of the earliest changes that takes place is the conversion of the leaves into the organs called Bracts. [BRACTS.] Instances are very often seen of monstrous forms of plants in which the leaves are not converted into bracts but retain their leaf-like character. This frequently occurs in the species of *Plantago*, giving the inflorescence a singularly different character to that which occurs under normal circumstances.

The leaf-bud is always seated in the axil of the leaf, but in the case of the bracts forming the involucre of the *Compositæ* neither leaf-buds nor flower-buds are seated in their axils; but in the case of the monstrous variety of the common daisy [BELLIS], known by the name of Hen and Chickens, flower-buds are developed in the axils of the bracts.

Next after the bracts the Sepals are formed in the flower-bud. [CALYX.] It not unfrequently happens that during the growth of cultivated plants, the sepals are found assuming the appearance of leaves. This is especially the case with the cultivated roses. This tendency to recur to the condition of the leaf is sometimes a normal tendency of plants. Thus, in the case of *Calycophyllum Stanleyanum*, one of the sepals after the corolla drops off begins to grow into a beautifully rose-coloured leaf. Other instances of this kind are seen in the order *Cinchonaceæ*. In plants with inferior fruits [FRUIT] the germen seems to contract an adhesion with the lower part of the sepals which thus produces the peculiar character of these fruits, such as the gooseberry, the currant, the apple, and the pear. In these fruits it is not uncommon to find amongst them leaves growing from the surface of the fruit, indicating the tendency of this sepallary part of the fruit to assume the condition of the leaf. The most remarkable example of this tendency of the sepal to assume the condition of the leaf has been observed in the Goat's-Beard (*Tragopogon pratensis*), in which the pappus surrounding the minute flower which represents the calyx has been found to have assumed the character of the leaf.

It frequently happens where one of the parts of a flower have a tendency to relapse to the foliar condition, that the whole of them partake of this character. Thus Mr. Austen has recorded very accurately the changes observed in a monstrous form of the White Clover (*Trifolium repens*). The following changes were observed in his specimens:—

"1. Calyx.—The calyx-teeth often rise into single leaves, but when compound leaves are formed the division seems to be as follows: the two large equal teeth, which are opposite the vexillum, form one serrate leaf, and another leaf is formed from the three remaining teeth.

"2. Corolla.—The part which here most frequently reverts to a leaf is the vexillum, and this is a perfect one. Of these leaflets, the alæ are often seen forming simple leaves, as also the carina; but their perfect union into a ternate leaf is less common.

"3. Stamens.—Whatever changes the flower may exhibit, these organs are always in a state to be recognised, and their reversion to leaves less frequent than in any other part; so that there is more difficulty in determining the number of leaves which go to form this portion. As two ternate leaves form the calyx and corolla, it might be supposed that the stamens were constructed out of the same number. The figures represent cases of a stamen reverting to a leaf with a true stamen attached to its stalk on either side; the single anterior stamen, where it reverts, seems always disposed to form more than a simple leaf; and it is therefore probable that the ten stamens (9 + 1) may be formed out of four sets of ternate leaves.

"4. Pod.—From the well-known character of the pod and pistil in *Leguminosæ*, it might be expected that instances of reversion to leaf would be most frequent in this part of the flower; and a series might easily have been produced which would have represented it in every stage of passage; some of these were given. From these it would appear that the pod is not formed of a whole compound leaf, as either two scales, or two abortive leaves, are constantly to be seen at the base of the imperfect pod on either side; the pod is therefore usually formed out of the middle leaflet. In one flower-head however each division of the pistil-leaf had become a pod, with a distinct stem and the ovules inwards.

"Ovules seem to be produced only when junction of the edges of the pistil-leaf takes place; in other cases leaflets are produced in the place of ovules.

"In cases where every other part of the floral series has been regularly developed, the Pistil occasionally will take the form of a perfect ternate leaf, and then the axis of the plant is continued through the flower." (Austen, 'British Association Report,' 19th meeting.)

Mr. Austen has likewise recorded in the same place an instance in which the staminiferous flowers of the Common Maize (*Zea Mais*) were converted into pistils. In this case we have an instance of the tendency of an organ not to relapse to a lower type, but to assume a higher type of development.

It is very frequently the case that stamens relapse to the condition of petals. This is the case with most of the double flowers of our gardens: and in the case of the rose, the pæony, the bachelor's-buttons, and others, the anthers may often be found tipping the petaloid bodies in the centre of the flower. This is seen as a normal condition in the water-lily.

The recurrence of the pistil to the form of the stamen and corolla is not so frequent, as its assuming the form of the leaf. In the double cherry of our gardens this condition of the pistil is frequently presented. It is this same tendency which is seen in monstrous oranges, in which this fruit is split up into the same number of parts as it possesses carpellary leaves. [Flower.]

The most central organ of the plant is the Seed, and its development is the great object of the production of the flower. In the seed is the young plant. The seed is however but a changed bud, and during the process of its development it sometimes recurs to the condition of the leaf-bud, and produces instead of an embryo a branch.

These instances will be sufficient to show how instructive the study of vegetable monstrosities really is. Many such have been recorded, and one of the best resumés of the whole subject will be found in Moquin Tandon's 'Teratologie Vegetale.' [Metamorphosis of Organs.]

MONTACUTA, a genus of Acephalous Lamellibranchiate *Mollusca*, belonging to the family *Kelliadæ*. The shell is small, thin, equivalve, inequilateral, transversely oblong or obliquely oval, surface smooth or concentrically striated, or rarely radiatingly furrowed; beaks inflected; inner margins smooth; hinge-margin with a trigonal incision and cartilage pit, and a pair of diverging laminar teeth in one or both valves; ligament internal; muscular scars suborbicular; pallial impression simple; animal oblong, its mantle freely open in front with simple margins, not furnished with siphonal tubes posteriorly; a single siphonal orifice, or none; foot, very large, strong, and broad, furnished with a byssal groove. Such are the characters of this somewhat unsatisfactory genus as given by Messrs. Forbes and Hanley. They enumerate three species as British—*M. ferruginosa*, *M. bidentata*, *M. substriata*.

MONTAGU, BASIL, Queen's Counsel, was born April 24, 1770, in London. He was a natural son of John Montague, fourth earl of Sandwich, and was brought up in his house. His mother was Miss Ray, who was shot in 1779 in the Piazza of Covent Garden, by the Rev. Mr. Hackman, who had fallen in love with her, and destroyed her in a fit of jealous frenzy. Basil Montagu received his early education at the Charterhouse School, London, of which the Earl of Sandwich was one of the governors. In 1786 he was sent to the University of Cambridge, where he was soon distinguished for his love of literature, and where he remained till after he had taken his degree of M.A. His father died in 1792, leaving him a competent income, of which, however, he was deprived by a suit in the Court of Chancery. Having selected the law as a profession, he entered himself of Gray's Inn, where he was called to the bar in 1798, but some years afterwards he became a member of Lincoln's Inn. After he had settled in London he formed an intimacy with Coleridge and others of that literary connection, and became so zealous a convert to the opinions of Godwin that he had serious thoughts of relinquishing the profession of a lawyer, as 'injurious to society in proportion to the power and attainments of the individual.' Sir James Mackintosh, however, with whom he travelled for some years on the Norfolk circuit, convinced him that the dogma of Godwin was not founded in truth, and he continued in the legal profession. He never rose to eminence as a pleader, but having devoted his attention chiefly to the bankrupt laws, acquired a high reputation and good practice in that department.

His first work was 'A Summary of the Law of Set-Off, with an Appendix of Cases argued and determined in the Courts of Law and Equity upon the Subject,' 8vo, 1801. It had not appeared many weeks before it was noticed with approbation by Sir Vicary Gibbs, who thus extended the practice of the young lawyer, then almost unknown. His most important legal work was 'A Digest of the Bankrupt Laws, with a Collection of the Statutes, and of the Cases argued and determined in the Courts of Law and Equity upon that Subject,' 4 vols. 8vo, London, 1805, 2nd edition, 1811. This 'Digest' became a standard work, and many other editions of it were published. He published also 'Law and Practice in Bankruptcy,' 2 vols. 8vo, with 'Supplement,' 1 vol.; 'The Law of Partnership,' 8vo; and 'The Law and Practice of Parliamentary Elections,' in conjunction with Mr. W. Johnson Neale, 8vo, 1839. His other legal works and compilations, partly in his own name, partly in conjunction with others, are too numerous to be quoted. Lord Erskine, during his brief tenure of the office of lord chancellor (1806-7) made Mr. Montagu a commissioner of bankrupts. While holding this appointment, and deriving a considerable income from it, he became so convinced of the delay and expense to suitors of this mode of administering the law, that he published a yearly detail of these injurious results, which, together with his statements before a Committee of the House of Commons, finally put an end to those commissionerships. A new law was made (1 & 2 Wm. IV. c. 56), under which three judges constituted a Court of Review, and six commissioners exercised functions similar to those previously exercised by the commissioners under the great seal. Mr. Montagu was very much dissatisfied with the new law, but he accepted the office of accountant-general in bankruptcy, which he held during ten years. While in this office he demanded from the governors of the Bank of England interest for the bankruptcy moneys in their possession, which had never previously been paid. His demand was at first resisted, but ultimately he obtained 20,000*l*. for the bankruptcy fund.

The works and compilations by which Mr. Montagu is best known to general readers are the following:—'Selections from the works of Taylor, Hooker, Hall, and Lord Bacon, with an Analysis of the Advancement of Learning,' 12mo, 1805. The analysis is carefully executed, and very useful for those who wish to study Lord Bacon's treatise. 'The Opinions of different Authors on the Punishment of Death,' 3 vols. 8vo, 1809-13. In furtherance of these 'Opinions,' he formed a society for "the diffusion of knowledge upon the punishment of death." His efforts for the abolition of hanging for forgery and other crimes without violence, in conjunction with those of Sir Samuel Romilly, Mr. Wilberforce, and others, were at length rewarded by complete success. 'Inquiries into the Effects of Fermented Liquors, by a Water-Drinker,' 8vo, 1814. 'The Works of Francis Bacon, Lord Chancellor of England,' 16 vols. 8vo, London, 1825-34. This work was commenced while he was at the university by the translation of Bacon's Latin works, in which he was assisted by Archdeacon Wrangham and others.

The 16th volume, in 2 parts, contains Montagu's 'Life of Bacon,' which, though not distinguished by much power of thought or beauty of style, is a useful exhibition of the leading events and labours of Bacon's life, active and contemplative. 'Essays and Selections, by Basil Montagu,' 12mo, 1837. He published altogether about 40 volumes, and is stated to have left about 100 volumes of manuscripts, a Memoir of himself and his contemporaries, and a Diary.

Basil Montagu assisted in the establishment of several mechanics institutes, and frequently gave lectures in them. He seems to have been not only an industrious and useful lawyer, but an honest, liberal-minded, and benevolent man. He died November 27, 1851, at Boulogne, in France. At the age of thirty-five he had been twice a widower, both wives having died in childbirth, leaving him four children. In 1808 he married the widow of Thomas Skipper, Esq., who survives him, and by whom he had four children. Of his eight children only a son and daughter are living. His daughter-in-law, Miss Ann Skipper, is the wife of Mr. Procter (Barry Cornwall).

MONTEREY. [CALIFORNIA, *S.* 2.]

MONTGOMERY, JAMES, was born at Irvine in Ayrshire, where his father was a Moravian preacher, on November 4, 1771. When only four years of age his parents removed to Grace Hill in the county of Antrim, Ireland, where he was first placed at school. In 1778 he was sent to the Moravian settlement at Fulneck near Leeds, in Yorkshire, to complete his education, and in 1783 his father and mother went to the West Indies as missionaries, where they died in 1790. At Fulneck the instruction was excellent, but the seclusion was monastic, and James Montgomery, during his ten years' residence there, distinguished himself for nothing "but indolence and melancholy." He had taken a fancy for poetry, which was utterly forbidden in the school; he had clandestinely read 'Robinson Crusoe,' which had greatly interested him; and he wrote, when only thirteen, some poor imitations of Moravian hymns. Though characterised by his teachers as indolent, he had contrived to procure and read a copy of Cowper's poems, and these he thought he could excel, so he wrote a mock-heroic poem of a thousand lines, and commenced a serious epic, to be called 'The World,' and this before he was fourteen. He also wrote other small poems; but his teachers, who wished him to become a Moravian preacher, were dissatisfied with his inattention to his studies. In the school-diary of July 3, 1787, it is recorded that, as "J. M., notwithstanding repeated admonitions, has not been more attentive, it was resolved to put him to a business, at least for a time." A situation was soon afterwards found for him with a shopkeeper at Mirfield. He was probably not much more attentive there, for it is stated that he continued to write poetry and compose music till June 1789, when he ran away. He had only a trifle of money when be started; but on reaching Wentworth, he presented one of his smaller poems to Earl Fitzwilliam, who gave him a guinea. He then settled for a twelvemonth at Wath-upon-Dearne as assistant in a general shop. The brethren at Fulneck discovered him, and wished him to return; but he refused. He continued in this situation, silent and recluse, but no doubt pondering over thoughts for which as yet he wanted fitting powers of expression.

He continued to write, and at the end of the year having sent a volume of manuscript poetry to Mr. Harrison, the publisher in Paternoster-row, London, followed it himself. Mr. Harrison declined publishing the poems, but engaged him as shopman. In London he led the same solitary and retired life as in the country. His sole amusement was writing, and he is stated to have never entered a theatre, or even the British Museum, to which it might have been thought his habits and disposition would have led him. While in London his first production, a tale in prose, entitled 'The Chimera,' appeared in 'The Bee,' an Edinburgh periodical work, in November 1791. He also wrote a novel, which be offered to Mr. Lane, of Minerva-press celebrity, who declined it, because the characters swore too much. The novel was never published, but the objection greatly hurt the religious feelings of Montgomery, who thought he had only imitated Fielding and Smollett. This disappointment made him resolve to return to his old shopkeeping occupation at Wath. He did go, but not to remain long. Towards the end of 1792 (having replied to an advertisement for a clerk), he entered the service of Mr. Joseph Gales of Sheffield, who was printer, bookseller, auctioneer, and editor, publisher and proprietor of a newspaper, 'The Sheffield Register,' which advocated principles at that time designated as revolutionary. Montgomery formed an attachment to his employer; wrote political articles for the paper; and when Gales, learning that a warrant had been issued to apprehend him for treason, fled to America, he started a new weekly paper, on "peace and reform" principles. The first number of 'The Sheffield Iris,' appeared on July 4, 1794, which he continued to edit till September 27, 1825, and it maintained its existence, with a few changes, till January 1857. The 'Iris' was at first very successful, but it was a singular position for Montgomery to fill, with his recluse habits, his mild and almost timid feelings, his dislike to the practical details of business, and his poetical and refined taste. He evidently felt it to be so. "I hate politics," he said, "and would as soon meet a bear as a ledger." Almost immediately after starting the newspaper, a poor man employed him to print a few quires of a ballad, for which he was charged eighteen-pence. It was 'On the Fall of the Bastille,' as mere doggrel as can be well conceived; but the attorney-general, Sir John Scott (afterwards Lord Eldon), discovered it to be seditious, indicted the printer, and in January 1795 he was tried at Doncaster, found guilty, fined twenty pounds, and sentenced to three months' imprisonment. He gave an account in his newspaper of a riot in Sheffield, to quell which the military had been called in and had fired on the people; for this, in 1796, he was again tried, again found guilty of sedition, fined thirty pounds, and sentenced to six months' imprisonment. During his confinement, which was in York Castle, he wrote a small volume of poems, entitled 'Prison Amusements,' which was published in 1797. After his release from prison his life flowed smoothly to its end. His honest sincerity, his gentle manners, and perhaps his increasing literary celebrity, won him the regard of even his political opponents, and secured him the esteem and love of the rest of his townsmen. He continued to write short poems, several of which are very pleasing; and in 1806 he published 'The Wanderer in Switzerland'—a work of which he thought so little himself, that he occupied three years in printing it at his own press, but which obtained so great a popularity, that a second and third edition were quickly demanded. His own estimate was probably juster than that of the public, and the 'Edinburgh Review,' in noticing the third edition, characterised it as "very weakly, very finical, and very affected." This censure is overcharged; the poem has not much power, but it cannot justly be styled affected, and it is very melodious. In 1809 'The West Indies' was published—a great advance on the former—containing some exquisite descriptive passages, and others of considerable power and pathos. In 1812 appeared 'The World before the Flood,' a work which enjoyed a great and deserved popularity; and in 1810, having by this time rejoined the Moravian community, he wrote 'Greenland,' commemorating their exertions in that desolate establishment, which contained much of beauty and of pathos. In 1827 'The Pelican Island and other Poems' was published, which fully maintained his poetic character. In 1836 a collected edition of his poems was issued in three volumes; another in four volumes in 1849; and another in one volume in 1851. In 1853 'Original Hymns, for Public, Private, and Social Devotion,' concluded the series of his poetical works. Of the smaller poems contained in the collected works, many are of great excellence. His restricted education, and his early habit of writing had given him a dangerous fluency; and the ideas, though frequently original, are generally too much expanded: his imagination seldom soars, nor does his fancy sparkle; but his sympathies with all that is good and holy are ever ardent and sincere; his pathos is touching, and his style melodious, though in his longer poems occasionally too ambitious and magniloquent. Such faults as they have are least likely to occur in his shorter poems; and in some of them, as 'The Common Lot,' and 'The Prayer,' they entirely disappear.

We have pursued Mr. Montgomery's poetical career to the end in order to give a collected view of it. We now return to the few remaining events of his life. His publication of 'The Wanderer in Switzerland' led to an engagement on the 'Eclectic Review.' He had few qualities for an able critic—indeed none but a poetical taste and good principles. His praise or blame depended more upon his feelings than his judgment of the character of the work or its literary attributes; consequently one of his earliest reviews was an onslaught on Moore's early poems, whom he termed in a private letter "a deliberate seducer." This feeling led him later in life to decline being introduced to Moore, who sought his acquaintance. In 1825, as we have said, he resigned the editorship of the 'Iris,' on which occasion a public dinner was given to him by the inhabitants of Sheffield, and funds were subscribed to establish a mission-station in Tobago, where his parents had died, which has been named Montgomery. When released from his constantly required attention to the newspaper, he took a lively interest in municipal affairs, and was a frequent speaker at religious meetings. In the spring of 1830 he delivered a course of lectures at the Royal Institution on the 'History of English literature,' a subject on which he was not well qualified to speak, and which therefore fell somewhat dull and flat. Later in the year he published 'A History of Missionary Enterprise in the South Seas,' for which he was better suited, and which is an interesting and valuable work. In 1835 he discreetly declined the office of Professor of Rhetoric in the University of Edinburgh; and in the same year a pension of 150*l.* was bestowed on him by the Queen, through Sir Robert Peel. In 1836, after having lived forty years in the house occupied by his old employer, Gales, with three of Gales's daughters, who kept the bookseller's shop, on the death of one of them he removed, with the remaining two, to a more convenient residence; and in the same year he delivered a course of lectures 'On the British Poets,' at Newcastle-on-Tyne; and for some years added to his income by delivering similar courses at other places. In 1841 he visited Scotland on a missionary tour. He was received everywhere with great distinction, particularly in his native town of Irvine, where he had a public reception, and was made a burgess. In 1842 he visited Ireland on a similar errand, saw his old abode at Grace Hill, and while occupied in these religious labours often lamented his not having become a Moravian minister. In 1852 he delivered a lecture 'On some Passages of English Poetry but little known,' but was so feeble as greatly to excite the compassion of his audience. On April 30, 1854, he died; and on the day of his burial the shops and manufactories of Sheffield were all closed, many members of the municipality attending the funeral, as did also the vicar of Sheffield and twenty-four clergymen. By his will he left 900*l.* to be distributed to various charities. His memoirs have been published in seven octavo volumes by John Holland and James Everett, to which we have been indebted for most of the facts in this notice.

MONTGOMERY, ROBERT, was born at Bath in 1807. Of his boyish years we know nothing, but he appeared before the world as an author at an early age, conducting in his native city a weekly publication called 'The Inspector,' which had but a short existence. His next publication was 'The Stage-Coach,' dated 1827 in his collected works; and in the same year he issued 'The Age Reviewed: a Satire,' an octavo volume, the poem being very fully illustrated with notes. The work was very decidedly directed against irreligion and scepticism, and this has formed the key-note of all his subsequent poems. In 1828, though stated to have been written two years earlier, he published 'The Omnipresence of the Deity;' it became astonishingly popular, and eight editions are said to have been sold in as many months. In the same year appeared another volume, 'A Universal Prayer; Death; a Vision of Heaven; and a Vision of Hell;' a second edition of which appeared in 1829, dedicated to Sharon Turner. 'Satan' quickly followed. All were successful; and encouraged by this success, and the advice and assistance of Mr. S. Turner and the Rev. W. L. Bowles, he entered himself in 1830 at Lincoln College, Oxford, with the intention of devoting himself to the Church. He graduated B.A. in 1833, passing in the fourth class, and M.A. in 1838. His residence at the university provided him with a new subject for his prolific muse, and in 1831 he produced a poem, with historical notes and engraved embellishments, under the title of 'Oxford,' which, though extremely laudatory, created more ridicule than applause among the members of the university. In 1832 he published 'The Messiah, a Poem, in Six Books,' which was dedicated to Queen Adelaide; and in 1833 'Woman, the Angel of Life.' In 1835 Mr. Montgomery was ordained, and for a time his ministerial labours seem to have nearly superseded his poetic efforts, a small volume on the local associations and scenery around his first curacy, Whittington in Shropshire, being the only exception until 1842. He quitted Whittington in May 1836, and became minister of Percy-street chapel, London; whence he removed, about the beginning of 1838, to St. Jude's episcopal chapel in Glasgow. Here he continued until December 1842, drawing large audiences; but his preaching excited so much controversy and bitterness of spirit that he resigned the incumbency, and returned to London, where he immediately published 'Luther, or the Spirit of the Reformation.' In October 1843 he resumed his ministry at Percy-street Chapel, where he continued till his death. He now began the publication of a number of prose theological works, the issue of which was continued till 1854. Neither was poetry altogether neglected. Besides some smaller things, he wrote in 1842 a series of 'Meditations' upon engraved Scripture subjects, published by Fisher; 'Sacred Meditations and Moral Themes,' 8vo, 1847; 'The Christian Life, a Manual of Sacred Verse,' 12mo, 1849; 'Lyra Christiana—Poems on Christianity and the Church,' 32mo, 1851; 'Lines on Wellington,' and 'The Hero's Funeral,' 8vo, 1852; and 'The Sanctuary, a Companion in Verse for the English Prayer-Book,' 1855. On December 3 of this year he died at Brighton, in his forty-ninth year, all his exertions in the cause of religion having been unrecognised by any preferment in the Church.

That Montgomery's poetical works should have been so successful as they undoubtedly have been, has excited much surprise. As early as 1830 Mr. Macaulay, in noticing a third edition of 'The Omnipresence of the Deity,' in the 'Edinburgh Review,' ascribed the poet's success to unblushing puffery. That his works have been most inordinately puffed is certainly true; but no amount of puffery would have carried a poem through twenty-six editions (which the 'Omnipresence' has reached), without some other qualities. These we think may be found in the gravely important nature of the subjects he has generally chosen, and the class, a numerous one, which he peculiarly addressed. This class, rejecting poetry usually as secular or profane, were pleased with his mediocrity; they welcomed him on account of his themes; he was earnest and sincere; and, prejudiced in his favour, to them his turgidity appeared eloquence, his obscurity assimilated to the mysterious, his vagueness kept him clear from points of doctrinal difference, his poetical adornments, though often selected without taste and scattered without fitness, kept attention alive; and as in so voluminous a writer it would be scarcely possible not to find some passages containing good thoughts happily expressed, these were produced as answers to objecting critics. As a preacher he drew large audiences, and his services were often asked and given in favour of charitable purposes. His style of preaching in some measure resembled that of his poetry; he ranted, was affected, and vague; but his ranting was accepted as earnestness, his affectation as refinement, and his vagueness as a happy generalising. His manners were engaging, and he always acquired the esteem and regard of his congregations, who on more than one occasion gave him substantial marks of their attachment.

MONTICELLITE. [MINERALOGY, *S.* 1.]

MOORE, THOMAS, was born in Aungier-street, Dublin, on the 28th of May, 1779. His father was a small tradesman, and both his parents were Roman Catholics. He was early placed at school under a Mr. Whyte, who paid much attention to elocution, who was fond of dramatic representations, and in whose school R. B. Sheridan had once been. Moore, a quick and lively boy, became a favourite pupil, and as early as 1790 exhibited his talents in reciting an epilogue at a private theatrical entertainment: other dramatic exhibitions were got up by his parents, for which he wrote epilogues or prologues. When he first began to rhyme, he says, he cannot remember; but in 1793 he contributed two poems to the 'Anthologia Hibernica,' a Dublin magazine, which were inserted, to his intense gratification. In this year the restrictions which prevented Roman Catholics from studying at the Dublin University were removed, though all honours and offices were still denied them. His mother, who wished him to be a lawyer, induced his father to enter him at Trinity College in the summer of 1794. At college he pursued the usual studies with tolerable success, gaining several marks of distinction, though, feeling an inability to write Latin hexameters, he substituted on one occasion some English verses, which were approved of by the judges, and for which he received a reward. He continued also to write verses for the 'Anthologia' while it existed, and afterwards for other publications. He learned to play the piano from his sister's teacher, Italian from the priest of the family, and French from an emigrant acquaintance. In the second year of his college attendance he soared yet higher, and wrote a masque with songs, which was performed in his father's drawing-room.

Born a Roman Catholic, accustomed from infancy to hear the wrongs of his fellow-religionists descanted on, influenced by his friendship with Emmett and others, and perhaps soured by his pretensions to a scholarship in the university being unavailable on account of his faith, it is little to be wondered at that he took a lively interest—though fortunately he was too young to be made an active participator—in the plots preparatory to the rebellion of 1798. He was examined before Fitzgibbon, the vice-chancellor; but as he could honestly avow himself ignorant of any plot, he was discharged. He at length took his degree of B.A., and left the university; but he had already commenced a translation of the so-called odes of Anacreon, a specimen of which he laid before the provost of the college, Dr. Kearney, with a hope to obtain a classical premium. Dr. Kearney thought the translation good, but that the subject was not likely to be patronised by the Board. Moore was then entered at the Middle Temple in London, whither he went, scantily supplied with money, to study law. In London he was introduced to Lord Moira, Lady Donegal, and others; he moved in a fashionable circle; he published in 1801 his 'Odes of Anacreon;' and of course paid little attention to his legal studies. His next publication, in 1802, was 'The Poetical Works of the late Thomas Little,' for which he received 60*l.* They were severely blamed and much read, and their somewhat loose morality did not prevent them from securing him friends, on account of their poetical ability. In 1803, by Lord Moira's influence, he was appointed to a government situation at Bermuda. In January 1804 he arrived there, having stayed upwards of a month at Norfolk in Virginia. He at once found that the situation did not suit him, and in March he left Bermuda, appointing a deputy to fulfil his functions. He then journeyed over a part of America, going from New York to Virginia, and back by Philadelphia and Boston to Niagara and Quebec. With the society in America he was much dissatisfied, and recorded his sentiments in some satirical poems. In November 1804 he was back in England. Here he expected much from Lord Moira's patronage, but only succeeded in getting the appointment of barrack-master in Dublin for his father. In 1805 he published 'Odes and Epistles,' which being in a similar style to the Little poems brought upon him the castigation of Jeffrey. This occasioned a bloodless duel, the cause of much merriment at the time, and led to a firm friendship between the combatants. He was now leading a life of fashionable excitement among the aristocracy of England, a visitor to Lord Moira at Donington Park, and a constant guest at Lansdowne House and Holland House. As early as 1797 Moore's attention had been attracted to Bunting's collection of Irish melodies, and at intervals he had written words for several of them, which he was accustomed to sing himself with much effect. In 1807 he entered into an engagement with Mr. Power to produce a work founded on them, in which he was to adapt the airs and furnish the words, while Sir J. Stephenson was to provide the accompaniments. This work was not completed till 1834, and upon it his true fame will rest. His amatory poems, though sweetly and playfully written, will always give offence to persons of good taste; his satires, however successful in attacking ephemeral subjects, will perish with the events to which they allude; but the melodies, combining beautiful words, purer morals, and good music, will have a lasting existence. They have an entirely original character; they have not the vigour, the truth to nature, and the deep passionate feeling of our other great lyrical poet, Burns, but they are never, as he sometimes is, coarse; they have a uniform elegance, a lightness, a pathetic tenderness, a play of wit, a brilliancy of fancy, and a richness of adornment, which, though too often giving the impression of being artificial, are always pleasing. In the same class may be included the songs written under the title of 'National Airs,' published in 1815. We cannot however place the 'Sacred Songs,' which he published in the same year, in the same category. In them there is a strained adaptation of scriptural words and ideas, with a lack of earnestness, that render them distasteful. In 1808 he published, anonymously, two poems, 'Intolerance' and 'Corruption;' and in 1809 'The Sceptic.' They were not very successful. Moore's muse was too sportive, his fancy too playful, his heart too genial, for him to excel in severe satire which he here attempted.

In 1811 he married Miss Bessy Dyke, a truly estimable woman, to whom he ever continued fondly attached, and who was the source of all his purest happiness for the remainder of his life. In the autumn of the same year his opera of 'M.P., or the Blue Stocking,' was produced on the stage. It was but moderately successful, ran a few nights, and has never been repeated, though some of the songs, published separately in his collected works (from which the opera is omitted), well maintained his lyrical reputation. Moore had now made up his mind to live by his pen; he quitted London, and went to reside with his family at Mayfield Cottage, near Ashbourne in Derbyshire, where in 1813 he produced the 'Twopenny Post-Bag, by Thomas Brown the Younger.' The wit, the variety, the ease, and the playfulness of these satires, directed against the Prince Regent and his ministers, made them immediately popular, and fourteen editions went through the press in a twelvemonth.

As early as 1812 Moore had contemplated the writing of an Oriental poetical romance, and his friend Mr. Perry of the 'Morning Chronicle' stipulated for him with Messrs. Longman, the publishers, that he should receive for a quarto volume the sum of three thousand guineas: this was agreed to; but it was not till 1817 that 'Lalla Rookh' at length appeared. It was eminently successful; it has passed through many editions, and it has been frequently translated. It may however be doubted whether it will contribute to his permanent fame. It is brilliant, melodious, in the 'Fire Worshippers' it is energetic, but it wants dramatic consistency and characterisation; it is untrue to nature, it is cloying with its sweetness, it is oppressive with its imagery; the feelings described are almost uniformly sensuous, and the art of the composition is painfully apparent. Immediately after the publication of 'Lalla Rookh,' he made a trip to Paris in company with Mr. Rogers, and this enabled him to produce 'The Fudge Family in Paris,' a series of poetical epistles, an entertaining collection of satirical remarks on character and political events, which was published in 1818. While seeing 'Lalla Rookh' through the press he had removed to Hornsey near London, and here in September 1817 he lost one of his children. Early in 1818 he learned that his deputy in Bermuda, "after keeping back from me the proper receipts of my office," he writes in one of his letters, "has now, it seems, made free with the proceeds of a ship and cargo deposited in his hands, and I am called upon by a monition from Doctors' Commons, to be accountable for it." The claim was for about 6000*l.*, of which little was hoped to be recovered from the deputy. On this occasion his friends flocked round him with offers of assistance, but he declined receiving any, as he preferred paying the money, whatever it might be, by the earnings of his pen. In 1819 he accompanied Lord John Russell to Paris, and extended his journey to Italy, visiting Rome in company with Chantrey the sculptor, and Jackson the painter. This expedition was recorded in 'Rhymes on the Road,' published together with 'Fables of the Holy Alliance,' the same year; they were said to be 'extracted from the Journal of a Travelling Member of the Pococurante Society,' and are serious, political, artistical, and satirical by turns. As the law proceedings respecting the defalcations were still pending, he did not return to England; but, sending for his family, took up his abode at Paris, where he continued until 1822. He purposed to work hard; but the gaiety of the place, the interruption of visitors, and probably anxiety as to his ultimate loss, prevented his carrying his intentions into full effect. He had entered into an engagement to write a life of Sheridan; but in Paris he found himself, or thought himself, so unfurnished with materials, that he gave it up and 'The Loves of the Angels,' a poem, issued in 1823, and the prose-poetical romance of 'The Epicurean' (published in 1827), were the only additional works produced during his residence abroad.

The claim with regard to the Bermuda defalcation had by this time been settled by Mr. Moore's friends in London, having been reduced to 740*l.*, which was paid by a cheque from Lord Lansdowne, and repaid by Moore, chiefly from the proceeds of his 'Loves of the Angels' and his 'Fables of the Holy Alliance.' He now settled at Sloperton Cottage, near Bowood, the residence of the Marquis of Lansdowne; and in 1824 issued the 'Memoirs of Captain Rock.' He at once began in earnest his 'Life of Sheridan,' which was published in 1825. In 1827 'The Epicurean' was published, with some fragments of a poem called 'Alciphron,' on the same materials.

Before 1821 Lord Byron had presented Moore with his manuscript autobiography, for his especial benefit, but not to be published till after his death. In this year, in order to raise money, Moore had sold it to Mr. Murray, with an engagement to edit it, for 2000 guineas; and the manuscript was assigned to, and deposited with him, in April 1824. In this month Byron died; and on the news reaching England, Moore was anxious to redeem the manuscript, which he considered he had a right to do: Lady Byron and the family were desirous that the manuscript should be destroyed, as they considered its publication would be alike hurtful to their feelings and injurious to the character of his Lordship, and offered to repay Mr. Murray the sum he advanced. Moore refused to accede to this; he was willing to defer to their feelings, to suppress or alter what was unfit to be made public, or even to burn it if competent persons should decide that its publication would be improper; but insisted that in any case he alone should be the loser. After a long and unpleasant altercation he repaid the 2100*l.* with interest to Mr. Murray, the manuscript was burnt, and he engaged for the like sum to write a 'Life of Lord Byron' for the Messrs. Longman. This he did, but ultimately the copyright was transferred to Mr. Murray, by whom it was published in 2 vols. 4to in 1830. In 1831 he wrote 'The Life of Lord Edward Fitzgerald;' and 'The Summer Fête,' celebrating an entertainment given at Boyle Farm in 1827. To this followed 'The History of Ireland,' which appeared in 'Lardner's Cyclopædia' in successive volumes. This was his last work of importance. In 1835, during the administration of Lord Melbourne, a pension of 300*l.* a year was bestowed on him by the Queen as a reward for his literary merits. It was bestowed in good time: he had become unwilling or unable to labour as he had done, and family bereavements distressed him. Of his two sons, one died in Algeria in the service of the French; the other died of consumption in 1842. In 1841 he commenced an edition of his collected poetical works, including the scattered pieces with which he had enriched almost every newspaper and magazine of the metropolis, and they were issued in ten monthly volumes. For the last three years of his life he was afflicted with a softening of the brain, which reduced him to a state of mental incapacity, though without pain, during which the sedulous attention of his wife was most exemplary. He died on the 25th of February 1852, and was buried in the churchyard of Bromham, near Devizes.

Of Moore's poetical genius we have already spoken. To his prose there is less praise to be given. His biographies, with many sparkling passages, are all faulty, diffuse, and uncharacteristic. His 'History of Ireland' is his best work, as it is an interesting and careful production, though not an impartial one.

Moore's character in many respects was truly estimable. His affection for his parents was unfailing and indelible: it carried him in early life safely through the seductions of fashionable society, as he would commit no extravagance that might require them to contribute to his expenses; it induced him to postpone his own hopes of official advancement to the provision of a small place for his father; and of the 3000*l.* received for 'Lalla Rookh,' 2000*l.* was left in the hands of the publisher to pay the interest to his parents. To his wife and family he showed the fondest attachment, and it was duly reciprocated. It has been urged against him that he too often left his wife in solitude while he was fluttering in fashionable circles; but it should be remembered that he believed much of his fame, and consequently his fortune, depended on his keeping himself well before that world which alone could become purchasers of the expensive quartos in which shape his works first appeared; nor should it be forgotten that even in these circles he always avowed himself proud of his wife, introduced her to all his aristocratical friends, and frequently urged her to mix more with them, which her native good sense made her decline as much as possible, while she ever willingly submitted to those absences she considered useful to their mutual interests. As a friend he was faithful, kind, and generous; and he secured the esteem of many of the most eminent men of his day. As a politician he was consistent in his principles, though not always right or always unchanging in his opinions. He was vain: but few men have had so much pains taken to make them so, petted as he was from his boyhood till old age withdrew him from the world, and his vanity was harmless and never obtrusive. The strongest proofs of it are given in his own private journal, published after his death in the 'Memoirs, Journal, and Correspondence of Thomas Moore,' by Lord John Russell, in 1853-55, in 8 vols.

MORACEÆ, a natural order of Exogenous Plants which were formerly placed as a sub-order of *Urticaceæ*. The species are trees or shrubs, with a milky juice, sometimes climbing. The leaves are commonly lobed and rough. The flowers are small, monœcious, and collected in heads, spikes, or catkins. The ovules are solitary and suspended. The embryo lies in the midst of fleshy albumen, hooked, with the radicle long, superior, folded down towards the cotyledons.

Although the Mulberry and Fig grow in Europe, all the *Moraceæ* are extra-European. The species inhabit the temperate and tropical latitudes of both hemispheres, often forming vast forests. The genus *Ficus* is the most distinguishing feature of this order. [FICUS.] Most of the plants of this order furnish caoutchouc. [CAOUTCHOUC.] The fruit of the Mulberry is edible, and the leaves of the genus *Morus* are the food of the Silk-Worm. [MORUS.] Several species of *Dorstenia* are used in medicine. [DORSTENIA.] Other genera of this order yielding useful products are *Broussonetia* and *Maclura*. [BROUSSONETIA; MACLURA, *S.* 2.]

This order embraces 8 genera and 184 species.

MORCHELLA, a genus of *Fungi*, one of the species of which is eatable. *M. esculenta*, the Morel, springs up in orchards, woods, and cinder-walks, early in the spring and summer, and is believed to be most plentiful in places where fires have been made. The country people in Germany are so persuaded of this, that they formerly set fire to woods in order to obtain a crop of morels, of which they are very fond. At last the practice was put down by law. This fungus has a stalk from one to three inches long, and a spherical cap, from the size of a pigeon's egg to that of a swan's, hollow, pale-brown, or even gray, and deeply pitted all over its surface, the depressions being separated by raised anastomosing lines. The plant has a slight smell and an agreeable taste, and is employed for various purposes of cooking, both fresh and dried. In the former state it is most commonly stewed or stuffed with force-meat; in the latter it is employed as an ingredient in sauces. In this country it is of rather rare occurrence.

MOREL. [MORCHELLA, *S.* 2.]

MORETON BAY. [AUSTRALIA, *S.* 2; WALES, NEW SOUTH.]

MORINGACEÆ, a small natural order of Exogenous Plants, embracing the species of the genus *Moringa*. They are characterised by the possession of a many-leaved calyx, perigynous petals and stamens, 1-celled anthers, stipitate and consolidated siliquose fruit, and seeds without albumen. This order is referred by most botanists to a position near *Leguminosæ*, but Lindley places them in his *Violales*. They are natives of the East Indies and Arabia.

The root of *Moringa pterygosperma* has a pungent odour with a warm biting and somewhat aromatic taste. The seeds of this plant are called by the French Pois Queinques and Chicot. They are the Ben-Nuts of old writers, from which the Oil of Ben was extracted. It is chiefly used by perfumers as the basis of various scents. It does not readily freeze, and on this account is used by watchmakers. The flowers, leaves, and other parts of this plant are added to curries in India.

MORMONS. [SMITH, JOSEPH, *S.* 2; UTAH, STATE OF, *S.* 2.]

MORPHOLOGY is that branch of science which treats of the laws which regulate the forms assumed by Plants and Animals. When this term was originally introduced into natural history science, its application was confined to the explanation of the changes which occur in the conversion of the leaves into the parts of the flower in plants. It is now however generally recognised as the science of form in the organic kingdoms. Schleiden, in his 'Principles of Scientific Botany,' treats of what is usually called the structure of plants, under two heads, that is General and Special Morphology. The following are his definition and remarks upon this subject:—

"Morphology is the study of the forms of plants, and of their several parts. It is divisible into a general branch, which elucidates all that has reference to plants and their organs in general, and a special branch, which treats of plants according to their principal groups, as well as their individual organs; and this latter branch again is separable into two parallel sections, namely the delineation of external form, and the delineation of internal structure, or of the peculiar composition of plants and their parts from various tissues.

"In my methodological introduction I have endeavoured to show that the external morphology of plants is really the most important section of botany. A mere glance at the history of the science will convince any one of the truth of this view; for it is truly wonderful to observe how far it has succeeded, to the almost entire neglect of all other scientific knowledge, in taking possession of the materials by merely examining its exterior, and arranging it in such a manner that the systems which in recent times have taken another path—I allude to the anatomico-physiological—have scarcely effected more than the introduction of extremely trifling changes, in some instances clearly untenable, and others at best of very doubtful validity. The morphological method of observation has certainly, from the origin of the science, been the basis of all treatises on botany; but those who have thus pursued it have been far from taking a strictly scientific view of the question, or seeking in this way for the solution of its difficulties. This task is two-fold, at once empirical and theoretical. In its first character the study requires us to examine into and characterise the fundamental forms which, as types, or conceptions of generic and specific shapes, constitute the basis of individual forms. In its second character this study has to unfold the natural laws according to which these types are formed, and which control and explain the deviations that occur in individual forms from their prototypes. For the first or empirical part of our researches, we may congratulate ourselves on having some little information, although of a very fragmentary nature; but in the second or theoretical department we have scarcely even an indication to guide us. That the solution of the difficulties must be sought by beginning from the simplest case is evident, and here Schwann has certainly shown eminent acuteness in establishing the analogy between the formation of crystals and that of cells; but unfortunately we have not yet brought the law of crystalline formation into the dominion of science. Thus at the present time we can do no more than specify the problem presented to botany, the solution of which is alone to be expected when the mathematical construction of the formation of crystals lies perfectly complete before us. If however this is ever to be effected, we must enter upon all possible construction in a very different way from what has hitherto been done. For this purpose we must consider somewhat more exactly the characteristics of organic form, especially the vegetable, as opposed to the inorganic. The inorganic form, the crystal, is permanent when once formed; it is unchangeable; the individual (the individual existence) is the form itself, and by its solution and change of form a new individual arises. In the plant, on the other hand, the form is not stable or permanent, but an ever-changing one. The analogies between the two hold good only in the simplest cases. The nucleus of a crystal originates in a definite form, and then passes through a series of forms, until it reaches the deduced crystalline form. As such it then remains unchangeable until the individual is destroyed with the form. Thus certainly it has a very simple history of development, but this continues merely so long as something is still being added to that which is already present, until the whole is completed. The cell is formed in a manner somewhat analogous to this, originating in a definite form, and passing through a series of changes, which, as it appears, only contribute new matter until the form is complete; this then remains stationary until its solution and the consequent destruction of its individuality. It is however wholly different in combined forms, and these it is which, with few exceptions, compose what we term plants. Here a number of cells combine together within definite external limits; but these cells themselves do not enter into the form as dead particles of the mass; they continue to develope new cells, whilst the old ones are partially destroyed: the newly originated cells change, by their arrangement, the form of the whole, and, since formation of new parts and destruction of the old are continually going on, the general boundary of the whole never appears as anything definitely fixed. As, however, this metamorphosis is constant in its nature, and only occurs in individual parts, we cannot regard each one of the forms resulting from this process as a new one, but merely as a slight modification of the one immediately preceding it; and this peculiar connection brings the whole to us as one individual, which, at its first appearance, may be entirely different in all its parts, both in shape and material, from what it is at last; but in the conception of which we must comprehend the whole series of changing forms, wherein the widely distant members have perhaps no element identical, if we would attain to scientific knowledge, if we would understand the object, and not merely acquire a disjointed, uncomprehended, and incomprehensible impression. From these considerations it follows, granting the paramount importance of the morphological method of observation, that we gain nothing by the comprehension of the forms complete at any one moment, but that we must trace out the law of morphological development, and direct our scientific inquiries, not to an individual complete at any one period, but to the comprehension of the collective constant series of normally changing forms. The conception of genera and species in botany is consequently, therefore, not merely the result of a comparison but also of a connection of the various individual characteristics with each other. In this manner we should lay a firm foundation for the inductions to lead us to a theory of organic morphology, if we could but succeed in completing the theory of the formation of inorganic forms. As yet we are far from this point, and simply because it is only in the most recent times, and yet very imperfectly, that the importance of the study of the history of development has been acknowledged; although, without this, botany would be wholly divested of all scientific principle. This deficiency renders it impossible as yet to treat morphology with scientific logical development, or in accordance with a perfectly systematic mode of arrangement, as will but too obviously appear in my manner of treating this subject, although the blame of this is only partially to be imputed to me. It seems however practicable perfectly to state the problem, and to this end I subjoin the following remarks:—

"We have to construct the laws of morphological formation, and to delineate the forms themselves. The first remains for the present a mere problem, the solution of which must be reserved for succeeding times. The second may be accomplished, although imperfectly. I say imperfectly, because, instead of those complete series of development of which we ought alone to treat, we only know a few individual conditions; and therefore the greatest portion of the task still lies unperformed before us. Here we must again distinguish between—1. Series of forms which occur in all or in very many plants of a very different nature, and may therefore especially serve as the foundation of the study of vegetable forms; that is, General Morphology. 2. Series of forms which are only peculiar to definite groups of plants: Special or Comparative Morphology. These two would further branch off into the consideration of form without reference to its composition from the different forms of the elementary organs: External Morphology; and into the consideration of the manner in which forms are composed from individual tissues: Internal Morphology (the theory of structure—'Comparative Anatomy'). This last part falls however away from General Morphology; for all that we can, for the present at least, say is, that every plant is composed of the different forms of the elementary organs which have already been treated of. Even with respect to the second part, in regard to Comparative Morphology, it appears to me unadvisable to divide the two sections, on account of our deficiency of material; I shall, therefore, in the examination of the individual groups and parts of plants, subjoin all that is known concerning their structure."

MORRISON, SIR RICHARD, architect, was born about the year 1767, and was the son of John Morrison, architect, of Cork. He was at one time intended for the Church, but subsequently became a pupil of James Gandon, the architect, in Dublin. Through his godfather, the Earl of Shannon, Morrison obtained a government appointment in the Ordnance department, but had to relinquish it in consequence of reductions, when he got into practice as an architect, and in the course of his life erected a large number of buildings. For a few particulars of some of these, reference may be made to Weale's 'Quarterly Papers on Architecture' (vol. i.), in which there is a memoir of *William Vitruvius Morrison*, son of Sir Richard, who was sometime in practice conjointly with his father, and who died at the age of forty-four. Sir Richard Morrison was last employed for Lord Longford and the Earl of Howth. His knighthood was received during the viceroyalty of the Earl de Grey. He left considerable property, including a well-stocked library, and died on the 31st of October, 1849, at the age of eighty-two. He was president of the Irish Institute of Architects.

MORTLAKE. [SURREY.]

MORTON, SAMUEL GEORGE, M.D., celebrated as an Ethnologist, was born at Philadelphia in the United States of North America in 1799. His parents were members of the Society of Friends, and he had the misfortune to lose his father early in life. His mother however married a second time when young Morton was thirteen years old, and from his step-father he seems to have derived a liking for the study of natural history. After leaving school he was placed in a counting-house, but his taste for natural science led him to abandon business and enter the medical profession. He was accordingly placed with Dr. Joseph Parrish of Philadelphia, who, although unconnected with any public medical office, had the highest reputation for the management and education of young men studying the medical profession. He attended the lectures and passed through the course of instruction prescribed for the students of medicine in his native city, and received his diploma of Doctor of Medicine in March, 1820. He was at the same time admitted a member of the Academy of Sciences (Philadelphia). Soon after this event he sailed for Europe, and, after visiting an uncle—Mr. James Morton of Clonmel, in Ireland,—he repaired to the University of Edinburgh. Here he studied two years, and graduated in medicine in 1823. His inaugural thesis was entitled, 'Tentamen inaugurale de Corporis Dolore.' During his period of preparation for graduating in Edinburgh he visited France and Italy, and made a stay in Paris. He returned to America in the summer of 1824, just in time to witness the departure of some of the most eminent literary and scientific men in Philadelphia to join in the ill-starred social experiment of Mr. Robert Owen at New Harmony in Indiana. He became immediately an active member of the Academy of Sciences, and commenced his contributions to its transactions by a geological paper. It was entitled, 'Analysis of Tabular Spar from Bucks County.' He subsequently contributed many papers on Geology and Palæontology to the transactions of the Academy. Several of the most important of these papers were published in a separate volume entitled, 'Synopsis of the Organic Remains of the Cretaceous Group of the United States.' This was a very valuable contribution to Geology, and was received with the warmest commendations by European geologists. He cultivated generally the natural history sciences, and wrote several papers on zoological subjects.

Whilst pursuing natural history with success, he did not neglect to cultivate professional knowledge. In 1834 he published a work entitled 'Illustrations of Pulmonary Consumption; its Anatomical Character, Causes, Symptoms, and Treatment.' He also edited an edition of Dr. Mackintosh's 'Practice of Physic,' with notes and additions. From 1839 to 1843 he filled the chair of anatomy in the medical department of Pennsylvania College. In 1849 he published 'An Illustrated System of Human Anatomy, Special, General, and Microscopic.'

His previous labours, however, were but preparations for the great works on which his reputation as one of the first ethnologists of his day is founded. The line of his research on the races of men lay more particularly in their anatomical configuration, and especially in the structure of the skull. During his researches, he made one of the most valuable collections of skulls extant, and which is now in the possession of the Philadelphia Academy of Practical Sciences. The origin of this collection may be given in his own words:—"Having had occasion," he says, "in the summer of 1830 to deliver an introductory lecture to a course of anatomy, I chose for my subject 'The different Forms of the Skull as exhibited in the Five Races of Men.' Strange to say, I could neither buy nor borrow a cranium of each of these races, and I finished my discourse without showing either the Mongolian or the Malay. Forcibly impressed with this great deficiency in a most important branch of science, I at once resolved to make a collection myself." The result of this determination was not only his great collection, but the two magnificent works, entitled 'Crania Americana,' and 'Crania Egyptiaca.' These works embraced not only an account and illustrations of the skulls, but general ethnological observations on the races of men. The collection on which these works were founded contains 951 human crania, collected from all parts of the world, 278 crania of mammals, 271 of birds, and 88 of reptiles and fishes.

Although in his earlier writings he maintained the specific unity of the human race, in the latter part of his life he was led to doubt this view, and to express his conviction of the existence of a diversity of species among men. This view has been strongly insisted on, in a work published since his death, under the title of 'Types of Mankind.' This work, edited by Messrs. Nott and Gliddon, contains a large mass of matter by the editors and others, with many "Excerpta" from Morton's inedited papers. In these he undoubtingly avows his belief in an "aboriginal plurality of races;" and expresses his conviction, that "man will yet be found in the fossil state as low down as the Eocene deposits, and that he walked the earth with the megalonyx and palæotherium." It is only right to add that these views have not been generally received; and that our most distinguished ethnologists, palæontologists, and geologists have not indorsed his later doctrines. Dr. Morton died at Philadelphia, after a short illness of five days, on the 17th of May, 1851.

MOSANDERITE. [MINERALOGY, *S.* 1.]

MOSQUITO. The following is an account of the structure of *Culex Mosquito*, the Mosquito of the Americans, by an American observer:—

"The male mosquito differs considerably, as is well known, from the female; his body being smaller and of a darker colour, and his head furnished with antennæ and palpi in a state of greater development. Notwithstanding the fitness of his organs for predatory purposes he is timid, seldom entering dwellings or annoying man, but restricts himself to damp and foul places, especially sinks and privies. The female, on the other hand, gives greater extension to her flight, and, attacking our race, is the occasion of no inconsiderable disturbance and vexation during the summer and autumn months.

"The head of the male mosquito, about 0·67 mm. [millimètres] wide, is provided with lunate eyes, between which in front superiorly are found two pyriform capsules nearly touching each other, and having implanted into them the very remarkable antennæ.

"The capsule, measuring about 0·21 mm., is composed of a horny substance, and is attached posteriorly by its pedicle, while anteriorly it rests upon a horny ring, united with its fellow by a transverse fenestrated band, and to which it is joined by a thin elastic membrane. Externally it has a rounded form, but internally it resembles a certain sort of lamp-shade with a constriction near its middle; and between this inner cup and outer globe there exists a space, except at the bottom or proximal end, where both are united.

"The antennæ are of nearly equal length in the male and the female.

"In the male the antenna is about 1·75 mm. in length, and consists of 14 joints, 12 short and nearly equal, and 2 long and equal, terminal ones, the latter measuring together 0·70 mm. Each of the shorter joints has a fenestrated skeleton with an external investment, and terminates simply posteriorly, but is encircled anteriorly with about 40 papillæ upon which are implanted long and stiff hairs, the proximal sets being about 0·79 mm. and the distal ones 0·70 mm. in length; and it is beset with minute bristles in front of each whorl.

"The two last joints have each a whorl of about 20 short hairs near the base.

"In the female the joints are nearly equal, number but 13, and have each a whorl of about a dozen small hairs around the base. Here, as well as in the male, the parts of the antennæ enjoy a limited motion upon each other, except the basal joint, which, being fixed, moves with the capsule upon which it is implanted.

"The space between the inner and outer walls of the capsule, which we term confidently the auditory capsule, is filled with a fluid of moderate consistency, opalescent, and containing minute spherical corpuscles, and which probably bears the same relation to the nerve as does the lymph in the scalæ of the cochlea of higher animals. The nerve itself of the antenna proceeds from the first or cerebral ganglion, advances towards the pedicle of the capsule in company with the large trachea which sends its ramifications throughout the entire apparatus, and, penetrating the pedicle, its filaments divide into two portions. The central threads continue forwards into the antenna and are lost there; the peripheral ones, on the contrary, radiate outwards in every direction, enter the capsular space, and are lodged for more than half their length in sulci wrought in the inner wall or cup of the capsule.

"In the female the disposition of parts is observed to be nearly the same, excepting that the capsule is smaller, and that the last distal antennal joint is rudimental.

"The proboscis does not differ materially in the two sexes; but the palpi, although consisting in both instances of the same number of pieces are very unlike. In the female they are extremely short, bnt in the male attain the length of 2·73 mm.; while the proboscis measures bnt 2·16 mm. They are curved npwards at the extremity.

"If an organ of hearing, similar to that described by Treviranns as belonging to the *Blatta orientalis,* exist in the head of the Mosquito, the tympanum must be of exquisitely minute proportions, because the head, which has a diameter of only 0·67 mm., is almost entirely occupied by the corneal plaqnes, the capsules, and tbe attachments of the neck and of the bnccal apparatus. The membrana tympani mnst therefore be so small as to preclnde the idea of its being put in vibration by any sounds other than those infinitely more acute than are produced by the insect itself, and the nse of such an organ for the purposes of intercommunication must be highly problematical. But no trace of snch a disposition is to be fonnd in the head, nor very certainly, also, in the body; and we are obliged to look for some organ which may answer the requirements of an effective auditory apparatns.

"The position of the capsnles strikes us as extremely favonrable for the performance of the function which we assign to them: besides which there present themselves in the same light the anatomical arrangement of the capsnles, the disposition and lodgment of the nerves, the fitness of the expanded whorls for recoiving, and of the jointed antennæ fixed by the immovable basal joint for transmitting, vibrations created by sonorons modnlations. The intra-capsular fluid is impressed by the shock, the expanded nerve appreciates the effect of the sonnd, and the animal may judge of the intensity, or distance, of the source of sonnd, by the quantity of the impression; of the pitch, or quality, by the consonance of particular whorls of the stiff hairs, according to their lengths; and of the direction in which the modulations travel, by the manner in which they strike upon the antennæ, or may be made to meet either antenna, in conseqnence of an opposite movement of that part.

"That the male should be endowed with snperior acuteness of the sense of hearing appears from the fact, that he must seek the female for sexnal union either in the dim twilight or in the dark night, when nothing save her deep sharp humming noise can serve him as a guide. The necessity for an equal perfection of hearing does not exist in the female; and accordingly we find that the organs of the one attain to a development which the others never reach. In these views we believe ourselves to be borne out by direct experiment, in connection with which we may allnde to the greater difficnlty of catching the male Mosquito.

"In the course of our observations we have arrived at the conclnsion that the antennæ serve, to a considerable extent, as organs of touch in the female; for the palpi are extremely short, while the antennæ are very moveable, and nearly equal the proboscis in length. In the male however the length and perfect development of the palpi would lead ns to look for the seat of the tactile sense elsewhere; and in fact we find the two apical antennal joints to be long, moveable, and comparatively free from hairs; and the relative motion of the remaining joints very much more limited." (Dr. Christopher Johnston, *Quarterly Journal of Microscopical Science.*)

MOTACILLA, MOTACILLINÆ. [Blue Bird; Blue Breast; Sylviadæ; Wagtails.]

MOTELLA, a genns of Fishes belonging to the family *Gadidæ.* It has the following characters: Body elongated, cylindrical, compressed posteriorly, the first dorsal fin very slightly elevated, delicate in structure, scarcely perceptible; second dorsal and anal fins long, continued nearly to the base of the tail.

M. vulgaris, Mustela marina (Ray), *Gadus tricirratus* (Bloch), the Three-Bearded Rockling, Sea-Loche, Whistle-Fish, Three-Bearded Cod, Three-Bearded Gade, has the following characters: The length of the head compared to the length of the body alone, without the caudal rays, is as one to fonr; the depth of the body equal to the length of the head; the first dorsal fin delicate in structure; the first ray elongated, the rest hair-like; the second dorsal fin commencing immediately behind the end of the first, and reaching along the back to the tail, but ending a little short of the base of the caudal rays; ventral fins with the first two rays elongated, the second most so, the two disunited; the other five rays nearly equal, united, and short; pectoral fins rather large and ronnded; the vent half-way between the point of the chin and the end of the fleshy portion of the tail; the anal fin commences immediately behind it, is one-fourth less in length than the sccond dorsal, and ends on tbe same plane with it; the tail moderate in size, and rounded at the end. The fin rays in number are—2nd D. 55; P. 20; V. 7; A. 49; C. 18. The head is depressed; the mouth wide; the jaws nearly eqnal, but when separated the lower jaw is the longer, with one barbnle at the chin; a mixtnre of large and small teeth in each jaw; the upper jaw with one barbule on each side the middle, between the lip and the nostril; inner part of the npper lip crenate; the irides golden yellow; the anterior portion of the body of the fish cylindrical, or slightly depressed; the tail compressed; the general colonr of the body and head is a rich yellow-brown, spotted on the top of the head, along the back, the pectoral, dorsal, and caudal fins, with rich chestnut-brown; the lower part of the sides, the ventral and anal fins pale yellow-brown approaching to white, and without spots.

Young fish of this species are of a nniform brown colonr, nntil they have acquired 6 or 7 inches in length; in this condition they are the *Mustela alia* of Ray. (Yarrell.)

This fish is common on the coasts of Cornwall, and also on the coasts of Ireland.

M. cimbria (*Gadus cimbrius,* Linnæns), the Four-Bearded Rockling. This fish has been taken in Scotland, and is common in the Baltic and the southern coast of Sweden.

M. quinquecirrata (*Gadus mustela,* Linnæus), the Five-Bearded Rockling. This fish is common on tbe British coast. Its habits resemble those of the Three-Bearded Rockling, and by some naturalists it is regarded as a variety of that species.

M. glauca (*Ciliata glauca,* Conch), the Mackerel Midge. This fish has been taken on the coasts of Cornwall by Mr. Conch. It dies instantly on being taken out of the water. It is like the young of some of the other species, but it has not been observed to grow.

M. argenteola (*Gadus argenteolus,* Montagu), the Silvery Gade. This fish is a miniature representative of the Three-Bearded Rockling, as the last is of the five-bearded species. It was first described by Montagu, and is admitted as a distinct species by Yarrell.

MOULMEIN, a town and port in tbo Tenasserim Provinces, which form a part of the British possessions on the eastern side of the Bay of Bengal. Moulmein is situated near the Gulf of Martaban, at the confluence of the rivers Saluen, Attayen, and Gyeng, in 16° 30′ N. lat., 97° 44′ E. long.: the three rivers when united are called the Moulmein River. It is 10 miles S. by E. from Martaban, and 30 miles N. by E. from Amherst. [Amherst.] Moulmein has a good harbonr, which admits vessels of 600 or 800 tons. Being favourably sitnated for commerce, and free from duties of import and export, it has drawn away much of the commerce which belonged to Martaban, and has in a great measure superseded Amherst. The population is estimated at upwards of 10,000. The exports are teak-timber, rice, tobacco, ivory, stick-lac, cocoa-nuts, and live-stock. The imports are cotton goods and other manufactures.

MOUNTMELLICK. [Queen's County.]

MOUNTRATH. [Queen's County.]

MUCIC ACID. [Chemistry, *S.* 1.]

MUCORACEÆ, an order in Lindley's alliance *Fungales.* The species have a floccose thallus and the spores surrounded by a vesicular veil or sporangium. They are amongst the smallest forms of *Fungi,* and attack decaying vegetable and animal matters. They are frequently known by tho name of Moulds. [Mouldiness; Fungi; Entophyta, *S.* 2.; Mildew.]

MUDARIN. [Chemistry, *S.* 1.]

MUDGE, WILLIAM, LL.D., F.R.S., a major-general in the army, the tbird in succession of the directors of the series of geodetical operations, which resnlted in the Trigonometrical Survey of Great Britain and Ireland, the production of the 'Ordnance Maps' by its means, and the measurement of the English Arc of the Meridian. The history of family and hereditary talent, and the occupation of certain offices by a succession of gifted men, have frequently been illustrated in this work. They are again forcibly recalled by the name now commemorated. The Rev. Zachary Mudoe, sometime master of the Grammar School at Bideford, in Devonshire, and vicar of Abbotsham, afterwards a prebendary of Exeter and vicar of St. Andrew's, Plymouth, was the author of an 'Essay for a New Version of the Psalms,' and of a much-admired volume of sermons, pnblished in 1727. He died April 3rd, 1769, and was eulogised by Dr. Johnson, whose intimate friend he had been. Thomas Mudoe, his second son, born at Exeter in

1716, was apprenticed to the celebrated watchmaker, George Graham, and became himself one of the most eminent mechanists of his time: a select committee of the House of Commons, assisted by a committee of men of science, philosophical instrument makers, and watchmakers, including Atwood, Ramsden, Troughton, and De Luc, declared in 1793, that it was "admitted on all hands that Mr. Mudge was one of the first watchmakers which this country has produced." In consequence of a report made by the select committee, a reward of 3000*l.* was granted by parliament for his improvement in the construction of chronometers. His decease took place shortly after, in 1794. A full account of his invention, and of the circumstances in the history of chronometry connected with it, will be found in a work published by his son, Thomas Mudge the Younger, entitled 'A Description, with Plates, of the Time-keeper invented by Mr. Thomas Mudge,' &c., Lond., 1799, 4to.

The fourth son of the vicar of St. Andrew's was Dr. John Mudge, F.R.S., for many years an eminent physician at Plymouth, who published treatises on the inoculated small-pox, and on catarrhous coughs. But he acquired a higher reputation in practical optics, founded on a paper in the 'Philosophical Transactions,' vol. lxvii., "containing directions for making the best composition for the metals of reflecting telescopes, together with a description of the process for grinding, polishing, and giving the great speculum the true parabolic form." For this paper, in which an anticipation of Newton was verified, the council of the Royal Society awarded him the Copley Medal for the year 1777, on which occasion Sir John Pringle, M.D., Bart., the president, delivered one of his celebrated discourses.

William Mudge, the subject of the present article, son of Dr. John Mudge, was born at Plymouth in 1762, and having received his principal education as a cadet in the Royal Military Academy at Woolwich, was appointed to the Royal Artillery, in which corps he served abroad for some time. After his return to England, the Trigonometrical Survey of England and Wales, which had been commenced by General Roy, was placed, by the recommendation of Dr. C. Hutton, under the superintendence of Lieut.-Col. Edward Williams, R.A., Lieut. Mudge, also on Dr. Hutton's recommendation, being appointed his personal associate in the work, and being promoted shortly afterwards to the rank of Captain. The survey, which had suffered some interruption after the decease of the former director, was actively resumed in 1791. In the 'Philosophical Transactions' for 1795 and 1797, are two papers of great length, by Lieut.-Col. Williams, Captain Mudge, and Mr. Isaac Dalby, giving an account of the Survey as carried on from 1791 to 1796. Not long afterwards Captain Mudge succeeded to the office of superintendent, and in 1798 he became a Fellow of the Royal Society. In the 'Philosophical Transactions' for 1800, he continued the account of the progress of the survey during the years 1797, 1798, and 1799; and having attained the rank of Major, R.A., he gave in the volume for 1803, 'An Account of the Measurement of an Arc of the Meridian, extending from Dunnose, in the Isle of Wight .... to Clifton, in Yorkshire .... in course of the operations carried on for the Trigonometrical Survey of England, in the years 1800, 1801, and 1802.' Major Mudge, who united with energy of character, mathematical talent and culture, and the valuable faculty of readily observing and appreciating the existence of corresponding qualities in others, recognising a kindred spirit in Lieutenant Colby, R.E., conferred an inestimable benefit upon the national work which he conducted, by securing his services as his chief personal assistant. In 1802, with Colby's assistance, he measured the base on King's Sedgmoor; in 1806, that on Rhuddlan Marsh; and during his superintendence a third base was measured by Colby on Belhelvie Links, near Aberdeen, in 1817. [Colby, Thomas, *S.* 2.]

In 1799 had appeared, as a kind of demi-official publication, in 4to, vol. i. of an 'Account of the Survey from the Commencement in 1784, to the end of the Year 1796,' revised from the 'Philosophical Transactions,' by Captain Mudge and Mr. Dalby. The second volume, published in 1801, was edited by Captain Mudge alone, and continued the account to the end of the year 1799; it was, in fact, a separate issue of the paper communicated to the Royal Society in 1800, already noticed. The third volume, 'by Lieut.-Col. William Mudge, of the Royal Artillery, F.R.S., and Capt. Thomas Colby, of the Royal Engineers,' published in 1811, continues the account of the Survey, as carried on from 1800 to 1809. But a very small proportion, however, of the whole body of observations was contained in these volumes, and no further account of the survey was made public until long after the decease of Mudge, when, in 1842, his successor Colby published all the observations made with Ramsden's zenith sector. The maps, however, known as those of the Ordnance Survey, on the scale of one inch to a mile, were first produced under Mudge's superintendence, and were issued from time to time (after an interval during the war, in which they were withheld from publication), admirably executed, and of the highest value in reference to the topography of the country.

Whilst General Mudge was superintendent, but by the personal exertion of Captain Colby, the principal triangulation of the survey was extended, as just indicated, to the north of Scotland. But in that of South Britain, as it had been carried on under his orders in former years, his successor had to correct errors and supply many omissions. These, as we are informed by competent authority, "had resulted from the hurried manner in which the work was performed, from the very imperfect means placed at General Mudge's disposal, and from the want [since supplied] of a legislative enactment for the preservation of the various trigonometrical observing stations throughout the country, which want sometimes led to a failure of identity between the observing and observed points; so that, all things taken into consideration, it is rather to be wondered at that the work should, generally speaking, be so good as it is known to be." ('Mem. Roy. Ast. Soc.,' vol. xxii., p. 213.)

General Mudge was afterwards appointed lieutenant-governor of the Royal Military Academy at Woolwich; into the administration of which he is stated to have introduced many excellent regulations, which were afterwards extended, under his direction, to the Military Seminary founded by the East India Company at Addiscombe. In addition to the public employments and distinctions which have been mentioned, he was a member of the Board of Longitude, a Fellow of the Society of Antiquaries, a member of the Geological Society, and Honorary LL.D. of the University of Edinburgh. The Royal Academy of Sciences of Paris elected him a correspondent, and the Academy of Sciences of Copenhagen, a Fellow. He died at his house in Holles-street, London, on the 17th of April, 1821, in his fifty-eighth year, leaving a widow, with three sons and a daughter.

One of the sons, Richard Zachary Mudge, who entered the army in 1807, and served in the Peninsula, became eventually a lieutenant-colonel in the royal engineers and F.R.S. He also was attached to the Trigonometrical Survey, in which, after Captain Colby had been appointed superintendent, he was entrusted for some years with the local charge of the 'drawing-room' in the Tower of London—where the results of the Survey were laid down, and the maps actually constructed—during the absence of his chief on other duties. He afterwards retired from the service, and entered into business as a banker in Devonshire. He died at Teignmouth on the 24th of September, 1854, aged sixty-five.

MUDWORT, the common name of the species of the genus *Limosella.* This genus belongs to the natural order *Scrophulariaceæ.* It has a 5-cleft calyx; a 5-fid bell-shaped equal corolla; a globose 2-valved capsule, with a central placenta, free, or connected with a short dissepiment below, 1-celled.

L. aquatica is the only British species. It has lanceolate spathulate leaves on long stalks; pedicles axillary, crowded, shorter than the petioles. It has small white or rose-coloured flowers. It is found growing in muddy places, where water has stagnated.

MULLET. [Mugilidæ; Mullus, *S.* 2.]

MULLUS, a genus of Fishes belonging to the group *Acanthopterygii* and the family *Percidæ.* The species have the body thick oblong; profile of the head approaching to a vertical line; scales large, deciduous; two dorsal fins widely separated, the rays of the first spinous, those of the second flexible; teeth on the lower jaw and palate only; two cirri at the symphysis of the lower jaw; branchiostegous rays 4. There are two species of this genus found in Europe, and both are inhabitants of the seas of Great Britain.

M. surmuletus, the Striped Red Mullet, or Striped Surmullet, has the following fin-ray formula:—D. 7—1 + 8; P. 17; V. 1 + 5; A. 2 + 6; C. 13.

The forehead, nape, cheeks, and operculum are covered with scales; irides pale-yellow; mucous-pores abundant; the colour of the body is from a pink to a bright-red; the membrane of the first dorsal-fin is tinged with yellow; those of the other fins transparent; the axilla of the ventral fin furnished with a pointed scale; the vent placed under the commencement of the second dorsal fin.

The Striped Red Mullet is abundant on the southern coasts of Great Britain, but is rarer on the eastern and northern coasts. This fish is good eating, and is sent in large numbers from the coasts to the London market. In the month of August, 1819, 5000 were taken off Weymouth, and in one week during the month of May, 1831, 10,000 were sent to London from Yarmouth. The Striped Red Mullet was a favourite dish amongst the ancient Romans, and large prices were paid for them. "A fish of 3 lbs. weight produced a considerable sum to the fortunate fisherman, while the cost of a fish of 4½ lbs., says Martial, was ruinous. A Mullet of 6 lbs. is recorded to have produced a sum equal to 48*l.*; one still larger 64*l.*; and even 240*l.* were given for three of unusual size, procured on the same day, for a repast of more than usual magnificence." (Yarrell.) On the coasts of Great Britain this fish seldom exceeds 14 inches in length.

The Striped Red Mullet spawns in the spring, and the young are 5 inches long in October. Their food consists of the softer crustaceous and molluscous creatures. The cirri, which are generally placed near the mouth, seem to act as organs of feeling, whereby these animals are enabled to distinguish their food. Mr. Yarrell says, "On dissecting these appendages in the Mullet, the Common Cod, and others, I found them to consist of an elongate and slender flexible cartilage, invested by numerous longitudinal muscular and nervous fibres, and covered by an extension of the common skin. The muscular apparatus is most apparent in the Mullet, the nervous portion most conspicuous in the Cod. These appendages are to them, I have no doubt, delicate organs of touch, by which all the species provided with them are enabled to ascertain, to a certain extent, the qualities of the various substances with which they are brought in contact, and are analogous in function to the beak, with its distribution of nerves, among certain wading and swimming birds which probe for food beyond their sight; and may be considered another instance, among the beautiful provisions of nature, by which in the case of fishes feeding at great depths, where light is deficient, compensation is made for imperfect vision." ('British Fishes,' vol. i., p. 34.) This and the next species must not be confounded with the Gray Mullet, which belongs to a very different family of Acanthopterygious Fishes. [MUGILIDÆ.]

M. barbatus, the Plain Red Mullet, the Surmullet, the Red Surmullet. This fish is much rarer on the British coasts than the last. They seem to be equally abundant in the Mediterranean. The fin-rays are as follows: D. 7—1 + 8; P. 16; V. 6; A. 1 + 6; C. 15. The scales are somewhat smaller than in the last and present some structural differences.

(Yarrell, *History of British Fishes.*)

MURÆNOIDES (Lacépède), a genus of Fishes belonging to the section *Acanthopterygii* and the family of *Gobiadæ*. The species have been included under the genera *Blennius* of Linnæus, and *Gunnellus*. They have the head small, muzzle obtuse; body elongated, smooth; scales minute, covered with a mucous secretion; dorsal fin extending the whole length of the back, the rays simple; ventral fins very small; teeth small, pointed, detached.

M. guttata, the Spotted Gunnel or Butter-Fish, is distinguished from its congeners by the consistence and quantity of mucous secretion by which its sides are covered. It is known from the true Blennies by its dorsal fin being but little elevated above the line of the back, and by its elongated, slender, and compressed body, from which circumstance it has obtained the name of Swordick in Orkney and Svardfisk in Norway, from a supposed resemblance to the blade of a sword. It is a common fish on the coasts of Great Britain, where it is often found in the little pools left by the tide. It feeds on small *Crustacea* and the spawn and fry of other fishes. In Greenland it is eaten, but it is only used for bait in this country, its flesh being hard. The length of the head is equal to the depth of the body, and is, when compared with the whole length of the body and head of the fish, without including the tail-fin, as one to eight. It is said to attain the length of 10 inches, but its more frequent length on the British shores is from 5 to 7 inches.

Mr. Yarrell states that the Spotted Gunnel of America is identical with the British fish.

MUREXAN, MUREXIDE. [CHEMISTRY, *S.* 1.]

MUSCALES, an alliance of Acrogenous Plants in Lindley's arrangement of the Vegetable Kingdom. It includes two divisions:—1. *Hepaticæ;* 2. *Musci*. The *Hepaticæ* include the orders *Ricciaceæ*, *Marchantiaceæ*, *Jungermanniaceæ* and *Equisetaceæ*. The *Musci* include the orders *Andræaceæ* and *Bryaceæ*.

MUSCARDINE, the name given to a disease to which silk-worms are subject, and which often causes great injury to those who cultivate these animals for the sake of their silk. This disease is attended with the development of a fungus belonging to the genus *Botrytis*, and has been named by Balsamo and Montagne *B. Bassiana*. This plant, which is characteristic of the disease, can be propagated by the introduction of spores into a healthy caterpillar. The result of the changes produced upon the blood and tissues of the animal is its death. This disease is much more common some years than others. It frequently spreads to other insects; and the caterpillars of other *Lepidoptera* can be inoculated by the spores of the *Botrytis*. When once the disease has appeared there seems to be no means of checking it. The best mode of prevention is to take care that the caterpillars are not over-crowded, and that they have a sufficient supply of fresh food. The predisposition to this disease amongst silk-worms seems to be brought on by the same causes as those which act upon the human system, and render it favourable to the attacks of epidemic diseases.

(Robin, *Hist. des Végétaux Parasites.*)

MUSCAT, a sea-port town on the east coast of Arabia, in the province of Oman, is situated on a peninsula which is joined to the island of Muscat by a reef of rocks, in 23° 48′ N. lat., 58° 40′ E. long., and has about 60,000 inhabitants. High lands to the south and west, and the island towards the east shelter the harbour, the entrance to which is from the northward, and protected by forts on each side; within there is room enough for a large fleet to moor in 4 or 5 fathoms water. A fort close to the town, and two other forts on the western side of the harbour command the whole of the port. The town is surrounded by walls and otherwise strongly fortified. The houses are only one story high, with the exception of some handsome stone buildings erected by the Portuguese. There are also some houses built in the Persian style, and an aqueduct.

Muscat is a great commercial entrepôt, and has a very active trade. A large number of ships belong to it, and trade to British India, Sumatra, the Malay Peninsula, the Red Sea, and eastern coast of Africa, the Comoro Isles, and Madagascar. Indeed wherever Arab traders are met with between Africa and China, they may be set down as belonging to Muscat. The port is resorted to by ships from every port of Persia and Arabia. British and French merchantmen trading to the Persian Gulf stop at Muscat to sell and purchase goods. Besides its maritime commerce, Muscat carries on an extensive trade with the Arab tribes of the interior. The principal articles of the commerce of Muscat are—asafœtida, almonds, raisins, pistachio nuts, socotrine aloës, gum ammoniac, sulphur, gum copal, and saltpetre. Other articles are frankincense, pearls, gall-nuts, coffee, cocoa-nut-oil, galbanum, hides, cotton-wool, mother-o'-pearl, gum, bees'-wax, raw silk, indigo, tortoise-shell, rhinoceros-horns, pepper, cochineal, cinnamon, sugar, rice, sandal-wood, dates, saffron, wheat, horses, salt, dried fish, &c. Most of these articles are imported in Arab vessels from Persia, Zanzibar, Africa, and Western Arabia, and are exported to India, the Mauritius, Bourbon, Calcutta, Bombay, America, France, Zanzibar, &c. The tissues imported at Muscat are British and American long-cloths, British calico-prints, India shawls, Chinese silks, &c. The country near the town is barren; but provisions, fruits, vegetables, and fresh fish are abundant in the markets. Bullocks, sheep, and fowls are to be had at a reasonable price. The annual imports into Muscat are probably under-estimated at a million sterling. Imports pay a duty of 5 per cent. if coming from Arabia, America, or Great Britain; 4 per cent., if coming from Bourbon. No duties are charged on exports. There is a large town called *Muttra*, 3 miles to the westward, nearly as large as Muscat. There is a good road between the two places. At Muttra vessels can be hauled ashore. In the interior there is another large town called *Rostak*.

Muscat was a place of considerable trade before the arrival of the Portuguese in the Indian Ocean, and it was then subject to Ormuz. Albuquerque took it in 1507, but had immediately to put down a bloody insurrection of the Arabs. On the destruction of Ormuz, Muscat became the principal centre of trade in this part of the East, and yielded enormous profits to the Portuguese, who held the town till 1648. During this interval they built the fortifications and greatly improved the city, having erected a handsome church, a college, and many other public structures, besides many superb stone houses. After being gorged with wealth the Portuguese treated the natives so badly and put so many restrictions on their commerce, that they took up arms and drove the Portuguese to their ships. Many unsuccessful attempts were made by the Portuguese to recover the town.

Left to themselves, the Arabs of Muscat—expert seamen, skilled in the use of fire-arms—soon raised a maritime force which overawed not only the neighbouring coasts, but also the European powers in India. By 1694 they had made themselves masters of several places in the Persian Gulf, and were threatening Gombroon; and the British government, acting upon the report of their resident at that place, proposed to send out an armament to clear the Indian seas, and "to root out that nest of pirates the Muscate Arabs." In 1707 the Arabs obtained permission to build ships at the ports of Pegu from the king of that country; and their fleets, comprising ships of from 30 to 50 guns, annoyed trade in the Indian Ocean, and frequently made descents on the towns along the Malabar coast. With the Persians they were almost continually at war; although Persian traders were always permitted to trade at Muscat or any of its dependencies, all Persian ships of war were considered fair game. Since the beginning of the present century they have laid aside their piratical practices, and have confined themselves principally to commerce; and during the rule of the present Imam the territorial dominions, naval power, and commercial importance of Muscat have increased so vastly as to entitle him to be numbered among the great powers of the world. He has commercial treaties with Great Britain and the United States, and has opened intercourse with several European powers.

The Imam of Muscat claims as his possessions in Asia all the south-east coast of Arabia from the frontier of the British settlement of Aden to Ras-el-Had; all the territory of Oman along the east coast of Arabia, the sea-coast and islands in the Persian Gulf, including the Bahrein Islands and the pearl-fishery contiguous to them; and the coast of the Mukran. In Africa he claims sovereignty over all the coast from Cape Delgado to Cape Gardafui, including the ports of Montgallow, Lindi, Quiloah, Melinda, Lamoo, Brava, Magadoxa, &c.; and the valuable islands of Mafea, Zanzibar, Pemba, Socotra, &c. Only a small part of this immense territory is garrisoned by his troops; but all, or nearly all, of it is tributary to him. He rules with patriarchal and despotic sway, but it is said in a just and liberal spirit. His government is strict and to Europeans courteous. A foreigner may walk the streets of Muscat at any hour of the night unmolested. Goods are piled up in the streets exposed night and day, and pilfering is never attempted.

The Imam derives his revenue, which is more than adequate to his expenditure, chiefly from commerce, in which he employs a great number of merchant vessels; from import dues on foreign merchandise; and from tribute money or the equivalent presents made him by princes under his sway. His naval force, more efficient than that of all the native emperors and princes from the Cape of Good Hope to Japan, numbered in 1837 15 vessels, carrying from 6 to 74 guns; 50 baghelas (one-masted vessels of 200 to 300 tons), carrying 8 to 18 guns; and 10 balits (one-masted vessels of 100 to 200 tons), carrying 4 to 6 guns. The number of vessels belonging to the port of Muscat at the same time, was estimated at 2000 of all sizes, a very large proportion of these being small craft. He has intelligent officers and abundance of sailors; but he keeps only a small number of regular troops, as he can have any number of Bedouins whenever he wants them, merely for the clothing and maintenance. His naval force however is sufficient to enable him to maintain his power against all native pretensions over all the territories he claims as his own.

MUSCIDÆ. The House-Fly (*Musca domestica*) is very common in houses in England. Its favourite position is the window, on the panes of which it may be constantly seen walking up and down. The power which this insect possesses of walking upon smooth upright surfaces has in consequence been a frequent theme of conjecture, and of not a small amount of observation. Dr. Derham, in his 'Physico-Theology,' speaking on this subject, says that flies have "skinny palms to their feet to enable them to stick to glass and other smooth bodies by means of the pressure of the atmosphere, after the manner as I have seen boys carry heavy stones with only a wet piece of leather clapped on the top of a stone."

This opinion, which has been entertained by the majority of entomologists of the present day, has acquired additional weight by the elaborate investigations of Sir Everard Home, undertaken at the suggestion of Sir Joseph Banks, with the assistance of that (then) unrivalled microscopic artist, M. Bauer, and published in the 'Philosophical Transactions' for 1816. The suckers, of which several kinds of flies possess three to each foot, are attached beneath the base of the claws, and are of an oval shape and membranous texture, being convex above, having the sides minutely serrated, and the under concave surface covered with down, or hairs. In order to cause the alleged vacuum, these suckers are extended; but when the fly wishes to raise its legs they are brought together, and folded up as it were between the hooks. Messrs. Kirby and Spence have likewise adopted this opinion, considering it as "proved most satisfactorily." Other authors of no mean repute have however entertained a different opinion, and have entirely rejected the idea of a vacuum being produced. Thus Dr. Hooke describes the suckers as palms, or soles, beset underneath with small bristles, or tenters, like the cone-teeth of a card for working wool, which he conceives gives them a strong hold upon objects having irregular or yielding surfaces; and he imagined that there is upon glass a kind of smoky substance, penetrable by the points of these bristles. The same opinion is also given by Shaw in his 'Nature Displayed;' and more recently, Mr. Blackwall has considered that the motions of the fly are to be accounted for upon mechanical principles alone; thus, upon inspecting the structure of the parts of the suckers, it was immediately perceived that the function ascribed to them by Dr. Derham and Sir E. Home is quite incompatible with their organisation. "Minute hairs, very closely set and directed downwards, so completely cover the inferior surface of the expanded membranes, improperly denominated suckers, with which the terminal joint of the foot of flies is provided, that it cannot possibly be brought into contact with the object on which those insects move, by any muscular force they are capable of exerting. The production of a vacuum between each membrane and the plane of position is therefore clearly impracticable, unless the numerous hairs on the under side of these organs individually perform the office of suckers; and there does not appear to be anything in their mechanism which in the slightest degree countenances such an hypothesis. When highly magnified, their extremities, it is true, are seen to be somewhat enlarged; but when they are viewed in action or in repose, they never assume a figure at all adapted to the formation of a vacuum." Moreover, on enclosing a House-Fly in the receiver of an air-pump, it was demonstrated to the entire satisfaction of several intelligent gentlemen present that the fly, while it retains its vital powers unimpaired, can not only traverse the upright sides, but even the interior of the dome of an exhausted receiver; and that the cause of its relaxing its hold, and ultimately falling from the station it occupied, was a diminution of muscular force, attributable to impeded respiration. Hence Mr. Blackwall is induced to believe that insects are enabled to take hold of any roughness or irregularity of surface, by means of the fine hairs composing the brushes, the most carefully polished glass not being found free from flaws and imperfections when viewed in a favourable light with a powerful lens. A still different opinion has been maintained by other authors upon this subject, who, setting aside all idea of a vacuum, have conjectured that the suckers, as they have been termed, contain a glutinous secretion, capable of adhering to well-cleaned glass; thus Abbé de la Pluche states that when the fly marches over any polished body, on which neither her claws nor her points can fasten, she sometimes compresses her sponge, and causes it to evacuate a fluid, which fixes her in such a manner as prevents her falling, without diminishing the facility of her progress. "But it is much more probable," he adds, "that the sponges correspond with the fleshy balls which accompany the claws of dogs and cats, and that they enable the fly to proceed with a softer pace, and contribute to the preservation of its claws, whose pointed extremities would soon be impaired without this prevention." Notwithstanding the ridicule which has been thrown upon this opinion in a recent entomological work, it appears, from still more recent investigations, to be the best founded of any hitherto advanced. Thus, in general, the foot of the fly is described as being composed of two hooks and two flaps, or hollow cups, which act as suckers. Rymer Jones, in his 'General Outlines of the Animal Kingdom,' 1841, says—"The House-Fly is furnished with a pair of membranous flaps, which, under a good microscope, are seen to be covered with innumerable hairs of the utmost delicacy; these flaps, or suckers, as they might be termed, adhere," &c.

The structure of the foot of the fly has recently been examined by Mr. Hepworth, who says:—"The flap varies in form in different species, from an irregular circle to that of an irregular triangle; and viewing it from one side, it is somewhat thicker at the base (near its attachment), the under surface being, when isolated, convex, but perfectly flat as a whole, when applied to the surface of that form. It appeared to be composed of an upper and under layer of areolar tissue, or something similar to it, between which a bundle of tubes, along with the fasciculi of a large muscle pass; these are placed at its base, and (sometimes protected by a 'coat of mail,' formed by long scales overwrapping each other as a Venetian blind, or in alternate ones, as the scales of a fish, &c., but more frequently wanting) expand in a radiated form; each tube, as it passes along with its fellows on each side, gives off a number of tubules alternately with them; these dip downwards from the under surface, and become expanded into trumpet-shaped extremities, the flap, becoming thinner and thinner as it approaches its margin, which sometimes terminates in an irregularly serrated edge, and at others by finely pointed hairs. The fly has the power of attaching itself to smooth surfaces by these trumpet-shaped extremities, and also of secreting a fluid from them, when vigorous, and it has occasion to make extra exertions; but in a partially dormant state (the best for making observations), it does not appear to be able to give out this secretion, although it can still attach itself; indeed this fluid is not essential for that purpose: when it is secreted, it is deposited on the glass with great regularity. I have often attempted to preserve these markings by applying colouring matter whilst they were moist, but have not yet succeeded. The tubules are often seen protruding from under the margin of the flap in a semi-arch-like form, giving it a fringed appearance. The foot of the male *Dytiscus* is a type, not only of many of the beetle tribe (not aquatic), but of the whole of that of flies possessed of flaps. The first joints of the tarsus of the anterior legs of this insect are extremely dilated, so as to form a broad circular palette. On examining the inferior surface of this expanded portion, it is seen to be covered with a great number of sucking cups, two or three being larger than the rest, but they form collectively a wonderful instrument of adhesion." ('Quarterly Journal of Microscopical Science.')

MUSCLE, MUSCULAR TISSUE. [TISSUES, ORGANIC, *S.* 1.]

MUSK-BEETLE. [CERAMBYCIDÆ.]

MUSK-ORCHIS. [HERMINIUM, *S.* 2.]

MUSK-OX. [OX.]

MUSK-ROOT, the root of a plant brought to this country from Russia and Persia, and known also by the name of Sumbul. This root exhales a powerful smell of musk, and has been used in medicine as a substitute for that substance. The plant yielding it is not known, but the root has the appearance of belonging to the natural order *Umbelliferæ.* Its tissues are full of starch.

MYCETOCHARUS. [CISTELIDES.]

MYGINDA. [AQUIFOLIACEÆ.]

MYOPHONUS. [CORVIDÆ.]

MYOPTERIS. [CHEIROPTERA.]

MYOSU'RUS (from μῦς, a mouse, and οὐρὰ, a tail, the seed being seated on a long receptacle "which looks exactly like the tail of a mouse"), a genus of Plants belonging to the natural order *Ranunculaceæ.* It has a calyx of 5 sepals, prolonged into a spire at the base; the petals 5, with a filiform tubular claw; the capsules closely imbricated upon a long filiform receptacle, not bursting; the seed pendulous; the embryo inverted with the radicle superior. The only species of this genus is *M. minimus,* which has a simple leafless single-flowered stem 2 to 5 inches high. It has a very long receptacle, numerous carpels, and linear leaves. It grows in damp places and in fields. It is a native of Europe and America. The American plant has been described as *M. Shortii,* but there is every reason to believe it is the same as the British and other European plants.

MYOTHERA. [MERULIDÆ.]

MYRIAPODA, an order of Invertebrate Animals belonging to the class *Articulata.* This order is represented by such species as the Centipede and Gally-Worm. They may be regarded as an intermediate form between the lower and higher forms of Articulate animals. They agree with the Annulose forms in the longitudinal extension of their trunk, in the similarity of the segments from one end of the body to the other, and in their cylindrical form. On the other hand, they possess more complete eyes than any of the Vermiform tribes, and their respiratory apparatus and the parts of their organisation are more nearly allied to Insects. Their covering is firm, and of a horny character.

The division into segments is very distinct, a flexible membrane being interposed between each pair of firm rings or plates. The legs and other appendages are inclosed in the same kind of integument, and their joints are formed in the same manner as those of the body. We find in this class however two distinct types of conformation, of which one approximates most nearly to the Vermiform tribes, and the other to that of the higher *Articulata;* in the former of which the *Iulus* (Gally-Worm) may be taken as an example. The body is generally cylindrical, or nearly so; the number of segments is considerable, and most of them bear two pairs of thread-like legs, so that the number of these members sometimes amounts to 160 pairs. The legs are very imperfectly developed, being scarcely large or strong enough to sustain the weight of the body, and their articulations being indistinct; and the animal seems rather to glide or crawl with their assistance, like a serpent or a worm, than to use them as its proper instruments of locomotion. This kind of movement is facilitated in some species by the incomplete inclosure of the body in the consolidated integument, for this merely forms plates above and below, which are connected at the sides by soft membrane; so that the trunk can be easily placed in any direction. When at rest the body is rolled up in a spiral form; so that the legs, concealed in the concavity of the spire, are protected from injury. The animals do not move with rapidity, and they chiefly feed upon decomposing organic matter. In the higher division, on the other hand, of which the *Scolopendra* (Centipede) may be taken as the type, the body is flattened, and each segment is completely inclosed in its horny envelope; the number of segments is not very great, never exceeding 22, and being sometimes as low as 12; and each segment bears a pair of well-developed legs, on which these animals can run with considerable rapidity. Still their bodies are possessed of considerable flexibility; and they are thus enabled to wind their way with facility through very narrow and tortuous passages, in search of the insects, &c., which constitute their food. In both orders, the first segment, or head, is furnished with numerous eyes on each side, and also with a pair of jointed antennæ; the mouth is adapted for mastication, being furnished with a pair of powerful cutting jaws; and it is also provided, in the Centipede and its allies, with a pair of appendages, formed by a metamorphosis of the legs of the first segment of the body, which are adapted not merely to hold and to tear the prey, but to convey poison into the wounds thus made, this poison being ejected through a minute aperture near their points. (Carpenter.)

The alimentary canal is mostly divided into gullet, stomach, and intestine. The stomach usually presents distinct muscular walls. The circulatory organs consist of a dorsal vessel, which propels a current of blood from behind forwards, which is distributed to the body and respiratory organs. In the higher forms respiration is effected by means of tracheæ, which convey air into the interior of the body as in Insects. The nervous system is arranged in a double series of ganglia, as in most of the Articulated Tribes. They possess cephalic ganglia, which meet above the œsophagus, and form a two-lobed mass, from which nerves proceed to the eyes and antennæ. In many parts of the double series of cords the ganglia of each side unite. The muscular apparatus is very complicated, consisting of a series of distinct muscles for the movements of the segments and legs. The sexes are separate. The embryo at the period of hatching consists of but few segments, but these increase in number till it is fully grown by the subdivision of the penultimate segment. The first number of segments is eight or nine, and they go on increasing in number till there are sixty or seventy. The larva has no legs, these organs making their appearance after the first moult. During their growth these animals have a considerable power of regenerating lost portions of their body as the legs and antennæ, but this power is lost when they cease to develope.

Mr. Newport divides the *Myriapoda* into two orders—*Chilopoda* and *Chilognatha*. [CHILOPODA; CHILOGNATHA.] The following synopsis of the genera of these two orders is drawn up from the list of the specimens of *Myriapoda* in the collection of the British Museum (1844):—

Order I. *Chilopoda.*

Family 1. *Cermatiadæ.*
1. *Cermatia*, Illiger. 9 species.

Family 2. *Lithobiidæ.*
1. *Lithobius*, Leach. 9 species.
2. *Henicops*, Newport. 1 species.

Family 3. *Scolopendridæ.*
1. *Scolopendra*, Linnæus. 38 species.
2. *Cormocephalus*, Newport. 8 species.
3. *Rhombocephalus*, Newport. 2 species.
4. *Heterostoma*, Newport. 7 species.
5. *Theatops*, Newport. 1 species.
6. *Scolopocryptops*, Newport. 1 species.
7. *Cryptops*, Leach. 5 species.

Family 4. *Geophilidæ.*
1. *Scolopendrella*, Gervais. 1 species.
2. *Mecistocephalus*, Newport. 2 species.
3. *Necrophlœophagus*, Newport. 3 species.
4. *Gonibregmatus*, Newport. 1 species.
5. *Geophilus*, Leach. 6 species.

Order II. *Chilognatha.*

Family 1. *Glomeridæ.*
1. *Glomeris*, Latreille. 4 species.
2. *Zephronia*, Gray. 6 species.
3. *Sphærotherium*, Brandt. 2 species.

Family 2. *Polyxenidæ.*
1. *Polyxenus*, Latreille. 1 species.

Family 3. *Polydesmidæ.*
1. *Fontaria*, Gray. 3 species.
2. *Polydesmus*, Latreille. 12 species.
3. *Strongylosoma*, Brandt. 2 species.
4. *Craspedosoma*, Leach. 2 species.
5. *Cambala*, Gray. 1 species.

Family 4. *Iulidæ.*
1. *Platops*, Newport. 5 species.
2. *Iulus*, Linnæus. 12 species.
3. *Blaniulus*, Gervais. 1 species.
4. *Spirobolus*, Brandt. 9 species.
5. *Spirostreptus*, Brandt. 15 species.

(*Monograph of the Class Myriapoda, Order Chilopoda*, by George Newport; *Linnæan Transactions*, vol. xix.; Carpenter, *Principles of Comparative Physiology*.)

MYRIOSPERMINE. [CHEMISTRY, *S.* 2.]

MYRISTIC ACID. [CHEMISTRY, *S.* 2.]

MYRMICA, a genus of Insects belonging to the order *Hymenoptera*, and the family *Formicidæ*. It is one of the genera formed out of the Linnæan genus *Formica*. Unlike that genus, however, it possesses a sting. The peduncle of the abdomen is composed of two knots, the antennæ are exposed; the maxillary palpi are long and 6-jointed, and the mandibles triangular. *M. rubra* is a common British species.

MYROBALANS. This is a name applied to almond-like kernels of a nut or dried fruit looking like a plum, of which there are several sorts known in the East. They are the produce of various species of *Terminalia*, as *T. Bellerica*, *T. Chebula*, *T. citrina*, and *T. angustifolia*. They vary from the size of olives to that of gall-nuts, and have a rough, bitter, and unpleasant taste. Many of the trees of this tribe, which are all natives of the tropical regions of Asia, Africa, and America, are used for tanning, and some for dyeing. They are highly valued by dyers, creating, when mixed with alum, a durable dark-brown yellow. Myrobalans fetch in the Bombay market 8*s.* to 26*s.* the Surat candy of 821 lbs. The bark and leaves of *T. Catappa* yield a black pigment, with which Indian ink is made; the seeds are eaten like almonds. A milky juice is said to flow from *T. angustifolia*, which, when dried, is fragrant, and, resembling Benzoin, is used as a kind of incense in the Catholic churches in the Mauritius. The fruit of *T. Bellerica* and of *T. Chebula*, both useful timber-trees, indigenous to the East Indies, are used medicinally as a tonic and astringent. One hundred and seventeen cwts. of Myrabalans were shipped from Ceylon in 1845.

The annual imports of Myrobalans into Hull, amount to about 1600 cwts. The quantity which arrived at Liverpool was 185 tons in 1849 and 851 tons in 1850; 27,212 bags in 1851, and 19,946 bags in 1852; they came from Calcutta and Bombay, and are also used for dyeing yellow and black. The price in January 1853 was 6*s.* to 12*s.* per cwt. The average annual imports into the United Kingdom may be taken at 1200 tons.

Myrobalans is also the English name given by Lindley to the natural order *Combretaceæ*, which yields these fruits.

(Symonds, *Commercial Products of the Vegetable Kingdom.*)

N

NAAS, county of Kildare, Ireland, a market and assize town, and the seat of a Poor-Law Union, is situated on the Dublin and Limerick road, in 53° 13′ N. lat., 6° 40′ W. long., distant $20\frac{1}{4}$ miles S.W. from Dublin by road. The population in 1851 was 3132. Naas Poor-Law Union comprises 38 electoral divisions, with an area of 216,622 acres, and a population in 1851 of 44,863.

Naas was in early times a seat of the kings of Leinster. In 1419 a parliament was held in it. The town obtained charters from Henry V., Elizabeth, and James I. It returned two members to the Irish Parliament, but was disfranchised at the Union. Naas is pleasantly situated in a fertile and improved district. It consists of a street extending along the Dublin road, with several branches on each side. In the main street is the parish church, an old building in the early English style, enlarged in 1822, and again a few years back. There are a large Roman Catholic chapel, with a nunnery adjacent; an Independent chapel; a diocesan school; and several schools partially endowed. The town also contains a market-house, a county court-house, and gaol, a large infantry barrack, a fever hospital, dispensary, and Union workhouse. There are the remains of an Augustinian monastery in the town; and a rath or high conical mound, on which the states of Leinster are said to have held their assemblies. A branch of the Grand Canal passes near the town. Quarter and petty sessions are held. The market-days are Monday, Thursday, and Saturday. Fairs are held twelve times a year.

NABALUS, a genus of Plants belonging to the order *Asteraceæ*. Two of the species, *N. Serpentarius* and *N. albus*, are found in North America, and have, with many other plants, a repute as a remedy for rattle-snake bites. They have a milky juice in their roots, which is very bitter.

NAIAS, a genus of Plants the type of the natural order *Naiadaceæ*. It has imperfect solitary sheathed flowers with no perianth. The barren flowers consist of one stamen, the fertile flowers have a single short style with two or three filiform stigmas. There is one British species.

N. flexilis has very narrow and very minutely denticulate, ternate, or opposite leaves, the sheaths ciliate-denticulate. The ovary is solitary and the style is short. It has been found in but one locality, and that is near Roundstone, Connemara, in Galway, Ireland.

NAIDES, a group of Abranchiate *Annelida*. The species have the elongated body and rings less marked than in the Earthworms. They live in holes which they bore in mud at the bottom of water, and from which they are constantly protruding their bodies. Some have black points on their heads, which have been regarded as eyes. To this family belong a large number of little-studied forms of very minute fresh-water worms. The smaller ones are sometimes called Vibrios, of which the very common *Vibrio fluviatilis* of the amateur microscopist is an example. It also appears to embrace the *Stylaria* of Lamarck, the *Proto* of Oken, and the *Clymene* of Savigny.

NAPHTHA is a compound of Carbon and Hydrogen, frequently found in the neighbourhood of coal-deposits, and in other parts of the earth. It contains 82·2 of carbon and 14·8 of Hydrogen. It is a limpid or yellowish fluid, lighter than water, and hence called Mineral Oil. Its specific gravity is 0·7 to 0·84. It hardens and changes to the substance called Petroleum on exposure to air. It may be obtained from Petroleum by heat, which causes it to pass off in vapour.

Naphtha issues in large quantities from the earth in Persia and the Birman Empire. At Rangoon, on one of the branches of the river Irawaddy, there are upwards of 500 naphtha and petroleum wells, which afford annually 412,000 hogsheads. In the peninsula of Abcheran, on the western shore of the Caspian, naphtha rises through a marly soil in vapour, and is collected by sinking pits several yards in depth, into which the naphtha flows. There is an abundant spring near Amiana, in the Duchy of Parma. Mr. Dana says that in the United States it was formerly collected for sale by the Seneca and other Indians; the petroleum is therefore commonly called Genesee or Seneca Oil, under which name it is sold in the market.

Petroleum is used as lamp-oil in Birma, and when mixed with earth or ashes as fuel. Naphtha is used both for fuel and light by the inhabitants of Bakou, on the Caspian. The vapour is made to pass through earthen tubes, and is inflamed as it passes out, and used in cooking. The spring at Amiana is used for illuminating the city of Genoa.

Naphtha has been recently used as a medicine, and is found to be a good stimulant in some chronic diseases. It has been externally applied as a lotion in cutaneous affections. It is sometimes substituted for drying oil in making paint. It is also employed for preserving the metals of the alkalies potassium and sodium, which cannot be kept in contact with any substance containing oxygen.

The Rangoon petroleum contains the compound Paraffine. This substance has also been obtained pure in a liquid form from the coal-pits of Derbyshire. It is used for the purpose of diminishing the friction of machinery as a substitute for sperm-oil. It is now obtained artificially from coal, and also in a solid form, from which candles are made.

NAPHTHALINE. [CHEMISTRY, *S.* 2.]

NAPIER, SIR CHARLES JAMES, G.C.B., was the eldest son of Colonel the Hon. G. Napier, comptroller of accounts in Ireland, by the Lady Sarah Lennox, daughter of Charles, second duke of Richmond. He was born at Whitehall, on the 10th of August, 1782. Having received his early education under his father in Ireland, he obtained his first commission as ensign in the 22nd foot before he had completed his twelfth year, and first saw active service during the Irish rebellion of 1798, and again in the insurrection of 1803. In 1806, having obtained his company, he joined the British forces in Spain, and commanded the 50th regiment of foot during the terrible retreat on Corunna under Sir John Moore, on which occasion he received five wounds and was taken prisoner. Being allowed to go to England on parole, he found his friends actually in mourning for him as dead, and administering his effects; and he employed his period of compulsory inactivity by writing on colonies, colonisation, and military law, and an essay on the state of Ireland. In 1809 he again joined the British army in the Peninsula as a volunteer. He had two horses shot under him in the desperate conflicts on the banks of the river Coa, and was severely wounded at Busaco; he also took part in the hard-fought battle of Fuentes de Oñoro, and in the second siege of Badajoz, as well as in a considerable number of lesser skirmishes. In 1813 we find him serving in a floating expedition on the coast of the United States, and occupying his time by the capture of American vessels, and frequent descents upon the coast. He returned to Europe a few days too late to be present at the battle of Waterloo, though he took part in the storming of Cambray, and accompanied the British army to Paris.

Not long after this, while stationed in the Ionian Islands, he was appointed governor of Cephalonia. Here his administrative powers were first developed; and the success of his governorship is proved by the fact that to the day of his death the Cephalonese called him their 'father,' and sent to him an annual tribute of the produce of their vines. While holding this post he joined with Lord Byron in a scheme for the deliverance of Greece. He was shortly afterwards superseded—an event which he regarded, whether rightly or wrongly, as a great affront and indignity.

After a short command of the military district of the north of England, in 1838 and 1839, Sir Charles Napier, now a major-general, was ordered in 1841 to take command of the army in Bengal. This was the turning-point of his career. At Bombay he attracted attention by his energetic plans of military reform, to which he continued to devote himself until the appointment of Lord Ellenborough to the governor-generalship of India. At his suggestion Sir Charles Napier drew out the plan of an Afghan Campaign. Sinde at this time was in a very disordered condition, and the British influence and prestige had been much impaired by the disasters in Cabul. The Ameers of Sinde were perfidious, and as they would be bound by no treaty, he resolved to subdue them by open attack. From the first his plans were eminently successful. He blew up the fortress of Emaum Ghur, which was always deemed impregnable. Having accomplished this exploit, which was characterised by the late Duke of Wellington as one of the most curious and extraordinary of all military feats, he pressed on, and with a very inferior force in point of numbers routed the Ameers at Meeanee, February 17, 1843. In a few days the army took possession of Hyderabad, and outflanking Shere Mohammed (surnamed the Lion) by a dexterous manœuvre, drove him from the field with prodigious slaughter. Having now become master of the fair territory of Sinde, Sir Charles Napier set vigorously to work to improve its condition. He re-organised the native society, re-distributed the collectorates of taxes, ameliorated the native law, put down the 'suttee' system, and set the tenure of land on a more just and judicious footing. Whilst in the midst of carrying out these reforms Lord Ellenborough was recalled by the East India Company, and Sir Charles Napier felt that he had lost his best friend and supporter. His Indian services are thus summed up, in the words of his brother Sir William Napier, in his 'Narrative of the Administration of Scinde:'—"Two years only elapsed since he quitted Sukkur to make war on the Ameers, and in that time he had made the march to Emaum Ghur in the great desert, gained two great battles, reduced four large and many smaller fortresses, captured six sovereign princes, and subdued a great kingdom. He created and put into activity a permanent civil administration in all its branches, conciliated the affection of the different races which inhabited Scinde, had seized all the points of an intricate foreign policy, commenced a number of military and other well-considered public works, and planned still greater ones, not only suited to the exigences of the moment, but having also a prospective utility of aim." And all these works he performed in spite of a press of correspondence, long journeys on camels and horseback beneath a tropical sun, and under frequent and severe attacks of illness, at the age of sixty-three, and in spite of every mortification that malice and intrigue could devise against him. Unwilling to leave Sinde without some permanent proof of his ascendancy over the popular mind, and the consciousness of having contributed to its temporal prosperity, he persuaded the people to change the feudal system of land-tenure for that of landlord and tenant, considering that such was the best plan of forming loyal subjects by raising a class of farmers and small landholders attached to the government by ties of a personal and pecuniary interest.

In 1847 Sir Charles Napier returned home, and met with an enthusiastic reception; but ever ready at the call of duty, he re-embarked for India in March 1849, at the suggestion of the Duke of Wellington, on hearing of the then recent reverses which we had sustained in the Sikh campaign. Happily however on his arrival at Bombay he found that the tide had turned, and that his military services were no longer needed. There was no enemy to contend with in the field, and no principality to administer; so he set his active mind to work forthwith to carry out a system of military reform, his immediate object being to school the luxury and extravagance of the British officers into a simple and severe mode of living. In this work he was partially successful.

He returned to England in 1850, but his health and spirits were fast failing, and the last time that he appeared in public was on the occasion of the funeral of his friend and patron the Duke of Wellington, in November 1852. He died of a gradual decline at Oaklands, his seat, near Portsmouth, on the 29th of August, 1853, like a gallant soldier, under the old colours of the 22nd regiment and other trophies of his European and Indian career, and was buried in the ground attached to the garrison chapel at Landport, near Portsmouth. Sir Charles Napier was twice married—first in 1827, to Elizabeth, daughter of John Oakley, Esq., of Deal, Kent, by whom he had two daughters; and secondly, in 1835, to Frances, daughter of William Philipps, Esq., and widow of Captain R. Alcock, R. N. A bronze statue of the conqueror of Sinde has been erected by subscription in Trafalgar-square.

NAPLES.—The continental territories of the kingdom of the Two Sicilies are divided into 15 provinces, the area, subdivisions, and population of which are given in the subjoined table. The provinces beyond the Faro are given under SICILY, *S.* 2.

Provinces.	Area in Square Miles.	Districts.	Communes.	Population in 1851.
Napoli	381	4	65	822,142
Terra-di-Lavoro	2,493	5	230	752,012
Principato Citra	2,262	4	158	558,809
Principato Ultra	1,407	3	132	383,414
Basilicata	4,145	4	121	501,222
Capitanata	2,916	3	62	318,415
Terra di Bari	2,358	3	53	497,432
Terra d'Otranto	2,871	4	180	409,000
Calabria Citra	2,619	4	146	435,811
Calabria Ultra (II.)	2,063	4	151	381,147
Calabria Ultra (I.)	2,194	3	104	319,662
Molise or Sannio	1,777	3	135	360,549
Abruzzo Citra	1,243	3	121	312,399
Abruzzo Ultra (II.)	2,519	3	110	329,131
Abruzzo Ultra (I.)	1,297	2	72	231,747
Total	32,475	52	1840	6,612,892
Population of Sicily at the Census of 1851				2,091,580
Total population of the kingdom of the Two Sicilies				8,704,472

NARBERTH. [PEMBROKESHIRE.]

NARCISSUS, a genus of Plants belonging to the class Endogens and the natural order *Amaryllidaceæ*, among which it is known by its flowers growing upon a scape, and having a cup at their mouth; the stamens, which are opposite the sepals being longer than the others. It consists of bulbous plants principally inhabiting the warmer parts of Europe.

The following is the arrangement of the European species of this genus given in Mr. Wood's 'Tourist's Flora:'—

A. **Leaves flat, linear, obtuse; tube of corolla short, obversely conical; crown campanulate dentate.**

N. Pseudonarcissus, the Daffodil. Scape 2-edged striate; flowers nearly sessile in sheath; crown erect, nearly as long as segments of corolla; stamens equal. It is found in woods and meadows throughout Europe.

N. minor, a native of Europe.

N. incomparabilis has the scape 2-edged. It is found in France and Italy and the coasts of the Mediterranean, and is naturalised in Great Britain.

B. **Leaves nearly flat; flowers hypocrateriform.**

I. Scape nearly terete.

N. calathinus. Scape 2-4-flowered. A native of the Isles of Glenans and of Brittany.

N. dubius. Scape 2-6-flowered. Mediterranean and France.

N. chrysanthus. Scape 3-10-flowered. Found near Grasse, in France.

II. Scape 2-edged.

a. Crown yellow.

N. poeticus. Scape 1-flowered; petals white. It is found on open heathy fields in Norfolk and Kent, in Great Britain; it is also found in Austria and various parts of Italy.

N. radiiflorus. Scape 1-flowered; striate. It is found in Austria, Styria, and the Vallais.

N. biflorus, with linear-obtuse keeled leaves; scape compressed, 2-edged, striated, 2-flowered, crowned, very short, concave, crenate at the pale margin; the petals of a pale sulphur colour. It is found in sandy fields in the south of England, and in Ireland; also in France and Italy.

N. patulus, *N. præcox*, and *N. Tazetta*, are other European species belonging to this section.

b. Crown and petals white.

N. polyanthus. Scape slightly 2-edged, 8-20-flowered. It is found near Toulon and Nice, in stony places.

N. niveus. Scape 6-10-flowered. It is a native of France.

N. unicolor. Scape 10-15-flowered. It is found at the base of Vesuvius.

C. Leaves convoluto-setaceous.

N. serotinus. Scape 1-flowered. It is found near Palermo, on open hills.

N. cupanianus has the scape 1-7-flowered, and is found on the coasts of Corsica, Sardinia, Calabria, and Sicily.

D. Leaves semi-cylindrical and channeled.

N. lætus has the scape 1-3-flowered. Found near Grasse, in France.

N. ochroleucus. Scape 4-8-flowered. Found in fields near Toulon.

N. odorus. Scape 1-5-flowered. It is found in the fields and olive-grounds of Lucca.

N. Jonquilla, the Jonquil. Scape 2-6-flowered. It is found in Italy. *N. intermedius* is probably a variety of this species.

N. Bulbocodium. Scape 1-flowered. A native of heaths in France.

The species, from their hardiness or gay colours, or sweet smell, have long been favourite objects of cultivation, especially the Daffodils, Jonquils, and Tazettas. A very full account of them will be found in the 'Amaryllidaceæ' of the Honourable and Reverend William Herbert, p. 292 (8vo, London, 1837), who however divides the genus into six others, after the example of Salisbury and Haworth; but as those genera are not likely to be adopted by botanists, with the exception perhaps of the genus *Corbularia*, no account need be given of them. With regard to *Corbularia*, to which the name of Hoop-Petticoat Narcissus is given, and of which five supposed species are enumerated, the peculiar form of the flower and the delicate stamens of that plant may perhaps entitle it to be regarded as a peculiar genus; the species are pretty, all yellow flowered, with the single exception of *C. cantabrica*, a little plant with white flowers found on the mountains of Biscay and the Pyrenees, but now lost in our gardens.

NATAL, a British colony on the south-east coast of Africa, is bounded S.W. by the river Umtacoune (about 30 miles W. from the Umzincula, the previous boundary), N.E. by the river Tugala, N.W. by the Drachenberg or Quathlamba Mountains, and S.E. by the Indian Ocean. The colony lies between 29° 20′ and 30° 50′ S. lat., 29° 40′ and 31° 25′ E. long. The area is about 20,000 square miles. The white population in 1853 was 7029, the native population 112,988.

The Drachenberg or Quathlamba Mountains form a broad range which runs nearly parallel with the coast, at a distance varying from 60 to 90 miles from the shore. The average height of the range may be estimated at 8000 or 9000 feet above the sea, and the summits are covered with snow at least four months in the year. On the north-west, or interior side, a table-land slopes gradually down almost from the summits of the mountains, exhibiting extensive plains, diversified by a few isolated mountain-groups and low ranges of hills. There is no pass in the whole range between 28° 30′ and 31° S. lat. practicable for horses or wheel carriages, and there are very few for pedestrians. Coal occurs not far from the sources of the Tugala, and ironstone is frequently found. Copper has been discovered within 20 miles of Pietermaritzburg. In Natal the country gradually rises from the sea to the foot of the mountains. A few mountain groups occur, which are offsets from the Drachenberg range. The country is diversified with hill and dale.

The rivers are very numerous, and all flow eastward to the sea. Two of the largest are the Tugala and the Umzincula; they both rise in the Drachenberg Mountains. The Tugala receives several tributaries, of which the principal are the Buffalo River, which forms a portion of the boundary to the north, and the Bushman River; and it reaches the sea in 29° 15′ S. lat., 31° 25′ E. long. It has a bar at the mouth, and is not navigable. The Umzincula flows through a rugged and almost inaccessible country, and falls into the sea in 30° 50′ S. lat., 29° 20′ E. long.

Along the coast, in summer, the average temperature is about 74° Fahr.; in winter about 63°. Nearer the mountains the climate becomes colder. The rains generally commence in March, and end in September. Thunder-storms are of frequent occurrence, and are very violent. The climate, on the whole, is pleasant and healthy.

The climate and soil have been found suitable for the cotton-plant, but it is doubtful if it can be cultivated profitably. Indigo, sugar, and coffee are cultivated, and it is expected that sugar and coffee will become articles of export. Tobacco, maize, sweet potatoes, oranges, pine-apples, and pumpkins are raised in abundance. Cattle thrive well; but the climate does not appear to be suitable to the growth of wool. Horses are liable to sickness in the spring months, and many die. The soil is generally more fertile than in the Cape Colony, nor does it appear to suffer so much from droughts.

The elephant, which was formerly common in the colony, is now nearly driven away. The lion and leopard are still met with along the mountain ranges. Hyænas, jackals, wild dogs, ant-bears, and porcupines are numerous. The hippopotamus abounds in several of the rivers, and in the Tugala are numbers of small crocodiles. The larger antelopes are becoming scarce, but there are still many of the smaller ones. The vulture, rock-eagle, and Kaffir crane are common. Several valuable timber-trees grow on the declivities of the mountains and in the mountain valleys.
