THE

SECOND SUPPLEMENT

TO THE

PENNY CYCLOPÆDIA

OF

THE SOCIETY

FOR THE

DIFFUSION OF USEFUL KNOWLEDGE.

COMPLETE IN ONE VOLUME.

LONDON:
PUBLISHED BY KNIGHT & CO., 90, FLEET STREET.

MDCCCLVIII.

LONDON:
BRADBURY AND EVANS, PRINTERS, WHITEFRIARS.

NOTICE.

The First Supplement of the 'Penny Cyclopædia,' in Two Volumes, was published in 1846. THE SECOND SUPPLEMENT, now completed in One Volume, follows the same plan as that of the original Work, comprising under one Alphabetical Arrangement, the accumulated information of the twelve years which have elapsed since the publication of the First Supplement. A limited number only of this Volume has been printed; and it will not be kept on sale after that number has been disposed of.

CHARLES KNIGHT.

May 28, 1858.

SECOND SUPPLEMENT

OF

THE PENNY CYCLOPÆDIA

OF

THE SOCIETY FOR THE DIFFUSION OF USEFUL KNOWLEDGE.

[The abbreviation *S.* 1, in the references and elsewhere, refers to the First Supplement; *S.* 2, to the present Second Supplement. The references without either of these additions are to the 'Penny Cyclopædia' as distinct from the two Supplements.]

AACHEN. [AIX-LA-CHAPELLE.]

ABACO. [BAHAMAS.]

ABATEMENT. Pleas in abatement for misnomer have been abolished (3 & 4 Will. IV. c. 42), and an objection thus taken to the nonjoinder or misjoinder of parties is no longer of any avail in a civil action, the courts having now ample powers of amendment. (Common Law Procednre Act, 1852.) A similar observation applies to pleas in abatement to an indictment or information. (14 & 15 Vict. c. 100.)

ABBEY-HOLME. [CUMBERLAND.]

ABBEYLEIX. [QUEEN'S COUNTY.]

ABBOT'S BROMLEY. [STAFFORDSHIRE.]

ABEAHKEUTAH, a large walled town, on the west bank of the river Agonee, which separates it from the kingdom of Dahomey, abont 60 miles inland from Lagos, in the Bight of Benin, and about 150 miles from Abomey, the capital of Dahomey. It is in the petty kingdom of Egba, which is tributary to Yorribah, bnt the town itself, which has sprung up within the last forty years, is independent, and is governed by a chief who is not a king. The inhabitants amount to upwards of 50,000, and are composed of the natives of Egba, a great number of liberated blacks, many of them from Sierra Leone, and several missionaries, who report that their labours have been highly sncccessful. The King of Dahomey has more than once attacked the town in vain. In 1848 one of his Amazonian regiments was almost entirely destroyed by the Abeahkeutahns in one of these attempts. In June, 1850, when Captain F. E. Forbes and Mr. Becroft were at Abomey, Mr. Becroft was told by the King himself to warn the missionaries to withdraw, as he was going to make war upon the town, when it was explained to him that the town was in alliance with Great Britain, and that there were great numbers of free negroes and several missionaries there. Nevertheless, he invaded their territory at the head of a large slave-hunting force, a great part consisting of Amazons, and met with a severe defeat under its walls, on March 3rd, 1851, which is said to have greatly crippled his power. The name of Abeahkentah, which means 'under the stone,' has reference to a large natural cave within the town walls, wherein the market is held. A new species of silk from Houssa in the interior, aud a peculiar description of wool, from Quotta to the westward of Abeahkeutah, have been introduced as articles of trade into England, and are likely to prove valuable.

A'BECKET, GILBERT ABBOTT, born in Golden-square, London, in the year 1810, was the son of a respectable solicitor, and was educated at Westminster School. He very early displayed great talent as a humonrist. As early as 1825 eight of his dramatic prodnctions, in prose and verse, but all of a burlesque character, were pnblished in Dnncombe's 'British Theatre;' in 1828-29 nine more appeared in Cumberland's 'British Theatre;' and in 1837 fonr others were printed in Webster's 'Acting Drama;' most of which had attained some sncccess on the stage. In 1843 he produced 'The Mirror, or Hall of Statues,' a musical burlesque. In connection with the drama, also, he published in 1844 'Scenes from the Rejected Comedies by some of the Competitors for the Prize offered by Mr. Webster:' these 'Scenes' were a series of parodies upon living dramatists (including one of himself), which had appeared in 'Punch' previous to their publication in a separate form. In 1846 he published 'The Quizziology of the British Drama.' In conjunction with his schoolfellow, Mr. Henry Mayhew, he started several comic periodical works, of which 'Figaro in London,' begun about 1830, was undoubtedly the precursor of 'Punch.' When that work had swallowed up its rivals, Mr. A'Becket became a constant contributor to it, and the adventures, the epistles, and anecdotes of Mr. Dunup were among the most laughable morceaux of that publication. He took a pride in the work, and it was his boast that, till the period of his death, no nnmber appeared without something, however small, from his pen. His humour was withont malice, and displayed a varied reading, with considerable knowledge of the law. In the midst of his ebullitions of fancy he had not neglected the more serious studies of his profession. He was trained as a lawyer; and in March 1846 his repntation induced Mr. Charles Buller to intrust to him the investigation of the iniquities practised in the Andover Union workhonse. This he conducted in a satisfactory manner, and in his report he displayed a clear and solid jndgment in sober and well-chosen language. Some leaders in 'The Times' on the same subject have been also attributed to him. He had previously been an occasional contributor to that journal. His conduct of the Andover inqniry led to his appointment in 1849 as magistrate of the police-court of Greenwich and Woolwich, whence he was removed in 1850 to that of Southwark—positions which he held in an irreproachable manner. Besides an edition of 'The Small Debts Act, with Annotations and Explanations,' published in 1845, he prodnced the 'Comic Blackstone,' which was published in 1844-46; a 'Comic History of England,' pnblished in monthly parts, forming a volnme completed in 1848; and a 'Comic History of Rome,' also in monthly parts, completed in 1852. He likewise, in 1845, edited George Cruikshank's 'Table Book.' After a very short illness he died at Bonlogne, on the 28th of April 1856.

ABERAVON. [GLAMORGANSHIRE.]

ABERAYRON. [CARDIGANSHIRE.]

ABERDARE. [GLAMORGANSHIRE.]

ABERNETHY. [PERTHSHIRE.]

ABORTION, a term nsed in Botany and Horticnlture. In Botany, Abortion is employed to express the absence of an organ in relation to an ideal type. Thns the flowers of

Scrophulariaceæ and *Lamiaceæ* have their sepals and petals arranged with the number five. According to a very general law the stamens equal in number the petals and sepals, but in this case they do not. In the majority of instances the stamens are but four: hence it is said that one stamen is aborted, or there is an abortion of one stamen. The want of harmony between the parts of the flower generally is thus spoken of. In other instances, where the ovules are numerous and the seeds only one, two, or three, the remaining ovules are aborted.

In Horticulture, the premature development of the fruit, or any defect in it, is called Abortion.

ABRAMIS. [Bream.]

ABRAXAS, a genus of Nocturnal *Lepidoptera*, to which belongs the common Magpie Moth, *A. grossulariata*. The caterpillar of this moth attacks the leaves of gooseberry and currant bushes at the beginning of the summer. It is of a yellowish-white colour, with an orange stripe on each side, and covered with black spots. The chrysalis is black, relieved at its pointed end with orange circles. The expanded fore-wings of the perfect insect measure about one inch and a half across. The wings are of a yellowish-white colour, variously spotted with black. The fore-wings have a band of pale orange. The body is orange, spotted with black. The eggs are deposited on currant or gooseberry leaves in July or August, and the caterpillars are hatched in September. To get rid of the attacks of these creatures, they may be picked off, or dusted with the powder of white hellebore, or the leaves of the plants attacked may be burned.

ABROMA (from α and βρῶμα, 'not fit for food,' in opposition to *Theobroma*, 'food for gods'), a genus of plants belonging to the natural order *Byttneriaceæ*. The species consist of small trees, with hairy lobed leaves and extra-axillary or terminal few-flowered peduncles at the tops of the branches.

Abroma augusta is a handsome tree, with drooping purple flowers, seated on peduncles opposite the leaves. It is a native of the East Indies. The fibrous tissue of the bark of this plant is manufactured into cordage.

ABRUS (from ἁβρὸς, soft), a genus of plants belonging to the papilionaceous division of the order *Leguminosæ*. The calyx is bluntly 4-lobed, with the upper lobe broadest. The legume is oblong, compressed, and 4-6-seeded. There is but one species, *A. precatorius*, which is a delicate twining shrub, with abruptly pinnate leaves, bearing many pairs of leaflets. It is a native of the East Indies, but is also found in the tropical parts of Africa and America, where perhaps it has been introduced. The seeds of the commoner variety are red, with a black spot, whilst other varieties produce various coloured seeds. These seeds are in much request as ornaments amongst the inhabitants of the countries where they grow. They are strung as beads, with shells, and other hard seeds. They are brought to Europe from Guinea and the East and West Indies. They are used frequently as beads for rosaries; hence the name *precatorius* given to this species. The leaves and roots of this plant secrete the sweet substance which characterises the liquorice plant (*Glycyrhiza glabra*). In the West Indies it is called Wild Liquorice, and used for the same purposes as the common liquorice. The seeds have been accused of possessing narcotic properties, but this is an error. When swallowed they are very indigestible.

ABSINTHINE. [Chemistry, *S.* 2.]

ABUTILON (ἀβύτιλον, the Greek for mulberry-tree, which the species of this genus resemble), a genus of handsome plants, belonging to the natural order *Malvaceæ*. The species of this genus, amounting to about 80, have been removed from *Sida*. They have a naked five-cleft calyx, with a multifid style, capsular one-celled carpels, 5-30 in a whorl. Several of the species are cultivated in this country. *A. striatum* blossoms freely nearly all the year round, when turned out under a wall in Hampshire. *A. vitifolium*, *A. venosum*, *A. rufinerve*, and *A. pæoniflorum*, are also tolerably hardy species. The plant known as Beucão de Deos, in the province of Rio Janeiro, in Brazil, is the *A. esculentum*. It has large purple solitary axillary flowers, which are dressed and eaten with their viands by the inhabitants of Rio. In cultivation the species require a light rich loam and peat-soil, and should be propagated by striking cuttings in sand in a close frame or under a glass in summer.

ACCIPITER. [Falconidæ.]

ACCRINGTON, Lancashire, a manufacturing town of recent growth, in the parish of Whalley and higher division of Blackburn hundred, is situated in a deep valley surrounded by hills on the banks of the Hindburn, or Accrington brook, in 53° 45′ N. lat., 2° 22′ W. long., distant 19 miles N. from Manchester, 207 miles N.W. by N. from London by road, and 210 miles by the North Western and East Lancashire Railways. The population of the town in 1851 was 7481. The livings are perpetual curacies in the archdeaconry and diocese of Manchester.

Accrington possesses two churches of the Establishment; one, the parochial chapel, is a plain building; the other, Christ Church, is a spacious gothic edifice erected in 1838, at an expense of about 8000*l*. The Wesleyan Methodists, Independents, Baptists, Roman Catholics, and Swedenborgians have places of worship. There are national schools, schools attached to some of the dissenting chapels, a subscription library, two news-rooms, and a savings bank. The town is paved, lighted with gas, and well supplied with water. The general aspect of the town is good, and the inhabitants claim for it the distinction of being the cleanest town in Lancashire. It requires, however, many sanitary improvements, especially in the smaller streets and lanes. The drainage is very defective. Accrington is considered to be the centre of the cotton-printing business. There are two large print works, employing upwards of 1000 hands, 10 cotton factories, employing about 1500 persons, and extensive bleaching works. The neighbouring coal-mines employ many of the inhabitants.

ACERAS, a genus of Orchidaceous Plants, of which one species, the *A. anthropophora*, is found growing in Great Britain. It is a small plant, from 8 to 12 inches in height. It has a long lax spike of greenish-yellow flowers, the parts of which are so arranged as to give them the appearance of the small figure of a man: hence this plant has been called the Man-Orchis.

ACETAL. [Chemistry, *S.* 1.]

ACETONE. [Chemistry, *S.* 1.]

ACETONITRYLE. [Chemistry, *S.* 2.]

ACETYLE. [Chemistry, *S.* 2.]

ACHILL, an island off the west coast of the barony of Burrishoole in the county of Mayo, in Ireland. With the adjoining peninsula of Corraun Achill it constitutes the parish of Achill, and one electoral division of the Poor-Law Union of Newport. It is separated from the mainland by a narrow arm of the sea, called Achill Sound, connecting Clew Bay with Blacksod Harbour. The length from Achill Beg island at the extremity of the Sound, on the south, to Achill Head, at the Atlantic extremity of the island on the west, is 15¼ miles; breadth from Achill Beg on the south to Ridge Point in Blacksod Bay on the north, 12¼ miles. It lies between 53° 51′ and 54° 5′ N. lat., and 9° 55′ and 10° 15′ W. long. The area is 35,283 acres. The population of Achill Island in 1841 was about 5000; in 1851 about 4000.

The island, the name of which signifies 'Eagle,' is in form nearly a right-angled triangle, of which one side extends from south to north, facing the mainland, from Achill Beg to Ridge Point; another from east to west, from Ridge Point to Achill Head, constitutes the southern boundary of Blacksod Harbour; and the third side, forming a re-entrant irregular coast-line of about 35 miles, and having the Bay of Tramore about midway, is washed by the Atlantic. The surface, which is excessively wild, barren, and boggy, rises towards the north and west into mountains of 2000 feet and upwards; and at one point near the western extremity of the island, Touacroghaun, the cliff towards Blacksod Bay descends precipitously from the highest point of the island, forming a shelving face of rock, of the extraordinary height of 2208 feet. Achill Head, at the extreme west, consists of a narrow ridge of rock, of about a mile in length, and from 300 to 400 feet in height, the summit of which is in some places but a few yards in width. The coast on the south-western side is also very precipitous: the cliff at Dooega Head, which forms the eastern boundary of Tramore Bay, rises 818 feet over the Atlantic, and is nearly perpendicular. The geological structure of the island is simple; the whole being a mass of mica slate.

Of the entire surface of Achill Island and Corraun Achill, comprising an area of 51,523 acres, and inhabited in 1841, by a population of 6392 persons, there were only 554 acres under cultivation in 1848, and in 1851 the population of the parish had fallen to 4950. The hamlets consist of the most wretched hovels huddled together without the least regularity. In the district between Touacroghaun and Achill Head, at Boley, some of the huts still inhabited are built of drystone in the beehive form. There are three considerable villages; one at Keem, on the south-west, where there is a good boat-harbour; another at Keel, on the sandy beach of Tramore; and a third at Doogort, at the opposite side of the island on a similar sandy beach in Blacksod Bay. About half a mile from Doogort, on the eastern slope of the mountain of Sleivemore, stands the missionary colony of the Rev. Mr. Naugle, a clergyman of the Established Church. The Achill mission consists of a row of several substantial slated houses, standing in the midst of about 40 acres of cultivated land, and comprises a church, dispensary, tuck-mill, corn-mill, schools, and a printing establishment.

(*Ordnance Survey of Ireland; Parl. Returns; Tour in Connaught.*)

ACHIME'NES (from α, prefix, and χεῖμα, winter), a genus of plants belonging to the order *Gesneraceæ*. The species of this genus are very numerous, and, although not useful, they are many of them extensively cultivated, on account of the beauty of their flowers. In consequence of their general culture, a great many varieties of the species are becoming known. After flowering, the stems die down; and the tubers should be dug up, and kept free from frost and wet till January, when, by planting them in succession, flowers may be obtained till the summer. They may be planted in a mixture of loam and leaf-mould, with a little silver sand. They can be placed out in the summer, but require shading on hot days.

ACHLYA, a genus of Cryptogamous Plants, belonging to the order *Confervaceæ*. It is composed of a single tubiform cell, which expands at the end into a large cell, which is cut off from the lower portion of the tube by the formation of a partition. In this enlarged cell a circulation of granular particles has been observed. In the course of time cells are formed in this enlarged cavity, and fill it up. The parent cell eventually bursts at some spot, and allows of the escape of the enclosed cells; but before this takes place the cells in the interior move about, and, after their escape, exhibit for a considerable time an active movement. They are good examples of the *Zoospore*. They soon attach themselves to some fitting object, and grow into little plants, like their parent. A similar process goes on in most of the *Algæ*, but is not so easily observed as in this case.

The only species of *Achlya* which has been described is the *A. prolifera*, which is found parasitic upon fish and other aquatic animals. This plant is more especially developed on fish and aquatic reptiles kept in confinement. It was first observed on gold fish, but several writers have described it as existing on other animals, as the Stickleback, Water Salamander, Frog, and Newt.

ACIDS, ORGANIC. [CHEMISTRY, *S.* 2.]

ACONCAGUA, a province of Chili, in South America, extends southwards from the river Chuapa between 31° 30′ and 33° 20′ S. lat., 70° and 72° W. long. Its length from N. to S. exceeds 120 miles; towards the east the province extends to the crest of the Andes, between which and the Pacific the width is about 100 miles. The area exceeds 12,000 square miles: the population in 1847 was 91,022.

In the range of the Andes, which separates this province from the Argentine province of Mendoza, is the volcanic Peak of Aconcagua, which has given its name to the department and to its principal river. The Peak of Aconcagua is the highest of all known volcanoes; it is said to be 23,200 feet above the sea-level. From the Andes many lateral ranges run off westward, which are very high near the Cordilleras; they grow lower in proceeding farther west, but even at a distance of a few miles from the shores of the Pacific their elevation rarely sinks below 2000 feet, and often exceeds 3000 feet. The coast itself is generally bold and high, barren and uninteresting. Between the lateral ranges which traverse the country there are a few cultivated valleys. The most extensive of these valleys, which receive their names from the rivers that drain them, are Quilimari, Logotomo, La Ligua (these open into each other near the shores of the Pacific), and Aconcagua. The three first are of moderate extent, but the valley of the Aconcagua is mostly 2 or 3 miles wide, and expands near its middle to a plain, 15 miles in length and 13 miles wide. Where the plain contracts again, at its western extremity, the valley of the river Putaendo opens into it from the north. This valley, though less wide than that of the Aconcagua, is yet of considerable extent, and both together contain probably two-thirds of the population of the province. Its soil is rather fertile, and the greatest part may be irrigated. The cultivation is extensive. The crops generally raised are wheat, maize, pumpkins, melons, beans, and other garden produce. Orchards and vineyards are numerous; lucerne is sown to a great extent for fattening cattle and for their maintenance during the winter. In summer cattle find excellent pastures on the declivities of the Andes, which however during four or five months are covered with snow. Hemp is also cultivated in some parts of the valleys. Great quantities of apples, pears, peaches, nectarines, figs, walnuts, muscatel grapes, and strawberries are sent to Santiago and Valparaiso. The sugar-cane is cultivated in the valley of La Ligua, but no sugar is made, the green shoots being taken to Santiago for sale.

The hills and mountains, which inclose the valleys and cover by far the greater portion of the surface of the country, are stony, mostly round-topped, and of gentle slope, except towards the Andes where they are steep. Their soil consists of a hard red clay, which is thinly covered with a few bushes and stunted trees, and many cactuses. The ravines present a few evergreen trees and shrubs. The nature of the soil and the scarcity of rain combine to render these hills nearly useless as pasture ground. In some places however near the coast there are some more fertile tracts, on which wheat is raised without irrigation. They are found on the gentle slopes of the hills, and have mostly a stiff clayey soil and a subsoil moistened by springs so small as never to issue from the surface. These tracts are distinguished in the country by the denomination of La Costa, but the quantity of corn raised is not great.

The chief metals are gold and copper. Gold is found in the districts north of the valley of Aconcagua; it is collected chiefly in the mountains surrounding Petorca at La Ligua and La Dormida. Copper ores are met with in most parts of the province, but mines are worked only in the mountains near the sea-coast.

The climate of this country differs considerably in different parts. On the coast, in the northern districts, there is somewhat less rain than in the southern; but even here there are seldom more than fourteen rainy days in the year. In summer the heat is not excessive, as a fresh southern breeze always prevails, by which it is moderated. In the interior, and especially in the wider part of the valley of Aconcagua, which is about 2500 feet above the sea, no rain falls, but in winter (June and July) there are heavy dews, which appear as a hoar-frost. The days at this season are very pleasant. In summer the heat is here excessive, the thermometer frequently rising above 90° in the shade. The southern winds blowing along the coast are interrupted by the intervening mountains, and a dead calm prevails during the day, but no sooner has the sun disappeared than a delightful current of air blows from the westward towards the cordilleras, which renders the evenings and nights very pleasant. Thus the climate of this valley resembles that of the southern parts of Italy. The scarcity of rain renders cultivation impossible without irrigation.

Aconcagua has no ports. The coast has no indentations of any extent in which vessels may be sheltered from the heavy swell which sets in continually from the south-west. The port of Quintero formerly had from one and a half to two fathoms water, but by the earthquake of 1822 its bottom was raised, with the adjacent coast, from four to five feet, so that it is now too shallow for vessels of any size. North of Quintero are the road-steads of Horcon and Papudo, with good landing places; and farther north the cove of Pichidanque, from which much copper is shipped.

The principal towns of the province, like most of those in Chili, are regularly built and on a uniform plan; so much so that a general description of one will suffice for all. In the centre is the Plaza or principal square, one side of which is formed by the cathedral or church and the buildings connected therewith; a second side is formed by the Cabildo, or municipal offices; on the other sides, which in most instances are fronted with piazzas, are the theatre, coffee-houses, and the principal shops. The area of the Plaza serves frequently during the early part of the day as a fruit and vegetable market; in the evening it forms a fashionable promenade; and during all political and religious festivals it is the great centre of attraction. From the Plaza branch off the principal streets, straight, wide, regular, and crossed by others at right angles and at measured intervals. The houses, as is usual in countries subject to earthquakes, are only one story high; they are built of sun-dried bricks, and in the Spanish fashion. Towards the street they present generally a blank wall, pierced only by a wide doorway or gate leading into a patio, or court-yard, on which the principal apartments open. Beyond this patio there is another, round which the private apartments are built, and beyond this even another quadrangle, containing the kitchen and servants' rooms. The patios are frequently roofed over with trellis-work, along which vines are trained to grow; and when water is abundant there is a pond or a jet-d'eau, or both, in the centre. To go from one part of the house to another the patio must be crossed. When we have added that each house has a garden or vineyard behind it, an idea may be formed of the great extent covered by a town of even a small population. Another distinguishing feature of these towns is the Alameda, or public walk. This consists mostly of shady alleys formed by trees regularly planted near a river, and on such a site as to command a succession of picturesque or sublime views. Near the Alameda is the exercising ground for militia or military parades. The streets seem to foreigners dull and lifeless in general; the Plaza and the Alameda, during the hours when they are frequented, are the chief sources of amusement and gratification, and this they often afford in a high degree; as during the hours of recreation in the evening the whole population, rich and poor, flock thither, with the exception of the very old or very young, who however indemnify themselves by enjoying the fresh air on the flat roofs of the houses. *San-Felipe-de-Aconcagua*, the capital of the province, situated on the right bank of the Aconcagua, at a distance of 50 miles due N. from Santiago, the capital of Chili, and the same distance W. by S. from the Peak of Aconcagua, has about 13,000 inhabitants. *Santa-Rosa*, 20 miles higher up the river, and E.S.E., of San-Felipe, has a population of 6000. *Petorca*, situated 50 miles N. by W. from San-Felipe, in the richest mining district of the province, is a small place, with hardly more than 1000 inhabitants.

The road from Santiago to San-Felipe crosses the range of hills called Cuesta-de-Cachabuco at the height of 2896 feet above the sea, and is continued northward through Petorca to La Serena. Another road leads down the valley of the Aconcagua through Quillota to Valparaiso, distant about 60 miles. The communication with the Argentine Provinces is kept up chiefly by the road up the valley of the Aconcagua and across the Andes by the Pass of La Cumbre (12,454 feet above the sea) through Uspallata to Mendoza. Another road, branching off from the northern road at the village of San-Antonio, about 10 miles N. from San-Felipe, and running up the left bank of the Putaendo, crosses the Andes by the Patos Pass, and leads to the Argentine town and province of San-Juan. The road by the Cumbre Pass is open for mules from November to the end of May; for the rest of the year it is closed to all but foot-passengers, and the crossing is then very dangerous. It was by the Patos Pass that General San Martin marched over the Andes into Chili with the army of Buenos Ayres in 1817.

(Miers, *Travels in Chili and La Plata;* Meyen's *Reise um die Erde;* Pöppig's *Reise in Chile, Peru und auf dem Amazonenflusse;* Parish, *Buenos Ayres and the Provinces of La Plata; Surveying Voyages of the Adventure and Beagle.*)

ACONITINA. [CHEMISTRY, *S.* 1.]

ACORI'NÆ, ACORI'DEÆ, or ACORA'CEÆ, a small natural order of Endogens, with the following essential character:—The flowers are hermaphrodite, surrounded with scales. The spathe is leaf-like, but not rolled up. The stamens are complete, placed opposite the scales, and have two-celled anthers which are turned inwards. The ovaries are distinct. The fruit is baccate, juicy at first, but finally juiceless. The seeds have the embryo seated in the axis of a copious albumen. The rootstock is jointed; the leaves sword-shaped, and embracing each other in the bud. Such is the character given this order, which was first separated from *Araceæ* by Agardh, and the separation was afterwards adopted by Schott, Link, and Lindley. The genera assigned to this order by Lindley were *Acorus, Gymnostachys, Tupistra*, and *Aspidistra.* The two last genera are now assigned by the same author to the order *Liliaceæ.* This small group of plants in its geographical distribution is confined to the eastern hemisphere. None of them have the acrid properties of some of the *Araceæ.* The *Acorus Calamus* is a British plant, and has slightly aromatic properties.

ACRITA (from ἄκριτος, indistinct), a division of the class *Radiata*, adopted by Owen, and applied to the *Acalephæ*, the *Polypifera*, except the *Bryozoa*, the *Polygastrica*, and certain forms of *Entozoa*, in none of which are the indications of a nervous sytem decided, and they constitute the lowest forms of the radiate group of animals.

ACROGENS. [POLYPODIACEÆ.]

ACROLEINE. [CHEMISTRY, *S.* 2.]

ACRYLE. [CHEMISTRY, *S.* 2.]

ACTION AT LAW. The procedure in personal actions has been much simplified by the Common Law Procedure Act, 1852; many of the old rules of pleading having been at the same time abolished. The Common Law Procedure Act of 1854 has conferred powers on the courts of common law to restrain the repetition or continuance of wrongful acts by *Writ of Injunction*, by a process analogous to the injunction granted by the Court of Chancery. The remedy by *Writ of Mandamus* to enforce the performance of duties has also been extended by the same statute; both of these writs being now obtainable in and by an ordinary action at law.

ADAIR, SIR ROBERT, was the son of Robert Adair, sergeant-surgeon to George III., by a daughter of the second Earl of Albemarle, through whom he became connected with many families of political influence. He was born in London on May 24, 1763, and was educated at Westminster School, whence he proceeded to Göttingen to complete his studies. On his return in 1780 he became acquainted with Mr. Fox, took his side in politics, and wrote a pamphlet or two, one of which, a letter to Mr. Burke, brought on him the ridicule of Canning in the 'Anti-Jacobin.' But in February, 1806, when Fox succeeded to power, he was sent as minister to Vienna, where he conducted himself ably, and of which mission he published a memoir in 1845; and in 1808, Canning, when in office, though he had ridiculed his appointment to Vienna, selected him for a special mission to the Porte, with Mr. Canning (now Lord Stratford de Redcliffe) and Mr. Morier as assistants, where he negociated the treaty of the Dardanelles, concluded in 1809, and of this mission he has also published an account. On its successful termination he was made a Knight Grand Cross of the Order of the Bath. In April, 1809, he was appointed ambassador at Constantinople, which office he held till 1811. In July, 1831, he was despatched by Earl Grey on a special mission to Belgium, where Prince Leopold, recently elected to the throne of that kingdom, was besieged in Liege by the Dutch troops under William Prince of Orange. Sir Robert urged Prince Leopold to fly; but he declined, saying, that 'flight ought not to be the first act of his reign; he was ready to fight, but would allow him to negociate,' and Sir Robert fastening a handkerchief to a ramrod, sought the hostile army, and in an interview with Prince William, succeeded in gaining his connivance for Leopold to withdraw to Malines, whither he accompanied him. In this post he remained till 1835, when he retired with the rank of privy councillor, and a pension of 2000*l.* per annum. He died on October 3, 1855, after a short illness. Sir Robert had represented Appleby in 1802, and Camelford in 1806 and 1807. In 1805 he had married Angelique Gabrielle, daughter of the Marquis of Hazincourt, but left no issue. Sir Robert possessed a wide range of information, and his views with regard to Russia have since been remarkably confirmed.

ADAMS, JOHN QUINCY, the eldest son of John Adams, the second President of the United States, was born in Massachusetts, June 11, 1767. Some of his early years were spent in Europe, whither he accompanied his father. In 1801 and 1802 he was minister plenipotentiary from the United States to Berlin, and during this time he travelled through Silesia, which country, its manufactures, and more particularly its educational establishments, were described by him in a series of letters addressed to his brother at Philadelphia. These letters, which were originally published in a journal called 'The Portfolio,' were collected in a volume and published in 1804. During the presidency of Jefferson, Adams was recalled from his embassy at Berlin. Upon his return he became a professor in Harvard College, and was subsequently elected a deputy to Congress for Massachusetts. Having been previously attached to the federalist party, he now allied himself to the democratic party. He was next charged with a mission to Russia, and in 1814 joined the Congress at Vienna as plenipotentiary of the United States. In 1815 he was ambassador at the Court of St. James's. In 1817 he became secretary of state for the interior; and in 1825 he succeeded Mr. Monroe as President of the Union. He was not however re-elected, his place being supplied by General Jackson. In 1830 he was elected deputy to Congress, where he distinguished himself until his death by his advocacy of the abolition of slavery. He died at Washington, February 17, 1848.

ADARE. [LIMERICK.]

ADDISON'S DISEASE. [MEDICINE, S. 2.]

ADMINISTRATION AND ADMINISTRATOR. The whole jurisdiction of the Ecclesiastical Courts in the grant and withdrawal of administrations, and the superintendence of administrators, has been transferred to the Court of Probate. (20 & 21 Vict. c. 77. [PROBATE, COURT OF, S. 2.] The customs of London, York, &c., (P. C. vol. i. p. 125) have been abolished, and the distribution of the estates of intestates thus rendered uniform throughout England. (19 & 20 Vict. c. 94; 'Blackstone's Comm.,' Mr. Kerr's ed., vol. ii. p. 554.)

ADMIRALTY, COURT OF. The jurisdiction of this Court in matters of wreck and salvage is regulated by the statute 9 & 10 Vict. c. 99. Questions relating to the attack and capture of pirates may now also be determined by this Court or the Vice Admiralty Courts abroad. (13 & 14 Vict. cc. 26, 27.)

ADOLPHUS, JOHN, was born in 1770 and died July 17, 1845. Mr. Adolphus was a barrister of high standing in the criminal courts, and at his decease was father of the Old Bailey bar. He was a keen advocate, a fluent speaker, and a good lawyer. His practice, previously very considerable, was highly increased by the manner in which he distinguished himself as leading counsel for Thistlewood and the other prisoners charged with a treasonable conspiracy in 1820, though he was retained on their behalf only a few hours before the trial. As a literary man Mr. Adolphus is best known as the author of the 'History of England from the Accession of George III.,' originally published in 3 volumes in 1805, but which he subsequently revised and greatly extended. Of this enlarged edition the seventh volume appeared just before his death, but it left the work unfinished, and the conclusion has not been published. It is a work of considerable research and very carefully executed, but it does not exhibit very high historical powers. He was also the author of 'Biographical Memoirs of the French Revolution;' 'Political State of the British Empire,' 4 vols. 1818; 'Memoirs of John Bannister;' and some fugitive pieces and pamphlets.

ADULTERY. The action of damages for criminal conversation, or *crim. con.*, has been abolished by the statute 20 & 21 Vict. c. 85, creating 'the Court for Divorce and Matrimonial Causes.' The injured husband, in applying to this Court for a divorce or a judicial separation, may claim damages, which however can only be awarded to him by the verdict of a jury, and the Court may then direct in what manner the damages are to be disposed of; for the whole or any part thereof may be settled on the children of the marriage, or as a provision for the maintenance of the wife. [DIVORCE, S. 2; SEPARATION, JUDICIAL, S. 2; HUSBAND AND WIFE, S. 2.]

ÆGOPODIUM (from αἴξ, a goat, and πόδιον, a little foot), a genus of plants belonging to the order *Umbelliferæ*. One species, *Æ. podagraria*, is common throughout the whole of Europe, and grows abundantly in Great Britain. It has a stem one or two feet high, with furrows. The leaves are two or three times ternate; the leaflets unequal at the base and acutely serrate. It has a creeping root, and grows in damp places. Although well known, and having the names of Goat-Weed, Ash-Weed, Herb Gerard, and Wild Masterwort, it seems to possess no medicinal properties. Linnæus says that it is boiled when young, and eaten as greens in Sweden.

ÆTHERS, SILICIC. [CHEMISTRY, S. 1.]

AFFIRMATION (in Law). Every person who has conscientious objections to taking an oath, may now be permitted to make a solemn affirmation in lieu thereof, the effect of which is the same as if the testimony were given on oath. (Common Law Procedure Act, 1854.)

AFFRE, DENIS AUGUSTE, archbishop of Paris, was born at St.-Rome, in the department of Tarn, Sept. 27, 1793. At an early age he evinced a desire to devote himself to the Church, and he became a student at the seminary of St.-Sulpice. He was ordained priest in 1818, and discharged a variety of ecclesiastical functions till he became archbishop of Paris in 1840. Although a man of ability and learning, and the author of several treatises (amongst which was one on Egyptian hieroglyphics), he would scarcely have found a place in the history of his times, but for the lamentable circumstance of his death on the 27th June, 1848. Paris was then the scene of a fearful contest between the soldiery and a vast body of insurgents. The archbishop was induced to apply to General Cavaignac, proposing to stand between the contending bodies as a messenger of peace. The general told him that the course was full of danger. "My life," he replied, "is of small consequence." Some hours afterwards the firing of the soldiery having ceased at his desire, the archbishop mounted a barricade erected at the entrance of the Faubourg St. Antoine: he was preceded by M. Albert, a national guard, wearing a workman's dress, carrying in his hand a green branch as an emblem of peace; and he had at his side a faithful servant named Pierre Sellier. The devoted ecclesiastic was not received with the confidence that he expected to inspire. Some indeed of the combatants stretched out their hands, but others remained silent, while others groaned and hooted. The prelate endeavoured to speak a few words; but the insurgents, fancying themselves betrayed, opened a fire upon the Garde Mobile, and the archbishop fell. Then a cry of horror went up from the crowd, and many, even of the insurgents, rushed to his aid. Albert and Sellier were leading him away, when Sellier was also struck by a ball. The insurgents who surrounded the archbishop cried out that the Garde Mobile had inflicted the wound, and that they would avenge him. "No, no, my friends," he replied; "there has been blood enough shed; let mine be the last that is spilt." He was carried to the archiepiscopal palace, and died the same day. The National Assembly issued a decree announcing its profound grief at the event of his death, and his public funeral took place on the 7th of July, amidst the deepest feelings of popular regret. (*Nouvelle Biographie Universelle*, 1852.)

AFREEDIS, an Afghan clan, sometimes spoken of under the more general name of Kyburees, inhabit the Kyber hills on the confines of Cabul and the Panjab. They command the passes in these hills, for a safe conduct through which their Maliks, or chiefs, consider themselves entitled to demand a toll. The toll for the celebrated Kyber Pass was formerly paid by the rulers of Cabul, and the nonpayment of it after the restoration of Shah Soojah to the throne excited the furious hostility of the Afreedis against the British and their auxiliaries. They resisted the march of Colonel Wade and the Sikh auxiliaries through the pass in July, 1839, but were compelled to evacuate the fort, Ali-Musjid, the key of the pass, which, with other posts between Peshawur and Jellalabad, was garrisoned by small detached parties. At a subsequent period of the Afghan war, January 19, 1842, they defeated two Sepoy regiments advancing under Brigadier Wild from Peshawur to the relief of two other Sepoy regiments under Colonel Moseley in Ali-Musjid, which had seized that fort some days before, and had been robbed of their provisions on their way. Cut off from all communication with the brigadier, and short of provision, Moseley evacuated the fort on the 24th, which was immediately seized by the Afreedis. On General Pollock's advance from Peshawur to the relief of Jellalabad, in the spring of 1842, the Afreedi chiefs offered to clear the pass from Jumrood to Dhaka for 50,000 rupees; but Pollock chose to force his way, sweeping the heights on each side of the defile with his light troops, whilst the main body advanced through the pass, having demolished the barrier raised by the enemy across the entrance. Before Pollock reached Ali-Musjid the Afreedis had evacuated it; it was then held by a strong force till the final withdrawal of the British troops from Afghanistan, when it was blown up. We next hear of the Afreedis in connection with another pass on the road from Peshawur to Kohat, leading to the Salt Range. On February 2, 1850, about 1000 Afreedis plundered the camp of a party of British Sappers employed in making a road through this pass, about 18 miles south from Peshawur, and killed several of the men. To avenge this massacre a strong force, under Colonel Bradshaw, scoured the hills in the neighbourhood, destroying six villages and a great number of the enemy, who however made some resistance on the return of the troops through the passes.

To the west of the Kyber hills, on the Cabul side, the Momund clan dwells along the banks of the Cabul River. Their chief place, Lalpoorah, the residence of the Malik, is opposite Dakha.

AFRICA. At the period when the article AFRICA in the 'Penny Cyclopædia' was written, the descent of the Quorra, or Niger, had recently been accomplished by the brothers Richard and John Lander. In a subsequent article, QUORRA, additional details are given respecting the river and the countries through which it flows; and the discoveries brought down to the year 1840. At that time an expedition was in preparation by the British government, the object of which was to check and supersede the foreign trade in slaves by the establishment of a commerce along the banks of the Quorra, which should be more beneficial to the native chiefs than the cruel traffic in slaves. This expedition, consisting of three steam-vessels, began the ascent of the river in 1841, but a fatal sickness unhappily seized the greater part of the crews and officers, and they were unable to ascend the river so far even as had been previously reached by the disastrous expedition of 1832. The failure of these two expeditions, attended as they both were by a fearful loss of life, prevented any renewal of the attempts to ascend the Quorra till the year 1854, when Dr. Baikie made his successful ascent of the river and its great eastern tributary, the Tchadda or Benuè. This ascent was made in Mr. McGregor Laird's screw-steamer the Pleiad, flat-bottomed and of a peculiar construction suitable for ascending a shallow river against a powerful current. In the first instance Lieutenant Lyons M'Leod, R.N., was to have had the command, his project of exploring the countries between the Quorra and the Gambia having been abandoned; but afterwards Mr. Becroft, already well acquainted with the Quorra, was appointed the chief. Mr. Becroft, however, died before the Pleiad had reached the mouth of the river, and the command was then assumed by Dr. Baikie, surgeon, R.N. The expedition occupied about four months, from July 12 to November 7, and ascended 250 miles of the course of the Tchadda above Dagbeh, which was the farthest point reached by Allen and Oldfield in 1832, and is about 100 miles from the confluence of the Tchadda and Quorra. The point reached by Dr. Baikie was only fifty-five miles from the place where Dr. Barth afterwards crossed the Benuè, thus proving that the Benuè of Central Africa is the same river as the Tchadda. Dr. Baikie is now (January 1858) engaged in another similar expedition, in which he hopes to ascend the Tchadda to a still higher point. He had ascended the Quorra to some distance above Rabba, when his steamer was wrecked by striking on a sunken rock in the bed of the river. All the persons, however, were saved, and they had everywhere entered into friendly relations with the natives. A new steam-vessel, suitable for navigating the Tchadda, has been sent out to replace the one which has been lost.

We now proceed to notice the discoveries made in the southern, central, and eastern parts of the continent since the publication of the article AFRICA, in the 'Penny Cyclopædia.'

In the years 1835 and 1836 Dr. Andrew Smith made a journey in South Africa, during which he visited the sources of the rivers Caledon and Maputa, ascended the mountains of Caffraria, and advanced in the tracks of the traders as far north as the Tropic of Capricorn. He was unsuccessful, however, in the principal object of his journey, which was to reach a large lake in the interior, the lake Ngami, since discovered by Messrs. Livingstone, Oswell, and Murray. In 1836 and 1837 Captain J. E. Alexander explored the countries inhabited by the Namaqnas, Bushmen, (Bosjesmans), and Hill Damaras, extending on the western side of Africa from about 30° to 23° S. lat.

At the end of May, 1849, while the Rev. Dr. Livingstone was residing as a missionary at a station named Kolobeng, he was visited by Mr. Oswell and Mr. Murray, two gentlemen who had come from the East Indies, partly for the purpose of hunting and partly of making geographical discoveries. They agreed to accompany him in a journey which he was desirous of making in search of a large lake, the position of which had long been known from the reports of the natives. Mr. Oswell undertook to defray the expenses of the journey, which was long, and rendered difficult by the Kalahari Desert lying between Kolobeng and the lake. This large district, however, is not absolutely a desert, but is without running water. On the 1st of June, 1849, the party commenced their journey, and managed to obtain water by digging, till, on the 4th of July, they reached a fine river named the Zouga. There they met with some friendly natives, who informed them that the river flowed out of the Lake Ngami, and that by tracing it upwards they would reach the lake. On the 1st of August they arrived at the north-east end of the lake, whence the river flows, and beheld a fine expanse of water. They could form no idea of its extent except from the reports of the natives, who professed to go round it in three days, whence they estimated the circuit to be from 70 to 90 miles. Mr. Macabe, who afterwards travelled round it, estimates the circuit at 90 or 100 miles. The lake is shallow, and the banks are flat. When full, the water is quite fresh, but brackish when low, and it is then difficult to reach through the boggy and reedy banks. The elevation above the sea was estimated at a little over 2000 feet and they had descended about 2000 feet in travelling to it from Kolobeng. The latitude of the upper end of the lake is 20° 20′ S., and the longitude probably between 22° and 23° E. The lake receives the Teoughe, a large river, at the north-western end, and discharges itself by the Zouga at the north-eastern end. The Zouga, soon after leaving the lake, receives the Tamunakle, which, as well as the Teoughe, flows from the north. The Zouga continues for a considerable distance to be a fine river, broad and deep, with beautifully wooded banks, but receiving no more affluents, becomes gradually narrower in its descent of about 200 miles in a winding south-easterly direction. It then flows into Lake Kumadan, which is about 12 miles in length, and 3 or 4 broad, and the water is there dissipated, gradually becoming more and more salt as evaporation proceeds. In September Lake Ngami becomes very low, and the rivers are dried up. The water begins to flow again in April, but makes little progress in filling Lake Kumadan till the end of June. The Bataoana tribe of natives live at the eastern end of the lake, where they have their principal village. After a short stay there, the party returned, and arrived at Kolobeng, October 10. There are prodigious numbers of the elephant, rhinoceros, and other large animals, in the vicinity of the lake and its rivers. The name Ngami is pronounced Ingámi, the first syllable very short. Dr. Livingstone paid another short visit to Lake Ngami in 1850, accompanied by his wife and three children.

In June, 1851, Dr. Livingstone, accompanied by Mr. Oswell, again started for the north. This time their route was in a more easterly direction, and they succeeded in pushing their researches northward to 17° 25′ S. lat., and between 24° 30′ and 26° 50′ E. long., traversing a considerable tract watered by deep and constantly flowing streams, which they believe to be feeders of the river Zambesi. They passed over a large salt incrustation of about 100 miles in length and 15 miles in width, and saw many others lying to the north of the spot where the Zouga terminates. Considerably to the north of these great natural salt-pans, in the country watered by the supposed tributaries of the Zambesi, the inhabitants are more intelligent than most of the native tribes of South Africa.

In 1851 Mr. Francis Galton left England with the intention of following up Dr. Livingtone's discoveries, but for certain reasons this project was abandoned, and, instead, he proceeded to Walfisch Bay on the western coast of Africa, north of the Tropic of Capricorn. He was accompanied by Mr. Andersson, a native of Sweden, and they explored the region between the bay on the south, and Ondonga, in 17° 58′ S. lat., near the river Nourse on the north, and as far inland as 21° E. long. Through this journey we obtain a description of the Damara people, who, though a race of fine stature, are in a low moral state, and likely to be extinguished by their more centralised, powerful, and intelligent neighbours on the north, the Ovampo. The high table-land, which was traversed to reach the Ovampo, is cut through by deep ravines, the chief of which serve as escapes for the periodical flood of the rivers. In delineating the moral character, as well as the physical conformation of the different tribes of South Africa, it is interesting to observe, from the observations of Mr. Galton, how their differences are connected with the form, subsoil, and vegetation of their respective lands. Thus, the arid inland plateaus, covered only with thick jungle and short brushwood, hold the dwarfed and sinewy Bushmen; the more open, hilly, and undulating pasture-lands, the Damaras; whilst the rich corn-lands on the north are occupied by the race which is the most civilised and advanced, the Ovampo. Ondonga, the capital of this people, is estimated to be about 70 or 80 miles to the south of the great river Amorongo Achilunda, the Nourse of our maps. The table-land inhabited by the Damaras rises in some points to 5000 and 6000 feet above the sea. Mr. Galton afterwards, in September and October, 1851, proceeded as far eastward as Tounobis, a distance of 500 miles from the coast, on the road to Lake Ngami, distant about 180 miles. Mr. Galton did not reach Lake Ngami, having made an engagement to embark at Walfisch Bay in a vessel which was expected, and the specified time not allowing him to remain longer. Mr. Andersson however afterwards proceeded again to Tounobis, and thence to Lake Ngami, from which he ascended some distance the river Teoughe, the principal affluent of Lake Ngami. Mr. Andersson reached the Lake at the end of July, 1853. Mr. Galton and Mr.

Andersson have each published a volume giving an account of their travels.

We shall now give an account of the missionary explorations from the eastern coast, and of the expedition to Central Africa.

The zealous and enterprising missionaries, Krapf and Rebmann, stationed at Rabbai 'Mpia, near Mombas, in about 4° S. lat., began their journeys into the interior of the continent in 1847. In that year Mr. Rebmann penetrated westward to Teita, a "country whose mountains rise to such a height out of the vast surrounding plains, that on some eminences near Rabhai 'Mpia they are to be seen at a distance of 90 miles;" and in the April following (1848), the same missionary performed a journey farther into the interior, to the still more elevated country of Djagga, where, at a distance of rather more than 200 geographical miles from the coast, in a direction about W.N.W. from Mombas, he made the remarkable discovery of a lofty mountain, named Kilimandjáro, of which the summit is covered with perpetual snow. The existence of snow on Kilimandjáro has been disputed in Europe, though it is difficult to say on what reasonable ground. However, on subsequent journeys, both Mr. Rebmann and his colleague Dr. Krapf satisfied themselves of the fact; and unless it be intended absolutely to impugn their veracity, their evidence cannot be rejected. In April, 1849, be again set out on his way into the interior, but was unable to proceed beyond Djagga. In November and December of the same year Dr. Krapf successfully penetrated as far as Ukambáni, a country situated northward of Djagga. Of the geographical results of this journey, one of the most important is the discovery of another snowy mountain, named Kénia, of larger size if not greater elevation than Kilimandjáro. Kénia, is thus described by Dr. Krapf:—"The sky being clear, I got a full sight of the snow mountain. . . . It appeared to be like a gigantic wall, on whose summit I observed two immense towers, or horns as you may call them. These horns or towers, which are at a short distance from each other, give the mountain a grand and majestic appearance, which raised in my mind overwhelming feelings. Kilimandjáro in Djagga has a dome-like summit; but Kénia has the form of a gigantic roof, over which its two horns rise like two mighty pillars, which I have no doubt are seen by the inhabitants of the countries bordering on the northern latitudes of the equator. Still less do I doubt that the volume of water which Kénia issues to the north runs towards the basin of the White ,Nile." In Rebmann's map ('Church Missionary Intelligencer') Kénia is placed in 1° S. lat., 35° 10′ E. long., at a distance of 320 geographical miles north and 55 west from Mombas. This position, however, can only be considered as a rough approximation. In the last journey of Dr. Krapf he again visited the country of Ukambáni and the river Dana, as the upper course of the Ozi is called. On this journey the enterprising traveller was subjected to the greatest hardships and sufferings, and indeed barely escaped with his life. No fresh discoveries were made in this journey, but some further information was collected respecting the river which flows from the Kénia (Ndukenia or Kirenia) northward, and forms most probably one of the head-waters of the Nile.

The expedition to Northern and Central Africa, conducted by Mr. Richardson, accompanied by Drs. Barth and Overweg, is one of great importance. This expedition originated with Mr. Richardson, who, after having returned from his travels in the northern portion of the Sahara in 1845 and 1846, induced the English government to send him out for the purpose of concluding commercial treaties with the chiefs of the desert-regions between Tripoli and Lake Tchad. Through the lively interest taken in it by Chevalier Bunsen, Baron Humboldt, and Professor Ritter, it was arranged that Dr. Barth and Dr. Overweg, two Germans, should accompany Mr. Richardson for the purpose of making scientific observations. Lord Palmerston sanctioned this proposal, and afforded the two travellers pecuniary assistance, in addition to their own private means and to grants from the Geographical Society in Berlin and the King of Prussia.

The three travellers departed from this country at the latter end of 1849, and arrived in Tripoli in the beginning of the following year. Previously to starting from that place, the mountainous region to the south was thoroughly explored and surveyed by the two Germans within a radius of 60 to 80 miles from the town. [Tripoli.] An unexpected degree of cold was experienced in these excursions. On one day the thermometer, before sunrise, stood as low as 26° Fahrenheit, and on the 2nd and 3rd of February, the snow obliged the travellers to remain in their tents. After their return to Tripoli, several weeks were required for their preparations; and the transport of a boat for navigating Lake Tchad caused considerable difficulty. For this purpose a beautiful wherry had been constructed by the direction of the admiral at Malta, broad in the beam, and very light on water; but it was necessary to take it to pieces, and several camels were requisite to convey it across the burning sands of the Sahara.

The travellers started at last on the 24th of March, 1850, the great caravan having departed before them; but the party formed a small caravan of itself, having about 40 camels laden with their effects and merchandise. Every possible assistance was rendered by her Majesty's consuls in Tripoli and Murzuk to the undertaking, so that the expedition started under the most favourable circumstances.

The direction of the route to Murzuk was almost due south from Tripoli, beyond the Gharian defile, the country consisting of a continuous table-land, of an average elevation of 2000 feet. As far as the well of Taboniyah, many deep wâdis intersect this table-land, and the ruins of several Roman monuments and columns were discovered by the travellers. Southward of that place is a table-land, or Hamadah, an immense desert of considerably greater elevation, and extending for about 110 geographical miles in the same direction. As far as the eye can reach, neither trees nor indications of wells are visible, and the scanty vegetation which occurs is only found scattered in the trifling irregularities of the surface. The ground is covered with small stones, pyramids of which, erected with great labour, serve as road-marks to the intrepid camel-drivers by day, while the polar star and Antares are their guides by night. After a journey of six days the expedition reached the southern edge of this table-land, which descends in perpendicular walls to the Wâdi el Hessi. Following the descent for about 60 geographical miles, the travellers came to the Wâdi Shi'ati, over another plateau of equally dismal aspect. It is composed of a black sandstone, the disintegration of which forms a dark yellow sand, covering the inequalities of the stony surface, from which stands out prominently the black rock, in high cones of the most fantastic forms, strikingly resembling basaltic rocks. They reached Murzuk on the 6th of May, and remained there till the 13th of June, collecting much important information respecting the countries and nations to the south. Murzuk is very unhealthy and dangerous for Europeans, but happily none of the party suffered during their stay.

On the 13th of June they set off for Ghat, which they reached on the 18th of July. The most interesting result of this journey was the discovery of several curious sculptures on the rocks of the Wâdi Felisjareh. One of them consists of two human figures with the heads of birds, and a bull, armed with spears, shields, and arrows, and fighting for a child; the other is a fine herd of oxen going to a watering-place, most skilfully grouped and executed. In the opinion of the travellers the two works bear a striking and unmistakeable resemblance to the sculptures of Egypt. They are evidently of much higher antiquity than many other sculptured tablets found by the travellers, on which camels formed generally the principal objects.

The party started from Ghat, after a stay of some days, for the kingdom of Aïr or Asben. They had to cross a vast desert, totally uninhabited, for about 250 geographical miles, and succeeded in reaching Taghajit, the first inhabited place in Aïr, on the 22nd of August.

The route from Ghat to Aïr is described by Dr. Overweg as a mountain-path leading over ridges, table-lands, and deep-cut rocky valleys. Wherever the wâdis become broader, and through the agency of rain are covered with disintegrated rocks and sand, they show a scanty vegetation of grass and trees. The geognostical character of the country is here of much greater interest. From Murzuk to Ghat, and farther to the south, the prevailing formation consists of sandstone of various colours, with throughout the same petrographical aspect of the rocks, the same slopes of the mountains and intersections of the valleys, and the same horizontal strata. At Aggeri, about 70 miles to the south of Ghat, the entire scene suddenly changes. The mountains are now rounded, and strata forming projecting terraces are no longer seen. The travellers found themselves all at once in the regions of granite, the whole country between Aggeri and Aïr consisting of crystalline primitive rocks, with mica-slate and enormous masses of granite in great diversity of mountain-forms. From Ghat the general surface of the country continues to rise, and at Selufiet the travellers saw around them the highest mountain-masses met with on their journey. After the middle of August they experienced the influence of the Soodan rains; the atmosphere then beginning to be humid, and the evenings or mornings being accompanied by fogs. Frequent thunder-storms and heavy rains also occurred. Under the influence of these rains the aspect of the wâdis became completely changed, luxuriant plantations of palms being everywhere met with to the south of Taghajit. According to the natives the rainy season lasts till the end of September. At Taghajit, near the frontiers of Soodan, the travellers having accomplished the exceedingly difficult and dangerous journey across the Great Desert, believed themselves to be in perfect safety from the attacks of considerable numbers of furious Tuaricks, who had for some time followed their caravan, with the intent to murder and plunder them. Between Taghajit and Selufiet, however, at a place about 60 geographical miles farther to the south, on the 25th of August, they were attacked the first time by 40, and the second time by 100 armed men, mounted on camels. By their own courage, however, and the bravery of the Kelowis, their companions, their lives were saved at the expense of a high ransom, and they reached Tintellust, the residence of the Prince Annoor, on the 4th of September. By this prince, to whom they were strongly recommended, they were very kindly received. In Tintellust, which is situated in 18° 34′ N. lat., the travellers staid till the end of November, and collected a great deal of information respecting Northern Africa.

The inhabitants of Tintellust and the country around live entirely on the productions of Soodan, in exchange for which they supply Soodan with salt. Every year the Prince Annoor takes to the south from 2000 to 3000 camels laden with salt, and returns with slaves and provisions. While the expedition remained at Tintellust, Dr. Barth made a successful journey to Agades, the capital of the kingdom of Aïr or Asben, which occupied him from the 4th to the 30th of October. [Agades, *S.* 2.] On the 12th of December, 1850, the travellers left Aïr on their route to Lake Tchad, and arrived at Damergu by the end of December. Here the travellers separated, Mr. Richardson going by the most direct route to Kuka, Dr. Barth southward to Kano, and Dr. Overweg south-west to Mariadi and Guber, two states of independent Pagans, where the latter explorer was very kindly received, and obtained much curious information. Kuka, the capital of Bornou, had been fixed as the rendezvous of the three travellers, and Drs. Barth and Overweg safely met there again in April, 1851, but Mr. Richardson unhappily died on the road to Kuka, at Unguratua, about 100 geographical miles W.N.W. from that place, on the 4th of March. The political objects of the expedition devolving now upon the two scientific travellers, Dr. Barth, who arrived first at Kuka, presented himself at the sheikh's palace as one of the surviving Christians who had come from England to bring presents from her British Majesty. Dr. Overweg also soon arrived. The two travellers were kindly received by the sheikh and his vizier, and were assisted in all their objects and wishes. Preparations were forthwith made for exploratory tours; and while Dr. Barth was absent on his journey to Adamaua, Dr. Overweg put the boat together, and launched it on Lake Tchad. Dr. Overweg embarked, and explored the lake, visiting the Biddumas, who inhabit the islands, of which there are about 100 large ones scattered over the lake.

On the 29th of May, 1851, Dr. Barth started on his adventurous journey to Adamaua, and on the 18th of June reached the great river Benuè, (which is the native name there given to the Tchadda) at the confluence of another large river called the Faro. This point of the Benuè is about 55 miles higher up than the point reached by Dr. Baikie in his voyage in 1854, previously noticed. The Benuè is here half a mile wide, and about 11 feet deep, running in a general direction from east to west, at the rate of about 3½ miles an hour. It is about 800 feet above the level of the sea. The banks are from 25 to 30 feet high. The Faro joins the Benuè from the south-east, and is from two to four feet deep, running with great rapidity. During floods the Benuè inundates the country on both sides. Dr. Barth crossed both the rivers, and proceeded in a south-west direction about forty miles to the town of Yola, which is the capital of Adamaua. It is situated in 9° 25′ N. lat., 12° 10′ E. long., and is a large open place, consisting mostly of conical huts surrounded by spacious courtyards. It is about three miles long from east to west, but does not contain more than 12,000 inhabitants. The huts have clay walls, and are thatched. The town has no industry, and the market is small. The province of Adamaua, of which the proper native name is Fúmbina, is very fertile, well cultivated, and full of villages. Dr. Barth arrived at Kuka, on his return from Adamaua on the 22nd of July.

On the 11th of September, 1851, Dr. Barth set out on an expedition to Kánem, a district on the eastern side of Lake Tchad. On the 18th of September Dr. Overweg joined Dr. Barth, accompanied by an escort of horsemen. They reached Kuka on their return October 14, after having been exposed to much danger from hostile natives.

On this expedition Dr. Barth had a favourable opportunity of investigating Lake Tchad. It is a vast lagoon without any outlet, of little depth and ever-varying extent. The circuit, when moderately full, is about 400 miles, travelling distance, or twenty days journey of about twenty miles a day. It receives only one perennial river, the Shary, which is very large, and in the wet season pours in a large quantity of water. The Shary comes from the south, and enters Lake Tchad at the south end. Another considerable river, the Yeou, or Yow, comes from the west, and enters the lake on the west side. The Yow ceases to flow in the dry season. Many of the numerous islands in the lake are permanently inhabited. The swampy parts, near the shores, contain large numbers of crocodiles and hippopotami, and elephants are very numerous in the vicinity of the eastern side of the lake. On one occasion Dr. Barth saw a herd of elephants proceeding to the lake for the purpose of drinking. The number amounted to ninety-five, and they were walking in a long line, like a regiment of soldiers, the males being in the front, the young ones in the centre, and the females in the rear.

On the 25th of November, 1851, Dr. Barth again left Kuka, in order to join a warlike expedition to the country called Mandara. The expedition started on the 8th of December, and on the 30th reached the village of Demmo, when Dr. Barth saw a broad watercourse flowing slowly from S.W. to N.E., shallow, but deep enough for canoes, and more than two miles in width. This watercourse appears to join the Serbewel, or upper course of the river of Logón, which is the chief affluent of the river Shary. At Demmo a considerable number of females and children were captured. The whole village was destroyed by fire, and made desolate. Slaughtered men, with their limbs severed from their bodies were seen lying about in all directions. The greater part of the men however escaped across the river. There was some fighting, and a few of the Bornu army were slain. The expedition reached Kuka, on its return, February 1, 1852.

On the 4th of March, 1852, Dr. Barth set out on an expedition to the kingdom of Bagirmi. On the 13th of March he arrived at Logón Bírni, capital of the territory of Logón. It is situated in 11° 47′ N. lat., 14° 56′ E. long., near the west bank of the river Logón, an affluent of the Shary, 350 or 400 yards wide. The population of Logón Bírni is about 15,000. On the 18th of March he reached the river Shary, 600 yards wide, and was passed over in a large canoe. On the 27th of April he arrived at Maseña, the capital of Bagirmi, in 11° 38′ N. lat., 16° E. long., and was not allowed to leave the place till the 10th of August. The town of Maseña was formerly much larger, and the extent of the wall has been reduced, but is still much too large for the town, and in the utmost state of decay. The town extends over a circumference of about seven miles; but only about half of this area is inhabited, the principal quarter being in the centre, and on the north and west sides of the palace of the Sultan of Bagirmi. A deep trough-like depression intersects the town from east to west, which, during the rainy season is filled with water, and in the dry season covered with the richest verdure. The surface within the wall is broken into many other hollows, which contain the wells.

On the 6th of July Dr. Barth received despatches from the Foreign Office of the British government, which were forwarded to him from Kuka, and which authorised him to carry out the objects of the expedition, and supplied him with the means. Lord Palmerston, in his despatch, allowed Dr. Barth, after he had completed the survey of Lake Tchad, either to proceed to the eastern coast of Africa, or westwards to Timbuctu. He decided on making the journey to Timbuctu.

On the 10th of August Dr. Barth was permitted to leave Masseña, and on the 14th of August crossed the Shary on his return. The rains had then commenced, and the river was above 1000 yards wide, very deep, and flowing at a rate of abont three miles an honr. He crossed the Logón river on the 15th of Augnst, and arrived at Kuka on the 21st.

On the 20th of September, Mr. Overweg died of an attack of fever. This date closes the 3rd volnme of Dr. Barth's 'Travels and Discoveries in North and Central Africa,' 3 vols. 8vo., 1857. Dr. Barth left Kuka on his journey to Timbuctu on the 28th of Novemher, 1852, and the other two volumes, which are to comprise his travels to Timhuctu, his residence there, journey hack to Kuka, where he arrived December 11, 1854, and his return to England, have not yet (Jan. 1858) been published.

In February, 1853, Dr. Edward Vogel, a young German, employed at Mr. Bishop's Ohservatory, Regent's Park, London, was sent to join Drs. Barth and Overweg. He was accompanied hy two volunteers from the corps of Sappers and Miners. They reached Lake Tchad on the 6th of January, 1854, and were received kindly hy the sheikh and his vizier. Dr. Barth was then absent on his journey to Timbuctu. Dr. Vogel is stated to have been put to death by the Sultan of Waday, and his papers have not yet been recovered, nor his fate ascertained with certainty. One of the Sappers and Miners has returned to England; the other, Corporal Maguire, appears to have been assassinated in the vicinity of Kuka. Dr. Vogel had sent to England a few notices of his explorations, had visited Yacoba, and on the 30th of April, 1855, had crossed the Tchadda at the place where Dr. Baikie had heen, in the Pleiad steamer, in 1854.

In January, 1853, accounts were received hy the Royal Geographical Society of London, which were subsequently confirmed in April, of the successful issne of a commercial journey across the continent of Africa hy a Moorish caravan, trading for ivory and slaves. It had started from Zanzihar on the east coast (5° S. lat., 39° E. long.), and had reached Benguela on the west coast (12° S. lat., 15° E. long.). The journey occupied six months; a day and a night were occupied in crossing the great lake of Tangauna, also called Nyassi, Zewa, and Maravi. In one part of the journey no inhabitants were seen for fifteen days.

We now proceed to give an acconnt of Dr. Livingstone's long and hazardous journeys from the interior to the west and east coasts of Africa, the greater part of which were through countries never hefore seen by any European.

In April, 1852, Dr. Livingstone proceeded to Cape Town, with his wife and children, and sent them home to England. He then returned in order to explore the conntry in search of a healthy district, which might prove a centre of civilisation, and open up the interior by a path to either the east or west coast. When he reached Kuruman, on his return, he learnt by a letter from the chief Sechele that the natives had been attacked at Koloheng hy the Boers of the Cashan Mountains; that the village of Kolobeng had been hurnt, about sixty of the males slain, many women and about 200 of the school children carried off for slaves, and his own residence plundered of everything.

Having returned to Koloheng, and remained a few days with the wretched Bakwains, he proceeded northwards on the 15th of January, 1853. The Bamangwato Hills, between Koloheng and Lake Ngami, are part of a range called Bakaa, which rises about 700 or 800 feet ahove the plains, and is composed of great masses of hlack hasalt. This mass of hasalt, ahout six miles long, has tilted up the rocks both on the east and west. Passing on to Letloche, about 20 miles heyond the Bamangwato, they found a fine supply of water. This spot was Mr. Gordon Cumming's farthest station north. Farther on they came to the hill N'gwa, 18° 27′ 20″ S. lat., 24° 13′ 36″ E. long. It is 300 or 400 feet high, and was the only hill they had seen since leaving the Bamangwato Hills. As they approached Linyanti, they found the river-heds filled by the annual inundation, and flowing into the Chohe, which is itself an affluent of the Leeamhye. With some difficulty they reached Linyanti, May 23, 1853. Linyanti is the capital town of the Makololo, and is situated in 18° 17′ 20″ S. lat., 23° 50′ 9″ E. long. The chief of the Makololo, named Sekeletu, a young man of 18 years of age, and the whole population of Linyanti, numhering 7000 or 8000, received Dr. Livingstone, whom they were expecting, with enthusiastic welcome. The Makololo are the most northerly of the Bechuanas.

Having waited a month at Linyanti, Dr. Livingstone, attended by a party of the natives, set out from Sesheke, for the purpose of ascending the Leeambye. Sesheke is ahout 100 miles east from Linyanti. Linyanti is on the northern hank of the Chohe. The conntry between the two places is perfectly flat, except patches which are only a few feet above the general level. From Sesheke they ascended the river Leeamhye to Nariele or Naliele, the capital of the Barotse country, situated in 15° 24′ 17″ S. lat., 23° 5′ 54″ E. long. The general course of the Leeamhye from the Victoria Falls, helow Sesheke, to Nariele is N.W. hy N. Having procured a sufficient number of canoes, they began to ascend the Leeamhye. They had 33 canoes, and ahout 160 men, Sekeletn and a large party of natives going with them to Nariele. The river, never before seen hy European, is magnificent, often more than a mile wide, and having islands of from three to five miles in length. The banks and islands are richly wooded.

From the bend up to the north, called Katima-Molelo ('I quenched fire'), the bed of the river is rocky, and the stream runs fast, forming a snccession of rapids and cataracts, which prevent continuous navigation when the river is low. The rapids are not visihle when the river is full, hut the cataracts of Nambwe, Bomhwe, and Kale, must always be dangerous. The fall at each of these is hetween four and six feet. But the falls of Gonye present a much more serious ohstacle. There they were ohliged to take the canoes out of the water, and carry them more than a mile hy land. The fall is ahont thirty feet. The main hody of water, which comes over the ledge of rock when the river is low, is collected into a space of 70 or 80 yards hefore it takes the leap, and a mass of rock heing thrust forward against the roaring torrent, a loud sound is produced.

The rocks here are of reddish, variegated, hardened sandstone, with madrepore holes in it. This and hroad horizontal strata of trap, sometimes 100 miles in extent, and each layer having an inch or so of hlack silicions matter on it, as if it had floated there while in a state of fusion, form a great part of the bottom of the central valley. These rocks, in the southern part of the country especially, are often covered with 12 or 15 feet of soft calcareous tufa. The hanks of the river in this part, viewed from the flat reedy hasin in which it flowed, seemed prolonged into wooded ridges 200 or 300 feet high, and stretched away to the N.N.E. and N.N.W. until they were 20 or 30 miles apart. The intervening space, nearly 100 miles in length, with the Leeamhye winding gently near the middle, is the true Barotse valley. It bears a close resemhlance to the valley of the Nile, and is inundated annually, not hy rains, but hy the Leeambye, exactly as Lower Egypt is flooded hy the Nile. The villages of the Barotse are huilt on monuds, and dnring the inundation the whole valley assumes the appearance of a large lake, with the villages on mounds like islands, just as occnrs in Egypt with the villages of the Egyptians. The Barotse are strongly attached to this fertile valley. They say, "Here hunger is not known." There are no large towns, the mounds being all small. Nariele (Naliele) is built on a mound artificially constructed. When the river is compressed between the high rocky hanks near Gonye, it rises 60 feet. The river presented the same appearance of low hanks without trees as it assumed when they came to 16° 16′ S. lat., until they arrived at Lihonta, 14° 59′ S. lat. Twenty miles beyond that there was forest down to the water's edge, and then there were tsetse. No locality can he inhahited hy Europeans where that scourge exists.

Finding that he was now near the confluence of the river of Londa or Lunda, named Leeha, or Loiha, and the chiefs of that country heing reported to he friendly to strangers, Dr. Livingstone pushed on to latitude 14° 11′ 3″ S. There the Leeambye assumes the name of Kahompo, and seems to be coming from the east. It is a fine large river, abont 300 yards wide. The Leeha is ahout 250 yards wide, and comes from the N.N.W. The Loeti, ahout 200 yards wide, enters here from the W.N.W. The waters of the Loeti are of a light colour, and those of the Leeba of a dark mossy hue. The Loeti enters the Leeamhye a little lower down than the Leeha.

The numhers of large game ahove Lihonta are prodigious, and they are remarkahly tame: 81 buffaloes defiled in slow procession hefore their fire one evening, within gun-shot; and herds of splendid elands stood hy day without fear at 200 yards' distance. The lions were in great numhers, as is always the case in Africa where game ahounds. A party of Arahs from Zanzibar were in the vicinity at this time. After remaining some days in this country, Dr. Livingstone returned to Linyanti, and made preparations for his journey to Loanda, on the west coast of Africa, as soon as the cooling influence of the rains should be felt in November.

He had few scientific instruments, but they were of the best kind—a sextant by Troughton, a chronometer by Dent, a thermometer by Dollond, a compass from the Cape Observatory, and a small telescope.

On the 11th of November, 1853, he left the town of Linyanti, accompanied by Sekeletu and his principal men, to embark on the Chobe. They crossed five branches. When the branches unite or re-enter it is a fine deep river. The banks are of soft calcareous tufa, like those of the Zonga. The bed is deep, and the sides perpendicular. The course is extremely tortuous.

The actual point of confluence of the Chobe with the Leeambye is ill defined, on account of each dividing into several branches before they unite, but when the whole body of water collects into one bed, it is very wide, and is a goodly sight for one who has spent many years in the thirsty south. Turning round they began to ascend the Leeambye, and on the 19th of November reached the village of Sesheke. After a short stay they proceeded up the Leeambye. Their progress was slow, owing to their waiting at the different villages for food.

Dr. Livingstone, in his journey to the west coast, was accompanied by a band of 27 men, belonging to the Makololo. It was the dry season. Parts of the river were only about 300 yards wide, and very deep. In other parts it is spread out to more than a mile, and the water flows rapidly over the rocky bottom. It requires great skill and care to manage the canoes in these shallow parts. The rapids are caused by rocks of dark-brown trap, or of sandstone stretching across the stream. In some places they form miles of the rocky bottom, with islets covered with trees. Libonta is the last town of the Makololo, and is situated on a mound like the rest of the villages in the Barotse valley.

On the 27th of December, 1853, they were at the confluence of the Leeba and Leeambye, 14° 10′ 52″ S. lat., 23° 35′ 40″ E. long. From the confluence down to Mosioatunya there are many long reaches where a vessel equal to the Thames steamers plying between the bridges could run as freely as they do on the Thames. It is often, even here, as broad as that river at London Bridge, and perhaps as deep. There are, however, many and serious obstacles to a continued navigation for hundreds of miles at a stretch. About ten miles below the confluence of the Loeti, for instance, there are many large sand-banks in the stream; then there are a hundred miles to the river at Simah, where a Thames steamer could ply at all times of the year; but again, the space between Simah and Katima-Molelo has five or six rapids, with cataracts, one of which, Gonye, could not be passed at any time without portage. Between these rapids there are reaches of quiet and deep water of several miles in length. Beyond Katima-Molelo to the confluence of the Chobe there are nearly 100 miles again of a river capable of being navigated in the same way as in the Barotse valley.

They now began to ascend the Leeba. The water is black in colour as compared with the Leeambye, which here assumes the name of Kabompo. The Leeba flows placidly, and, unlike the main river, receives numbers of little rivulets from both sides. It winds slowly through the most luxuriant meadows, each of which has a soft sedgy centre, or a large pond, or else a gentle rill flowing down the middle. The meadows are probably inundated, as the trees are on spots elevated three or four feet above the meadows. The rains were now set in, and the travellers were much drenched.

When they had ascended somewhat more than one-third of the Leeba, they left the river, and travelled overland on the eastern side by the village of the chief Shinte, till they camo to the Lake Dilolo. On their route they crossed several affluents of the Leeba, and travelled over extensive plains, much of which was under water.

On the 20th of February, 1854, they reached the small end of the Lake Dilolo. Dr. Livingstone, being exhausted by fever and abstinence, could not visit the wider end. After passing a little farther to the N.W., they came to rivers which flowed northwards into the fine river Kasai, or Lokè, which has a northern course, while all the rivers they had previously passed flowed southwards; thus showing that the flooded plains in which the Lake Dilolo stands are an elevated flat which forms the water-parting of the streams that flow to the north and south respectively.

On the 4th of April they reached the banks of the Quango (Coango), a river 150 yards wide, and very deep. This fine river flows among extensive meadows clothed with gigantic grass and reeds, in a direction nearly north. They crossed it after a dangerous contention with the natives, and passed on westwards to the village of Cassange (pronounced Cassanje), which is the farthest station eastward of the Portuguese. They were now safe, and in the kingdom of Angola. Cassange is situated in 9° 37′ 30″ S. lat., 17° 49′ E. long. The distance to Loanda is about 300 miles. On the 14th of May they reached the village of Golungo Alto, 9° 8′ 30″ S. lat.. 15° 2′ E. long., and on the 31st of May arrived at Loanda.

St. Paul de Loanda has been a very considerable city, but is now in a state of decay. It contains about 12,000 inhabitants, most of whom are people of colour. It possesses two cathedrals, one of which, formerly a Jesuits' college, is now a workshop. The forts are in a good state of repair. The Portuguese bishop of Angola resides at Loanda, and was very kind to Dr. Livingstone. The harbour is formed by a low sandy island, between which and the mainland is the station for ships. There was not a single English merchant there, and only two American merchants. Mr. Gabriel, the British commissioner for the suppression of the slave-trade, treated Dr. Livingstone with great kindness and hospitality.

On the 20th of September, 1854, Dr. Livingstone and his party of Makololo departed from Loanda on their return to Linyanti. They passed round to the mouth of the river Bengo, and ascending that river, arrived at Icollo i Bengo, and on the 28th of September at Kalungwembo, on the same path by which they came. There are plantations of fine coffee, and sugar is also cultivated. Dr. Livingstone proceeded in a canoe down the river Lucalla to Massangano. The river is about 85 yards wide, and navigable for canoes from its confluence with the Coanza to about six miles above the point where it receives the Luinha. Massangano stands on a tongue of rather high land formed by the left bank of the Lucalla and right bank of the Coanza. It has more than 1000 inhabitants. The latitude is 9° 37′ 46″ S. The fort is small, but in good repair. The lands on the north side of the Coanza belong to the Quisamas (Kisamas), an independent tribe whom the Portuguese have not been able to subdue. Returning to Golungo Alto he found several of his men ill of fever.

On the 14th of December, Dr. Livingstone and his men, having recovered from severe attacks of fever, proceeded to Ambaca, 9° 16′ 35″ S. lat., 15° 23′ E. long. On crossing the Lucalla they made a detour to the south in order to visit the famous rocks of Pungo Adongo, the fort of which stands in 9° 42′ 14″ S. lat., 15° 30′ E. long. It is situated in the midst of a group of curious columnar-shaped rocks, each of which is upwards of 300 feet in height. They are composed of conglomerate in a matrix of dark red sandstone, and rest on a thick stratum of this sandstone, with very few of the pebbles in its substance. Cambambe, to which the navigation of the Coanza reaches, is reported to be thirty leagues below Pungo Adongo.

On the 1st of January, 1855, they departed from Pungo Adongo. Their path lay along the right bank of the Coanza. On reaching the confluence of the Lombe, they left the river, and proceeded in a north-easterly direction. Passing over the heights of Tala Memgongo, 9° 42′ 37″ S. lat., 17° 27″ E. long. (Jan. 15), they arrived again at Cassange.

On the 28th of January they crossed the Quango in canoes. Having reached the eastern side of the river, they ascended the eastern acclivity which bounds the Cassange valley, and found it to be 5000 feet above the level of the sea, the bottom of the valley being 3500 feet. They crossed the Loange, a deep but narrow stream, by a bridge. It is the boundary of Londa on the west. On the 25th of March they crossed the Chikapa, and then the Kamane, an affluent of the Chikapa, coming from the S.S.W. On the 30th of April they reached the Loajima, where they had to form a bridge to cross.

On the 7th of May they arrived at the Moamba, a stream 30 yards wide, which they crossed by canoes, and arrived at Cabango, a village on the banks of the Chihombo, in 9° 31′ S. lat., 20° 31′ E. long.

On the 24th of May they left Cabango, and on the 28th reached the village of the chief Bango, 12° 22′ 53″ S. lat., 20° 58′ E. long. On the 30th of May they left the village of Bango, and proceeded to the river Loembwe, which flows to the N.N.E., 60 yards wide, and 4 feet deep. Having passed the Loembwe, they reached (June 2) the village of Kawawa, who wished to detain them, but borrowing one of his hidden canoes by night, they crossed to the southern bank of the river Kasai.

After leaving the Kasai they entered upon the extensive level plains which they had formerly found flooded. On the 5th of June they forded the Lotembwa, there about a mile wide and three feet deep, and regained their former path. It is N.W. of Lake Dilolo, and seems to flow from it northwards, and enter the Kasai, whilst another river Lotembwa flows from the other end of the lake southwards. Thus, this little Lake Dilolo, by giving a portion of its contents to the Kasai, and another to the Zambesi, distributes its waters to the Atlantic and Indian Oceans. From these elevated plains all the rivers seem to unite in two main drains, the one flowing to the north, and the other to the south. The northern drain finds its way out by the Congo to the west, and the southern by the Zambesi to the east. Dr. Livingstone was thus on the watershed, or highest part, of those two great river-systems, but still not more than 4000 feet above the level of the sea, and 1000 feet lower than the top of the western ridge they had already crossed. Instead of lofty snow-clad mountains appearing to verify the conjectures of the speculative, there were extensive plains, over which a person may travel a month without seeing anything higher than an ant-hill or a tree.

Sir Roderick Murchison, in his Address, as President, to the Royal Geographical Society, in 1852, explains the peculiar geological structure of the African continent. "Such as South Africa is now, such have been her main features during countless past ages, anterior to the creation of the human race. For the old rocks which form her outer fringe unquestionably circled round an interior marshy or lacustrine country, in which the dicynodon flourished, at a time when not a single animal was similar to any living thing which now inhabits the surface of our globe. The present central and meridian zone of waters, whether lakes or marshes, extending from Lake Tchad to Lake Ngami, with hippopotami on their banks, are therefore but the great modern residual geographical phenomena of those of a mezozoic age. The differences, however, between the geographical past of Africa and her present state are enormous. Since that primeval time the lands have been much elevated above the sea-level, eruptive rocks piercing in parts through them; deep rents and defiles have been suddenly formed in the subtending ridges through which some rivers escape outwards. Travellers will eventually ascertain whether the basin-shaped structure which is here announced as having been the great feature of the most ancient as it is of the actual geography of South Africa (that is, the primeval times to the present day), does or does not extend into Northern Africa. Looking at that much broader portion of the continent, we have some reason to surmise that the higher mountains there also form, in a general sense, its flanks only."

The elevated partition in the great central valley of Africa seems to be between 6° and 12° S. lat., and thence in all probability the head-waters of the great rivers of the Nile as well as the Zambesi have their origin.

The Lake Dilolo is a fine sheet of water, 6 or 8 miles long, and 1 or 2 broad, and somewhat of a triangular shape. A branch proceeds from the southern angle, and flows into the southern Lotembwa.

The town of the chief Shinte, which they left July 6, 1855, is in 12° 37′ 35″ S. lat., 22° 47′ E. long. They descended the Leeba by canoes. The river seemed to be upwards of 200 yards wide. They reached Linyanti early in September.

Dr. Livingstone having resolved to make a journey to the east coast of Africa, two routes offered themselves, one in a direction N.E. by the town of Cazembe and the southern end of the Lake Taganyenka to Zanzibar; the other nearly east by the course of the Zambesi. He chose the latter.

On the 3rd of November, 1855, he left Linyanti, and commenced his journey to the east coast. Having descended the river to the commencement of the rapids, and to a point where they intended to strike off to the north-east, Dr. Livingstone resolved to visit the Falls of Victoria, called by the natives Mosioatunya (Moai oa tunya, 'smoke sounds here'). This is the connecting point between the known and unknown portions of the Zambesi. The name Falls of Victoria is the only one which Dr. Livingstone affixed to any part of the country. After twenty minutes' sail they came in sight, for the first time, of the columns of vapour, appropriately called 'smoke,' rising at a distance of five or six miles, exactly as when large tracts of grass are burned in Africa. Five columns of vapour arose, and bending in the direction of the wind, they seemed placed against a low ridge covered with trees. The tops of the columns at that distance appeared to mingle with the clouds. They were white below, and higher up became dark, so as to resemble smoke very closely. The whole scene was extremely beautiful. The banks and also the islands scattered over the river were adorned with abundance of trees and other vegetation of great variety of form and colour. No one can imagine the beauty of the view from anything witnessed in England. The only want felt is that of mountains in the back-ground. The Falls are bounded on three sides by ridges 300 or 400 feet high, which are covered with forest. When about half a mile from the Falls Dr. Livingstone left the canoe by which they had come down thus far, and embarked in a lighter one, with men well acquainted with the rapids, who by passing down the centre of the stream in the eddies and still places caused by many jutting rocks, brought him to an island situated in the middle of the river, and on the edge of the lip over which the water rolls. The water was low. If it had been high it would have been impossible to have reached the island without being precipitated down the Falls. But though they had reached the island, and were within a few yards of the edge of the Falls, no one could perceive where the vast body of water went; it seemed to lose itself in the earth, the opposite lip of the fissure into which it disappeared being only 80 feet distant. Dr. Livingstone could not comprehend it, until, creeping with awe to the verge, he peered down into a large rent which had been made from bank to bank of the broad Zambesi, and saw that a stream of 1000 yards broad leaped down 100 feet, and then became suddenly compressed into a space of 15 or 20 yards. The entire falls are simply a crack made in a hard basaltic rock from the right to the left bank of the Zambesi, and then prolonged from the left bank away through 30 or 40 miles of hills. In looking down into the fissure on the right of the island, nothing is seen but a dense white cloud, which at the time had two bright rainbows on it. From this cloud rushed up a great jet of vapour exactly like steam, and it mounted 200 or 300 feet high. There condensing, it changed its hue to that of dark smoke, and came back in a constant shower, which soon wetted them to the skin. On the left of the island the water is seen at the bottom, a white rolling mass moving away in the prolongation of the fissure, which branches off near the left bank of the river. The walls of this gigantic crack are perpendicular, and composed of one homogeneous mass of rock. The edge over which the water falls is partly worn and broken, so as to have a serrated appearance. The other edge is straight, except at the left corner, where a rent appears. The rock is dark brown in colour. The columns of vapour are evidently formed by the compression suffered by the force of the water's own fall into an unyielding wedge-shaped space. Of the five columns two were on the right side of the island, and two on the left, and these were larger than the central column. It was low water in the Leeambye, but there was a flow of 500 or 600 yards of water, which at the edge of the fall seemed at least 3 feet deep. Farther to the eastward the fissure is said to be very much deeper. Dr. Livingstone could not obtain an observation of the moon to determine the position of the Falls, but that of Kalai, about 10 miles N.W. from the Falls, is 17° 51′ 54″ S. lat., 25° 41′ E. long.

Sekeletu and his large party having conveyed Dr. Livingstone thus far, and furnished him with 114 men to carry the elephants' tusks to the coast, on the 20th of November, 1855, he bade adieu to the Makololo, and proceeded northwards to the river Lekone. Both the Lekone and Unguesi flow back towards the centre of the country; so that it was obvious that they were then ascending the farther they went eastward. The country around was very beautiful, and was once well peopled with the tribes called Batoka, who possessed large herds of cattle. There is abundant evidence that a vast freshwater lake once existed in this part of Africa, extending from about 17° to 21° S. lat., and 22° to 26° E. long. The Barotse valley was another similar lake. These lakes were let out by means of cracks or fissures made in the subtending sides by the upheaval of the country. The fissure made at the Victoria Falls let out the water of this great valley, and left a small patch in what was probably its deepest part, and is now called Lake Ngami. The Falls of Gonye furnished an outlet to the lake of the Barotse valley, and so of the other great lakes of the remote times.

The party travelled in a direction E.N.E., leaving the Zambesi a considerable distance to the south. From the 24th of November to the 18th of December, they crossed several rivers flowing southwards into the Zambesi, and passed on their route numerous villages inhabited by the Batoka. On the 18th of December they reached the bank of the Kafue, a river upwards of 200 yards wide, and full of hippopotami. The Kafue there enters a narrow gorge, 15° 48′ 19″ S. lat., 28° 22′ E. long. They crossed it by a ford 250 yards broad, but rocky and shallow. They then went along the left bank (the northern) and approached nearer the Zambesi. They struck upon the river about eight miles east of the confluence of the Kafue. It appeared to be broader here than above the Victoria Falls. There were vast numbers of water-fowl.

January 14th, 1856. The party reached the confluence of the Loangwa with the Zambesi. They found the remains of a church, with a broken bell, having the letters I.H.S. and a cross, but no date. The church stands in 15° 37′ 22″ S. lat., 30° 32′ E. long. This was at Zumbo, which is situated in the angle of the confluence of the two rivers, and was formerly a commercial station, for which it is admirably suited. From this point the merchants had water communication in three directions beyond, namely from the Loangwa to the N.N.W., by the Kafue to the W., and by the Zambesi to the S. W. Their attention, however, was chiefly attracted to the north, or Londa, and the principal articles of trade were ivory and slaves. It was a Portuguese colony, and, like the rest, military. The Zambesi is very broad here, about 1200 yards, and contains many inhabited islands.

January 15th. They crossed the Loangwa in a canoe, and on the 24th of January passed in canoes from the north bank of the Zambesi to the south. They then proceeded at some considerable distance from the bank of the river.

On the 3rd of March they arrived at the Portuguese settlement at Tetè (16° 9′ 3″ S. lat., 33° 28′ E. long.), and were very kindly received and treated by the commandant. The village of Tetè is built on the south side of the Zambesi, on a long slope down to the river, the fort being close to the water. The rock beneath is grey sandstone. The rocks at the top of the slope are much higher than the fort, and of course command it. The whole of the adjacent country is rocky and broken, but every available spot is under cultivation. The stone houses are cemented with mud instead of lime, and thatched with reeds and grass. There are about 30 European houses; the rest are native, and of wattle and daub. The population is about 4500. Only a small proportion of these live on the spot, the majority being engaged in agricultural operations in the adjacent country. Generally there are not more than 2000 resident; for, compared with what it was, Tetè is now a ruin. The fort of Tetè has been the salvation of the Portuguese power in this quarter. It is a square building. The guns are in a much better state than any seen in Angola. The country around, as indeed all the district lying N. and N.W. of Tetè, is hilly; and the hills being covered with trees, the scenery is very picturesque. The soil of the valleys is very fruitful, and well cultivated. There is coal in the vicinity, which might be easily wrought.

On the 22nd of March they left Tetè, and sailing down the river, arrived at Senna on the 27th (17° 27′ 1″ S. lat., 35° 10′ E. long.). It was found to be 23½ hours sail from Tetè. Dr. Livingstone thought the state of Tetè quite lamentable, but that of Senna was much worse. The fort, built of sun-dried bricks, was in a wretched state. The village of Senna stands on the right bank of the Zambesi.

The Zambesi at Mazaro, where the delta begins, is a magnificent river, more than half a mile wide, and without islands. The delta is an immense flat, covered with high coarse grass and reeds.

Sailing down the branch of the river on which Kilimane stands, they reached that village, it being then May 20, 1856, only a few days less than four years since Dr. Livingstone started from the Cape. Kilimane is in 17° 53′ 8″ S. lat., 36° 40′ E. long. The village stands on a great mud-bank, and is surrounded by extensive swamps and rice-grounds. Dr. Livingstone waited there about six weeks, when her Majesty's brig Frolic arrived off Kilimane, and took him on board. There is a dangerous bar at the mouth of the Kilimane branch.

Dr. Livingstone left Kilimane, July 12, 1856, and arrived at Mauritius, August 12. He returned by the Red Sea and the Overland route, and arrived in England on the 12th December, 1856.

The preceding sketch of Dr. Livingstone's arduous journeys is taken from his interesting volume, 'Missionary Travels and Researches in South Africa, including a Sketch of Sixteen Years' Residence in the Interior of Africa, and a Journey from the Cape of Good Hope to Loanda on the west coast; thence across the continent down the river Zambesi to the Eastern Ocean,' 8vo. 1857.

Dr. Livingstone is at present (Jan. 1858) in London, making preparations to return to the Zambesi, in order to form an establishment in a healthy locality, and to enter into friendly commercial relations with the natives. He will be supported by the British government, and his project has received the sanction of the King of Portugal. A suitable steam-vessel has been prepared for him, and he will be accompanied by three or four scientific gentlemen, who will assist him in his well-intentioned labours.

In 1854, Lieutenant Burton of the army of the East India Company, who had previously distinguished himself by his hazardous journeys to Mecca and Medina, performed a short but still more perilous journey to Harar in the Somauli peninsula, of which he has given an account in his 'First Footsteps in Eastern Africa.' Though at no great distance from the torrid coast-line, its elevation of 5000 feet above the sea gives to this country a comparatively temperate climate. Fortified sufficiently to repel the incursions of the surrounding savage tribes, and under the rule of a young and very arbitrary sovereign, Harar is the rude emporium of a considerable traffic in choice products, more particularly coffee. [HARAR, *S.* 2.] Lieut. Burton has since undertaken a journey from the eastern coast of Africa in the direction of the Lake Nyassi, yet unvisited by Europeans, and may possibly reach the sources of the White Nile, and thus solve a question which has excited the curiosity of the learned world from the time of Herodotus to the present day.

AGADES, or, as the Tuaricks call it, Ekade, is a town of Africa, situated in 16° 33′ N. lat., 7° 30′ E. long., on a Hamadah, or high plain, consisting of sandstone. It is the capital of the kingdom of Aïr or Asben, with which we have recently become acquainted through the travels of Dr. Barth, who visited Agades in 1850. No author is known who has mentioned this place before Leo Africanus, in whose time it was a flourishing town. Agades from its situation, must always have formed an important central place between the Kelowis and the tribes inhabiting the districts to the south and west. There are traditions among the inhabitants of the place that it owes its origin chiefly to some tribes coming from the north, probably belonging to the Berber race. There is, no doubt, a good deal of slave blood among the present inhabitants of Agades, as is the case with the whole population of the south-eastern portion of Aïr; but there must have been a very ancient stock of indigenous black people, who have transmitted a peculiar language of their own, which is the same language as that spoken by the people of Timbuctu.

Agades formerly contained not less than from 50,000 to 60,000 inhabitants. Dr. Barth was assured by the Turvati, one of whom had been at Timbuctu seven times, that it was much larger than that place. At present the appearance of the town is that of an almost ruined place, scarcely the sixth part of it, namely about 700 houses, being inhabited. The number of the inhabitants is estimated to be from 7000 to 8000, who are partly merchants and partly artisans. The merchants seem to visit only the markets of Katsena, Tasawa, Marado, Kano, and Sacotu, and do not go to the northern markets of Ghat or Murzuk, unless on a journey to Mecca. There exists no intercourse with Timbuctu. The commerce of Agades itself is principally in millet, which constitutes the principal food of the inhabitants. The manufactures are very limited, consisting of leather-work and mats. The saddles made in Agades, particularly those used in riding upon the meheris, or swift camels, and also the sandals, are far famed.

Respecting the degree of civilisation of the inhabitants, it may be mentioned that there are five or six schools in Agades, where the boys are taught to read the Koran, and to write. The women seem to enjoy great freedom. Some of them are pretty, and have Arab features; and among the men Dr. Barth observed fine faces and good figures. The population is so mixed that it would be difficult to make out the type of the original stock.

The houses are generally spacious, built of clay, and a few are whitewashed; they are all flat-roofed, the roof being formed by planks of the doom palm covered with mats, over which earth is thrown. Agades has a tower, which is from 90 to 95 feet high. For such a place, situated in the midst of warlike hordes, a tower is of the greatest importance, in order to be aware beforehand when a razzia or a caravan is approaching. There are wells of very good water near the town, and there is also plenty of brushwood.

AGDE. [Herault.]

AGNES, St. [Cornwall.]

AGRICULTURAL IMPLEMENTS. Few of the productive arts have made more signal progress within the last few years than those relating to the cultivation of the soil. In the application of chemical science to practical farming, and in that of mechanical science to implement-making, this advance has been equally observable. When the corn-laws were repealed, and agriculturists were deprived of the support—or, perhaps it would be more correct to say, relieved from the incubus—of protection, a wonderful amount of energy was thrown into those two departments of industry. As a consequence, greater improvements have been developed in twelve years, than in twice or thrice that space of time under the old order of things.

When the jurors prepared their report on the Agricultural Implements displayed at the Great Exhibition in Hyde Park in 1851, they grouped them all under certain headings, according to the kind of service they were intended to render in field and farm operations; such as Instruments of Tillage; Implements used in the Cultivation of Crops; Harvesting Implements; Preparations for Market; Machines for Preparing the Food of Stock; and Draining. Such will also be a convenient mode of grouping to adopt here.

Instruments of Tillage.

Ploughs.—Until about the year 1840, four-horse ploughs were still used in many parts of England; notwithstanding that in the very same parishes ploughs with two horses had been shown to be equally efficient. The cumbrous plough had been adopted for clay soils, when such formed the chief corn-lands throughout the island; but they were not suitable for an altered state of agriculture, when the heavy lands were laid down for grazing, and the downs became corn-lands. Even when the swing-plough was invented as an improvement on the old wheel and gallows plough, the weight of draught was little less than before. It was the Messrs. Ransome of Ipswich who furnished the modern English plough with two low wheels, and with mould-boards adapted to different soils. Messrs. Howard and Mr. Busby afterwards paid particular attention to the curvatures of the mould-board; for this is indeed the essential acting part of a plough; raising, turning-out, and throwing over every furrow-slice of earth in true parallelism with other slices. Foreign agriculturists have often expressed surprise at the length of the mould-boards in modern English ploughs; since it is seen that short boards are better able to pulverise the soil while they turn it over. It has been found, however, by experience, that clay lands require longer mould-boards than those which are drier and lighter; and hence a plough suitable in England might not be so advantageous in Scotland, or on the continent. Among the ploughs exhibited at Hyde Park, eighteen were put to trial at Mr. Pusey's estate in Wiltshire, by Mr. Miles, Mr. Shelley, and Mr. Owthwaite; while eleven others were tried at Mr. Mechi's farm in Essex, by Baron Mertens D'Osten, Colonel Challoner, and Mr. Johnson. Of the former group, nine were two-wheel, three one-wheel, and six swing-ploughs. Some were found best at a seven-inch furrow; some broke the land too much in a furrow of that depth. All the swing-ploughs were clearly ascertained to be inferior to those with two wheels. It was further found that a particular curvature of mould-board suitable for a five-inch furrow worked unsatisfactorily in one of seven inches—showing, as many an old farmer would be astonished to hear, that there are mathematics even in farming. The Royal Agricultural Society had in recent years recommended the use of ploughs for two distinct purposes—the ordinary ploughing, and a deeper ploughing once in four years, when the root-crop recurs, to give the land a more thorough stirring. A common plough is fitted for this extra work; but Mr. Busby and other makers have constructed powerful ploughs, to be worked at leisure in winter with four or six horses.

Mr. Fisher Hobbs, in reporting on the ploughs exhibited at Carlisle Agricultural Show in 1855, said that enough had been indicated at the trials to show that improvements have been introduced in recent years, in nearly all parts of the English plough. Eleven ploughs were tried on a strong loamy soil, with a considerable quantity of herbage upon it. The Cumberland swing-ploughs were found decidedly inferior in power and efficiency to ploughs with iron wheels, made by Ransome, Howard, and other celebrated manufacturers; these latter, averaging about 90*s.* in price, were pronounced to be among the best ever produced. A machine for deep ploughing, by Messrs. Ransome, cut a furrow twelve inches deep, as clean and as well laid as any produced at shallower depths. Some persons have expressed an opinion that the plough has now reached the highest point of perfection; but Mr. Fisher Hobbs remarked with praiseworthy caution, "I still look forward to the time when its construction will be better adapted to the present operations on the soil, and for leaving the land in a fit state for drills or other machines required to complete its cultivation."

Harrows.—The old harrow was always made with square bars and square-set teeth; but as it was difficult to make such a harrow work always in different tracks, even though dragged from the corners, modern makers have constructed harrows which have the teeth set cross-wise, enabling the harrows themselves to be drawn straight. Mr. Coleman's expanding harrow is a very complete implement. The bars at every point of crossing are united by a loose pin, on which they work freely; the width of the harrow can thereby be increased or diminished; the tines, according to the state of the land, can be brought nearer together or spread wider apart; and there are small wheels, easily let down, by which the harrow can readily be moved from one field to another, without disturbing its general mechanism.

Rollers.—"Not many years ago," said the late Mr. Philip Pusey, one of the most enlightened encouragers of scientific agriculture, "the landlord was often asked by his tenant for some old tree to convert into a roller; the tree roller, when manufactured, had its framework loaded with rough materials to give it weight; but it soon wore and cracked, so as to become in a year a most ungainly instrument." Iron rollers of excellent construction have since been introduced. Their regularity of surface has, however one disadvantage, in passing over small clods so smoothly as merely to press and not to grind them. M. Claes, of Belgium, has invented a roller, intended for narrow round ridges, but also fitted to produce the action just adverted to; it consists of four rings or partial rollers, so adjusted on one axis as to have independent and irregular movements. Rollers for pulverising the soil have, however, been nearly superseded by

Clod Crushers.—This apparatus, invented by Crosskill, is used chiefly for breaking down turnip land which has been fed off by sheep in wet weather and afterwards baked by the sun; it is also a good presser for young wheat in March, when the soil has been swollen, and the roots thrown out by alternating frosts and thaws. The jagged iron teeth form the chief characteristic of this implement. Mr. Gibson has since invented one on a different principle, being formed of two rows of very narrow wheels, alternating one with another. Each of these kinds of clod-crushers has some advantages over the other. A third variety, of later introduction, is Patterson's 'Self-Cleaning Clod-Crusher;' it contains a series of eccentrics upon an axle, which, in revolving, rub and clean each other.

Scarifiers, Grubbers, and Cultivators.—The implements denoted by these several names are intended to save a great part of the time spent in ploughing on the old method. In an ordinary four-course system of arable culture, the land receives seven or eight ploughings in the four years; but if a scarifier be employed to pare the surface to a depth of two inches immediately after the wheat harvest, much of the four years' labour will be economised. The scarifier may be likened to many ploughs set abreast, so as to cut up and turn over a slice of soil five, six, or seven feet in width. Not only is the time spent in ploughing lessened, but less subsequent employment of the harrow and the roller is needed. Many forms of these time-saving implements have been invented. Coleman's scarifier, with six horses, is adapted for very hard ground. Biddle's, made by Messrs. Ransome, is suitable for going deeper into looser ground. Kilby's and Bentall's paring ploughs are midway in character between ordinary ploughs and scarifiers, and are useful for a very close surface of land. Cotgreave's plough is a cultivator, in which these processes are combined in rather a curious way; it first ploughs and turns a furrow five inches in depth; then it digs another 5-inch furrow, inverts the soil, and deposits it on the top of the first; and lastly, a sub-pulveriser loosens the soil to a further depth of 3 or 4 inches. Beauclerk's patent plough and subsoiler may be likened to a common plough with an Archimedian screw attached, which revolves in the bottom of the furrow, thus ploughing and subsoiling at the same time. Such farmers as have duly provided themselves with some or other of these various instruments, find that they may lessen their ploughings from seven or eight to two or three in the four years. In 1851 Mr. Pusey said:—"I will venture to add, what may appear theoretical, that if ever steam be employed successfully in cultivation, it will probably be less by ploughs or digging than with an implement like one of these cultivators; because they are able to work so much wider a space as they pass along in their course." Some of these implements have shares, some points, to dig into and turn up the soil. Several attempts have been made to introduce steam-cultivators. One, exhibited by Mr. Usher in 1855, consists of a steam-engine moving itself by the revolution of a large circular roller placed under it; and to it are attached numerous ordinary plough-shares reversed, revolving behind the engine. Another, brought forward about the same time by Mr. Fiskin, consists of two ordinary ploughs fixed to a carriage or framework of iron, and moved by an endless rope communicating with a steam-engine fixed in one corner of the field. Others have since been brought forward; but this department of the art is confessedly in its infancy.

Implements used in the Cultivation of Crops.

Drills.—The drill has almost driven the hand-sower from English farms. One half of the horse-power formerly expended in harrowing is saved by the adoption of some of the modern drills or sowing-machines; a saving of seed is also effected; and there is also an avoidance of the necessity for that previous harrowing into ridges at a particular angle, which was formerly deemed necessary as a preliminary to hand-sowing. The drill is, in fact, the key to a whole system of husbandry; for, in addition to the advantages just enumerated, the drill is applicable to the use of many artificial manures, distributing them beneath the ground by special coulters, and covering them with earth, that their excessive strength may not injure the seed, which is deposited last of all; while the use of the horse-hoe is almost wholly dependent on the previous use of the drill. The drills of recent invention exhibit much variety and ingenuity of construction. Some are for general purposes, capable of drilling, with or without manure, wheat, beans, and turnips, at the different intervals suited to those seeds respectively, from seven inches up to two feet. Some are turnip drills, in which manure, generally ground bones, or superphosphate, is distributed as well as seed. Some, for use in unusually dry weather, pour down each manure-coulter the requisite amount of water mixed with powdered manure. Some, to economise manure, drop the seed and the manure only at those spots in the lines or rows where the plants are intended to stand without molestation from the hoe: each machine having a power of adjustment to different widths or distances. All the celebrated makers have contributed to the excellence of the modern drills. Messrs. Garrett have improved the wheeling or moving power of the general-purpose drill, to the ease of the horse and the driver; the turnip drill they have greatly improved; and they have constructed a hand-barrow drill for distributing grass-seed broadcast in a very effective manner. Messrs. Hornsby have constructed a drill for depositing manure-dust and turnip-seed on ridges, and reducing the ridge by concave rollers to a compact rounded form; they have also introduced india-rubber tubes for conducting the seed down to the channel made by the coulter, instead of using a series of tin cups; and they have also done much to enable the drill to deposit seed and manure on hill-sides, and to work equally well on ridges and on the flat. Messrs. Horsman have invented a 'self-adjusting steerage corn-drill,' adapted for being driven with great nicety, and for delivering the seed equally well going up or down hill. One of the drills lately invented is especially contrived for distributing equally well liquid manure or the thickest sewage. In short, the drill is now an implement to which all the makers devote very sedulous attention.

Top-Dressers or Manure-Distributors.—Although wheat is seldom sown with the manure drill, being usually provided with its requisite nitrogen by farm-yard dung or by sheep-folding, yet it generally requires a top-dressing of manure during its growth. This used to be applied by hand; but several machines, of which one is by Mr. Holmes, have been invented to perform this service more efficiently. It distributes three or four bushels per acre of guano or nitrate of soda, or a larger proportion of rape-cake or superphosphate, on wheat in the spring of the year. The machines are much more simple than drills.

Horse-Hoes.—The hoe not only clears away a host of young weeds, but, by loosening the crusted surface, admits the air, and stimulates the growth of the true crop. Formerly this used to be done by hand; the ridged root-crops were hoed by a horse, one row at a time; but the modern horse-hoes of Messrs. Garrett and other makers hoe at one time four rows of turnips, six of beans, or nine of wheat. The modern machine does the work at half the expense of the hand-hoe, and much more completely. A revolving horse-hoe is much used in some of the best Norfolk farms; by its revolving principle the plants and soil attached are thrown up together, but the soil by its greater weight reaches the ground before the plant, which, lying bare with its roots exposed on the surface, soon withers away.

Harvesting Instruments.

Reaping-Machines.—No other implements applied to agriculture have attracted so much attention within the last few years as reaping-machines; partly for the singular ingenuity displayed in their construction, and partly owing to the emulation between European and American inventors. At the opening of the present century it was thought that a successful reaping-machine had been constructed; and a reward was voted by Parliament to its inventor; but it was so intricate as speedily to fall into disuse. Another was invented many years afterwards, which cut off the heads of the corn, but left the straw standing—a fatal defect. When the Great Exhibition of 1851 was held, M'Cormick's American reaping-machine at once riveted attention; Mr. Hussey competed with him by means of another invention; and the different implement-makers, entering into manufacturing arrangements with these and other inventors, speedily introduced various novelties in the mechanism. The essential part of each machine is a horizontal saw or serrated knife, which by a rapid reciprocating motion cuts the straws very near the ground; while there are peculiar adjuncts for laying or depositing the straws with their ears of corn regularly after being cut.

This display of Hussey's and M'Cormick's machines in Hyde Park led to a curious revelation. The world then learned, almost for the first time, that England, or rather Scotland, had long possessed a reaping-machine of somewhat analogous character, although not in use. The facts brought to light were in brief as follows: In 1827 the Rev. Patrick Bell, son of a tenant farmer on Lord Panmure's estate in Scotland, became impressed with the disadvantages under which Scottish farmers lay through the scarcity of labour at a critical period of the year, and he constructed a rude machine intended to do much more in a given time than a sickle would perform. The machine acted on the principle of a number of shears placed side by side. He made the wooden model with his own hands, and then had the iron-work fashioned from it by a village blacksmith. He first tried his invention in cutting some oaten straw stuck up by himself on end in a layer of mould in his father's shed; and then observing certain deficiencies, he invented an attached piece of apparatus to deliver the corn in regular swathes; and another for collecting and pressing the corn against the cutter. The invention soon became known to the neighbourhood; others were made on the same model; and the Highland Society's premium was that year given to Mr. Bell; but, probably from defects in the construction, the machine did not work satisfactorily to the farmers, and they declined to use it. To an offer made by Lord Panmure, to defray the expenses of patenting the invention, Mr. Bell replied that he had no wish to make a profit out of any agricultural invention. For twenty-four years the subject was allowed to stagnate; insomuch that when men were told of the humble Scottish minister's reaping-machine at Inchmichael, they received the news with surprise. Intelligent implement makers, learning that Bell's invention had not been patented, examined it with a view to its capabilities; and it was speedily found that the substitution of a tooth-edged knife for a row of shears would be a vast improvement. Messrs. Crosskill bought the interesting old machine from Mr. Bell's brother; and the Americans found that "Crosskill's Bell" was a formidable competitor to their inventions.

Every year, since the Exhibition year, reaping-machines have been tried at the annual meetings of the Royal Agricultural Society. At the Carlisle meeting, for instance, in 1855, there was one of Bell's original construction improved by Crosskill; one of M'Cormick's improved by Lord Kinnaird; another of the same inventor, improved by Burgess and Key; one of Hussey's, improved by Messrs. Dray; and one of Forbush's, improved by Palmer. The prices ranged from 25*l.* to 42*l.* Trials were made of them near Carlisle, and again on Mr. Miles's estate at Leigh Court—in three fields exhibiting striking contrasts. The machines were worked from morning till night—each in cutting both wheat and barley, in light standing crops and in heavy and lodged crops, in clean stubble and in foul, and under circumstances as varied as an extensive farm could supply. The different instruments varied in capabilities. Crosskill's Bell's reaper excelled in the power of its corn-cutting, and the breadth of its stroke, nearly six feet; but was more cumbrous and heavy of draught than many of the others. Dray's Hussey's machine had the merit of compactness, simplicity of arrangement, and economy of price; but its working efficiency did not place it in the first rank. Burgess and Key's adaptation of M'Cormick's reaper was on that occasion found to be the best of all; it has a peculiar apparatus by which the corn, on being cut, falls on a series of rollers fitted with Archimedian screws, by which it is delivered in a continuous and well-formed swathe at the side of the machine, dispensing with the attendance of any person besides the driver. In the trials made in the years 1856 and 1857, the respective makers introduced several minor improvements into their machines; and scientific agriculturists look forward hopefully to the time when reaping-machines will be generally used in this country; but an opinion is at the same time expressed in many quarters, that "completeness is only to be effected by the combination in a single machine of those principles of construction in which different parties, under the present patent-law, claim individual right." When M'Cormick's machine first attracted notice, it was estimated that 15 acres of average wheat usually cost 6*l.* 15*s.* for reaping by the hand method, and only 2*l.* 8*s.* by the machine; but all such estimates require to be corrected by numerous subsidiary considerations.

Horse-rakes and Haymakers.—The ingenuity of modern makers has been bestowed on many implements and machines for cutting and gathering up the ripened crop. In many of these, the rotation of the wheels puts in motion other apparatus for lifting hay or other produce off the ground; and the price-lists of our chief implement-makers show how keenly any available improvements are sought after and adopted.

Waggons and Carts.—The last harvesting operation by which the produce is brought home to the barn, has received like attention with other departments of farm labour. The waggons and carts seen on modern English farms, for conveying produce, manure, &c. are strikingly different from those in use twenty years ago. A very profitable discovery has been made, that the Scotch and Northumbrian farmers, by using one-horse carts, effect a great saving over those south-country farmers who use three-horse waggons and three-horse dung carts. Hence the makers are applying all their skill to produce good workable one-horse carts for farmers. So much has been accomplished in this way, that in a trial at Grantham, five horses with five new carts were tried against ten horses with five old waggons, and clearly beat them in the amount of work performed. Some makers attend most to the form of the harvest-rail, that the corn may be carried more steadily; some endeavour to make the cart low, for ease of loading and ease of draught; some try to give horizontality to the shafts; some make their wheels by machinery; while others strive for excellence in a 'cart-of-all-work,' which shall be adapted to as many kinds of farm-service as possible. At the Great Exhibitions in London and Paris, foreigners were much struck with the superior neatness and compactness of English farm-carts over those made and used on the Continent.

Preparation for Market.

Moveable Steam-Engines.—Fixed steam engines have long been used for certain farm operations in Northumberland and East Lothian, chiefly for working threshing machines; but the Royal Agricultural Society, some years ago, pointed out reasons for thinking that moveable steam-engines would present superior advantage. One is, that if a farm be very large, it will be greater economy to wheel a locomotive steam-engine to different parts, than to employ horses and men in bringing all the corn in the straw to one point, and in again carrying out the dung to a distance of two or three miles. Another is, that if a farm be of small or moderate size, it will not support the expense of a fixed steam-engine; whereas a portable engine may be available for two or three farms, at a fair ratio of expense for each. A third is, that whereas threshing can only be performed under cover in barns by fixed engines, it is perfectly feasible in the open air by a locomotive engine—a plan, healthier and more expeditious for the labourer, and rendering probable a diminution in the number of farm-buildings requiring to be constructed by the landlord. The Royal Agricultural Society gave the first impetus to the construction of moveable steam-engines for farm purposes; and the annual prizes and exhibitions have been very influential in determining a constant course of improvement. At the Great Exhibition of 1851, there were engines of this kind exhibited, made by Hornsby, Tuxford, Clayton, Barrett, Hensman, Bullin, Roe, Ransome, Garrett, and other makers. Every one felt that the invention was still in its infancy; for the worst specimen exhibited consumed three times more coal than the best. Of thirteen specimens examined, the nominal horse-power varied from 4 to 9; the time of getting up steam, 28 to 83 minutes; the coal used in getting up steam, 25 lb. to 75 lb.; the coal burnt per horse-power per hour, 6·79 lb. to 25·80 lb. Mr. Locke, the eminent engineer, in reporting on these trials, said, "If I might be permitted to suggest a little advice to the makers of these engines, I would beg of them to attend more to the proportions of the various working parts and less to external ornament. There is a want of good proportion in several of the engines; and this to a mechanic or an economical farmer, is of more importance than a profusion of brass."

At the Carlisle Agricultural Meeting in 1855, a manifest improvement was observable in the moveable steam-engines. The maximum consumption of coal per horse-power per hour was 10 lb.; while the minimum (in Messrs. Tuxford's engine) was only 3·7 lb. It was, however, considered by some of the judges that this element of merit had been somewhat too exclusively attended to. "The conditions of competition laid down by the Society for portable engines have unfortunately led to the production of engines only intended for winning the Society's prizes, and known as 'racing engines,' requiring the nicest care; instead of those simple and effective engines which may be safely entrusted to the management of intelligent farm-servants;" and it was recommended in future "to submit the prize engines to subsequent trials, for a lengthened period, under the ordinary management of a farm establishment." At the Salisbury Agricultural Meeting in 1857, there were no fewer than twenty exhibitors of agricultural steam-engines; of which one firm, that of Messrs. Clayton & Shuttleworth, made at the rate of 500 engines per annum. In some of the best farms, at present, a steam-engine, under the charge of an intelligent farm-labourer, may be seen driving the barn machinery, cutting chaff or roots, crushing oats, grinding corn, pulping mangold-wurzel, splitting beans, sawing wood, pumping water, and lending its boiler for steaming potatoes or roots.

Threshing-Machines.—Threshing-machines worked by horses were considered, in their day, a vast improvement over the flail of earlier times; and so they unquestionably were. It occurred to Mr. Amos, the agricultural engineer, however, that a large amount of power was wasted in dragging dead weight; and he found on experimenting in 1849, much to the astonishment of farmers, that in a four-horse machine the strength of three horses was expended in moving the wood and iron work itself, while only one horse-power was available in threshing the corn. The makers immediately began to reform their methods of construction; and they gradually succeeded in bringing down the friction and dead weight to two and a-half, two, one and a-half, and one-horse power out of four. At that point, however, the higher class of farmers began to think more of steam-threshing than horse-threshing. In the one case, as in the other, the threshing arms or levers begin their work as soon as a central axis or shaft is set in motion; but there is much difference in the connecting machinery. Several threshing-machines were tested by the Exhibition Jury in 1851; they differed greatly in excellence; but on an average they required fifteen-horse power to thresh two and a-half cwt. of wheat sheaves per minute, or nine-horse power per minute for barley. It was found, however, that those which worked with least horse-power were not necessarily the best in the quality of work done, as denoted by the three tests of excellence—clean threshing, unbroken grain, and uninjured straw. Maltsters continued up to that year to distrust machine-threshed malting barley, on the ground that the grain was often too much bruised and injured for germinating. The makers had therefore every reason to try and improve these threshers. It was calculated that wheat is usually threshed for about 3*s*. 5*d*. per quarter, all expenses included; whereas steam threshing cost less than 1*s*.; and therefore if quality were good, the economy in quantity would be unquestionable. By the year 1855 the improvement in the machines was most decided. There were several exhibited in that year at Carlisle, of about eight-horse power, which threshed 130 sheaves of wheat in twelve to twenty minutes. The judges, in reporting on the trials, said, "These machines are now become of material importance, inasmuch as they enable the farmer in so short a time to prepare the corn for market. They have, in fact, almost entirely superseded the flail; and without their powerful aid the full supplies of corn could not this autumn have been furnished for consumption. The extraordinary demand for the threshing machine, and its daily use on the farms, are circumstances that prove its estimation by the agricultural community." A fixed steam-engine, working systematic barn-machinery, threshes corn more economically and effectively than portable machines; but the latter are of great importance in so far as they can be let out by their owners to different farmers, so as always to be employed according to the exigencies of the harvest. No kind of agricultural machine has met with more opposition from hand-labourers than threshing-machines; but the prejudice in favour of the old and inefficient way is dying out in this as in other directions. It has been recorded that "A small farmer was hanged at Salisbury in 1830 for firing barns containing machinery; whereas in the same town in 1857 the labourers cheered loudly on witnessing the success of the reaping machine."

Winnowing-Machines.—Instead of trusting the threshed corn to the wind, as in the old process, it is now winnowed by very ingenious and intricate machinery. Messrs. Hornsby were among the first to achieve success in the construction of such machines. Their winnowing apparatus is fitted with a spiked roller, working through a grating, and forming a sort of hopper; it separates the corn from the chaff in the rough pulsy state, as it comes from the threshing machine, without being previously riddled; and it can be adjusted to suit corn either in rough chaff or in any other state. The meshes of the grating are so varied, and placed in such relative positions, that the winnowing-machine will separate the whole produce of the threshing-machine into 'best corn,' 'good tailings,' 'tailings,' 'whites,' 'screenings,' and 'chaff,' at the rate of fifteen quarters an hour, and dressing over the second time at the rate of twenty quarters per hour. Not only has the flail been nearly superseded by the threshing machine, and horse-power by steam-power, but the threshing-machine itself, instead of being a mere box for beating out the corn in a rough way, as it was in 1847, has now been so perfected as to combine the threshing and winnowing machines in one, beating the grain from the ears, and then cleaning and separating it ready for market.

Machines for Preparing the Food of Stock.

Turnip-Cutters.—Formerly farming stock was fed with hay, or turned out to pick over straw, occasionally mixed with turnips; but scientific and practical men aided each other by degrees in discovering that this labour of the jaws wasted the muscle of the animals, and retarded their progress. Hence the invention of many ingenious machines for facilitating the preparation of food for live stock. One of these is the turnip-cutter, for mincing or cutting into small pieces one important variety of this food. Some farmers have asserted that lambs fed with machine-cut turnips are at the end of a winter worth 8*s*. per head more than other lambs which have wasted their muscle in masticating whole turnips; and assuming this to be true, it has been calculated that, allowing for wear and tear and labour in using the machine, the improvement is equivalent to a saving of 70*s*. per acre upon turnip crops. These estimates are frequently disputed in detail; but no one now disputes that the saving is a real one, be its amount what it may. All the varieties of this machine act by sharp-edged instruments, working horizontally or vertically according to the nature of the machine adopted. Some of them cut turnips for cattle-food, some for sheep, according to the size of pieces required.

Chaff-Cutters.—The cutting of straw into very small pieces, to supply the deficiency in natural chaff for cattle-food, was at first done by hand, with a sort of knife hinged at one end; then by a series of knives working round an axis; then by steam-power, by means of a strap connected with the fixed or moveable steam-engine on a farm. The process now costs only one-sixth or one-eighth of the charge formerly incurred. The machine is useful even to cut hay itself as a means of facilitating the masticatory process. In the trial of chaff-cutters at Carlisle, in 1855, one made by Cornes cut 1485 lbs. of chaff per hour, by steam-power; those that worked by the muscular power of one man each cut quantities varying from 90 to 210 lbs. per hour.

Crushers, Grinders, Bruisers, &c.—These machines, of modern introduction, act by the crushing movement of rollers rather than the grinding movement of mills, and are intended to facilitate the comminution of substances for cattle-food. One is a linseed crusher; another a corn crusher; a third an oil-cake bruiser; a fourth a fine-meal mill; a fifth a gorse bruiser. It is evident, from a mere inspection of this list, that there is much scope for ingenuity in the arrangement of working parts for such machines. Some of the fine-meal mills, made principally to crush barley, beans, and oats, admit of adjustment that will "enable them to grind anything from linseed up to flint-stones." Messrs. Hornsby, Garrett, Crosskill, and other manufacturers, now make steam-worked oil-cake breakers that will break 3000 lbs. of cake per hour for sheep, or 4000 lbs. for cattle.

Pulping-Machines.—Farmers are not agreed concerning the amount of advantage derivable from the reduction of root-food to a softened state. In reference to potatoes, it has been found worth while to steam potatoes for pig food; and even diseased potatoes, if not very far decayed, by being thus treated, may be rendered good victuals to be stored up for months. The pulping of turnips enables the root to be incorporated with other nutritious articles of food; but on the other hand, there is a tendency in highly reduced pulp to suffer a separation of the liquid from the solid portion, and then much of the saccharine qualities is lost in the liquid. The turnip pulping machines, which are both hand-worked and steam-worked, are on this account less decidedly successful than most modern agricultural implements.

Draining.

Tile-Machines.—There is much land that does not require more draining than the farmer can easily effect in the course of his yearly operations; but where a landlord systematically drains his poor land to increase the rental obtainable for it, his operations require to be conducted on a considerable scale; and then it becomes an important matter with him how to procure his draining tiles. Can he make them on his own estate, with clay dug close at hand? To answer this question has been a matter to which a large amount of ingenuity has been applied. Until about the year 1840, draining tiles were made by hand, cumbrous arches with flat soles, costing from 30s. to 50s. per thousand; but so active then became the exertions of machine makers, that at the York Agricultural meeting in 1848, there were no fewer than thirty-four different tile-machines sent in for competition. So rapid was the improvement, that tiles enough to drain an acre of land could be made for about sixty or seventy shillings. Most of these machines produce the tiles by forcing soft clay through an aperture shaped like the tile in section, on the same principle that maccaroni is formed; the action is horizontal in some machines, vertical in others. It has been calculated that between the years 1841, when drain-tile machines were first exhibited at the Shrewsbury Agricultural Meeting, and 1857, no less than 2,000,000 acres were drained in the United Kingdom; by this means many hundred thousand acres of land, formerly in waste, or only fit for poor pasture, and many hundred thousand acres of retentive clays which could only bear corn in favourable dry seasons, have been brought into a regular course of arable cultivation.

Draining Ploughs.—A most ingenious machine has been invented—not for making draining tiles, but for laying them down when made. Under ordinary circumstances a trench is dug to the proper depth by means of a narrow spade, sometimes concave, sometimes triangular lance-headed; but in a machine invented by Mr. Fowler, there is a furrow ploughed, and a string of pipes laid in it almost without any visibility on the surface. When this machine was tested by the Exhibition Jury in 1851, it excited general wonder and admiration. "The spectators," said Mr. Pusey, on whose estate the machine was tried, "are surprised to see two horses at work by the side of a field, on a capstan which, by an invisible wire rope, draws towards itself a low framework, leaving but the trace of a narrow slit on the surface. If you pass, however, to the other side of the field, which the framework has quitted, you perceive that it has been dragging after it a string of pipes, which—still following the plough's snout, that burrows all the while four feet below ground—twists itself like a gigantic red worm into the earth; so that in a few minutes, when the framework has reached the capstan, the string is withdrawn from the necklace, and you are assured that a drain has thus been invisibly formed under your feet." The machine is worked by two horses; a capstan, firmly and easily fixed into the ground, affords a firm traction to the plough by means of a wire rope and pulley. The chief defect in the earlier specimens was an inequality in the level of the channel excavated by the plough, because the upper and lower parts being fixed at an unvarying distance apart, any unevenness of the surface was faithfully copied by an undulating drain below. This defect was partially remedied afterwards; but the difficulty of ensuring horizontality in the drain has continued to be an obstacle to the use of this machine. The cost being considerable, none but a large landowner would find profit in buying such a draining plough; but the machine can easily be let out for a month, or other definite period.

The aggregate result of all these various improvements in the construction and application of agricultural implements has been immense. Mr. Pusey, in reporting on this subject, as Chairman of the Exhibition Jury, in 1851, made the following estimate: That by using lighter ploughs, cultivators that lessen the necessity for ploughing, drills that economise both seed and moving-power, horse-hoes instead of hand-hoes, varied manures instead of manures of a few kinds, reaping machines instead of sickles, well-constructed carts instead of clumsy waggons, fixed and portable steam-engines, steam-thrashing and winnowing machines, turnip and chaff cutters, drain-tile machines and draining-ploughs—*there had been effected in twelve years a saving of one-half the former outlay in cultivating a definite amount of crop.* It had been rendered further demonstrable that machinery had given comparative *certainty* to agriculture, by enabling many of the operations, in doubtful or unfavourable weather, to be done with quickness, which could hardly have been done at all by the hand method.

Mr. Evelyn Denison (afterwards Speaker of the House of Commons) prepared a Report on the Agricultural Implements displayed at the Paris Exhibition De l'Industrie, in 1855, in which he endeavoured to estimate the material saving accruing from the use of machinery in agriculture. Mr. Sidney, at the close of 1857, gave a few figures intended to bring down the estimate to that year. In this last-named estimate it was supposed that within six years—that is, since Mr. Pusey prepared the Great Exhibition report—the landowners of the United Kingdom had expended ten millions sterling in draining two million acres of land, on principles and with tools not known until 1845. Then, besides all the saving on the items already enumerated, there is that precious, though not easily-calculated advantage resulting from the economy of *time*, by employing machinery at full force during short intervals of fine weather.

(*Report of the Great Exhibition*, 1851. *Report of the Paris Exposition*, 1855. *Journal of the Royal Agricultural Society of England*, 1845-1857. *Journal of the Society of Arts*, No. 264; *paper by Mr. Sidney*.)

AGRICULTURAL STATISTICS can scarcely be said to exist as yet in England. Notwithstanding the acknowledged importance of exact information as to the amount of our agricultural production and consumption, especially to farmers, and the interest that is taken in the subject as shown by the attention to the Mark Lane reports, which are little better than ingenious guesses, no steps have yet been taken to insure a correct estimate of the expected amount of the incoming crops, and the state of live stock. Such estimates as are made are derived from individual instances, than which nothing can be more fallacious. The great differences in cost, cultivation, and even of climate in England, make the application of the doctrine of *averages* almost more indispensable in agriculture than in any other trade. It is by the accumulation of individual parts that we arrive at something like a *law*. A law prevails in agriculture as in everything else, and the more any subject has the appearance of chance, the more necessary it is that the experiences should be registered, in order to arrive at the law expressed by an average. The inconvenience and loss occasioned by the absence of statistical returns has been often felt. After the harvest of 1846, the average price of corn for six weeks, from the middle of August to the end of September, was 48*s.* 2*d.*, the lowest price being 45*s.* 1*d.* In October, the price improved; but in November it again fell to 50*s.* But as soon as the new year had begun, symptoms of scarcity, manifested themselves, and the wheat of that same harvest, notwithstanding the importation of four millions and a half of quarters, reached the price of 102*s.* 5*d.* per quarter. In this case, a knowledge of the produce of the harvest would have saved the farmer from the sacrifice of his property at the beginning; it would have saved the country from a great loss in the price of the foreign corn imported, occasioned by a sudden rush into the market for large supplies; it would have probably saved considerable waste of food during the period when it was improperly cheap; it would have saved inconvenience to the foreigners in whose markets our purchases inevitably increased the price of wheat; and the gains of the merely speculating corn-dealers would have been saved to the community.

The desirableness of some knowledge on so important a subject has led many individuals to form, from the best available sources, general estimates, but the discrepancies show the unreliability of such estimates for any practical purposes. Some endeavoured to arrive at it by taking the acreage of the kingdom, the proportion supposed to be cultivated, and the probable amount of produce per acre. Gregory King, who wrote in 1685, was among the earliest. He estimated England and Wales to contain 39,000,000 acres, of which he supposed half to be uncultivated. Davenant, Grew, Templeman, Sir William Petty, Arthur Young, Dr. Beeke, Mr. M'Culloch, Mr. Porter, and others, formed estimates varying from 31,648,000 acres, to 46,916,000 acres, which was the estimate of Arthur Young, and was adopted by Mr. Pitt in his calculations for the probable amount of the Income Tax. In the census of 1851, the area is stated at 37,324,915 acres, which was very near the estimate of Dr. Beeke, who gave it as 38,498,572. Others, again, have endeavoured to ascertain the consumption by multiplying that of each individual by the number of the population, but here they differ materially, varying from 6 bushels to 8 bushels for each individual, an unsatisfactory difference of one third. We will now enumerate what measures have been taken in providing statistics by the government.

What are called the *corn averages*, are entries or tables originally intended to regulate the duty on corn; but if modified and improved, they might be made an auxiliary to agricultural statistics. For a century previous to the year 1851, such returns were collected from the principal seaports of twelve maritime counties—entirely in relation to the imposition of duty on foreign corn; the collector of the returns was appointed by the magistrates of the town or borough in which the return was made, but his salary was paid by the government. In 1821 a change was made. The averages were ordered to be collected from 120 large market-towns in England and Wales. Every corn-merchant, miller, baker, and maltster, was ordered to make weekly returns to the inspector. The inspector provided a place for the reception of these returns; he posted up in some convenient locality the gross weekly returns, with the average price of each description of grain sold in the preceding seven days. These averages were then forwarded to the Comptroller of Corn Returns, in London, who added up all the gross amounts from all the inspectors, and struck a six weeks' average for the whole kingdom—which average regulated the duties on the admission of foreign corn for home consumption. When the 'sliding-scale' came into operation, there were several instances of the averages being tampered with, in London and some of the outports, by false returns; this was done by fraudulent persons, with a view of lowering the rate of duties by fictitious sales of large quantities of corn; thus swelling the quantity returned, raising the prices, and lowering the duty. In 1842 a motive of economy, whether wise or not, led to the appointment of excisemen, without any increase of salary, in place of inspectors, as the latter might die off, for taking the corn averages; and the returns are believed to have suffered in accuracy from this change. When the corn laws were repealed, further changes were made; the corn averages ceased to be as valuable as before in respect to fiscal regulations; but they remained important in connexion with the commutation of tithes; and it is now considered that they might render useful aid to the agricultural statists. The list of towns whence the returns are made has been largely increased; in all the towns thus added, excisemen have been appointed instead of inspectors.

These returns, it is evident, showed nothing beyond the average prices. In 1832 the attention of the government was directed to the attainment of more satisfactory results. In the previous year, a statistical inquiry had been made by a committee of the magistracy of Norfolk, respecting the acreage and crops of that county. The committee addressed circulars to 680 parishes; but 254 of these declined to answer the questions snbmitted to them, and the committee had no other resource than to infer from the 426 affirmatives to the 254 negatives. Still, though imperfect, the result was useful as a beginning; and in 1832, when the Statistical Department of the Board of Trade was established, Lord Auckland saw the importance and necessity of obtaining correct agricultural statistics. Nothing was effected, however, until 1836, when the Board of Trade resolved to make a small experiment of its own. Circulars were sent to the clergymen of 126 parishes in Bedfordshire, enclosing schedules of the returns required, and asking for co-operation. This experiment was a most signal failure; for out of 126 parishes applied to, only 27 returned any answer. It was a time when the clergy and the high Tory party distrusted the suspected radicalism of most new Government projects, and it was on that account an unfortunate period in which to make the attempt. Eight years passed over; when, in 1844, Mr. Gladstone, at that time President of the Board of Trade, stated in the House of Commons that the subject was under his consideration. The Board of Trade, the Home Office, and the Poor Law Board, next had a long correspondence in reference to the question, whether the last named of these three might undertake the management of a system of national agricultural statistics; and it appears to have been decided that, as constituted at the time, the Poor Law Board could not adequately fulfil this duty. In 1845 the Board of Trade resolved to make another attempt, or rather three small attempts in the three kingdoms—North Hants in England, Mid-Lothian in Scotland, and Bailieborough Union in Ireland. The Irish inquiry was made by a private individual, and was satisfactory; the Scotch inquiry was managed by the schoolmasters of the respective parishes, and was equally successful; but the English inquiry was an utter and disheartening failure. The Board of Trade, in this last-mentioned case, addressed communications to the Board of Guardians of the different Unions; while the Poor Law Commissioners backed the application, by requesting the Board to employ their own paid officers to induce the occupiers of land to fill up the schedules that were sent to them. The result was almost *nil;* scarcely any returns were obtained; and a strong impression was left that nothing less than compulsory powers would be available for obtaining the desired statistics.

The next attempt was made in 1847, when Mr. Milner Gibson, Vice-President of the Board of Trade, brought into Parliament a 'Bill to make Provision for the Collection of Agricultural Statistics in England and Wales.' By the provisions of that Bill, the duty of obtaining the statistical information was to devolve upon the Registrar-General of Births, Deaths, and Marriages; the superintendent registrars throughout the kingdom were to be charged with the appointment of 'agricultural enumerators' in their respective districts; the enumerators were to prepare lists of all the occupiers of land exceeding three acres, to send specified blank forms to those occupiers, and to collect those blank forms after an interval of fourteen days filled up with the several entries of particulars. This being done, the enumerators were to classify the returns, and construct general tables from them. These tables were to be transmitted to the superintendent registrars, by them to the Registrar-General, and by him to the Board of Trade. These returns and tables were to apply to the month of June in each year. The bill was read a first time; but as the public had not yet learned to feel much interest in the subject, and as various party questions were then on the *tapis*, the bill shared the fate of many others, and fell to the ground.

In 1854, an attempt was made to obtain complete statistical details through the machinery of the Poor Law Board. The selection was unfortunate, for the impression was instantly received that the returns would lead to additional assessment, and no explanation availed to remove that belief. In addition it was generally feared that such returns would be used against the farmers by their landlords in order to raise their rents, they, in very few cases, holding their farms upon lease. The West Riding of Yorkshire was the only division from which a complete return was procured. In all the other counties the returns were so incomplete as to be useless. Many Unions refused altogether, alleging that their officers had sufficient other duties to perform, and in some Unions up to a proportion of one half, where the guardians had consented, many parishes made no returns. In 1855, a Committee of the House of Lords was appointed on the subject, before which a number of witnesses were examined, and among them most of the Poor Law Inspectors. Notwithstanding their ill-success, and the many admissions they were compelled to make of the continued opposition that would be offered to the investigation of a farmer's affairs by Poor Law officials, the most of them represented that all that was required was a compulsory act; and accordingly the Lords' Committee embodied a series of resolutions in their report, recommending the government to introduce a bill into parliament for two returns a year, in July and November, to be carried out by the same machinery. The government however have not yet adopted the recommendation.

Under these disadvantages we will endeavour to give a few of such statistics relating to agriculture as rest upon sure bases. It is quite certain that a rapidly increasing population must have been fed, and that the means of feeding them can only arise from land not previously cultivated, from importation, or from improved cultivation. The following figures will give some notion of what has been effected in each division; unfortunately however, though the inclosures and population only apply to England and Wales, there is no separating the application of the imported wheat from that consumed in Scotland. The amount is no doubt very small, for wheaten bread was not generally used in that part of the kingdom in the early periods recorded; and from the vast improvement in cultivation during the latter portions of them, there is probably more than sufficient corn produced in Scotland to supply the population.

	Acres inclosed.	Qrs. imp.	Increase of Pop.
1800 to 1810	1,657,980	6,009,458	2,173,589
1810 to 1820	1,400,930	4,585,780	945,588
1820 to 1830	340,380	5,349,927	1,110,793
1830 to 1840	236,070	9,076,379	2,032,525
1840 to 1850	369,127	23,298,353	2,048,573

The increase of population is taken from between each of the decennial censuses commencing with 1801. The inclosures of course must necessarily decrease, and the best lands will have probably been among the earliest enclosed. Since 1846 the inclosures of commons have been conducted by commissioners, and are passed in acts in groups, in which the acreage is only occasionally stated. The amount on the whole since 1850 does not average more than a few thousand annually, while the population has increased in about the same proportion as in the previous decennaries. The result is that somewhat above four million of acres have been acquired for the support of upwards of eight millions and a-half of additional mouths. In 1851 there was imported 3,833,636 qrs. of foreign wheat, and 5,363,478 cwt. of wheat flour; in 1852, 3,068,892 qrs. of wheat and 3,889,583 cwt. of flour; in 1853, 4,949,314 qrs. of wheat, and 4,646,400 cwt. of flour; in 1854, 3,431,227 qrs. of wheat, and 3,646,505 cwt. of flour; in 1855, 2,667,702 qrs. of wheat, and 1,904,224 cwt. of flour; and in 1856, 4,072,833 qrs. of wheat, and 3,970,100 cwt. of flour. During the whole of this period the price of wheat has on the whole decreased. During the long war with France, from 1800 to 1815 inclusive, the average price per quarter was 84*s.* 9*d.*; from 1816 to 1820, it was 78*s.* 4*d.*; from 1821 to 1830, it was 58*s.* 3*d.*; from 1831 to 1840, it was 57*s.*; from 1841 to 1850, it was 56*s.*; in 1851, it was 38*s.* 6*d.*; in 1852, 40*s.* 5*d.*; in 1853, 52*s.* 11*d.*; in 1854, 73*s.*; in 1855, 74*s.* 9*d.*; in 1856, 69*s.*; and in 1857, the highest point reached was 63*s.* in July, and the lowest in December 45*s.* 3*d.*

All the statistical returns obtained by Government have a fiscal basis. The only real agricultural statistics we possess are those for hops, of which we know every cultivated acre and every pound of produce; and barley, of every bushel of as much as is made into malt. These we owe to the duty; but when, as in the case of live stock, the duty is discontinued, no account is taken by it even of importations, though the Board of Trade in their monthly returns give the number imported as obtained from other sources. The following is the return so given for the month ending November, 30th, 1857, and for the eleven months of 1857, ending the same date.

		Month.	11 months.
Oxen and bulls, and cows	number	9892	61,045
Calves	"	2738	23,846
Sheep and lambs	"	25,270	159,426
Swine and hogs	"	1459	10,194
Bark	cwts.	28,686	342,579
Wheat	qrs.	456,804	2,988,933
Barley	"	100,597	1,593,947
Oats	"	197,296	1,657,053
Peas	"	14,831	153,302
Beans	"	36,368	260,881
Indian corn or maize	"	152,770	1,014,353
Wheatmeal or flour	cwts.	267,160	1,702,358
Indian corn meal	"	58	1082
Hemp	"	108,779	702,783
Guano	tons.	43,289	179,455
Oilseed cakes	"	10,283	85,380
Potatoes	cwts.	215,386	633,597
Hops	"	1857	10,960
Bacon and hams	"	5331	362,642
Beef, salt	"	5561	120,887
Pork, salt	"	4433	63,360
Eggs	number.	6,645,000	119,508,200
Butter	cwts.	31,189	413,389
Cheese	"	33,882	346,268
Lard	"	54	171.082
Clover seed	"	8823	148,602
Flax seed and linseed	qrs.	164,734	823,358
Rape seed	"	21,363	177,820
Timber, of various sorts, from British possessions and Foreign	loads.	282,184	2,180,341
Wool, from British possessions and Foreign	lbs.	11,680,071	110,995,577

These returns apply, however, to the whole of the United Kingdom.

The remainder of the estimates for England rest only upon probabilities. Thus in the Journal of the Royal Society of Agriculture for 1856, the number of sheep in England and Wales is estimated at 27 milliens, worth upon an average 30s. per head. About 10 millions are annually slaughtered for food, producing 800 millions of pounds of mutton, which at 6d. per lb. amounts to £20,000,000; and calculating the weight of each fleece at 4½ lbs. 157,500,000 lbs. of wool is obtained, worth at 1s. 3d. per lh. nearly £10,000,000. The number of cattle has been estimated at 5,620,000, and that of swine at about 5,000,000. The number of horses is given by Mr. M'Culloch in 1847, and they have probably not greatly increased since, as 1,500,000, the value of which he estimates at from £18,000,000 to £22,500,000. Such statements bear upon their faces evident marks of uncertainty, while the trouble any individual must have taken to procure materials even for a guess, shows the call there has been for this species of information.

In Scotland, where leases are, and have long been, almost universal, and where a less objectionahle machinery was employed, statistical returns were much more easily obtained. Tenants there had indeed been long accustomed to the term, which some have asserted had no little influence in affrighting the farmers of England. In 1800, Sir John Sinclair had, with the assistance of the parochial ministers and others, produced a 'Statistical Account of Scotland,' giving in detail the state of every parish. This had been re-produced between 1834 and 1845, in so complete though hulky a form, and the agricultural improvements had been so great, as to justify the committee of ministers who had carried it through, in saying "They now present not merely a new statistical account, but in a great measure the statistical account of a new country." In 1847 the members of the Highland and Agricultural Society of Scotland, hy whom agricultural improvement has been greatly promoted, felt the need of statistics, and by means of their secretary, Mr. Maxwell Hall, set about obtaining them. They memorialised Sir George Grey on the subject, and were desired to communicate a scheme, which was done, but without result. In 1852 they again memorialised the Home Department, offering their assistance if any project were legalised, hut again without anything being effected. In 1853 the Government allowed the sum of £5000 to make the experiment, and Mr. Maxwell Hall determined to endeavour to obtain the returns though without any legal support. Complete returns were obtained for three counties, Haddington, Roxhurgh, and Sutherland. In 1854 he travelled through a great part of Scotland requesting the assistance of farmers; he succeeded in removing their objections, and convincing them of the advantages; and hy means of local hranches of the parent institution succeeded in procuring complete returns for the kingdom. These have been continued annually, and though there have been a few omissione, are the most complete in their details of any yet known. Though the absence of similar returns of England deprives them of mucb of their value, they are still, conjoined with those of Ireland, of great importance. We give an ahstract of the returns for 1856 and 1857. We may premise that the returns are from holders paying a yearly rent of 10*l.* and upwards (exclusive of tenants of woods, villas, feuars, householders and the like) in all the counties of Scotland except Argyle, Inverness, Ross and Cromarty, Sutherland, and tbat part of Bute wbich lies in Arran, in both years, and in Caithness, Sutherland, and Orkney, in 1856, where the returns are only from holders paying a rent of 20*l.* and upwards. Woods, sheep-walks, bouses, roads, and waste, are omitted in the calculation.

In 1856 the number of occupants was 42,919; in 1857 there were 43,432. Tbe number of acres under rotation of crop was 3,545,191 in 1856; of which, of wheat there were 263,328, of harley 165,738, of oats 918,644, of rye 4020, of bere 15,368, of beans 40,470, of peas 4817, of vetches 18,231, of turnips 460,131, of potatoes 149,351, of mangold 3531, of carrots 1532, of cahbages 1485, of rape 1407, of flax 2723, of turnip seed 1759, other crops 795, bare fallow 14,464, and grass and hay in rotation 1,475,775, which leaves 1602 of the stated total unaccounted for. The produce was 7,270,952 hushels of wheat, 5,581,970 of barley, 31,966,381 of oats, 6,540,267 tons of turnips, and 413,800 tons of potatoes. In 1857 the number of acres under crop was 3,556,572, of whicb there were of wheat 223,152, of barley 198,387, of oats 938,613, of rye 5989, of bere 21,607, of beans 39,186, of peas 3687, of vetcbes 18,418, of turnips 476,691, of potatoes 139,819, of mangold 2803, of carrots 1401, of cahbages 1704, of rape 2032, of flax 1534, of turnip seed 2576, of other crops 577, of bare fallow 18,582, and of grass and hay in rotation 1,459,805, an excess of 989 acres over the stated total. The produce was 6,154,986 husbels of wbeat, 6,494,534 of barley, 32,750,763 of oats, 6,690,109 tons of turnips, and 430,468 tons of potatoes. In 1856 the total number of horses was 179,853, of milch cows 209,960, of other cattle 473,384, of calves 197,709, of sheep and lamhs 5,816,560, of swine 128,924. In 1857 the numbers were, of horses 185,409, of milch cows 303,912, of calves 195,198, of sheep and lambs 5,683,168, and of swine 140,354. In this account the horses, cows, and swine kept in towns are not included: and it is estimated that above 300,000 head of stock, and upwards of 200,000 acres of tillage are held hy occupants not in these returns. Fife and Haddington sbow the greatest proportional acreage in wheat and in white crops generally, and Aherdeen and Argyle the greatest in turnips; those counties also possessing the greatest number of live stock.

In Ireland, where the interest felt migbt have been supposed to be less, statistical returns have been ohtained in an excellent form, and with no opposition. The task of gathering the returns was confided to the constahulary in 1852, and they have been continued annually since. We append the return of 1857:—In that year the returns sbow that there were 5,860,089 acres under crop, heing an increase of 106,542 acres over the quantity in 1856. Of these 562,581 acres were in wbeat, 1,978,878 in oats, 246,257 in harley, beans, peas, &c., sbowing a small increase of cereal crops generally, but a decrease on oats of 58,559 acres. On green crops there was a general increase of 45,637 acres, potatoes occupying 1,146,920 acres, an increase of 42,216 acres, and flax had decreased from 106,311 acres in 1856 to 98,074 acres in 1857; and turnips had decreased 4,487 acres. Meadow and clover had increased from 1,302,787 acres to 1,369,421 acres.

The produce of the 5,753,681 acres in cultivation in 1856, had been 2,738,163 barrels of wheat of 20 stone eacb; 14,778,045 barrels of oats of 14 stone eacb; 1,367,453 barrels of barley of 16 stone each; 50,709 barrels of heer of 16 stone; 72,165 barrels of rye of 20 stone; 431,561 bushels of beans and peas; 35,268,345 barrels of potatoes of 20 stone each; 4,581,172 tons of turnips; 287,838 tons of mangel wurzel; 332,650 tons of cabbages; 3,006,553 stones (14 lbs.) of flax; and 2,492,732 tons of hay. The total number of holders of land was 592,489; of wbom 36,474 held not more than one acre; 82,035 not more than five acres; 179,931 not more than fifteen acres; 138,424 not more than thirty; 71,156 not more than fifty; 53,279 not more than one hundred; 21,292 not more than two hnndred; 8243 not more than five hnndred; and only 1655 held upwards of five hnndred acres.

Live stock, except sheep, had increased remarkahly. The number of horses was 600,693, an increase of 27,285; the nnmber of cattle 3,618,544, an increase of 30,686; the nnmber of sheep 3,448,676, a decrease of 245,618. Pigs nnmhered 1,252,152, an increase of 333,627.

Road contractors in Ulster are reqnired to keep the road-sides and fences free from weeds, and surveyors in the other provinces are recommended to obtain anthority from grand jnries, &c., to enforce in them similar regulations.

Most foreign conntries have fonnd the necessity of having statistical returns of their agricnltnral prodnce. Austria, Prussia, France, Denmark, Hnngary, Belginm, and the United States of America, have all such returns more or less perfect, among which those of Belginm take a high rank, and are nearly eqnal to those of Scotland. Snch statistics for the whole of a kingdom are highly valuahle for the regulation of the inhabitants of that kingdom; hut if we possessed them for the whole of the civilised world, what are called the chances of agricnltnre wonld prohably he reduced to a certainty, and the price of food wonld remain with little or no variation.

AGRODROMA. [ALAUDINÆ, *S.* 2.]

AGROSTEMMA (from ἀγρός, a field, and στέμμα, a crown), a genns of plants helonging to the Silenious division of the order *Caryophyllaceæ.* It has several species, the best known of which is the Corn-Cockle, which is now referred to the genus *Lychnis*, or *Githago.*

AHUN. [CREUSE.]

AIGUESMORTES. [GARD.]

AIGUILLON. [LOT-ET-GARONNE.]

AIKIN, ARTHUR, the eldest son of John Aikin, M.D., was horn in 1784. Arthnr Aikin hegan his literary career, we helieve, as editor of 'The Annnal Review;' npon the title-page of the first six volumes of which—1803-1808—his name appears as editor. His earliest scientific work was 'The Manual of Mineralogy,' of which the first edition was pnblished in 1814. Besides these he was the author of a 'Tonr in North Wales,' a 'Dictionary of Chemistry and Mineralogy,' and a 'Dictionary of Arts and Mannfactures;' and also of numerons papers in varions scientific journals. For a long series of years Mr. Aikin was the resident secretary of the Society of Arts, and a freqnent contrihutor to its 'Transactions.' He was also one of the oldest fellows of the Linnæan and Geological societies. Mr. Aikin was a man of qniet retiring habits, and ontlived his scientific reputation; hut was well known in scientific circles as one of the most regular freqnenters of the meetings of the learned societies in the metropolis, and was generally esteemed. He died at his honse in Bloomsbury, London, April 15, 1854, in his 81st year.

AIRA, a genns of Grasses helonging to the tribe *Sesleriæ*, and distinguished hy possessing a lax panicle, two-flowered glnmes, the outer pale terete on the back, and a dorsal awn. There are several species, hut that which is hest known is *A. cæspitosa*, the Tufted Hair-Grass. It has long and flat leaves, with a fibrons perennial root. It flowers in the heginning of Angust, and reaches a height of fonr feet. It grows naturally on marshy damp soils, in the form of large tufts. It is a wiry harsh grass, and is rejected hy domestic animals. It may, however, be advantageously sown as a cover for game, and also by the side of ponds and marshes for snipe and wild fowl. (Lawson, *Acrostographia.*)

AIRE, RIVER. [YORKSHIRE.]

AITONIA (after Mr. W. Aiton, for many years head-gardener at Kew) a genns of plants belonging to the order *Meliaceæ.* The *A. Capensis* is a native of the Cape of Good Hope, and is cultivated in our greenhonses.

AKHALZIKH, a town in Russian Armenia, situated near the watershed between the Black Sea and the Caspian, on a feeder of the Knr, which flows towards the south-east from the Perengah Dagh, in 41° 40′ N. lat., 43° 10′ E. long. Popnlation abont 15,000, who are chiefly Armenians. It was formerly the chief town of a pashalic in Tnrkish Georgia; since the cession of which province to Russia, it is the capital of the province of Akhalzikh. [GEORGIA.] The town is fortified, and of considerable extent. The most remarkahle huilding after the citadel is the mosqne of Ahmed, which is huilt on the model of that of Santa Sophia at Constantinople. Connected with the mosque is a college, and a library rich in Oriental literatnre; hut it is said that the best works it contained have been carried away to the royal library of St. Petershnrg. The Armenians have several large chnrches, and there is also a synagogue. The chief trade is in silk and honey; there is also some transit trade, as the town lies on the road between the port of Batoum and Tiflis, being 80 miles E. from the former and 105 miles W. from the latter.

ALAGOAS, a province of Brazil, which, np to abont 1840, was a district, or comarca, of the province of Pernambuco; but, on acconnt of its increasing population and wealth, was formed into a separate province, which is nnder the administration of its own governor. It is sitnated between 9° and 10° S. lat., 36° and 38° 30′ W. long. It borders on the sonth of the province of Seregipe del Rey, from which it is separated hy the Rio de San Francisco, along the northern hanks of which it extends to the great cataract, called Cachoeira de Panlo Affonso. On the west and north it is snrrounded hy the province of Pernambnco, from which it is separated for a considerahle space hy the Rio Unna. The Atlantic washes its eastern side. In length, from east to west, it extends abont 150 miles; its average width prohahly does not exceed 60 miles. The area is about 9000 sqnare miles.

Two-thirds of this surface are covered with mountains. They form the sonthern declivity of the elevated and hilly tahle-land, which occupies nearly the whole of the conntry, and projects into the Atlantic between 3° and 9° S. lat. These monntains come close up to the river San Francisco as far east as the month of the Rio Sacare, and terminate in Alagoas, at a distance of about 20 miles, or little more, from the sea. This region is almost entirely covered with wood, and contains many high timber-trees, which afford a considerable article of exportation. The valleys and more gentle slopes of the mountains exhibit a considerahle degree of fertility. Along the eastern base of the monntains extends an nndulating or rather hilly tract, which occupies about half the country hetween the declivity and the sea. It is likewise wooded, and has a light soil, very fit for the cnltnre of cotton, which is rapidly extending. The country along the sea-shore, and at a distance of ahout 10 miles or somewhat less from it, is low, level, and covered with a thick allnvium, which has been hronght down hy the nnmerous small rivers that rise on the eastern declivity of the monntain-region, and deposited along the edge of the nndnlating tract. This soil is of the best qnality, and fit for the cultivation of every kind of intertropical prodnctions. A considerable portion, however, of this tract is still covered with swamps, and the tide, which rises along the coast from 4 to 5 feet, enters the mouths of the rivers, and has changed the adjacent low conntries into lagnnes. The most considerable of these lagunes is the Lake of Manguaba, from which the river Alagoas runs to the sea in a southern direction. It is stated to be 30 miles long, and abont 3 miles wide at an average, and consists of two lagunes nnited by a strait. The northern is called Lagoa do Norte, and the sonthern Lagoa do Sul. Its water is salt. Only canoes can navigate the river Alagoas, which carries its water to the sea. The rich plantations situated aronnd the Lagoa do Sul carry their prodnce to the northern lake and the town of Alagoas, whence it is transported to the harbonrs of Taragua and Pajassara. Farther sonth is the Lagoa do Siqniha, which is 15 miles long from north to south, with an average width of 3 miles. A river of the same name runs sonthwards to the sea.

Thongh all the rivers which disembogne along this coast are small, and have bars at their months, with so little water on them that sea vessels of even the smallest size cannot enter them, the province has a few harbonrs snfficiently deep for vessels of moderate magnitude. The most northern are the harbours of Pajassara and Taragua, which are close together and separated by a low tongue of land. The port of Taragua is the hetter of the two. Merchandise disembarked at this port is transported by land three miles to the Lagoa do Norte, and there embarked on canoes for Alagoas and other towns. Cnrurippe, which is farther sonth, is a harbour of moderate size, formed hy a reef extending to a distance of 300 yards from the shore, which hreaks the fury of the sea. The harbour may he entered hy two breaks in the reef, hut the anchorage is not generally good. The river which falls here into the sea bears the same name, and is navigable for canoes for several miles, bnt has very little water on the bar at its month.

The only river which here deserves to be noticed is the

San Francisco, which enters Alagoas at its western extremity at the great cataract of Paulo Affonso, where it is said to descend 50 feet in perpendicular height. It then runs for nearly 50 miles to the Aldea do Caninde, forming several rapids and smaller cataracts, between rocky banks several hundred feet high, and extremely rugged. Many rocks occur in the bed of the river, and it is not navigable. At Caninde the width of the river increases to half a mile and more, and the navigation to its mouth is not interrupted. Its banks are of moderate height as far down as Penedo. Below Penedo the river enters the alluvial tract, in which it divides into several branches, forming a great nnmber of islands, generally low and abounding with woods. They have a fertile though partly a sandy soil, where rice, maize, mandioc, sugar, and vegetables are raised in abnudance. In the rainy season they are overflowed. The branches of the river unite again, and it disembogues by two months of different size. The northern is the larger, being nearly 2 miles wide, but has so little depth that smacks can enter it only at high-water, and must there wait for the full tide to go ont. They can sail as far np as Penedo, 25 miles from the month. Farther up the navigation is solely by ajojos, that is, two or more canoes moored together with cross-pieces of timber above. In ascending the river sails are always nsed, as the wind from eight o'clock till the following morning's dawn blows always from the east. The ajojos always descend the river with the cnrrent, which is rather rapid.

The climate is warm and humid. The heat in the rainy season is frequently oppressive, except along the coast, where it is moderated by sea-breezes. It is less hot in the dry season, and also more healthy. The wet season occnrs from November to March, and then the rains are very abundant, but showers are not rare in the dry season also.

Tobacco was once the staple article of this province, and was especially sent to the western coast of Africa; but since the abolition of the slave-trade this branch of agricnlture has continually been decreasing, and has been replaced by sngar and cotton, which at present constitnte the staple articles, the first being raised in the allnvial and the second in the undulating tracts. As food are raised—mandioc, maize, rice, plantains, beans, and some roots, as yams, sweet potatoes, &c. The most common fruit-trees are oranges, pine-apples, jack-trees, cocoa-nnts, and palms. The mamona-tree is carefully cultivated in some districts on acconnt of its oil, which affords an article of exportation. Alagoas has extensive forests of timber-trees, even in its lower districts, and affords the best timber in Brazil. It is exported to Bahia and Recife; and many small vessels are built in the province. Some of these timber-trees are very durable, especially those named Sncupira, Pao Roxo, Vinhatico, and Tatahy, but their wood affects the iron, and the bolts become loose in a few years, which is ascribed to the great quantity of tannin contained in the wood. The forests abonnd also in several kinds of wild fruit-trees, and there are also the trees which produce dragon's blood, mastic, ipecacuanha, copaiba, and caoutchouc. Other woods are nsed as dyes, among which Brazil-wood is the most prized. An inferior species of quinine, or Jesuit's Bark, is not rare.

The European domestic animals are far from being nnmerous, except asses and mnles. The onnce exists at present only in the monntain-districts. The most nnmerous animals are deer and monkeys of different kinds, and also ant-eaters, armadilloes, and others. The tapir and peccary are rather rare. Alligators abonnd in the lakes and rivers; land-tortoises are numerous. The number aud variety of birds are very great, especially of parrots. Honey and wax are obtained from wild bees. Several kinds of fish abound in the lakes and lagunes, and on the sea-coast, and they constitute one of the principal articles of food for the lower classes and the Indians. The river San Francisco is noted for the abundance of its fish. Several kinds of snakes are poisonous.

It does not appear that any kind of metal is found; none at least is worked.

The population was stated more than 20 years ago to amount to nearly 100,000; and it is supposed that at present it hardly falls short of 200,000, as cnltivation has greatly increased in late years. But this number is very uneqnally distributed over the surface. More than 120,000 probably inhabit the low and hilly tracts, which may comprehend 3000 square miles, so that in these regions there are abont 40 persons to a sqnare mile. No part of Brazil, with the exception of the Reconcave of Bahia, is so populons as this portion of Alagoas. The nnmber of negro slaves may amount to nearly one-fourth of the population. The greater portion of the mountain-region is still the haunt of some native tribes, who mainly depend on the produce of the chase for their subsistence. Several families of Acconans, Carapotes, and Cayriris, have been converted to Christianity, and live in the parish of Collegio, on the banks of the San Francisco, where a tract 3 miles wide and 6 miles long has been given to them for purposes of agriculture, but they cnltivate only a little maize. Their women make earthenware.

Agricnlture is the principal occupation of the inhabitants. Only a few persons are employed in the exercise of the most necessary arts of civilised life. Common cotton-cloth is made in the families, but most of the mannfactnred goods are imported. Boat-building is the most important branch of industry.

The province retnrns two senators and five representatives to the imperial parliament of Brazil.

In this province is one city, Alagoas, and seven towns, namely, *Porto de Pedras*, *Porto Calvo*, *Matsayo*, *Anadia*, *Atalaya*, *Pozim*, and *Penedo*. Besides these places, there is San Miguel, which is bnilt about 18 miles from the sea, and is a populous place in a very fertile district. The village of Caninde, on the Rio de San Francisco, is the place where the navigation of the river terminates. Goods destined for the consumption of the conntry adjacent to the npper conrse of the river are here disembarked, and transported on the backs of mules to Vergem Redonda, which is about 20 miles distant, and built where the cataracts begin. There they are again embarked, and carried in boats to the places of consnmption.

A railway has been projected from Pernambnco to the cataract of Panlo Affonso, which will pass throngh the best part of this province, and connect the conntry along the San Francisco with the important city and port of Pernambnco.

(Henderson's *History of Brazil*; Spix and Martius's *Reise in Brasilien*.)

ALAGOAS, the capital of the province of Alagoas, in Brazil, is sitnated in 9° 40′ S. lat. 35° 50′ W. long. It is bnilt on the western margin of the Lake of Manguaba, by means of which and a road about 3 miles long, it sends the prodnce of the rich conntry snrronnding the lake to the harbour of Taragua. This produce consists chiefly of sngar and tobacco. The town has a population of 12,000, and contains several convents and a grammar-school. The country about it abounds in fruits, especially orange-trees and jack-trees.

(Henderson's *History of Brazil*.)

ALANINE. [Chemistry, *S.* 1.]

ALAUDA. [Alaudinæ, *S.* 2.]

ALAUDINÆ, a sub-family of birds belonging to the order *Passerinæ*, and the family *Conirostres*, is thus characterised by Mr. Swainson:—

Bill more lengthened than in any of the *Fringillidæ*; the tip entire or obsoletely notched. Tertial qnills considerably lengthened, pointed, and generally as long as the qnills. Claws very slightly cnrved; the claw of the onter toe always shorter than that of the inner toe; the hinder claw considerably lengthened, and either nearly straight or very slightly cnrved.

Alauda (Linn.)

Bill cylindrical; nostrils concealed. Wings very long; no spnrious quill; the first, second, and third quills longest, and nearly equal; the rest considerably gradnated; tips of the lesser quills emarginate. Tail forked. Head crested. (Sw.)

The Larks are characterised by their having the hind-claw, which is like the fore-claws, somewhat straight, and longer than in the pipits and the wag-tails. The bill is straight, and rather short and strong, the upper mandible being arched without any notch, and not longer than the nnder. The nostrils, situated at the base of the bill, are ohlong, and protected by small plumes and bristles directed forwards. The feathers on the back part of the head can be raised up at the will of the bird into the form of a crest.

Various species of larks are fonnd in all parts of the globe, and are everywhere distinguished by their vigilance and their singing. They are pecnliarly birds of the fields, meadows, and other open places. The conformation of their feet, except in a few instances, such as the wood-lark, does not adapt them to perch npon trees. They accordingly always build on the ground, making in general a rather slight though neat nest, and laying abont five eggs, nsually of a grayish white, with specks of a brown colour. They frequently rear two broods of young during the summer.

They are almost all birds of passage; for even in Britain, where some remain during the winter, the greater number flock together and migrate, either southward or to the sea-coast. During these migrations immense numbers are caught in nets for the table, particularly on the continent, where small birds are more sought after for this purpose than in Britain.

Localities.—Europe and America.

Mr. Swainson considers this as the Fissirostral type.

Example:—*Alauda arvensis.* This is the *Alouette*, *Alouette Ordinaire*, and *Alouette des Champs* of the French; *Lodola*, *Lodola Canterina*, *Lodola di Passo*, and *Lodola di Montagna* of the Italians; *Feld Lerche* of the Germans; *Hedydd* and *Uchedydd* of the Ancient British; and *Skylark* (in Scotch *Laverock*) of the modern British.

The Skylark is too well known, from its inexpressibly beautiful song, chanted forth far up in the air when at liberty and in its natural state, to require any description.

Food.—Insects and their larvæ, with many sorts of seeds and grain.

Nest.—On the ground. Eggs four or five, greenish white, spotted with brown.

Localities.—All the parts of Europe; also in Asia and the northern parts of Africa, but not in the south of that vast continent (Temm.); the whole of Europe within the temperate zone, many parts of Asia, and the north of Africa. (Selby.)

Calendula. (Linn.)

Bill thick, much compressed; the culmen curved and convex; the commissure arched; the tip of the upper mandible wide above and inflexed. Wings long or moderate; the first quill very small and spurious; the second nearly equal to the third and fourth; lesser quills, short, emarginate. Tail slightly forked. Lateral toes equal. Africa. The Dentirostral type—*C. magnirostris*, 'Ois. d'Afr.,' pl. 193. (Sw.)

Sub-genera:—*Myrafra*, Horsf.—Bill as in *Calendula.* Wings short, rounded; greater quills hardly longer than the secondaries and tertials; the first quills spurious, half the length of the second, which is shorter than the third; the third, fourth, fifth, and sixth equal, and longest. Tail short, even. Legs long.—*M. Javanica*, 'Linn. Tr.,' xiii. 159. (Sw.)

Braconyx, Sw. (*Brachonyx*).—Bill as in *Calendula.* Hinder claw very short. Wings and tarsi much lengthened. Africa. (Sw.)

Agrodroma. (Sw.)

Bill slender, considerably compressed; both mandibles of equal length; the tip of the upper one not reflected over the lower, and with a small notch, almost obsolete. Wings long; the first four quills nearly equal; the rest rapidly diminishing, and emarginate at their tips; tertials lengthened, pointed, as long as the quills. Tail moderate, even. Legs pale, long, slender. Tarsus longer than the middle toe. Lateral toes equal, but the outer claw shorter than the inner. Colour brown, lark-like. Distribution universal. The Insessorial or pre-eminent type—*Agrodroma rufescens*, 'Enl.,' 661, f.1. (Sw.)

Macronyx. (Sw.)

Bill slender, compressed, thrush-like, entire; nostrils large, naked, the aperture lateral. Wings short; the primaries not longer than the tertials, the first four of equal length; secondaries long, emarginate. Tail moderate, even. Feet enormous. Tarsus and hinder toes very long, and of equal length. Lateral toes unequal, the inner shortest. Africa. The Rasorial type—*M. flavicollis*, 'Ois. d'Afr.,' pl. 195; *M. flavigaster*, Sw., 'Birds of West Africa,' ('Naturalists' Library,' *Ornithology*, vol. vii., p. 215.)

Certhilauda. (Sw.)

Bill slender, lengthened, more or less curved; nostrils round, naked. Wings very long; the first quill spurious; the three next nearly equal. Tail moderate, even. Feet lengthened; the lateral toes equal; length of the hinder claw variable, although typically short and straight. Africa. The Tenuirostral type—*Certhilauda longirostra*, 'Ois. d'Afr.,' 192; *C. bifasciata*, Rüpp., 'Atlas,' plate 5; *C. nivosa*, Sw., 'Birds of West Africa' (vol. vii., p. 215.)

Such are Mr. Swainson's views as to the arrangement of this sub-genus. [FRINGILLIDÆ.] The genus *Anthus*, Bechst., is placed by Mr. Swainson at the end of his sub-family *Motacillinæ* (Wagtails), under his family *Sylviadæ* (Warblers).

Fossil Larks.

Dr. Buckland figures a lark (*Alauda*) among the land Mammifers and Birds of the third period of the Tertiary Series, in the first plate of the illustrations of his 'Bridgewater Treatise.' He had previously noticed the remains of the lark in Kirkdale Cave. ('Reliquiæ Diluvianæ,' pp. 15, 34, plate xi., ff. 24, 25.

ALBRECHT, WILHELM, was born in Germany, in 1786. He was one of the most distinguished pupils of Thaer, in the agricultural school at Möghin, in Prussia; and he afterwards taught rural economy in Fellenberg's school at Hofwyl. In 1819 he was employed by the government of Nassau to edit a weekly publication devoted to agricultural subjects; and in the following year he was made director of an experimental agricultural school, established at Idstein. The experimental farm was transferred to Geisberg, near Wiesbaden, and it became at once distinguished as the source of agricultural improvements for the west of Germany. As it was found impossible constantly to employ all the pupils on the farm, Albrecht determined to open the school, during the six winter-months, for instruction in the theory of agriculture; while in April of each year the students went to the homes of their parents, or to some farming establishment, in order to familiarise themselves with the practical labours of an agriculturist. During the life of Albrecht the school was highly successful. "The best students for our institute," said he, "are young men from about eighteen to twenty-two, who, after distinguishing themselves at the primary schools, have followed agriculture for some years at home, or on some well-managed farm; they bring a well-disposed mind, not fatigued with study, nor distracted by too many pursuits." While managing these establishments, Albrecht, besides his weekly paper, edited the 'Annals of the Agricultural Society of Nassau;' to which society he was perpetual secretary. Albrecht died in 1848, at his house in Franconia, whither he had retired on resigning the direction of the establishment at Geisberg, a short time previously. (*Nouvelle Biographie Universelle*, 1852.)

ALBUCA (from *albus*, white), a genus of plants belonging to the natural order *Liliaceæ.* The species are mostly found at the Cape of Good Hope. They are cultivated in this country, and require the treatment of greenhouse bulbs.

ALBURNUM, ANIMAL AND VEGETABLE. [CHEMISTRY, *S.* 1.]

ALDEHYDAMMONIA. [CHEMISTRY, *S.* 2.]

ALDEHYDE. [CHEMISTRY, *S.* 1.]

ALDEHYDIC ACID. [CHEMISTRY, *S.* 1.]

ALHAGI (from the Arabic *Aghul* or *Algul*), a genus of plants belonging to the natural order *Leguminosæ.* The species are under-shrubs or herbs with simple leaves and minute stipules. The flowers are red, and disposed in racemes along the peduncles.

A. Maurorum is a native of the deserts of Egypt, Syria, Mesopotamia, and other countries of the East. This plant yields a species of manna, which is called Truugibin or Terengabin. It is chiefly gathered in the neighbourhood of Tabriz where the plant grows abundantly. The manna is a natural exudation from the leaves and branches of the plant, and is most abundant during hot weather. In Arabia it is supposed that the manna falls from heaven on the plant. It first appears in the form of a small drop as of honey, which goes on increasing in size till it is about as large as a coriander seed. The manna yielded by this plant does not appear to be imported into this country. It is principally made use of at the present day in Persia, and is known by the name of Persian Manna. It is employed as food for cattle. Two other species, *A. Camelorum* and *Nipaulensis*, are described by botanists, and cultivated in the greenhouses of this country. They also yield manna.

ALIASKA, a peninsula projecting from the N.W. coast of North America into the Pacific Ocean, and separating, together with the Aleutian Islands, the Kamtchatka Sea from the Pacific. The large lake of Iliamna or Shelikoff, and the isthmus which separates that lake from Cook's Inlet, may be considered as forming its natural N.E. boundary. A river, called Kortchak, or Bristol River, issues from the lake, and falls into Bristol Bay, or the Bay of Kanïsko, which washes the N.W. side of the peninsula. From the lake of Iliamna the peninsula extends in a general direction from E.N.E. to W.S.W. between 59° and 54° 40′ N. lat., and between 153° and 163° 40′ W. long. It is more than 450 miles long, and opposite the mouth of the river Nahnek (157° W. long.) 110 miles wide, but its breadth decreases in proceeding farther west, where in some places it is hardly 20 miles wide. It terminates at the strait of Issanakh, which separates it from the island of Oonimak.

The two coast-lines differ greatly in aspect. The south-eastern shores rise with a steep ascent, are indented with numerous inlets and bays, and lined with numerous isles, islets, rocks, and reefs, partly under and partly above water, and in some places extending to a distance of ten, and nowhere less than five miles from the coast. Between these islands and the coast the sea is commonly very deep. The north-western coast, on the contrary, is everywhere low with a sandy beach, and has only a few open bays, but it is free from the islets and shoals, and offers in many places an anchorage of moderate depth. A chain of mountains extends through the peninsula from the strait of Issanakh to the isthmus of Iliamna along the south-eastern shores, but east of 155° W. long. its highest part is at a greater distance from the coast than to the west of that meridian. It contains several very elevated peaks towards its western extremity, and four at least are always covered with snow, but farther east it becomes considerably lower.

It is remarkable that in the western and more elevated portion of the chain, which consists mostly of volcanic rocks, and where some still active volcanoes exist, there occur four breaks in the range. These depressions intersect the mountains to such a depth, that their surface is not many feet above the sea-level; the soil in them consists of loose sand, and it appears likely that these depressions were once straits, and the most south-western part of the peninsula a series of islands separated from each other by narrow sounds, like the eastern islands of the Aleutian chain, but the straits have been filled up by sand in the process of time.

The low country along the Bay of Kanaïsko consists mostly of sand, covered in many places with swamps, and in others with mosses. Several plants grow on it, and bushes of dwarf willow and alder, but no trees. Along the southern coast, especially east of 158°, also occur some level plains at the innermost recesses of the bays; they do not much differ in plants from the district just noticed, except that their vegetation is much more vigorous, and the bushes attain a greater height. The best harbour on the north-western shore is in the Bay of Moller (56° N. lat., and 160° 40′ W. long.), between which and the Bay of Pavlovskaja the peninsula is narrowed to about 4 miles. On the south-eastern coast several harbours are met with. The most considerable from west to east are Morjevskaïa, Belkowskaïa, Pawlowskaïa, the Bay of Wrangell (156° W. long.), the best of them all, and the Bay of Katmaï.

The Russians, who have a few settlements almost entirely inhabited by natives on both coasts, have introduced agriculture, and though no kind of grain succeeds, the inhabitants of the few dispersed villages raise considerable quantities of potatoes and turnips, and keep fowls. They derive their principal subsistence from fishing, the sea abounding in cod, soles, turbots, and several kinds of mollusca. Whales are frequent along the northern coast, but rather rare on the southern. Morses in immense numbers visit the northern coast, and their teeth constitute the principal article of commerce, since the sea-otters, which formerly were very plentiful, have been nearly destroyed by the avidity of the inhabitants. Rein-deer, bears, and red foxes, are the only large animals which are found in great numbers, but towards the east are also wolves and a kind of mountain-sheep, perhaps also the musk-ox. Seals and sea-lions visit the deeper inlets, and afford to the inhabitants some additional articles of commerce.

The number of settlements made on this peninsula does not exceed ten. Those west of 155° W. long. are dependent on the establishment of Oonalashka, and those east of it on that of Kodiak. The largest of those settlements is the village of Katmaïskoi, on the Bay of Katmaï, which has 90 inhabitants.

(Lüthe's *Voyage autour du Monde;* Krusenstern's *Voyage round the World;* Kotzebue's *Voyage of Discovery to the South Sea.*)

ALLAMANDA, a genus of plants belonging to the natural order *Apocynaceæ*. It was named after Frederick Allamand, a surgeon who travelled in Guiana, in 1769, and afterwards in Russia. He was a correspondent of Linnæus.

The species of this genus are shrubs yielding a milky juice, with verticillate leaves, and many-flowered peduncles of large yellow flowers. They are worthy of cultivation on account of the beauty of their flowers and foliage. They are all natives of South America, and when cultivated require a strong moist heat to make them flower freely.

An infusion of the leaves of *A. cathartica* is said to act as a powerful purgative, and an overdose to produce poisonous effects.

ALLAN, SIR WILLIAM, was born in Edinburgh in 1782. After receiving his early education at the High School, he was placed with a coach-painter; but displaying a strong attachment to art, he was entered as a pupil in the Trustees' Academy, where Wilkie was his fellow-student. When his term expired he proceeded to London, and became a student of the Royal Academy. In 1805 his first picture of a 'Gipsy Boy and Ass' appeared at the exhibition of that institution. Not succeeding in at once attracting public attention, Allan resolved to try his fortune abroad, and selected St. Petersburgh for the scene of his experiment; incited partly, it is said, by the expectation of finding novel and picturesque objects for the exercise of his pencil. He remained in Russia nearly ten years, making occasional journeys to distant parts of the country, to Turkey, Tartary, the shores of the Black Sea, &c., and everywhere industriously employing himself in gathering materials for his art.

On his return to Scotland in 1814, he made a public exhibition of his sketches and finished pictures of Russian, Tartarian, and Circassian scenes and costume. Among the pictures was a large one of 'Circassian Captives,' which at the suggestion of Sir Walter Scott was purchased by one hundred gentlemen, who subscribed ten guineas each; it fell to the lot of the Earl of Wemyss, in whose possession it now is. From this time Allan settled in his native city, sending regularly some of his works to the exhibition of the Royal Academy. For a while his pencil was chiefly employed on pictures suggested by the countries in which he had travelled; he then turned to the annals of his native land, and for several years was mostly engaged in illustrating the history or the romance of Scotland. To this period belong the 'Murder of Archbishop Sharpe,' 'Parting of Prince Charles Stuart and Flora Macdonald,' 'Knox admonishing Mary Queen of Scots,' 'Murder of the Regent Murray,' and others of his best works. In consequence of a disease in the eyes he was compelled for a year or two to cease from painting, and being advised to try a change of climate, he visited Italy, Asia Minor, and Greece. On resuming his pencil, his 'Slave Market at Constantinople,' and pictures of a like kind, showed that he had profited by his travels.

Meanwhile he had been gaining the distinctions awarded to success in his profession. In 1825 he was elected associate of the Royal Academy. In 1835 he became R.A. In 1838 he was chosen, on the death of Mr. Watson, to be president of the Scottish Academy. On the death of Wilkie in 1840 Allan was appointed to succeed him as her Majesty's Limner for Scotland; and in 1842 he received the honour of knighthood. Sir William Allan was best known by his Russian and Circassian *genre* pieces, and by his Scottish historical works. In all of them there is much skill and refinement, but in none any very evident marks of a high order of genius. But he was also a very successful painter of a special class of portraits, such, for instance, as his 'Scott in his Study Writing,' and its companion, 'Scott in his Study Reading;' and in his later years he essayed with success the more laborious task of depicting scenes of actual warfare. Of these the most important were two pictures of the 'Battle of Waterloo,' which met with the marked approval of the Duke of Wellington, and one of which his grace purchased; the 'Battle of Preston Pans;' 'Nelson Boarding the San Nicolas;' and the 'Battle of Bannockburn,' a large painting, on which he was engaged at the time of his death. One of his last considerable works, 'Peter the Great teaching his Subjects the Art of Ship-building,' was a commission from the Emperor of Russia.

Sir William Allan died on the 23rd of February, 1850. As a painter he was generally acknowledged by his countrymen to be at the head of Scottish art, by right of his talent as well as of his office.

ALLANTOINE. [CHEMISTRY, *S.* 2.]

ALLEN, JOSEPH W., a landscape painter of considerable reputation, was born at Lambeth, Surrey, in 1803. His father was a schoolmaster, and the son was designed to follow the same profession. Having completed his education at St. Paul's school, he for a time practised as an usher in Taunton, but he soon threw aside the pen and the ferula, and returned to London in the hope of maintaining himself by his pencil. While acquiring the technicalities of his art he was often reduced to great straits. At first he was constrained to paint signs and transparencies for blind-makers; and when he was more advanced he had for a long period to manufacture paintings for picture-dealers. Under the necessity of producing many showy pictures at low prices, he soon acquired considerable mechanical dexterity, and he was led not unnaturally to turn his attention to scene-painting for theatres—then a very popular branch of art. After working for a while as assistant to Stanfield and others, he obtained the situation of principal scene-painter at the Olympic Theatre, when that establishment first came under the management of Madame Vestris; and his clear style and vigorous pencil did much to secure the success of the brilliant spectacles which formed the distinguishing feature of the management. Allen's early oil-paintings were generally of small size, and represent quiet, homely, pastoral scenery, which was rendered with great delicacy, and a nice appreciation of the freshness of natural colour. But though they found purchasers among well-known patrons of art, his reputation extended slowly, and he attributed his tardy progress to the placing of his pictures at the annual exhibition of the Royal Academy. He joined himself therefore to the newly-founded Society of British Artists, and became one of its most ardent supporters. All his most important works were thenceforward exhibited in the first instance on its walls; and he eventually became its secretary.

Allen did not attain the position his early pictures promised. His inclination and his *forte* lay towards pastoral scenery. He loved and he could well depict those fresh, open, country scenes, so characteristic of our 'home counties,' which Milton describes as affording constant delight to the city dweller. For these Allen had all a Londoner's relish, and while he painted them with continual reference to the reality, his pictures commanded the sympathy of all who enjoy this style of art. But when he had obtained skill in producing those "brilliant effects," which are so attractive in conjunction with gas light and theatrical 'properties,' he began to employ them in his pictures, and though he succeeded by such means in sparing himself much thought and labour, while he rendered his pictures more attractive in the exhibition-room, it was at the expense of those higher qualities of truth and propriety which are essential to lasting fame. And the evil was fostered and strengthened by another influence under which he fell, when he appeared to be about to escape from that of the theatre. From the first establishment of the Art-Union his landscapes won the favour of the prize-holders. Seldom possessing any knowledge of art, their taste is commonly caught by glare and glitter; and Allen permitted himself to be driven by the pressure of his circumstances to paint more and more with a special regard to them. His earlier pictures have many admirable qualities, and his latest display great technical and manipulative skill; but his life was not one of artistic progress, and his is not a name that can permanently take a high place among the artists of England.

Allen died August 26, 1852, of disease of the heart, at the early age of 49; leaving a widow and eight children, for whom unhappily he had not been able to secure a sufficient provision.

ALLONBY. [CUMBERLAND.]

ALLOTOIN, ALLANTOIC ACID. [CHEMISTRY, *S.* 1.]

ALLOXAN, ALLOXANIC ACID, ALLOXANTIN. [CHEMISTRY, *S.* 1.]

ALLYLE. [CHEMISTRY, *S.* 2.]

ALMADINE. [GARNET.]

ALPINIA, a genus of plants belonging to the natural order *Zingiberaceæ*. The species have thick tuberous horizontal roots. The stems are numerous and perennial, with lanceolate leaves, having a slit ligulate sheath. The flowers are in panicles, or loose racemes or spikes. The tube of the corolla is short, the inner limb 1-lipped. The filament of the stamens linear. The fruit is capsular and 3-celled, with winged seeds.

A. Galanga is a native of Sumatra, and is cultivated in the Indian Archipelago. Its roots are pungent, acrid, and aromatic, and are often substituted for ginger. They are sold by druggists under the name of *Galanga major*. A plant related to, if not identical with, the *A. exaltata* of Linnæus, is called *Corowatti* in British Guyana, and is described by Dr. Hancock as a bitter pungent plant, and when taken acting as a diaphoretic and diuretic, and in large doses as emetic. [GALANGA.]

ALTKIRCH. [CHER.]

ALUMINA. [CHEMISTRY, *S.* 1.]

ALUMINIUM. [CHEMISTRY, *S.* 2.]

AMADIYAH, a town and district in Kurdistan. The town is situated upon a lofty isolated rock in 36° 47′ N. lat. 43° 21′ E. long. in a plain which is screened on the north and south by mountain-ranges and drained by the Ghara River, which flows eastward into the Great Zab. The southern range called Ghara is high, well-wooded, and in parts precipitous and very difficult of access. It separates the Amadiyah district from the country of the Missouri Kurds. The northern range, which is also well wooded but does not seem to be so high as the southern one, separates the plain of Amadiyah from the extensive valley of Berwari.

The plain of Amadiyah is cut up into innumerable ravines by the torrents which rush down the mountains into the Ghara River, by which they are carried to the Zab. It is well wooded with the gall-bearing oak and with fruit and forest trees. It contains many villages, which were formerly inhabited by Chaldean or Nestorian Christians and were very flourishing, but many of them have been deserted by the inhabitants in order to escape the violence of the Kurds and the tyranny of their Turkish governors; most of those who remain have joined the Roman Catholic Church. Around the town and the villages are well-cultivated gardens and orchards. Tobacco, rice, grain, water-melons, fruit, and gall-nuts are among the products, but Kurdish robberies and Turkish oppression afford little encouragement to cultivate the land.

The town is described by Dr. Layard as a heap of ruins; porches, bazaars, baths, and habitations were laid open to their inmost recesses; every part seemed crumbling to ruin, filthy, and nearly deserted; for the population at the time of his visit, in August, had retired to their summer habitations in the mountain valleys. The fort or castle, which is surrounded by walls flanked with towers, is considered of great importance as a key to Kurdistan and is defended by a small garrison. Amadiyah was formerly a place of considerable importance and strength, and contained a very large and flourishing population. It was governed by hereditary pashas, who traced their descent from the Abbasside Caliphs, and were on this account always regarded with religious respect by the Kurds. The ladies of their family enjoyed the title of Khan. Ismail Pasha, the last of these hereditary chiefs defended himself long against the Turks in his inaccessible castle, but at last a mine was sprung under a part of the walls, which the Kurds thought safe from attack, and the place was taken by assault. Amadiyah (which is said to mean 'Town of the Medes') is frequently mentioned by early Arab geographers and historians, and its foundation most probably dates from a very early epoch. Some have asserted that it was called Ecbatana. To a defaced bas-relief on the rock near the northern gate, Dr. Layard assigns the date of the Arsacian kings. Amadiyah is proverbially unhealthy. Fever and agues are very prevalent in summer, at which season the population remove to the neighbouring mountains, in the valleys of which they live in tents and ozailis, or sheds made with boughs. The population has greatly diminished since the place became subject to the Turks.

(Dr. Layard's *Nineveh and its Remains;* Colonel Chesney's *Expedition to the Euphrates and Tigris.*)

AMALFI. The story of the discovery of a copy of the Pandects at the siege of this place, A.D. 1137, is now considered entirely without foundation. (Savigny's 'Geschichte des Römischen Rechts im Mittelalter,' Heidelberg, 1815-31, 6 vols. 8vo.)

AMAND, ST. [CHER.]

AMBLESIDE. [WESTMORELAND.]

AMELANCHIER (the Savoy name of the Medlar), a genus of plants belonging to the sub-order *Pomeæ* (*Pomaceæ*, Lindley), of the order *Rosaceæ*. It has a 5-cleft calyx with lanceolate petals, and an ovary of 10 cells, with a solitary ovule in each. The mature fruit is 3-5-celled, with one seed in each cell. The species are small trees, with simple serrated deciduous leaves, and racemes of white flowers.

A. vulgaris, the common species, is a native of rugged places throughout Europe. It is the *Avonia rotundifolia* of Persoon.

A. Botryapium, the Grape-pear or Canadian Medlar, is a very common plant in Canada; it is also a native of Newfoundland, Virginia, and the higher parts of Columbia. It is a shrub 6 or 8 feet in height, with a purple fruit.

A. ovalis is also a shrub 6 or 8 feet high, and is a native of North America, throughout Canada from Lake Huron to the Saskatchewan and Mackenzie rivers, and as far as the Rocky Mountains. Sir John Richardson says that it abounds on the sandy plains of the Saskatchewan. Its wood is prized for making arrows and pipe-stems, and is thence termed by the Canadian voyageurs 'Bois de Flèche.' Its berries, about the size of a pea, are the finest fruit in the country, and are used by the Crees both in a fresh and dried state. They make a pleasant addition to pemmican, and excellent puddings very little inferior to plum-pudding.

Another North American species is known by the name of *A. sanguinea*. Its fruit is of a blood-red colour.

AMENDMENT. The powers of Amendment possessed by the Superior Courts of Law have been greatly extended by the Common Law Procedure Acts of 1852 and 1854; both of which expressly require that all amendments shall be made which are necessary for the determination in the ensuing suit of the question in controversy between the parties.

AMERICA. In the article AMERICA, in the 'Penny Cyclopædia,' the narrative of discoveries terminates with the voyage of Captain Ross (afterwards Sir John Ross), in search of a North-West Passage. He left England in 1829, and did not return till 1833. He was forced to pass four successive winters in the dreary regions of Boothia Felix, and emerged with his crew from the icy seas when the hope of return had almost been universally abandoned at home. In this expedition, which was entirely a private one, and had been fitted out through the munificence of Sir Felix Booth, a London distiller, some additions were made to our stock of geographical knowledge by the exploration of Prince Regent's Inlet, the Gulf of Boothia, and the country to the west of these seas, which was found to be continuous from Barrow's Strait to the American continent; thus proving the impossibility of a passage to the westward in that direction. The position of the magnetic north pole was likewise one of the discoveries made. Commander Back (now Sir George Back) was sent out in 1833 on a land journey in search of the preceding expedition; and he traced the Back River, named after him. Having returned in 1835, he was again appointed the commander of an expedition in 1836, which was destined to proceed to Wager River and Repulse Bay. This was a most disastrous voyage, the expedition having to pass the winter in the ships tossed about in the ice. No geographical results were gained. During the years 1836 to 1839, Dease and Simpson, two officers of the Hudson's Bay Company, surveyed a considerable line of the northern shores of the American continent, leaving only the southern part of Boothia Gulf, of the entire coast line, unexplored. This latter portion was surveyed by Dr. Rae in 1848. In 1845 one further attempt was undertaken to solve the 300 years' problem of the North-West Passage, when the expedition under Sir John Franklin was despatched to Lancaster Sound. The expeditions which have been sent out in search of Sir John Franklin and his associates, and the discoveries which have been made in the Arctic Regions, are described in the articles NORTH-WEST PASSAGE, *S.* 2, and POLAR COUNTRIES AND SEAS, *S.* 2.

The progress of discovery and settlement in the territories of the United States has proceeded without interruption, and new States and Territories have been established since the article AMERICA was written, which are described under their respective names in the two Supplements. Among the discoveries which have enabled the government of the United States to extend its territories from the eastern to the western side of the continent the most important are those made by Lieutenant Fremont in his exploring expeditions of 1842, 1843, and 1845. The tides of emigration have since swept from the east to the west through the passes of the Rocky Mountains, large acquisitions of territory have been obtained from Mexico, and the important State of California, and town of San Francisco with its capacious harbour, established on the shores of the Pacific Ocean. The discovery of gold in California has led to many important explorations, the Salt Lake City has been founded by the Mormons, and the territory of Utah added to the United States, on the western side of the Rocky Mountains. On the eastern side railroads have been formed in various directions to the extent of more than 20,000 miles; and several important expeditions have been despatched, by order of Congress, to discover the best route for a railway from the Mississippi to the Pacific between the parallels of 32° and 49°. These expeditions, organised by the Secretary of War under various leaders, have contributed very largely to American geography, observations having been made from the Mississippi to the Pacific, between the parallels of 49° and 47°, 41° and 43°, and near those of 38°, 35°, and 32°, touching upon the Pacific Ocean at Puget Sound, San Francisco, San Pedro, and San Diego. On the results of these labours the Secretary of War has reported, that "the route of the 32nd parallel is, of those surveyed, the most practicable and economical route for a railroad from the Mississippi River to the Pacific Ocean."

In British North America, an extensive region, including at least 112,000 square miles, remains almost completely unexplored. This region extends from the head-waters of the Assiniboine River to the foot of the Rocky Mountains, and from the northern branch of the Saskatchewan to the parallel of 49°, which forms the boundary between the British possessions and the United States. The exploration of this portion of British America has been undertaken by Mr. Palliser, a traveller who has spent a considerable time in the neighbouring districts of the Upper Missouri. For the purposes of this expedition the Lords of the Treasury, on the recommendation of the Secretary for the Colonies, have obtained a grant from Parliament of 5000*l.*, and Lieutenant Blakiston of the Royal Artillery, Mr. Bourgeau a botanist, and Dr. Hector a medical gentleman, have been associated with Mr. Palliser. The chief objects of exploration are stated to be, 1, the exploration of the water-parting between the basins of the Missouri and Saskatchewan, and the course of the south branch of the Saskatchewan and its tributaries; 2, the exploration of the Rocky Mountains, for the purpose of ascertaining the most southerly pass across to the Pacific, within the British territory; and 3, to report on the natural features and general capabilities of the country, and to construct a map of the routes. The expedition sailed on the 9th of May, 1857, and having arrived safely at New York, proceeded to Fort William on Lake Superior, and thence to Lake Winnipeg as the starting point of exploration.

The great project of communication by a ship-canal between the Atlantic and Pacific has led to the investigation of routes across the narrow Isthmus of Panama by different exploring parties, but no route has yet been discovered which will admit of a ship-canal being formed without locks or tunnels.

In South America, not long after the important journeys of Spix and Martius, three European travellers crossed the whole breadth of this continent, from the Pacific to the Atlantic, descending the Amazonas, which was first explored by the intrepid Orellana three centuries ago; namely, Lieut. Mawe, R.N., in 1828; Dr. Pöppig, in 1831; and Lieut. Smith, R.N., in 1834. Of these travellers Pöppig added most to our geographical knowledge. He went first to Chili, where he spent two years chiefly in exploring the Andes; he then sailed to Lima, whence he ascended the high table-land of Pasco, and descended thence by the eastern declivity of the Andes to the valley of the Huanuc or Huallaga, where he remained nearly two years, during which he collected a great deal of information respecting the climate, productions, and geography of that country. From the Huallaga he passed down the river Marañon, and thence returned to Europe, after five years (1827 to 1832) of wandering in the wilds of the New World, laden with 17,000 specimens of dried plants, some hundred stuffed animals, many plants before unknown, 3000 descriptions of plants, and many sketches. His work is a most valuable addition to our knowledge of South America.

Nearly simultaneously, namely from 1826 to 1833, another extensive journey was accomplished by Alcide d'Orbigny, who travelled through the Banda Oriental, Patagonia, La Plata, Chili, Peru, and Bolivia, and published a very full account with many illustrations.

More important still are the results of the great Surveying Expeditions of the Adventure and Beagle, 1825 to 1836, commanded by captains King, Stokes, and Fitzroy. The coast-surveys of this expedition were very extensive; in addition to which it brought home a greater mass of accurate geographical information than any expedition since the voyages of Cook and Flinders. Very valuable collections in all departments of natural history were made by Charles Darwin, the naturalist of the expedition.

During the years 1835 to 1844 Sir Robert Schomburgk explored British Guyana and the country to the west as far as the Orinoco and Cassiqniari. In reaching the Upper Orinoco he was enabled to connect his observations with those of Hnmboldt; and thns was completed a connected series of fixed points, astronomically determined, along a line extending from the Atlantic to the Pacific. One of the most interesting of his discoveries is that of the water-lily named *Victoria Regia*, the most beantiful specimen of the flora of the western hemisphere, which has so sncceesfully been broght to Enrope, and has been an object of admiration dnring several years.

In the same region, and extending over the whole of Veneznela, Colonel Codazzi, by order of the government of that conntry, has made a complete snrvey, which is embodied in a valnable work and atlas, execnted at Paris.

Prince Adalbert of Prussia has explored the Xingu and some other rivers and regions in the lower basin of the Amazonas, not before visited by any Enropean.

In the more southern portion of the continent some interesting observations were made by Mr. Pentland in the elevated regions of the Titicaca Lake in 1827 and 1838. Accordiug to these observations the heights of the Sorata aud Illimani, sitnated to the east of the lake, were long given out to be greater than that of Chimborazo, and the highest peaks of Sonth America, bnt it has since been fonnd by the trigonometrical surveys of M. Pissis, a French engineer, that the alleged elevation of Illimani was abont 3000 feet too high; and Mr. Pentland himself, on recalculating his observations, admitted this error, and fonnd that the elevation of Sorata had even been assumed by him 4000 feet too high.

W. Bollaert and G. Smith, who since 1826 had been residing for a considerable time in the province of Tarapaca, Peru, have made us acqnainted with a very remarkable region of Sonth America, a full account of which was pnblished in 1851 by Mr. Bollaert. In it the silver mines of the region along the coast, the Desert of Atacama with its deposits of nitrate of soda, salt, and other saline substances, and the Andes, have been well described. Mount Lirima, the highest peak of that portion of the Andes, is estimated at 24,000 to 25,000 feet, which, if correct, would place it above all other American mountains.

The provinces of La Plata have been well described by Sir Woodbine Parish, in a work pnblished in 1839, of which a second edition, mnch enlarged, appeared early in 1852; and the French traveller Castelnan, accompanied by the English naturalist Weddell, has since explored the little-known regions between the upper course of the Plata and the Peru-Bolivian table-land.

Respecting the snrveys of the American coast, Sir Francis Beaufort, in a retnrn to the Honse of Commons, thns stated their progress in 1848:—"From the eqnator to Cape Horn, and from thence ronnd to the river Plata, on the eastern side of America, all that is immediately wanted has been already achieved by the splendid snrvey of Captain Fitzroy.

"Some parts of the great empire of Brazil we owe to the labonrs of Baron de Roussin and of other French officers; but there is much yet to be done on that coast between the Plata and the Amazon rivers, and again along Gnyana and Veuezuela np to the month of the Orinoco.

"The shores of the mainland between Trinidad Island and the Gnlf of Mexico have been charted and published by the Admiralty; but many of the West India Islands are still wanting to complete a wholesome knowledge of those seas.

"The United States are carrying on an elaborate snrvey of their own coasts, and to the northward of them; a part of the Bay of Fundy has been done by ourselves, as well as all the shores of Nova Scotia, Canada, and Newfonndland; and when these surveys are finished, we shall only want to complete the eastern coast of America, those of Labrador, and of Hudson's Bay, which, being in our possession, ought to appear on our charts with some degree of truth."

Since 1848, Captain Kellett, in H.M.S. Herald, has continued the survey of the western coasts from the eqnator northward, along Central America, Mexico, part of California, and other regions, and has thns completed the entire western coast-line of America. The Americans advance steadily with the surveys of their coasts.

Since the publication of the article AMERICA many political changes have taken place in the governments of North and South America. The present names of the various states, with the area, population, and capital town of each, are stated in the following table—of which however some of the figures are only approximations.

North and South America.

Governments.	Area in sq. miles.	Population.	Capitals.
Danish America (Greenland)	380,000	9,400	Lichtenfels.
French Possessions (St. Pierre, &c.)	118	200	St. Pierre.
Russian America	394,000	66,000	N. Archangel.
British North America	1,800,000	180,000	York Factory.
Canada West	147,382	999,847	Toronto.
Canada East	201,989	890,261	Quebec.
New Brunswick	27,700	200,000	Frederickton.
Nova Scotia, &c.	18,746	800,000	Halifax.
Prince Edward's Island	2134	62,348	Charlotte Town.
Newfonndland	57,000	120,000	St. John's.
Vancouver Isl. & Br. Oregon	218,500	7500	Fort Langley.
United States of North America	3,306,834	23,191,876	Washington.
United States of Mexico	1,038,865	7,200,000	Mexico.
San Salvador	14,000	450,000	Cojntepeqne.
Nicaragua	49,000	430,000	Granada.
Honduras	72,000	380,000	Comagagua.
Gnatemala	28,000	1,100,000	N. Gnatemala.
Costa Rica	17,000	200,000	San José.
Mosquitia	23,000	6000	Blewfields.
British Hondnras	62,740	11,066	Balize.
Veneznela	416,600	1,356,000	Caraccas.
New Granada	380,000	2,200,000	Santa Fé.
Ecuador	325,000	665,000	Quito.
Bolivia	374,480	1,000,000	Chuquisaca.
Peru	580,000	2,400,000	Lima.
Chili	170,000	1,200,000	Santiago.
Argentine Confederation	927,000	800,000	Parana.
Buenos Ayres	200,000	250,000	Buenos Ayres.
Uruguay	120,000	250,000	Montevideo.
Paraguay	74,000	260,000	Asuncion.
Brazil	2,300,000	7,560,000	Rio de Janeiro
British Guiana	76,000	120,695	George Town.
Dutch Guiana	88,500	64,270	Paramaribo.
French Guiana	21,500	30,000	Cayenne.
Patagonia	380,000	120,000	
Total	14,237,088	54,080,463	

AMHERST, WILLIAM PITT, LORD AND 1ST EARL, nephew and sncceesor of the first Lord Amherst [AMHERST, JEFFERY, BARON], was born in 1773. He was sent as ambassador to China early in the present century, bnt was wrecked on his return in the Eastern seas, and with difficulty reached Java in an open boat. He sncceeded the Marquis of Hastings as governor-general of India in 1823. He signalised his administration by the first Birmese war, which was brought to a snccessful issne by the arms of Lord Combermere, and resulted in the annexation of Assam, Aracan, Tenasserim, and other provinces of the Birman Empire to the British dominions. He was created an earl in 1826, and resigned his post in India in 1827, when he was sncceeded by Lord William Bentinck. He spent the latter years of his life in retirement, and died in March 1857, in his eighty-fifth year.

AMIDES and AMIDOGEN. [CHEMISTRY, *S.* 1.]

AMMANIA (in honour of John Amman, a distinguished botanist), a genus of plants belonging to the natnral order *Lythraceæ*. The species are aqnatic plants, with smooth opposite entire leaves, 4-cornered stems, and small pink or red flowers. They are natives of both the New and Old Worlds, and very generally distributed. One species, *A. vesicatoria*, has a strong peculiar smell, and the leaves are very acrid. They are nsed by the native doctors of India for the purpose of raising blisters, which they do in the conrse of half an honr.

AMMELIDE. [CHEMISTRY, *S.* 1.]

AMMELINE. [CHEMISTRY, *S.* 1.]

AMYGDALIN. [CHEMISTRY, *S.* 1.]

AMYLE. [CHEMISTRY, *S.* 2.]

AMYOT, THOMAS, was born at Norwich about 1775, and settled in that city as a solicitor. In 1802 he was appointed law-agent for Mr. Windham in a contested election, and this led, on Windham's becoming Secretary-at-War in 1806 in the Grenville administration, to his being appointed his private secretary. His tenure of this office was something less than a twelvemonth, bnt dnring it he had obtained also one of the ordinary clerkships in the Colonial Office; and in 1807 he was appointed Registrar of Records in Upper Canada, an office execnted by deputy. In 181[illegible] Mr. Windham died; and in 1812 Mr. Amyot published the speeches in parliament of his late patron, with a short sketch of his life. Mr. Amyot's leisure was now devoted to the stndy of the antiquities and history of his country, all his other works being contribntions to the 'Archæologia,' his principal papers being on the Bayeux Tapestry, and on the asserted existence of Richard II. in Scotland. In 182[illegible] he was appointed treasnrer of the Society of Antiquaries, an office which he filled very effectively till within a short time of his death, which took place in London, September 2[illegible] 1850.

ANÆSTHETICS. [MATERIA MEDICA, *S.* 2.]

ANAPA, a sea-port town and fortress of Russian Circassia, situated on the eastern shore of the Black Sea, in 44° 55′ N. lat., 37° 16′ E. long., 20 miles N. from the harbonr of Sudjuk-Kalé, and about 30 miles S.S.E. from the mouth of the Kuban: popnlation, exclnsive of the garrison, abont 3000. It was founded by the Tnrks in 1784, to protect their Tartar subjects on the left bank of the Knban, as also to keep up their relations with the Cancasian tribes. The products of Circassia soon began to circulate throngh Anapa, as they did formerly throngh Taman, which was then recently occupied by the Russians. There is no harbonr, bnt only a roadstead at Anapa. The imports are cotton and woollen cloths, steel ware, nails, glass, salt, &c.; the exports are ox, buffalo, and cow hides; hare skins, furs; tallow, wax, &c.

The fortress of Anapa is bnilt on a projecting crag, the most north-western extremity of the Cancasian Monntains. The surface is smooth and slopes down in an extended plain on the north and east towards the Knban. The walls towards the sea are 425 yards long, and the entire circnmference exceeds 2 miles. To the south-west the walls are built upon a calcareons rock, which rises 65 yards perpendicularly above the sea. Towards the roadstead, which is on the northern side of the town, the white cliffs that line the shore subside. Some bastions and a ditch defend the fortress on the side of the plain. Dnring the Tnrkish possession of the place, abont one-third of the space inclosed by the fortifications was occnpied by 200 shops, several coffee-houses, and cabins built of wood, hnrdles, and mud. It was ill-bnilt, irregularly laid ont, and had a very turbnlent population; bnt it is said to have improved in every respect under the Rnssians.

A body of 8000 Rnssian troops made an nnsuccessful attempt to take Anapa in 1790; in the next year it was taken by assault by General Goudovitch, though defended by 10,000 Turks and 15,000 monntaineers. It was soon after restored to Turkey, bnt the Rnssians seized it again in 1807 and in 1809. It was again restored to Turkey by the treaty of Bukharest. The Russians finally took Anapa, Jnne 23, 1828, after an obstinate defence, and held it till the Rnssian War of 1854-5, when they were obliged to evacnate it; bnt they have since reoccnpied it.

ANAMERTA. [MATERIA MEDICA, *S.* 2.]

ANAS, the Dnck, a genns of birds nnder which Linnæns included a great number of species now separated into several genera by recent natnralists. [DUCKS.]

ANASTATICA, a genus of plants belonging to the natural order *Cruciferæ*. One species, *A. hierochuntina*, is the rose of Jericho. [JERICHO, ROSE OF.]

ANATHERUM, a genns of Grasses, belonging to the group of which species yield fragrant volatile oils. *A. muricatum* is the *Vetian* of the French, and the *Khus* of the Hindoos. Its fragrant roots are employed in making tatties, covers for palanqnins, &c. It is administered medicinally, and has stimulating and diaphoretic qnalities. *A. nardus* is also, on account of the volatile oil it contains, called Ginger-Grass, or Koobel.

ANCON-SIN-SALIDA, a deep and extensive inlet on the western coast of Sonth America, sitnated between 50° 30′ and 52° 30′ S. lat., 72° 30′ and 73° 40′ W. long., is remarkable as bounding the southern extremity of the Andes. The Ancon opens into Smyth Sonnd, which separates the Adelaide Archipelago from the continent of America. It penetrates by a very winding channel (40 miles long. and from 1 to 4 miles wide) through the monntains from Smyth Sound, and expands at its eastern extremity into a large sheet of water, called Kirke Water, which is 20 miles long and 10 miles wide. From the channel several arms branch off north and sonth. The most western, which is called the Canal of the Monntains, runs northward for abont 30 miles. It is screened by steep ranges of mountains, broken here and there by deep ravines, which are filled with frozen snow, and surrounded by extensive glaciers, whence avalanches freqnently descend. The mountain range which incloses this arm on the west is considered to be the sonthern extremity of the Andes. From Kirke Water two deep inlets branch off. One of these, called Last Hope's Inlet, extends first northward and then northwestward, with a total length of abont 30 miles, and a width of 2 to 4 miles, and terminates not far from the northern extremity of the Canal of the Mountains, from which it is separated by a high snow-capped ridge. The other, called Obstruction Sound, runs sonthward for above 70 miles, and is from 3 to 6 miles wide. The western shores, both of Obstruction Sound and of Last Hope's Inlet, are lined with high mountains, in some places covered with perpetnal snow, bnt the greater part of their eastern shores, as well as the eastern shore of Kirke Water, consists of level gronnd, which extends some distance inland, where only a few low hills and some rising ground appear. It is therefore evident that the Ancon-sin-Salida cnts through the whole range of the monntains, and terminates in the eastern plains of Patagonia. (*Surveying Voyages of the Adventure and Beagle.*)

ANCO'NA, a delegation or province in the States of the Chnrch, is bonnded N. and W. by the province of Urbino, E. by the Adriatic, and S. by the province of Macerata. Its greatest length is abont 38 miles, and the breadth is about 16 miles. The area is 408 square miles, and the popnlation in 1843 nnmbered 166,114. The surface is traversed by nnmerons offshoots of the Apennines, which are separated by fertile valleys. Of the rivers which are small, the principal are—the Misa, the lower part of which is in the province of Urbino-e-Pesaro, and enters the sea at Sinigaglia; the Esino, which has its sonrce in the province of Macerata; and the Mnsone, which forms the boundary between this province and that of Macerata. Of the whole area of the province (260,804 acres), 103,016 acres are under cnltivation; 85,780 acres are covered with plantations and copses, and the rest consist of olive-gronnds, meadows, natnral pastnre, forest land, &c., so that the amonnt of absolntely barren land is only 250 acres. The chief agricultnral prodncts are wheat, maize, hemp, hay, tobacco, wine, oil, and beans. Some silk is also prodnced. Sheep and hogs are reared in great nnmbers. There are also many horned cattle.

The province comprises the northern part of ancient Picennm, with a small portion of Umbria; these two provinces were separated by the Æsis, now the Esino, which river also formed the boundary between the Galli Senones and Picennm, and was therefore the northern limit of Italy on the side of the Adriatic nntil this was afterwards extended to the Rnbicon. The province contains only a part of the old Marches of Ancona, which formerly extended from the dnchy of Urbino on the north, to the Marches of Fermo on the south. The capital is ANCONA. The other towns which reqnire notice here are Iesi and Osimo.

Iesi, 15 miles W. by S. from Ancona, near the left bank of the Esino, and about 10 miles from its month, occupies the site of the ancient Umbrian town Æsis or Æsinm, which became a Roman colony, and was famons for its cheese. It gives title to a bishop, and is a walled town of considerable size, with a cathedral, five parish churches, and several convents. Silk and woollen hosiery are mannfactured. The popnlation is abont 6000.

Osimo, the ancient *Auximum*, and a bishop's see, is situated on a high hill in the midst of a beantiful and fertile country, 8 miles S. from Ancona, on the road to Loreto, in 43° 29′ 36″ N. lat., 13° 27′ 30″ E. long.: popnlation about 7000. It is a healthy and well bnilt place, with a cathedral dedicated to St. Tecla; a town-honse containing a mnsenm of ancient statues and inscriptions fonnd in the neighbonrhood; a handsome episcopal palace; and several churches which contain some good paintings. Auximnm, from the strength of its position, was a place of importance in ancient times. The Roman censors had walls built round it B.C. 174, and it became a Roman colony B.C. 157. In the great civil war the partisans of Pompeius seized the town B.C. 49, bnt the inhabitants opened the gates to Cæsar. Under the empire Auximnm became the capital of Picenum, of which it was always one of the strongholds. Belisarius took it from the Goths after a long siege, dnring which he narrowly escaped death. Under the Byzantine empire, Auximnm was one of the cities of the Pentapolis in the Exarchate of Ravenna.

ANCUD, THE GULF OF, extends between the mainland of Sonth America and the island of Chiloe, from 41° 30′ to 43° 30′ S. lat., and from 72° 40′ to 73° 50′ W. long. It communicates with the Pacific on the north of the island by the Narrows of Chacao, which are of considerable depth, but at some places hardly a mile wide. On the sonth of the island of Chiloe it is connected with the Pacific by the wide opening which occnrs between the Chonos Archipelago and the island, which is nearly 20 miles across. This gnlf is nearly 150 miles long (including its expansion towards the north, which is called Reloncavi Sonnd), and at an average 60 miles wide. Its shores are everywhere high, and formed by rocks.

In the middle of the gulf, between 42° 10′ and 42° 50′ are a great number of high rocky islands and islets. The southern part of the Bay of Ancud is in some maps named the Gulf of Corcovado. (*Surveying Voyages of the Adventure and Beagle.*)

ANGLESEY, HENRY WILLIAM PAGET, MARQUIS OF, eldest son of Henry, first Earl of Uxbridge, was born May 17, 1768. He was educated at Westminster school, and Christchurch, Oxford; and entered Parliament as member for the Caernarvon boroughs in 1790. His predilection was however for a military life, and it found free scope at the outbreak of the revolutionary war in 1793, when he eagerly set about raising from his father's tenantry a regiment called at first the Staffordshire Volunteers, but which was admitted into the establishment as the 80th foot. Of this regiment he was appointed lieutenant-colonel on its having made up its complement of 1000 men. At the same time he received corresponding preferment in the army, his lieutenant-colonel's commission bearing date September 12, 1793. In 1794 he joined the army of the Duke of York in Flanders, and greatly distinguished himself during the remainder of that campaign.

On his return to England, Lord Paget was transferred to the command of a cavalry regiment, and commenced the career which at no distant day caused him to be regarded as the first cavalry officer in the service. As commander of the cavalry he accompanied the Duke of York into Holland in 1799. This short and disastrous campaign afforded few opportunities of acquiring distinction, but in the general attack Lord Paget succeeded in defeating a much superior body of the enemy's cavalry; and in the retreat, where he occupied the rear, he gained a signal triumph over a much larger force under General Simon. From this time he remained at home diligently occupied in training the regiment of which he was colonel, and in carrying out the system of cavalry evolutions which he had introduced, until near the end of 1808, when, having previously been made major-general, he was sent into Spain with two brigades of cavalry to join the army of Sir John Moore. In forming this junction General Paget was perfectly successful, and on the road he succeeded in cutting off a party of French posted at Rueda—this being the first encounter between the English and French in Spain. On joining Sir John Moore the cavalry under Lord Paget was pushed forward, and on the same day, December 20, came up with a superior body of French cavalry, and defeated it, taking above 150 prisoners, including two lieutenant-colonels. These victories gave the English cavalry an amount of confidence in themselves and their commander, which in the subsequent retreat was of the utmost value. During the retreat Lord Paget with his cavalry formed the rear-guard. After the infantry and heavy artillery had quitted Benevente he received intelligence that the enemy had arrived, and that their cavalry were crossing the Esla. Lord Paget hastened to the ford, and directed the 10th Hussars under General Stewart to charge the Imperial Guard, who had crossed the stream. The French were driven back with considerable loss in killed, wounded, and prisoners, among the latter being General Lefebvre Desnouettes, commander of the Imperial Guard. At the battle of Corunna Lord Paget had the command of the reserve, and his charge in support of the right wing, which was menaced by a far superior force, decided the fortune of the day.

Lord Paget returned to England in 1809, and did not again serve abroad during the Peninsular war. In 1810 he was divorced from his first wife, by whom he had had eight children. Soon after the divorce Lady Paget married the Duke of Argyll, and Lord Paget married Lady Cowley, who had just been divorced from Lord Cowley. In 1812 he succeeded, by the death of his father, to the title of Earl of Uxbridge.

In the early part of 1815 the Earl of Uxbridge commanded the troops collected in London for the suppression of the corn-law riots; but a more important service soon devolved upon him. When Napoleon escaped from Elba, and startled Europe by the ease with which he re-assumed the imperial crown, the armies of the allied sovereigns were at once set in motion against him. The Earl of Uxbridge was appointed commander of the cavalry of the English army, and his management of this arm of the service excited general admiration. At the battle of Waterloo his gallantry, as well as his skill, was conspicuous amidst the almost unequalled gallantry of which that field was the theatre. It was the final charge of the heavy brigade, led by the earl, that destroyed the famous French Guard, and with it the hopes of the emperor. Almost at the close of the battle a shot struck the earl on the knee, and it was found necessary to amputate his leg. The limb was buried in a garden by the field of battle, and some enthusiastic Belgian admirers erected on the spot a monument, with an inscription commemorating the circumstance, which is always one of the objects shown to visitors to Waterloo. The service rendered by the earl at Waterloo was generally recognised and duly rewarded. Immediately the despatches of the commander-in-chief were received the earl was raised to the dignity of Marquis of Anglesey, and nominated a Knight Grand Cross of the Order of the Bath; while he received from the emperors of Austria and Russia, and other European sovereigns, corresponding knightly dignities. In 1818 he was elected Knight of the Order of the Garter; in 1819 he attained the full rank of general; at the coronation of George IV. he held the office of Lord High Steward of England; and in 1826 he received the sinecure office of Captain of Cowes Castle.

When Canning became prime minister, April 1827, the Marquis of Anglesey formed one of his cabinet, having succeeded the Duke of Wellington as Master-General of the Ordnance; but this office he resigned in the following spring to become, under the ministry of the Duke of Wellington, Lord-Lieutenant of Ireland. To the duties of this important station the marquis addressed himself with characteristic energy, and by his zeal, impartiality, and ardent temperament, won a remarkable share of popularity. But his ardour outran his discretion. He had already in conversation expressed opinions which the ministry regarded as imprudent, and found to be inconvenient; and when, in December 1828, he wrote a letter to the Roman Catholic primate directly favourable to Roman Catholic emancipation, he was at once recalled. The day of his departure from the castle was kept in Dublin as a day of mourning; the shops were closed, business was suspended, and his embarkation was attended by large numbers of all classes of the citizens. In the House of Lords the marquis was a warm advocate of the measure which his letter had done much to hasten forward. Earl Grey became prime minister in November, 1830, and the Marquis of Anglesey was restored to his vice-regal office. But his popularity did not return to him. He set his face against the proceedings of O'Connell, and his former services were forgotten. The coercion acts which he thought it needful to obtain for securing the public peace in Ireland led to great dissatisfaction: misunderstandings and recriminations occurred between O'Connell, who declared himself tricked, and the ministry, and in consequence Earl Grey resigned July, 1833; and with him the Marquis of Anglesey, who was regarded as the cause of the ministerial break-up, also quitted office. Of the thorough honesty of purpose of the marquis's administration of his vice-regal functions, after the temporary clamours against him had subsided, there has been nowhere any doubt. That he displayed any high order of statesmanship there can be no pretension raised. The institution by which his tenure of office is most likely to be remembered is the Irish Board of Education, which was originated and carefully fostered by him, and which has proved one of the greatest benefits conferred on Ireland in recent years.

From this time the marquis took little part in public affairs until the formation of the administration of Lord John Russell in July, 1846, when he again became Master-General of the Ordnance; the duties of which office he sedulously performed till February, 1852, when the Russell ministry was replaced by that of Lord Derby. He was made colonel of the Horse-Guards in 1842, and was advanced to the dignity of field-marshal in 1846. He died full of years and honours April 29, 1854. By his first wife the Marquis of Anglesey had issue two sons and six daughters; by his second wife he had six sons and four daughters. He was succeeded in his title, and as lord-lieutenant of Anglesey, by his eldest son, the present marquis.

ANGOULÊME, DUC and DUCHESSE D'. *Louis Antoine de Bourbon*, Duc d'Angoulême, and afterwards Dauphin of France, the son of the Comte d'Artois (afterwards king by the name of Charles X.), and of Marie Thérèse de Savoie, was born at Versailles on the 6th of August, 1775, and died at Göritz on the 3rd of June, 1844. He was fourteen years of age when the revolution broke out. The Comte d'Artois, in order to protest by his absence against those concessions for which he blamed his brother, the king, emigrated in 1789; his two sons followed him to Turin, the court of their grandfather, where for some time they devoted themselves to the military sciences. In 1792 the young duke received a command in Germany, but attained no distinction. The ill success of this campaign induced him to return to a state o inaction, in which he continued until 1814. In 1799 he married his cousin, the unhappy orphan of the Temple, whose whole life had been one continued series of misfortunes.

Marie Thérèse Charlotte, the daughter of king Louis XVI. by his marriage with Marie Antoinette of Austria, and who from her cradle bore the title of Madame Royale, was born at Versailles on the 19th of December, 1778, and died October 19th, 1851. She was not fourteen years old when the events of the 10th of August, 1792, overthrew her father's throne, and drove her entire family from the pomps of Versailles to the prison of the Temple. Her parents were led thence to the scaffold; and the young princess had successively to deplore her father, her mother, her aunt Elizabeth, and her brother. At last Austria remembered the grand-daughter of Marie Thérèse; negociations were made in her favour; and on the 26th of December, 1795, at Riehen, near Bâle, they effected an exchange of the daughter of Louis XVI. for four members of the National Convention. Arrived at Vienna, the princess remained there more than three years, living on a legacy bequeathed to her by her aunt, the Duchess of Saxe Teschen. She married her cousin at Mittau on the 10th of June, 1799. The newly-married couple remained at Mittau till the commencement of 1801. They then sought an asylum at Warsaw. Fortune tossed them from place to place. Given up by Prussia, they returned to Mittau in 1805; and the following year the Emperor Alexander, in his turn, abandoned them. England, to which the power of Napoleon could not reach, alone offered them a lasting refuge. Here Louis XVIII. repaired towards the end of 1806, and some time after purchased a residence at Hartwell, in Buckinghamshire, where all the family were soon re-united. There the Duc and Duchesse d'Angoulême lived in the most profound retirement, until the Anglo-Spanish army passed the Pyrenees, when the Duc d'Angoulême joined it, having landed at a Spanish port on the Mediterranean.

After the restoration of the Bourbon family the Duc and Duchesse d'Angoulême were at Bordeaux, which was regarded as an eminently royalist town, and very favourable to the Bourbon cause, when on the 9th of March the news of Napoleon's landing was conveyed to them from Paris. Having been appointed the preceding year colonel-general of the Cuirassiers and Dragoons, and high-admiral of France, the duke then received the extraordinary powers of a lieutenant-general of the kingdom. He immediately formed a government for the southern provinces, collected troops, and on the road to Lyon gained several advantages over the Bonapartists. On her part, the duchess evinced great resolution; reviewed the troops, visited them in barracks, and endeavoured to rekindle the dying spark of love for the Bourbons. It was no doubt concerning this conduct that Napoleon remarked of her, that she was "the only man of her family." Her efforts were however as fruitless as those of her husband. But the second abdication of Napoleon after the battle of Waterloo decided the question without a civil war.

On the accession of Charles X., September 16th, 1824, the Duc d'Angoulême took the ancient title of Dauphin.

The decrees of the 25th of July, 1830, re-opened the road which was for the third time to conduct the royal family to the land of exile. They arrived in England on the 23rd of August, and were received as private individuals. Charles X. asked and obtained leave to take up his abode, when at Edinburgh, in Holyrood Palace.

They soon after removed to the continent, and fixed their residence at Göritz, in Hungary. The duchess survived her husband seven years.

ANILINE. [CHEMISTRY, *S.* 2.]

ANISOINE. [CHEMISTRY, *S.* 2.]

ANISOLE. [CHEMISTRY, *S.* 2.]

ANISYLE. [CHEMISTRY, *S.* 2.]

ANNI, a ruined city in the Kars district of Turkish-Armenia, is situated on the right bank of the Arpa, a feeder of the Araxes, in 40° 25′ N. lat., 43° 34′ E. long., at a distance of about 65 miles N.W. from Erivan. It was founded in the 6th century, and became the residence of the Armenian kings from the 8th century till the year 1064, when it was taken and ravaged by Alp Arslan. The Armenian patriarchs also resided in Anni from 993 to 1064. The town stood upon an area terminating on two sides in abrupt and rocky declivities; on the south is a deep ravine, in the bottom of which the Arpa flows: the area is open towards the north, on which side it is defended by a massive wall flanked with numerous towers. The towers are remarkable for the gigantic crosses formed by huge blocks of red sandstone let into the masonry. The walls, towers, and churches are in good preservation; so much so, that at a distance the city does not seem deserted. Besides the buildings named there are several baths, a mosque, and a palace. All the public buildings display much splendour and architectural beauty, and the fretwork of the arches is very rich. Some of the churches are decorated with rude wall-paintings representing scriptural and legendary subjects. There are inscriptions on most of the buildings chiefly in Armenian, but some are Turkish. The private houses of Anni are supposed to have been of an humble description, as none of them are left standing, and the whole area on which they stood is covered merely with mounds of loose stones. The city continued to be inhabited till A.D. 1319, when its ruin was completed by an earthquake. (Wilbraham's *Travels in the Trans-Caucasian Provinces of Russia.*)

ANNUITY. The restrictions imposed on contracts for annuities by the Statute 53 Geo. III., c. 141, have been removed, and parties are now left perfectly free to make their bargains in the terms on which they can agree. (17 and 18 Vict. c. 90.)

ANOPLURA, a family of insects, including the *Aptera* of Linnæus, and the various forms of *Pediculus* [PEDICULUS] and Parasitic Insects of other authors. The researches which were commenced on this family by Dr. Leach have been carried on by Mr. Denny, and resulted in the discovery of a vast number of new forms. The result is that it has been found that every animal is infested with, or, for some wise purpose is accompanied by, one or more creatures belonging to this family, having a peculiar form in each species. Nearly 500 different forms of these curious insects, all formed on the type of the common human louse, have been described by Mr. Denny, in the catalogue of the specimens which at present exist in the British Museum. In most cases but one species of the parasite exists on one species of animal, but there are instances, as in the eagles and gulls, in which a species of the bird is attacked by five species of *Anoplura*. The best series of illustrations of these insects which exist are contained in Denny's 'Anoplura Britannica,' published in 1842.

ANTARCTIC REGIONS. [POLAR COUNTRIES AND SEAS, *S.* 2.]

ANTHERI'DIA, in Botany, organs found in many of the tribes of Cryptogamic or Flowerless Plants. They have been observed in the Characeæ, Horse-Tails, Ferns, Mosses, and Algæ, and are supposed to represent the anthers in Phanerogamic or Flowering Plants. In the cells of which they are composed certain moving filaments are observed, which have received the name of *Phytozoa* or *Spermatozoids*. Many of these phytozoa move by cilia attached to their surface. For the nature of their functions, development, and forms, see REPRODUCTION IN PLANTS AND ANIMALS, *S.* 2.

ANTHRI'SCUS, a genus of plants belonging to the natural order *Umbelliferæ* and the tribe *Scandicineæ*. It is known by possessing little or no calyx, with heart-shaped petals bent down at the point; a fruit narrowed below the short beak, and without any ridges. The beak has five ridges.

A. sylvestris, Wild Chervil, is known by its terminal stalked umbels, and its linear glabrous fruit with a short beak. It is a common weed in hedges and banks throughout Europe.

A. Cerefolium (*Scandix Cerefolium*), the Garden Chervil, is probably an escape from cultivation in England. It is common enough in waste places. [SCANDIX.]

A. vulgaris has the umbrels lateral and stalked, and an ovate hispid point. The leaves are slightly hairy. It is common in the waste places of Great Britain. (Babington's *Manual of British Botany.*)

ANTHRO'POLITES, the name given to Human Fossil Remains. Although at one time it was thought that human remains were often found fossilised, the investigations of modern anatomists have shown that in most of these cases the supposition has been false. Daubenton first demonstrated that some bones which had long been regarded in Paris as the remains of a gigantic human being belonged to a lower tribe of beings. The researches of Cuvier gave a clue by which all cases might be tested, and most of the earlier instances brought forward have been referred to their correct types.

Human fossil bones have, however, been discovered in the

Belgian bone-caverns, with bears, rodents, &c., and are figured hy Dr. Schmerling, in his interesting work on the hones found iu a cavern near Liège.

Dr. Buckland ('Bridgewater Treatise') remarks that frequent discoveries have heen made of human houes and rude works of art in natural caverns, sometimes inclosed in stalactite, at other times in heds of earthy materials, which are interspersed with hones of extinct species of quadrupeds. These cases, he thinks, may he explained by the common practice of mankind in all ages to hury their dead in snch convenient repositories. "The accidental circumstance," continues Dr. Buckland, "that many caverns contained the bones of extiuct species of other animals, dispersed through the same soil in which human hodies may, at any snhseqnent period, have been huried, affords no proof of the time when these remains of men were introduced. Many of the caverns have been inhahited hy savage tribes, who, for conveniеuce of occupation, have repeatedly disturbed portions of soil in which their predecessors may have been hnried. Such disturbances will explain the occasional admixtnre of fragments of human skeletons and the bones of modern qnadrupeds with those of extinct species introdnced at more early periods and hy natural causes. Several accounts have heen published within the last few years of human remains discovered in the caverns of France and in the province of Liège, which are described as heing of the same antiqnity with the bones of hyænas and other extinct qnadrupeds that accompany them. Most of these may probahly admit of explanation by reference to the causes jnst enumerated. In the case of caverns which form the chanuels of subterranean rivers, or which are subject to occasional inundations, another cause of the admixtnre of hnman hones with the remains of animals of more ancient date may be found in the movements occasioned hy running water."

The same learned author observes that the most remarkable and only recorded case of human skeletons imbedded in a solid limestone rock is that on the shore of Guadaloupe, adding that there is however, no reason to consider these bones to be of high antiquity, as the rock in which they occur is of very recent formation, and is composed of agglutinated fragments of shells and corals which inhahit the adjacent water. Such kind of stone is frequently formed in a few years from sand-banks composed of similar materials, on the shores of tropical seas. ('Bridgewater Treatise,' vol. i.) One of these skeletons, describhed hy Mr. König (Phil. Trans.,' 1814) is in the British Mnseum. See further as to the rock in which the skeletons are imbedded, 'Linn. Trans.,' 1818, vol. xii.

Dr. Lund published, some years ago, the discovery of human remains with those of *Megatherium*, &c.; and he was of opiniou that the former were of the same epoch as those of the latter. The cranium had the peculiar shape which distinguishes the ancient Peruvian.

ANTIORIN. [CHEMISTRY, *S.* 1.]

ANTOMMARCHI, FRANCESCO, a snrgeon of some reputation as an anatomist, hut more likely to he remembered iu his capacity of physician to Napoleon I. at St. Helena. Antommarchi, a native of Corsica, studied medicine at Pisa, and was towards the close of the year 1812 elected anatomical dissector to the hospital of Santa Maria Nuova of Florence, attached to the university of Pisa. This appointment reudered him the principal assistant of his anatomical teacher, Mascagni. In 1818 the Chevalier Colonna, chamherlain to Madame Mère, made overtures to Antommarchi for the purpose of inducing him to accept the appointment of snrgeon to the Emperor Napoleon I., and he accepted the offer. The history of Antommarchi, from this time till his return to Europe in 1821, is part of the biography of Napoleon. Immediately on his return he was involved in a dispnte with the heirs of Mascagni, who wished to reclaim from him the plates and manuscript of the 'Grande Anatomia,' which he had undertaken to edit, and he eventually gave them up. In 1825 a series of anatomical plates, the size of life, by Autommarchi, were announced as on the eve of puhlication at the lithographical estahlishment of Connt de Lasteyrie at Paris. The heirs of Mascagni forthwith puhlished a letter to the connt, in which they asserted that Autommarchi's lithographed drawings were mere copies from the plates of Mascagni. A favonrable report of the work however was presented to the Académie des Sciences hy Mageudie and Duméril. Fifteen parts of this work were published with the title 'Planches Anatomiqnes du Corps Humain,' Paris, 1823-1826, royal folio, including forty-five finished and thirty-five outline lithographed drawings of inconsiderable merit. The controversy appears to have died away, through lapse of time, without a positive decision heiug pronounced iu favour of the claims of either party. During the Polish revolution he went to Warsaw, where he was appointed general inspector of military hospitals.

The following acconnt of another curious controversy, in which Antommarchi was engaged, is translated from the 'Nouvelle Biographie Universelle,' Paris, 1852:—"Soon after the revolutiou of Jnly," says Dr. Bourdon, "Antommarchi rememhered that he had taken a cast of the head of the dying hero. Now, about nine years after his return from St. Helena, he first decided on puhlishing this cast of the emperor. It created a great sensatiou [in Paris], and for a time drew Antommarchi from his obscurity, probably also relieving him from pecuniary distress; hut at the same time it greatly injured his reputation. As it did not appear from this cast that Napoleon's skull presented that phrenological conformation which, according to Gall, ought to have iudicated the most glorious and least contested of his faculties, the adversaries of that scieuce made use of it as an argument against Gall and Spnrzheim; and thence sprang the disputes which still continue. The fact is, that there were some reasons for doubting whether the cast puhlished by Antommarchi had really been moulded at St. Heleua after the death of the emperor; it was found to bear more resemblance to Bonaparte the first consul than to the illustrious exile, worn out hy six years of sorrow and want of sleep, emaciated hy disease, and with the furrows ploughed by 52 years. Neither does this cast of Antommarchi accord with what Dr. O'Meara aud General Montholon have related of the thinness of Napoleon, and of the alteration of his features in the latter part of his existence. Suspicions were set afloat of Antommarchi's veracity; it was affirmed that he had uulawfnlly assumed the title of professor, and that nobody had heen able to fiud two works that he said he had published—the one a treatise on the cholera, the other concerning physiology. The advocates of the new science of phrenology, in their spiteful ardour, went so far as to throw a suspicion npon the ideutity of the cast considered with regard to the material. 'Your cast,' they said to him, 'is of a fine plaster; it is white and pure, such as is only to be seen at Lucca, where beautiful statuettes are formed of it; you could not have found any such at St. Helena.' Wearied with all these vexations, Antommarchi ahout 1836 took the desperate step of euigratiug, in order to practise homœopathically at New Orleans, and afterwards at Havanna." He died at St. Antonio in Cuba, about 1844.

ANUS, DISEASES OF. [SURGERY, *S.* 2.]

AORTA, DISEASES OF, [SURGERY, *S.* 2.]

APIIN. [CHEMISTRY *S.* 1.]

APIUM. [CELERY.]

APOPHYLLIC ACID. [CHEMISTRY, *S.* 1.]

APPERLEY, CHARLES JAMES, a writer on sporting suhjects of considerahle reputation, hetter known by the pseudo-name of *Nimrod*, was the second son of Thomas Apperley, a Welsh conntry gentleman, and was born at his father's seat of Plâsgronow, in Denhighshire, in the year 1777. At Rughy school he acquired some knowledge of the classical languages, and much more of the sports of the field. In 1801 he married the daughter of William Wynne, Esq., and in 1804 he took up his resideuce at Bilton Hall, once the country seat of Addison, in Warwickshire. Here he devoted himself so entirely to the chase that for some years his only pursuit was that of a fox-hunter. He often rode thirty or forty miles to distant covers, and he contrived to defray the expenses of the sport hy disposing of hunters, after he had ridden them for some time, to those of his friends whose knowledge of the horse was not so intimate as his, and who therefore could uot trust their own judgment in the purchase of an untried animal. In 1821 he removed into Hampshire, and commenced farming on a large scale; and in the same year he began to write for the press. His contrihutions to the 'Sportiug Magazine,' especially his Hnnting Tours, attracted so mnch attention that the circnlation of the work was doubled in two years; and Mr. Pitman, the proprietor of the magazine, not only remunerated him handsomely, hut also paid the expenses of his tours, and kept for him a stud of huuters. On Mr. Pitman's death differences followed, which led to a suit hy his representatives for money advanced, the result of which was that, to avoid a prisou at home, Nimrod was compelled to take np his residence in France. In

1830 Mr. Apperley established himself at a château called St.-Pierre, near Calais, where he chiefly resided for the remainder of his life, supporting himself by his pen. He died in London on the 19th of May, 1843.

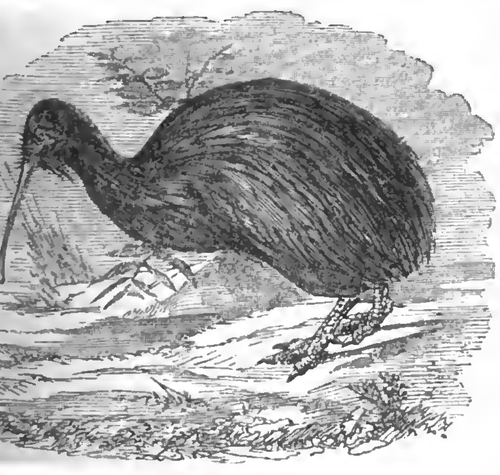
Nimrod's superiority consisted in his perfect knowledge of his subject, and in a certain air of good humour, which won upon the reader. His works are made up almost entirely of anecdote, and partake of a gossiping character. His knowledge of fox-hunting could not be disputed, for previous to his leaving England he had hunted with no less than eighty-two different packs, in every quarter of Great Britain.

Almost all Mr. Apperley's works were written for periodicals, but many afterwards appeared in a collected shape. 'The Chase, the Turf, and the Road,' may be classed as Nimrod's best production. Published separately in the 'Quarterly Review,' in 1827, their appearance in so grave a periodical excited no small sensation. The liveliness with which they were written however carried them through triumphantly, and the result was a considerable addition to the number of Nimrod's admirers, as a consequence of his introduction to a new and wider circle of readers.

APTENODYTES. [PENGUINS.]

APTERYX, a genus of Struthious Birds, inhabiting Australia and the islands of New Zealand. It was first described by Dr. Shaw, who regarded it as an extinct form of bird. It evidently belongs to a group of birds that were destined to live on the earth, only as long as they were free from the attacks of carnivorous enemies endowed with greater powers of motion than themselves. Numbers of wingless birds, not belonging to the Struthious division, as the Dodo and Solitaire, seem already to have become extinct; whilst the smaller congeners of the *Dinornis* are suffering in like manner. The Apteryx is not however extinct, as many stuffed specimens exist in the museums of England; and a living specimen has been exhibited in the gardens of the Zoological Society, Regent's Park. Of all birds at present known the Apteryx appears to have the wings the most reduced to their simplest rudiments. Its general form is that of the Penguin, and in size it is seldom quite so big as our common goose. The beak is very long and slender, marked on each side with a longitudinal groove, and covered with a membrane at its base. It differs from other birds in the completeness of its diaphragm, and in the absence of abdominal air-cells. The bones are not hollow, as is mostly the case in birds; the sternum is very small, and the ribs are extraordinarily broad; the feathers have no accessory plume, and their shafts are prolonged beyond the back; the feet have a short and elevated hind-toe, of which the claw alone is externally visible.

The native name of this bird is *Kiwi-Kiwi*, given it on account of its peculiar cry. It is a nocturnal bird, and preys on snails, insects, and worms. Whilst at rest it has the singular habit of resting on the tip of its bill, which is its most characteristic position.



Apteryx (*A. australis*).

It runs with considerable rapidity, and when hunted by dogs it makes a hole in the earth for the purpose of concealment, or it retires into the natural cavities of the rocks. When attacked it defends itself with considerable vigour. The natives hunt it for the sake of its skin, which is used by the chiefs for their dresses, and on this account it is highly valued.

AQUARIUM, a contraction for *Aquavivarium*, a term applied to arrangements of living aquatic animals and plants inhabiting either fresh or salt water. Although it has been known from the earliest times that animals living in water may be kept in small glass vessels for exhibition by the daily supply of fresh-water, the discoveries of modern chemistry have pointed out how animals may be kept living in only limited quantities of water which never demand renewing. The possibility of accomplishing this depends on the absolute balance in nature which exists between the animal and vegetable kingdoms. The one set of these beings are engaged in giving off what the other requires, and in taking up what the other rejects. It is thus that the carbonic acid which is thrown off from the tissues of animals is taken up by plants, and thus prevented from contaminating the atmosphere; whilst the plant gives off oxygen gas, and supplies the atmosphere with this element of its composition which is necessary to the life of animals. The relations which are thus found to exist on the large scale of the whole surface of the earth, are found also to occur in a jar of water. If an animal is placed in pure water it quickly exhausts the oxygen it contains, and gives out into it carbonic acid gas; the consequence is, that it dies. But if we place with the animal some plant that lives in water, it will be found that the carbonic acid given out by the animal will be taken up by the plant, and that the plant will give out oxygen in its place. Thus the water becomes cleared of its injurious compound, and the needed element, oxygen, is supplied. Such an arrangement on a small scale is called an Aquarium.

The first experiments were made with fresh-water by Mr. N. B. Ward, and one of the earliest accounts of such an arrangement was given by Mr. Warington, chemist to the Apothecaries' Company. The latter found out, however, that it was not sufficient to have simply any kind of plants and animals; but that, in order to maintain the balance correctly, it was necessary that certain animals which lived on decomposing vegetable matter should be present. At certain seasons of the year the tendency to decomposition in the water-plants becomes so decided that the water would be rendered impure if this decomposition was not arrested. The cure for this was found in the addition of Fresh-Water Mollusca to the jars containing such fish as the gold-carp and stickleback, and such plants as the *Valisneria spiralis*, *Callitriche*, &c. The best kind of snails for this purpose are the various species of *Planorbis*. Not only is it necessary that this latter precaution be taken to ensure the success of the experiment, but it is of importance to guard against the preponderance of animal life. Although in most cases it appears that there cannot be too many plants for the health of the animal as long as they grow healthily and do not decompose, yet it often happens that the excess of animals over plants in a given space will destroy the balance, and lead to the destruction of life.

Amongst the fresh-water plants adapted for growing in the Aquarium are the *Valisneria spiralis*, the various species of *Chara*, *Anacharis Alsinastrum*, *Stratiotes Aloides*, *Callitriche autumnalis*, *C. vernalis*, *Myriophyllum spicatum*, and *Ranunculus aquatilis*. Such jars afford a good opportunity for cultivating the various species of fresh-water Confervæ, which all assist in keeping the water pure.

Although these results have been known for many years, it is only recently that any attempts have been made to carry out the same plan with regard to marine animals and plants in sea-water. The difficulties, however, are greater in maintaining the balance between the plants and animals in sea-water than in fresh. This arises from the more sluggish life, both of marine plants and animals, and the greater amount of disorganised matter which they throw from their surfaces. By care in the selection of sea-weeds, avoiding those which are large and throw off much matter from their surface, and not overcrowding the water with animal life, jars or tanks containing sea-animals and sea-plants can be easily managed. Mr. Warington recommends green seaweeds, such as the species of *Porphyra*, &c. Mr. Gosse speaks favourably of *Chondrus crispus*, *Iridæa edulis*, and the *Delesseriæ*. In jars or tanks containing these plants various forms of sea-animals have been successfully kept for many months.

The greatest experiment of this kind which has hitherto been attempted is in a large glass-building that has been erected in the gardens of the Zoological Society, Regent's Park. It was opened to the public in May, 1853. This building contains an area of 60 feet by 25 feet. The sides of this parallelogram are bounded hy reservoirs of plate-glass, each being abont 6 feet in length and 2 feet 6 inches in depth. They are placed at a height of ahont 3 feet from the ground, so that each division presents as it were a suhmarine picture 'on the line,' and may he approached so closely that the minntest animals not microscopic, may be watched with the most perfect success, under circumstances which differ as little as possihle from those of nature. The whole of these tanks are snpplied with gravel, sand, rocks, and sea-weed, so as to imitate the rock-pools left on the sea-shore hy a receding tide, which indeed they may he said to represent; hut with this great advantage to the ohserver, that instead of looking vertically into a cavity in which the light becomes less and less in proportion to the depth, he has here the means of examining each animal in its turn, under an effect which is not only most delightful in itself, hnt which, the water being seen in section throngh perfectly transparent walls, affords the best possihle position for investigating the structure and functions of the living heings contained in it.

The tanks contain fresh-water animals and marine animals. The fresh-water tanks present all the more common species of British Fishes, as the Pike, Tench, Perch, Roach, Rudd, Carp, Eel, Sticklehack, Minnow, Gudgeon, &c. Some of the larger forms of fresh-water Crustacea, as the Crawfish, have also been introduced. With these are placed a large variety of the fresh-water Mollnsca, helonging to the genera *Limneus*, *Planorbis*, *Anodon*, *Unio*, &c. These tanks have been occupied since Christmas, 1852, with scarcely any loss.

Amongst the Radiate Animals none are more remsrkshle for their power of resisting destruction than the *Actiniadæ*, and all experimenters sgree that they are amongst the animals which may be most sneccssfnlly kept in the Marine Aqnarium. All the more common British species are now to he seen in the Regent's Park, and some of remarkahle size and beanty. The Sertularian Zoophites and the Polyzoa are also there, hnt their animal inhahitants are too minnte to be seen with the naked eye. Specimens of the *Echinodermata*, including several forms of Star-Fishes (*Asterias*), the Sun-Star, the common Sea-Egg, the *Holothuriæ*, and other rare forms of this class of animals have been from time to time introduced.

As was to be expected, the *Mollusca* thrive. In the sea they play the same part as in the fresh-water: they are the scavengers of the ocean. The Pinna, the Oyster, the Pecten, the Cockle, amongst hivalves; and the Whelk, the Periwinkle, with many other nnivalves, have demonstrated how large a field of observation is in store for those who study the Mollusca. Several species of those gems of the ocean, the Nudihranchiate Mollusca, whose forms and colonrs are only known to ns through the great work of Alder and Hancock, have been successfully kept alive; whilst the red leaves of the species of *Rhodymenia* have been starred with their eggs. Various forms of Ascidian Mollusca have lived, and complete the evidence that this great group of animals may he watched in their living habits as easily as their shells may be examined in a cahinet.

The *Articulata* have been represented in these tanks hy species of Lohster, Crab, Shrimp, and Prawn. Thongh many of these are inhabitants of the deep ocean, and only reward the labonrs of the dredger, yet they live perfectly well in the shallow lodgings provided for them hy the Zoological Society. These facts demonstrate that amongst the Invertehrate trihes there are none whose hahits may not be stndied in the Aqnarinm.

With regard to fish it is fonnd that those which live in shallow water thrive hest in the Aqnarium. The Cork-Wing (*Crenilabrus Cornubicus*), the Fifteen-Spined Sticklehack, the Long-spined Cottus, two species of Blenny, the Gohy, the Grey Mullet, and the Flat Fish have lived remarkably well.

(*Athenæum*, May 28, 1853; *Annals of Natural History*, May, 1853; Gosse, *A Naturalist's Rambles on the Devonshire Coast*; Dalyell, *Remarkable Animals of Scotland*; Lankester, *The Aquavivarium*.)

AQUILA. [FALCONIDÆ.]

ARABGIR, a town of Asia Minor, in the pashalik of Sivas, is situated on an elevated plateau hetween the Göl-Dagh and Sari-Chi-Chak hranches of the Anti-Tanrus [ANATOLIA]; at a distance of 16 miles N.W. from the junction of the Kara-Sn and Murad-Su, on the caravan ronte from Aleppo to Trehizond, from which places respectively it is distant 270 and 198 miles. It is huilt amidst a forest of fruit-trees, among which the White Mnlberry is most common. The fruit of the mulberry is eaten fresh, or nsed for making hrandy, or it is made into a sweetmeat called Petmez, which is common all throngh Armenia. The soil in the neighbourhood where it is free from rocks yields fine crops of wheat. The climate is cold in winter, and mnch snow falls. The town contains 4800 Tnrkish and 1200 Armenian families. A few years ago the Armenian population had 1000 hand-looms at work, weaving cotton goods from British yarn. This industry and the caravan trade rendered Arabgir a thriving place. In the snrrounding highlands, which are bare and barren, iron-ore is ahundant; and near the spot where the above-named two rivers meet and form the Euphrates, are the lead and copper-mines of Kaben-Maden. (*Royal Geographical Journal.*)

ARAGO, FRANÇOIS JEAN DOMINIQUE, was born in the commnne of Estagel, near Perpignan, province of Ronssillon (now the department of the Eastern Pyrenees), on the 26th of Fehrnary, 1786. His father, a licentiate in law, supported a numerons family on the income derived from a small landed property. François, the son, acquired the rndiments of reading, writing, and vocal music at the primary school of his native place, and in private lessons at home. He became an eager reader, and at an early age conceived a taste for a military life, which was nourished by the continual passing of troops on the march to or from the frontiers of Spain. When hut seven years old he attacked with a lance the leader of a few Spanish troopers who had ridden hy mistake into the village after a hattle, and was only saved from a sahre-stroke hy the arrival of the neighhours armed with hsy-forks. His father having been appointed Treasurer of the Mint in Perpignan, the family removed to that town, where the boy entered as ont-door pnpil at the municipal college, and pursning his literary stndies, made himself acqnainted with the classic authors of his native country. Bnt walking one day on the rampsrts, a little incident occurred that confirmed his military inclinations. Seeing a yonthful officer directing the repairs of the walls, and surprised at one so young wearing an epaulette, he inqnired hy what means it had heen won, and was answered—By stndy at the Polytechnic School, which was open to those who had passed a preliminary examination. From that time Arago, then in his twelfth year, betook himself to the stndy of mathematics and geometry, not in elementary manuals, but in the original works of the best anthors, and mastered their contents with characteristic energy. He soon ontstripped the ahbé who tanght mathematics in the school; and assisted hy the kind advice of a neighhonring proprietor, who was a mathematician, he familiarised himself with the writings of Legendre, Lacroix, and Garnier. His real master, to quote a passage from his autohiography, "was a cover of Garnier's 'Treatise of Algehra.' This cover consisted of a printed sheet, on the outside of which hlne paper was pasted. The reading of the nncovered side inspired me with a desire to know what the hlne paper concealed. I damped it, and removing it with care, read underneath this advice given hy D'Alembert to a young man who was telling him of the difficulties he met with in his stndies: 'Keep on, sir, keep on, and conviction will come to you;' which was for me a ray of light. Instead of trying obstinately to comprehend at first sight the propositions that came before me, I kept on, and was astonished the next day at understanding perfectly that which, the evening before, had appeared to me wrapped in thick clouds."

In eighteen months Arago was ready for his examination, but the examiner having been detained hy illness, a delay occurred, dnring which his friends songht to divert him from the pnrsnit he had chosen. He kept on, however, and stndied the works of Enler and Laplace, and took lessons in fencing and dancing, having heard that these accomplishments were essential to an officer. In the summer of 1803 he was examined by Monge at the University of Toulouse, and passed with high commendations first of his class. He repaired forthwith to Paris, and entered the Polytechnic School, where, after a few months, he came off as trinmphantly from an examination by Legendre as from that at Tonlouse. In either case, his readiness and familiarity with the suhjects required, overcame the prejudices of the examiners.

He was studying for the artillery hranch of the service when, in 1804, the post of Secretary to the Ohservatory at Paris, then under Bouvard's direction, having fallen vacant, he was persuaded, bnt with great reluctance on his part, to undertake the dnties. The temporary appointment, as he thought it, effected an entire change in his pnrsuits, for he remained attached to the Observatory for the rest of his life. At the instance of Laplace he worked with Biot, who was assistant-observer, at experimental researches for determining the refractive power of different gases—an inqniry commenced by Borda—tbe resnlts of which formed the subject of a paper presented to the Academy of Sciences, and printed in their 'Memoirs' for 1806. In the same year the two young men were appointed by the government to extend and complete the measurement of the arc of the meridian, which, carried from Dunkirk to Barcelona by Delambre and Méchain, had been interrupted by the death of the latter. It was now to be extended from Barcelona to the Balearic Isles, and from thence to Formentera, by an immense triangle, the measnrement of whicb had been thought impossible. The fatigues of this survey in a wild mountain region, exposed to heat, cold, and storm, were excessive. For six months Arago was stationed on an elevated peak in the Desierto de las Palmas, watching for the light set np on Ivica, which, owing to a defect in fixing the mirror, was seldom visible. A space of about seventy-five square yards was all the ground he had for exercise; and two Carthusian monks, who, forgetting their vow of silence, used to ascend the mountain to converse with him in the evenings, were his only society. The work involved frequent journeys, in which, apart from the fierce heats, much risk was incurred owing to the hostile feeling between France and Spain, and from parties of brigands. On two occasions a notorions robber-chief intruded himself as a nightly guest on the zealous surveyor.

The geodesical union from the mainland to Ivica, and thence to Formentera—an arc of parallel of one degree and a half in one triangle—was successfully accomplished. Biot had returned to Paris, when, in the snmmer of 1808, the fire-signals on Mount Galazo in Majorca were snspected to be advices to the French army then invading tbe Peninsula, and Arago was denounced as a spy. To escape the threatened violence, he obtained permission from the governor to imprison himself in the citadel of Belver. Having a safety-pass from the Englisb Admiralty, he escaped in a half-decked boat to Algiers in July. In August he sailed for France in an Algerine frigate, and was in sight of the coast of Provence when the vessel was captured by a Spanish privateer, and carried into Rosas. Here he was again exposed to great danger: the anthorities, bitterly snspicions, snbjected him to repeated examinations, and consigned him to the hulks at Palamos, where his sufferings from want of food were, as he tells us, aggravated by the sight of the Pyrenees, and the thought that his mother might then be looking up at their peaks, anxious for her son.

Being liberated on demand of the dey, he sailed once more for France on September 28, and was off the port of Marseille when the ship, canght by the mistral, was drifted all across the Mediterranean to the coast of Africa. Arago landed at Bougie, and having travelled to Algiers, found a new dey in power, who would have sent him to the galleys but for consular interference. Here he lingered, waiting for an opportunity to retnrn home, until June, 1809, when he again sailed, and thongh chased by an English cruiser, landed at Marseille on the 2nd of July, with his manuscripts and instruments. For eleven months had be been tossed about amid hardships and privations, of all of whicb he has left a narrative, interesting as a romance, in his 'L'Histoire de ma Jeunesse.'

While yet in the lazaretto, he received a letter from Humboldt—the commencement of a lasting friendship with the illustrious Prussian. Tenderly attached to his mother, his first visit was to her at Perpignan. She had monrned him as dead.

Arago hastened to Paris to communicate his observations to the Academy and the Bnreau des Longitndes. Though but twenty-three years of age, he had already gained a reputation by his labonrs and misfortunes; and the death of Lalande having left a vacancy in the Academy, he was elected a member by 47 out of 50 votes on the 17th of September, and had the hononr of the usual presentation to the Emperor. Thereafter Arago's inflnence was felt in the learned body; and his opposition to unworthy candidates brought him at times into collision with some of the most eminent of his colleagues. Before the close of 1809 he was appointed assistant-astronomer to the Observatory, and to succeed Monge in the chair of analytical mathematics at the Polytechnic School.

In 1811, taking up the researches of Malus, he read a paper to the Academy in which knowledge of the laws of light was greatly extended, and the changes described that take place in polarised rays on passing through different kinds of crystalline plates. The pbenomena of colonr, of intensity, of rotation, and of reflection, were examined, and in a way that laid the foundation of that branch of physical optics known as 'chromatic polarisation;' and the interesting fact was first announced, that "while the light from a clonded sky undergoes no modification, that reflected from the atmosphere when the sky is nnclouded is polarised, the intensity of the polarisation varying with the hour of the day and tbe position of tbe point with respect to the sun."

In 1812, authorised by the Bureau des Longitudes, Arago commenced that course of lectures on astronomy and kindred subjects which he continued up to 1845 with the most brilliant success. The higb and the low througed to hear him; the learned to catch his animated manner and lucid style—the many to be charmed. As tbe Emperor Napoleon III. said, when a captive at Ham, Arago "possessed in a high degree those two facnlties so difficult to meet with in the same man—that of being the grand-priest of science, and of being able to initiate the vnlgar into its mysteries." The effect was heightened by the tall commanding form of the lecturer, his full sonorons voice, his strikiug features, and dark piercing eyes, shaded by thick bnsby brows.

Conjointly with Gay-Lnssac, Arago established the 'Annales de Cbimie et de Physiqne' in 1816—a serial still published, and mnch valued by scientific men. In the same year he annonnced what has been received as a crucial experiment, demonstrating the truth of the nndnlatory theory of light over the rival theory of emission. Young had sbown in his experiments that the interposition of an opaque screen in the path of a ray nnder certain circumstances, prevents tbe formation of fringes. Arago fonnd that tbe ray was only retarded, and that by a modification of the apparatus the fringes were still discernible.

In 1816, also, Arago for the first time visited England, where he made the acquaintance of Young and other eminent men of science. With a Frenchman's feeling, he had a painfnl dislike to hear any allusion to the battle of Waterloo; and while in London he positively refused an invitation to see Waterloo Bridge. His entertainers adopted the stratagem of proposing an excnrsion on the Thames, which, being accepted, the party descended tbe river admiring the prospect, and presently coming to the imposing structure of granite then stretching fresh and new from side to side, Arago was asked for his opinion of it. He perceived tbe trick, and replied—"Your bridge has at least an arch too many; and that one, to be in its place, should be transported to Berlin."

Another task commenced by Arago in 1818, again in conjuuction with Biot, was the connection of the French arc with the English arc by a system of signals and measurements from one side of the channel to the other. The resnlts, together with those of the Spanish triangulation, were pnblished by order of the Bnreau des Longitndes, in a volume entitled 'Recneil d'Observatious Géodesiques, Astronomiqnes, et Physiques.' In 1819, jointly witb Fresnel, Arago pnblished a series of experiments on the action exercised by polarised rays on each other, singularly remarkable for the ingenuity of the methods employed. Space fails here to give the details; bnt it was by means of these experiments that Fresnel was enabled to give a complete explanation of the prodnction of colours in crystalline plates, whicb had been referred by Young to the interference of transmitted rays. The co-operation of the two savants prodnced happy results; for Arago, though rich in inventive facnlty, lacked the perseverance whicb works a thought ont to its ultimate consequences. "We complete one another," he nsed to say; "I know how to point out the difficnlty, and Fresnel how to conquer it."

In 1820 Arago took up a new line of inquiry. Having witnessed a demonstration of Oersted's discovery at Geneva, he repeated it before the Academy, and with further results. The Danisb philosopher had shown that a voltaic current passing along a wire would deflect a magnetic needle: Arago found that non-maguetic substances were equally affected; that bars of iron and steel became temporary magnets, and lost their magnetism with the cessation of the

F

current. He proved moreover the best magnet to be a steel bar inclosed by a helix of copper-wire, to which we owe the discovery of the electro-magnet, and all that has since been accomplished thereby. Four years later other facts were published. Arago showed that metals not magnetic exert a powerful influence on the magnetic needle, particularly when in movement. Such metals appeared to become magnetic by mechanical motion—a phenomenon which has since been referred by Faraday to general laws of magnetic induction.

In 1822 Arago was chosen a member of the Bureau des Longitudes, and from 1824 till his death the 'Annuaire,' published by the board, contained a notice on some scientific subject from his pen as delightful as instructive. "They will always be reperused," says M. Combes, president of the academy, "with the same pleasure by men of science and by the ordinary reader. In them we find an admirable clearness, with an erudition as correct as it is extensive, and joined thereto the most rigorous accuracy in the statement of the phenomena, and the consequences which result from them." Arago won the position and honour he most prized in 1830, when on the death of Fourier he was elected Perpetual Secretary of the Academy. And now the duty devolved upon him of writing those 'éloges' of deceased members which are among the most interesting of his literary productions—graceful in style, and abundant in anecdote and illustration. They appeared to be written with a fluent pen; but he was a slow composer, and only acquired his felicities of expression by real and repeated hard work of mind and hand. In the same year he was appointed director of the Observatory.

In 1834 Arago visited England a second time, and attended the meeting of the British Association at Edinburgh. He continued his scientific researches, among which are—the discovery of a neutral point in the polarisation of the atmosphere—determination of the synchronous perturbations of the magnetic needle at places wide apart, by observations carried on simultaneously with Kupffer at Kasan—and the suggestion of a decisive proof of the truth of the undulatory theory, which has since been demonstrated by Foucault—besides other points of photometry and astronomy.

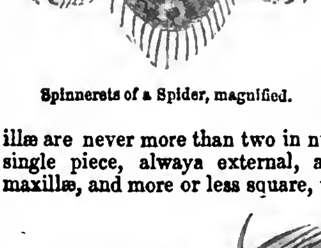
The later years of Arago's life were passed amid much bodily suffering, when, with failing sight and afflicted with diabetes, he set himself to finish his incomplete papers. In the summer of 1853 he went, attended by his niece, to his native place, seeking relief in change of air; but the hope was disappointed: he returned to Paris and died on the 2nd of October, aged 67. He was buried in the cemetery of Père-la-Chaise, followed by a concourse of 3000 persons to the grave, where Flourens pronounced the funeral oration.

Arago was elected a foreign member of the Royal Society in 1818. In 1825 their Copley medal was awarded to him for his "discovery of the magnetic properties of substances not containing iron;" and their Rumford medal in 1850, for his "experimental investigations of polarised light." The Royal Astronomical Society elected him one of their associates in 1822; he was also a member of some of the leading scientific societies on the continent. Arago was once married: his wife died in 1829, leaving two sons, who still survive. He had been accused of hoarding up wealth, but he left no other fortune to his relatives than a name and reputation of which they may be justly proud. His entire works are easily accessible, as they have been collected and published in a series of octavo volumes in French and English. It is said that he has left a narrative of his later years, not less interesting than that to which reference has been made above, for publication when the fitting time shall arrive.

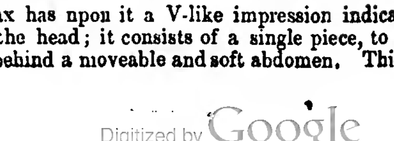
National vanity and an impassioned nature at times involved Arago in bitter controversies with other savants, in which he too often lost sight of truth and justice. It is certain also that he was occasionally tempted to sacrifice accuracy to effect. In politics he was an ardent republican, to which he owed his election to the Chamber of Deputies after the 'Three Days' of July, 1830. By his eloquent advocacy the observatory of Paris was placed on its proper footing among the observatories of Europe, and the works of Laplace and Fermat were published at the national expense. His voice was always raised in favour of science. To him Melloni, the Italian philosopher, owed his return to Naples from a wearisome exile. In 1840 he became a member of the Council-General of the Seine; and in 1848 he was chosen into the Provisional Government, in which he discharged the functions of minister of war and marine. In bitterness of spirit he despaired of the republic on witnessing the popular caprice. He refused to take the oath of allegiance after the coup-d'état of 1851, and justified his refusal in a memorable letter to the government, which elicited a concession alike gratifying to his conscience as a politician and his dignity as a philosopher. "A special exception," so wrote the minister authorised by the Prince-President, "would be made in favour of a philosopher whose labours had rendered France illustrious, and whose existence the government would be loth to sadden."

ARAGUAYA, one of the largest and most important rivers in the interior of Brazil, though up to the present time it is not much navigated, because the countries along its banks are unreclaimed, except at a few isolated places. It divides the province of Goyaz, which lies east of it, from Matto Grosso, which extends west of its course. It rises in the Serra de Santa Martha, south of 18° S. lat., in a lake, and runs under the name of Cayapo about 180 miles, when it unites with the Rio Claro, which traverses the town of Villa Boa, the capital of Goyaz, and takes the name of Araguaya. Continuing in a northern direction to about 12° 30′ S. lat., the river divides into two branches, which do not re-unite until 9° 30′. The island which is thus formed is called Ilha de Santa Anna or Bannanal. It is more than 200 miles long, and at an average 30 miles wide, so that it covers a surface of more than 6000 square miles. The western arm of the river preserves the name of Araguaya, whilst the eastern is called Furo. The latter is most used by the boats bound from Villa Boa to Parà; and at a very few places on its shores the Portuguese settlers have formed establishments, whilst none exist on the western arm. In both arms some falls occur, but they are not considerable. After its arms have re-united, the river runs to 6° S. lat., where it joins the Tocantins. The whole course of the river probably does not fall much short of 1000 miles, and it receives the waters of several navigable tributaries south of 10° S. lat., among which the Vermelho and Crixa from the right, and the Rio das Mortes and San João from the left, are the largest. (Henderson's *History of Brazil.*)

ARANEIDÆ, the first family of the first order of the class *Arachnida*. [ARACHNIDA.] They are also called *Spinning Arachnida*, from their peculiar habit of producing long filamentous cords with which they form their nests and webs. It is to this family that the term *Spider* is more especially applied; and scientifically it embraces all those creatures which are commonly called Spiders. All these are embraced under the old Linnean genus *Aranea*. Externally this family is distinguished by the following characters:—The palpi resemble small feet without a claw at the tip, terminated at most in the females by a small hook, but in the males supporting various appendages, more or less complicated, connected with the function of reproduction in this family. The frontal claws are terminated by a moveable hook which curves downwards, and has on its under-side a little slit for the emission of a poisonous fluid which is secreted in a gland of the preceding joint. The maxillæ are never more than two in number; the tongue is of a single piece, always external, and situated between the maxillæ, and more or less square, triangular, or semicircular.

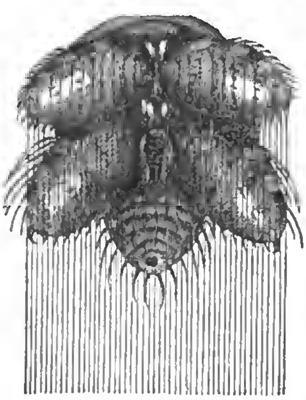


Spinnerets of a Spider, magnified.



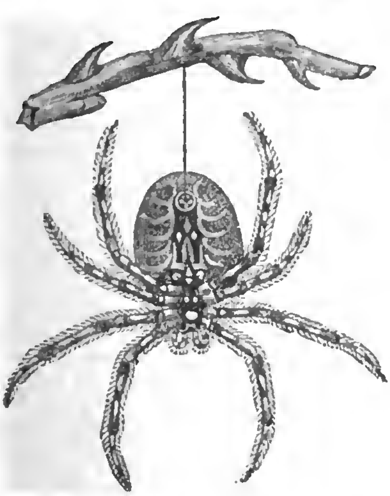
Clawed foot of a Spider, magnified.

The thorax has upon it a V-like impression indicating the region of the head; it consists of a single piece, to which is attached behind a moveable and soft abdomen. This part of the body is furnished with four or six nipples, fleshy at the tips, round or conical, jointed, placed close together, and pierced at the extremity with an immense number of minute orifices for the discharge of silken threads, which are produced from matter formed in internal reservoirs. These are called Spinnerets. The legs vary in length, but are composed of seven joints, of which the first two form the haunch, the next the femur, the fourth and the fifth the tibiæ, and the two others the tarsus. The last is ordinarily terminated by two claws, generally toothed beneath, and by a third smaller claw which is not toothed.



Single thread of a Spider, magnified.

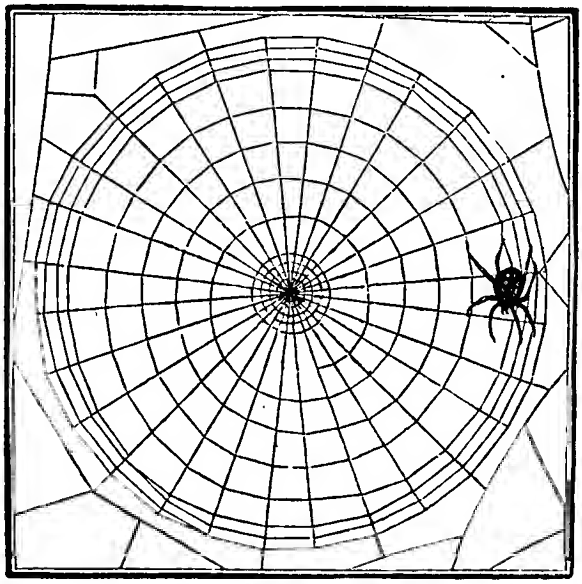
The most remarkable function performed by the *Araneidæ* is that of producing silken threads by means of the Spinnerets above described and figured. From each one of the minute orifices of the spinneret there exude as many little drops of a liquid, which becoming dry the moment it comes in contact with the air, forms so many delicate threads. Immediately after the filaments have passed out of the pores of the spinneret they unite first together and then with those of the neighbouring spinnerets to form a common thread; so that the thread of the spider, when it suspends itself from any object, is composed of an immense number of minute filaments, amounting even to many thousands, each of which is of such extreme tenuity that the naked eye cannot detect them till they are formed into a common thread. The spinnerets of the same spider differ in structure, and Lyonnet has shown that one set of spinnerets is employed in producing threads which are glutinous, whilst another set produces threads which are smooth. This may be seen by throwing a little dust on a spider's web, such as that of *Epeira diadema*, when it will be found that it adheres to the threads which are spirally disposed, but not to those that radiate from the centre to the circumference. These last are also found to be stronger than the spiral ones.



Garden-Spider suspended by a thread.

The spinnerets are in connection with an internal apparatus which secretes the matter they thus elaborate. This apparatus consists of a number of intestine-like canals which are united together, and vary both in number and extent according to the species in which they occur. These canals empty themselves into tubes which open into the spinnerets from whence the thread is extruded.

It is by means of these threads that spiders construct the various webs which they throw from one object to another, for the purpose of entrapping their prey. It is said that some of the larger species construct webs in which even small birds, such as the humming-bird, are caught and made subservient to the wants of the spider. No sooner is an insect or other small animal ensnared than the spider, placed in the centre of its net, or in a cell built at its side for the purpose of watching, darts forth, and uses all its efforts to inflict upon it wounds into which it pours the venom contained in its frontal claws. When the creature



Geometric Net of *Epeira diadema*.

thus caught offers too great a resistance, so that the spider becomes endangered, he retires for a time from the contest to renew his strength, leaving his victim secure in his meshes, and gradually getting exhausted from the attempts it makes to escape. When the spider returns he frequently twists the web round and round the body of his victim, and then either at once commences to make a meal of him, or waits till his appetite suggests the proper time for feeding.

Although Spiders are not provided with wings, and are consequently incapable of flight, they have a power of ballooning with their silken threads, by means of which they can make distant journeys through the atmosphere. These aërial excursions, which appear to result from an instinctive desire to seek some more favourable spot for the gratification of their appetite or other cause, are undertaken when the weather is bright and serene, especially in the autumn, both by adult and immature individuals of many species, and are effected in the following way:—They first mount to the summit of an object, and then raise themselves still higher by straightening their limbs; the abdomen is then elevated into an almost perpendicular position, and they emit from their spinnerets a small quantity of viscid fluid, which is drawn into fine lines by the ascending current of air from the heated ground. Against these lines the current of air from below keeps impinging till the animals, finding themselves acted on with sufficient force, quit their hold of the earth and mount into the air. It has been sometimes stated that spiders can forcibly propel or dart out lines from their spinnerets; but when placed on sprigs set upright in glass vessels, with perpendicular sides, all their efforts to escape are unavailing.

The webs named gossamer are composed of lines spun by spiders, which on being brought into contact by the action of a gentle air, adhere together, till by continual additions they are accumulated into irregular white flakes and masses of considerable extent.

The poisonous effects of the wounds of spiders are produced by means of the mandibles, or frontal claws, which are each armed with a moveable and extremely sharp unguis, near to the point of which is a minute orifice, whence there is poured out a drop of poison into the wound. This orifice, which is very difficult to detect, communicates with a canal in the interior of the mandible; this canal proceeds from a gland situated in the interspace of the muscles of the thorax. The gland consists of a vesicle having internally a number of spiral filaments, which are connected together by a membrane in the form of a bag. Although dreadful stories are related of the effects of the bites of spiders on the human body, it appears from experiments made by Mr.

Blackwall on British Spiders, that none of these have the power of producing any ill effects on human beings. There is still wanting good evidence on which to rest a charge of poisoning man by biting him, even against the larger forms of spiders, which inhabit tropical climates.

A curious feature in the history of spiders is the power they possess of reproducing their limbs after they have been broken off. This power, however, is not confined to spiders, as we find it in the *Crustacea* [CRUSTACEA], and even in the vertebrate animals amongst the *Amphibia*. [AMPHIBIA.] In tho case of the spiders, it is never a part of a limb which is reproduced, but if a part of a leg is removed, it proceeds to throw off the remainder, and after the next moult the missing member reappears.

The species of the family *Araneidæ* are very numerous and have been arranged by natnralists nnder several genera. They have been investigated with great care by M. Walcknäer, who has made them the special study of his life, and has drawn up a natural arrangement of them according to their structure and habits of life. A synopsis of this arrangement we subjoin, as by a little study it will furnish an insight into the surprisingly varied habits of this family:—

TABLE OF THE SUBDIVISION OF THE ARANEIDÆ OR ARACHNIDA FILOSA, INTO GENERA.

				Genera.				
First Family.—ARANEIDÆ—SPIDERS.	*Mandibles* articulated horizontally; moving vertically.	8 Eyes.	*Eyes* aggregated.	Mygale. Oletera. Filistata.	LATEBRICOLÆ, hiding in holes and fissures.	*Venantes*, incessantly running or leaping about the vicinity of their abode to chase and catch their prey.	*Terrestres*, living on land or in holes in the ground.	ARACHNIDA.
			Eyes segregated.	Missulena. Sphodros.				
		6 Eyes.	*Eyes* anterior.	Dysdera. Segestria.	TUBICOLÆ, inclosing themselves in silken tubes.			
			Eyes anterior and lateral.	Uptiotes. Omosites. Scytode.	CELLULICOLÆ, sheltering themselves in small cells.			
	Mandibles articulated vertically or on an inclined plane; moving laterally.	8 Eyes.	*Eyes* anterior and lateral, very unequal in size.	Lycosus. Dolomedes. Storena. Ctenus. Hersilia. Sphasns. Dolophenes.	CURSORES, running swiftly to catch their prey.			
				Myrmecia. Eresus. Platiscelum. Attus.	SALTATORES, leaping and springing with agility to seize their prey.			
			Eyes anterior, almost equal in size.	Delena. Thomisus. Selenops. Eripus. Philodromus Sparassus. Clastes.	LATERIGRADÆ, walking and running sideways or backwards; occasionally throwing ont threads to entrap their prey.	*Vagantes*, wandering abroad, and incessantly spying out for prey; no fixed residence except at the period of oviposition.		
				Clubiona. Drassus.	NIDITELÆ, going abroad, but making a web for their nests, whence issue threads to entrap their prey.	*Errantes*, prowling about the neighbourhood of their nests, or near the threads which they throw ont, to catch their prey.		
				Clotho. Emyo. Latrodectus. Pholcus. Artema.	FILITELÆ, going abroad, but spreading long threads of silk abont the places where they prowl in order to entrap their prey.			
				Tegenaria. Lachesis. Agelena. Nyssns.	TAPITELÆ, spinning great webs of a close texture like hammocks, and dwelling therein to catch their prey.	*Sedentes*, spinning large webs to entrap their prey, lying in wait in the middle or at the side.		
				Epeira. Tetragnatta. Uloborus. Zosis.	ORBITELÆ, spreading abroad webs of a regular and open textnre, either orbicnlar or spiral, and remaining in the middle or on one side to catch their prey.			
				Lynyphia. Episina. Theridion.	RETITELÆ, spinning webs of an open meshwork and of an irregular form, and remaining in the middle or on one side to catch their prey.			
				Argyroneta.	AQUITELÆ, spreading filaments in the water to entrap their prey.	*Natantes*, swimming in water and there spreading their filaments to entrap their prey.	*Aquaticæ*, living in water.	

(*Cyclopædia of Anatomy and Physiology*, article '*Arachnida*;' Blackwall, in *Report of British Association*, 1844; Owen's *Lectures on Comparative Anatomy*; Cuvier's *Règne Animal*; *Insect Architecture*, in *Library of Entertaining Knowledge*.)

ARBITRATION. The defects in the law, which permitted any agreement to refer disputes to arbitration, if disregarded by any of the parties thereto, to be of no avail, and which allowed arbitrations to come to an end by the death of arbiters or umpires, or the refusal of any of the parties to proceed therein, have been remedied by the Common Law Procedure Act, 1854. (Blackstone's 'Commentaries,' Mr. Kerr's ed., vol. iii., p. 17.)

ARCHER-FISH. [TOXOTES, *S.* 1.]

ARCHES, COURT OF. The jurisdiction of this Court in Testamentary and Matrimonial Causes has been transferred partly to the Court of Probate (20 & 21 Vict. c. 77), and partly to the Court for Divorce and Matrimonial Causes (20 & 21 Vict. c. 85); and as no suit for subtraction of legacies, (20 & 21 Vict. c. 77 s. 23), or for defamation (18 & 19 Vict. c. 41), can now be entertained by any Ecclesiastical Conrt whatever, its jurisdiction is now confined to a few pecuniary causes, peculiarly connected with the Established Church. (Blackst. 'Comm.,' Mr. Kerr's ed. vol. iii. p. 93.)

ARCHITECTURE. [PUBLIC IMPROVEMENTS.]

ARCTIC REGIONS. [NORTH-WEST PASSAGE, *S.* 2; POLAR COUNTRIES AND SEAS, *S.* 2.]

ARDEA, ARDEIDÆ. [HERONS.]

ARENICOLA, a genus of Annelidous Animals, referred by Cuvier to tho Dorsibranchiate group on account of their external gills. The general structure and habits of the genus determine most naturalists in placing it with the Terricolous Annelids. [ANNELIDA.] The gills are branched, and placed upon the rings of the middle part of the body only. The mouth is fleshy, more or less dilateable, bnt there are no discernible teeth, tentacles, or eyes. The posterior extremity of the body has not only no gills, but is devoid of the silky bristles which are found on every other part.

A. Piscatorum, the Lob or Lug-Worm, is the most common species. It is found very abundantly in the sand of the sea-shore, where its habits afford a close resemblance to those of the earth-worm away from the shore. It is bigger than the earth-worm, sometimes being found nearly a foot in length. It is of a reddish colour, and when tonched throws out a qnantity of yellow fluid which stains the hand. It is employed by fishermen as bait for various kinds of sea-fish.

AREOLAR TISSUE. [TISSUES, ORGANIC, *S.* 1.]

ARGELES. [PYRÉNÉES, HAUTES.]

ARGULUS, a genus of Entomostracous Crustacea, belonging to the section *Pœcilopoda*. There is but one species of this genus, the *A. foliaceus*. This little creature is not unknown to fishermen, as it is freqnently found parasitic upon various kinds of fish. It was first described by Baker in his 'Employment for the Microscope,' in 1753, nnder the name of the 'Lonse of the Carp and Banstickle or Prickleback.' It is about the tenth of an inch in length, and is almost as broad as it is long. The head is in the form of a circular-shaped shield. The antennæ are short, thick, and two-jointed. Instead of a second pair of foot-jaws it has a pair of circnlar or disc-shaped suckers, by means of which it attaches itself to the animals on which it is parasitic. These suckers are admirably constructed for their use. Four muscles are attached to the base of each of these organs, and extend up by the sides. By this arrangement the creature can make use of these organs, by exhausting the air in the same way as in cupping glasses, to fasten itself, and also by relaxing the muscles, to walk, when it wishes to change its position. These little creatures are nearly transparent, or of a slightly greenish hue, so that its internal organisation can be readily seen by means of the microscope by transmitted light. The body is marked on both sides by a series of ramifications of a dark colour. The female is larger than the male, and is distinguished, in addition to the ovary, by a black mark on each lobe of the abdomen.

The Argulus is found upon various fresh-water fishes. It is most frequently met with near London on the Stickleback, but it has been noticed as occurring on the Carp, the Roach, the Trout, the Pike, the Rudd, and even upon the tadpole of the common Frog. It seems to abound especially when fish are in ill health.

Although mostly found upon fish it frequently leaves them, and swims freely about in the water. Fish have an instinctive knowledge of these creatures as their enemy, and it is amusing to watch in a basin of water the efforts which the stickleback will make to avoid its minute persecutor; but the efforts of the fish are in vain, for it is opposed to a creature which has the power of darting through the water with such rapidity that it is almost impossible to follow it with the naked eye. The females deposit their eggs from 400 to 1500 in number on stones or other solid bodies. They are laid side by side in rows and glued together. They are hatched in about 35 days, and the young resemble their parents to a greater extent than is the case with many of the forms of *Entomostraca*. The best account, with figures and anatomy, of this parasite, is given in Dr. Baird's 'History of the British Entomostraca,' published by the Ray Society. Mr. Yarrell has given a figure of it in the second volume of his 'British Fishes.'

ARICINE. [Chemistry, *S.* 2.]

ARIÉGE. [Arriège.]

ARQUERITO, a native amalgam, consisting of six parts of silver and one of quicksilver. It has been regarded as native silver. It is malleable, and is worked with great success in the mines of Arqueros in Chile.

ARREST. The Commissioners of the district Courts of Bankruptcy and the Judges of the County Courts have now power to grant a warrant for the arrest of absconding debtors and for their detention for seven days, until a writ of *capias* can be procured from one of the Superior Courts of law. By this means debtors absconding from the seaports at a distance from London, may be arrested on the spot, and detained until they pay the debt or give bail to an action, or deposit the money in the hands of the sheriff. ('The Absconding Debtors Arrest Act,' 1851.)

ARSENIC, DETECTION OF. [Chemistry, *S.* 1.]

ARTERIES, DISEASES OF. [Surgery, *S.* 2.]

ARTERIOTOMY. [Surgery, *S.* 2.]

ARTERY, from the Greek ἀρτηρία, signifying an air-vessel, because the ancients, ignorant of the circulation, and finding the arteries always empty after death, supposed they were tubes containing air. Why after death the arteries are empty and the blood accumulated in the veins will be explained hereafter. By the term Artery is meant a vessel which conveys blood from the heart to the different parts of the body: a Vein, on the contrary, is a vessel which conveys blood from the different parts of the body to the heart. [Circulation of the Blood.] All the arteries of the system proceed from two great trunks immediately connected with the cavities of the heart, namely, the Pulmonary Artery, which arises from the right ventricle, and the Aorta, which springs from the left ventricle. [Aorta; Heart.]

The arterial system is arborescent, that is, the branches which spring from the aorta successively increase in number and diminish in size as they proceed from the heart towards their ultimate terminations in the system. Each trunk commonly ends by dividing into two or more branches, the combined area of which is always greater than that of the trunk from which they spring. The capacity of the branches is estimated to exceed that of the trunks in the proportion of one and a half to one. The arterial trunk always dividing into branches, and the larger branches into branches more and more minute, it is obvious that the blood in the arterial system is always flowing from larger into smaller tubes.

The arteries are of a yellowish-white colour, loose and flocculent on their external surface, but their internal surface is smooth and polished. They are composed of three distinct membranes, which are super-imposed one upon the other, and which are ultimately united by delicate cellular tissue. Each of these membranes is called a tunic, or coat, and each possesses a peculiar structure, and performs a separate function in the circulation of the blood.

1. The internal tunic consists of a membrane, colourless, transparent, and thin, yet so firm and strong that it is supposed to resist more than any of the others the bursting of the artery by the current of the blood; for if, in a living animal, the other coats be entirely removed, this alone is found capable of sustaining the impetus of the circulation, and of preventing rupture from the dilatation of the artery.

2. The middle tunic, called also the fibrous and the muscular, is composed of yellowish fibres, which pass in an oblique direction around the calibre of the vessel, forming segments of circles which are so joined as to produce complete rings. In the larger trunks, several layers of these fibres can be raised in succession by the forceps, so that this coat is of considerable thickness, and it is proportionally thicker in the small branches than in the large trunks. This coat is firm, solid, and highly elastic. It is the main tunic by which the artery resists dilatation in the transverse direction, which it does so effectually that when the left ventricle of the heart propels a fresh current of blood into the aorta little or no dilatation of the vessel is perceptible. The characteristic property of the fibrous coat is contractility. If it be mechanically irritated, or if a chemical stimulant, such as ardent spirit or ammonia, be applied to it, the vessel contracts forcibly upon its contents. The contractile power, which properly belongs to the muscular fibre, induced anatomists to believe that the fibrous tunic consists of muscular fibres; but careful examination has shown that its organisation possess nothing in common with that of the muscular tissue, while chemical analysis has demonstrated that it contains no fibrin, which is the basis of muscle.

3. The external tunic, called also the cellular, consists of small whitish fibres, very dense and tough, interlaced together in every direction. It is much thicker in the large trunks than in the small branches, the reverse of the fibrous coat. Its outer surface is covered by a loose and flocculent cellular substance, which connects the artery with the surrounding parts, and particularly with the sheath of the vessel. Its firmness and resistance are so great that it is not divided however firmly a ligature may be placed around the artery; and its elasticity, especially in the longitudinal direction is so remarkable that it has been called, by way of eminence, the elastic coat.

Arteries are themselves abundantly supplied with arteries, constituting their nutrient vessels, and called *Vasa Vasorum;* but these nutrient vessels of the artery form but few anastomoses, that is, few communications with any other arteries.

The principal nerves of arteries are derived from the ganglionic or the organic system, but with these are mingled branches derived from the sentient or the animal system. [Nerve.] Accordingly, under ordinary circumstances, arteries carry on their functions independently of any influence derived from the brain and spinal cord, but they are capable of being affected by agents applied to those organs.

Among the physical properties of arteries, the most important are their extensibility and their elasticity. Their extensibility is chiefly in the direction of their length.

After an artery has been extended, either lengthwise or transversely, it suddenly retracts on itself when the extending force is removed. If the finger be forcibly introduced into the section of a large artery, the sides of the vessel re-act on the finger, and proportionally compress it. If an artery be divided in the dead body, though emptied of its contents, it maintains its cylindrical form, and preserves its capacity unimpaired. The elastic property on which these phenomena depend is common to all the coats, but it is greatest in the external tunic, and least in the internal tunic, and it is also much greater in the large trunks than in the small branches.

The most important vital property of the artery is its contractility, that is, its power of diminishing its capacity, or approximating its parietes, and thus proportionally acting upon its contents. Even the large trunks possess this property in some degree; but it resides chiefly in the ultimate divisions of the arterial branches, that is, the capillary vessels. [Capillary Vessels.]

ASARONE. [Chemistry, *S.* 2.]

ASHBURTON, ALEXANDER BARING, BARON, was born October 27, 1774, and was the second son of Sir Francis

Baring, Bart., an eminent merchant in the city of London. He was removed from school at a rather early age, and placed in the mercantile establishment of his father. Having here completed his commercial training he was sent to the United States, where, and in Canada, he for some years conducted the American business of the firm. Here he acquired much of that wide and varied commercial knowledge which, later in life, gave so much authority to his opinions on all matters connected with trade and commerce. In 1798 he married the daughter of William Bingham, Esq., Senator of the United States; and on the death of his father in 1810 he became the head of the great firm of Baring, Brothers, and Co.

Mr. Baring entered Parliament in 1812 as member for Taunton, which town he continued to represent till 1820, when he was returned for Callington, and remained its representative until it was disfranchised by the Reform Act. Prior to the introduction of the Reform Bill, Mr. Baring had voted steadily with the whig party; but he warmly opposed that measure, and in future ranked among the supporters of Sir Robert Peel. When Peel accepted office in December, 1834, he acknowledged the advantage which he had derived from the adhesion of his proselyte, by introducing Mr. Baring into his Cabinet as President of the Board of Trade and Master of the Mint. The appointment was a popular one, especially in the City and with the House of Commons, where Mr. Baring had long been regarded as a high authority on all commercial subjects. But the ministry had but a short tenure of office, Peel resigned in April, 1835, and the President of the Board of Trade of course went out with him—having, however, first been created Baron Ashburton. When Sir Robert Peel returned to office, September 1841, the differences of the United States respecting the boundary question excited some anxiety, and Peel requested Lord Ashburton to proceed to America as special commissioner, with powers to conclude a definite treaty. Both in England and America the nomination was received with satisfaction; and Lord Ashburton conducted the negociations in so conciliatory a spirit, that Sir Robert Peel was able at the opening of the session of 1843 to announce that a treaty had been concluded with the United States, in which "the adjustment of the boundary question was far more favourable to this country than the award of the King of the Netherlands," and that the other points under discussion between the two governments had been arranged in an equally satisfactory manner. In the House of Lords, Lord Ashburton continued to support the policy of Sir Robert Peel until that statesman brought forward his bill for the repeal of the duties on the importation of corn, when he gave to that measure a resolute opposition. After it became law he took little part in politics. He died May 13, 1848, and was succeeded in the title by his son the present peer.

Lord Ashburton cannot be termed a statesman in the proper acceptation of the term. But he brought to the consideration of political questions a clear calm business-like understanding and considerable experience, and though far from an eloquent speaker, his extensive knowledge and unquestioned probity, as well as his high mercantile standing, caused him in his place as a member of either branch of the legislature to be always listened to with respect. As a public man he will be remembered in connection with the treaty which is usually called by his name. Lord Ashburton was also well known as a liberal patron of arts and artists, not neglecting while forming a valuable collection of pictures by ancient masters to employ living painters. He held the office of trustee of both the National Gallery and British Museum.

ASIA. Of late our knowledge of Asia has been considerably augmented. The Russians have steadily and systematically pursued the exploration of their vast dominions in the north; while the English have continued their surveys and researches in the south and west. The eastern and central portions of Asia alone, particularly the Chinese and Japanese empires, have remained little known; hitherto inaccessible to and unaffected by the rapid tides of progress and civilisation which have extended over the rest of the world. The Euphrates and the Tigris, with the adjoining regions from the Mediterranean to the Persian Gulf, were thoroughly explored and surveyed by the expedition under Colonel Chesney in 1835 and 1836, despatched to ascertain the practicability of a steam-boat communication with India by that route. In 1836 an expedition was despatched by the Imperial Academy of Sciences at St. Petersburg, for the purpose of making a trigonometrical survey from the shores of the Black Sea to those of the Caspian, in order to ascertain the difference of their comparative levels; a question which had excited great interest for twenty-five years previously. This expedition consisted of Messrs. Fuss, Sabler, and Sawidsh, who within two years succeeded in making a most accurate survey, by which it was determined that the level of the Caspian was 84 feet below that of the Black Sea.

During the years 1834 to 1837 Asia Minor was explored by Callier, De Texier, Brant, and W. J. Hamilton, the last of whom has given us a very valuable account of the physical geography of the peninsula, and has ascertained the sites of many ancient cities. From 1832 to 1837 Fedorow accomplished an important journey through Siberia, between Oreuburg and Irkutzk, and between the parallels of 46° and 66° N., and determined many points astronomically and trigonometrically, which formed a new basis for the geography of those regions. During the same years Baer, Pakhtusow, and Ziwolka made additions to the geography of Nova-Zembla, and determined a portion of its eastern coast. In 1836 and 1837 Professor Koch explored the Caucasus, and published the results of his researches in various works, to which a large map was subsequently added.

In 1837 the interesting discovery was made by Moor and Beke of the level of the Dead Sea being considerably below that of the ocean. Shortly afterwards Shubest corroborated this curious fact, and ascertained that this great depression extends over the whole of El Ghor, comprising the valley of the Jordan as far as the Lake of Tiberias. The first accurate measurements of the altitude of both the Dead Sea and the Lake of Tiberias were made in 1838 and 1839 by De Berton and Russegger, and subsequently repeated by Symonds, Wildenbruch, and the American expedition in 1841, 1845, and 1848. By Symonds's trigonometrical survey it was found that the depression of the Dead Sea amounted to 1312 feet; but his result for the depression of the Lake of Tiberias was shown to be very erroneous. This latter point has been ascertained by the American expedition to be 652 feet below the level of the sea, a result which agrees satisfactorily with the previous observations of De Berton, Russegger, and Wildenbruch.

Arabia, particularly its eastern extremity, was explored by Wellsted in the years 1835 and 1836; and in the latter year Lieutenant Cruttenden visited the south-western portions of the same country. In 1843 Baron von Wrede made an important journey to Hadramaut, and in 1853 Lieutenant Richard F. Burton, of the Bombay army, in the disguise of an Afghan pilgrim, performed an interesting journey from Yamba on the Red Sea to Medina and Mecca. In 1836 an interesting journey was made in Kuzistan and Luristan by Major Rawlinson; and an expedition to Kurdistan, under Ainsworth, started from Constantinople in 1838, and during two years explored a considerable portion of Asia Minor, Armenia, and Kurdistan. The still more recent travels and discoveries of Dr. Layard have greatly increased our acquaintance with the geography of Kurdistan and Assyria. In the regions of the Himalaya Mountains and Afghanistan important additions to geography were made by Burnes, Wood, Vigne, and others. Vigne proceeded as far as Iskardob, and thoroughly explored the valley of Cashmere; while Lieutenant Wood reached the source of the river Oxus, or Amur of the moderns, formed by a lake on the plateau of Pamir, at an elevation of upwards of 15,000 feet above the level of the sea. Cashmere was also visited by Baron von Hügel. Lycia and other parts of Asia Minor were visited by Fellows in 1839 and 1840, and also by Hoskyn. In 1843 a Russian expedition under Middendorf was despatched for the purpose of reaching Cape Taimura, the northernmost point of Asia; but the country they had to traverse was found to consist of immense marshes, uninhabited, and possessing scarcely any animal or vegetable life, and after having undergone considerable hardships the expedition had to return without having reached its destination. About the same time the northern Ural was scientifically explored by Hoffmann, Keyserling, Krusenstern, and others, and rich gold alluvia were discovered in the regions of the Altaï. The Aralo-Caspian regions were also visited by Basiner and Lehmann. In 1847 an exploring expedition to the Tibetan frontiers was undertaken by the Indian government. This expedition consisted of Captain Cunningham, Lieutenant Strachey, and Dr. Thomson. Previously, in 1846, Lieutenant Strachey had succeeded in reaching the lake of Manasarowara

(Cho Mapan), and Rakas Tal (Cho Lagan), situated far within the Tibetan frontier on the northern flank of the Himalaya Mountains, and the reputed source of the Sutlej and Sampoo. Their elevation he found to be 15,250 feet above the level of the sea. The expedition proceeded along the upper valley of the Sutlej, Lieutenant Strachey continuing his course down the Parang River, while Captain Cunningham and Dr. Thomson proceeded to Haulé, over the Ladak Pass, and subsequently proceeded to Lé, the capital of Ladak, whence Dr. Thomson proceeded to the Karakorum Pass. Independently of this expedition great additions were made to the geography of the Eastern Himalaya by Dr. Campbell and Dr. J. W. Hooker. The latter gentleman has examined the whole of the Sikkim and Himalaya of East Nepaul, with the adjacent provinces of Tibet to the north. Among other researches Dr. Hooker traced the course of all the Sikkim rivers to their sources in Tibet, and examined glaciers and moraines at heights extending to 19,000 feet. He confirmed the statement first published by Dr. Thomson, and afterwards by Captain R. Strachey, that the Himalaya mountain ridge of our maps is an imaginary line drawn through certain lofty peaks which, catching all the moisture of Hindustan, retain it in snow and ice; and that the country of Tibet, north of the snowy Himalaya, is no plain or plateau, but presents for seventy miles a succession of mountains, which, though ranging from 19,000 to 20,000 feet in height, with flat narrow valleys between, are wholly uncovered by snow.

The brothers, Adolf and Robert Schlagintweit, who travel by the desire of the king of Prussia, and at the suggestion of Baron Humboldt, were employed, under the patronage of the East India Company, in the physical survey of the distant trans-Himalaya regions. They have laid down the entire mountain-system of Kumaon. Adolf Schlagintweit, after visiting the glaciers of Pindari, was joined by his brother Robert; and they examined together the glacier of Milum, which surpasses in extent all those of Switzerland, being from eight to ten miles in length, and 3000 feet broad. In 1855 their geological excursions in Eastern Tibet by Niti and Gertope to the glacier of Ibi Gamin, have been of great interest. They reached it in August 1855, and fixed the height they attained on Ibi Gamin at 22,260 feet. In Western Tibet, in August, 1856, they passed the chain of the Kuen-Luen mountains, the axis of which had never before been crossed by any European traveller, and reached Eltsehi in the province of Khotan. These two brothers have, in fact, penetrated farther into Tibet and Tartary, from the plains of India, than any other European; they have even made photographic sketches at heights of 20,000 feet above the sea, and their physical, geological, and geographical observations are of the highest value.

Borneo of all the East India Islands has most advanced in respect to geographical elucidation. The researches of Sir James Brooke, Captain Keppel, Mr. Low, Marryat, Captain Mundy, Sir E. Belcher, and Baron Melvill de Carnbee have accumulated and brought to public notice a rich store of geographical knowledge, particularly on the north-western side of that magnificent island.

The trigonometrical survey of India has steadily progressed under the superintendence of Lieutenant-Colonel Waugh, the surveyor-general. Among other interesting results he carefully measured the altitude of the Sikkim Himalaya, and found Kunchinjinga to be 28,178 feet above the level of the sea, the highest point of the globe as yet measured. A valuable map of the whole of India, divided into collectorates and provinces, with some of the recently acquired territories, was published by the East India Company in June, 1853. As already mentioned in a preceding part of this article, our knowledge of the Chinese empire has but little increased; Mr. Gutzlaff has left voluminous but rather undigested materials; Mr. Fortune's explorations of the tea-growing provinces are interesting, but do not extend far into the interior. The travels of the French missionaries, Huc and Gabet, have given some insight into the interior of this vast empire. Some light has likewise been thrown by French missionaries on the great northern region of China, called Mandchouria. A complete and exhaustive account of the island of Chusan has been published by Sir John Davis.

ASPARAGIN. [CHEMISTRY, *S.* 1.]

ASPE'RULA, a genus of plants belonging to the natural order *Rubiaceæ* or *Galiaceæ*. The genus is known by its funnel-shaped corolla, and by the fruit being dry and not crowned with the limb of the calyx.

A. odorata, the Woodruff, has its leaves six or eight in a whorl, with perfectly white flowers. It occurs in woods, and is found throughout Europe. It is abundant in some parts of England. The whole plant is remarkable for its fragrance when dried.

A. Cynanchicha has it leaves four in a whorl, and flowers of a lilac colour. It is found on dry banks and hills in limestone districts. It is common in Great Britain, where it is called Quinsy-Wort on account of its supposed value as a remedy in sore throat. It is slightly astringent. Two other species, *A. arvensis* and *A. taurina*, are doubtful natives, but found wild now in England.

ASPIDOPHO'RUS, a genus of Acanthopterygious Fishes. One species, the *A. Europæus* is found on the coasts of England and Scotland. It is known by the names of the Armed Bullhead, the Pogge, the Lyrie, Sea-Poacher, Pluck, and Noble. It is a small fish seldom exceeding 6 inches in length. (Yarrell, *British Fishes.*)

ASSIGNMENT OF CHATTELS. [BILL OF SALE, *S.* 2.]

ASTERI'NA, a genus of Star-Fishes, including the smallest of the British species, *A. gibbosa* of Pennant. The Gibbous Starlet has a 5-sided body, which is thick and covered above and below with short spines; the avenues are bordered by a single row of spines, and the suckers are in two rows. De Blainville makes out of this species two, which he calls *Asterias minuta* and *A. pulchella*. *A. gibbosa* is found very generally around the British Islands, and also in the Mediterranean, and on all the shores of Europe.

ASTRONOMY. [URANOGRAPHY.]

ASTROPHY'TON, a genus of Star-Fishes, remarkable for the branched character of its rays. One species, the *A. scutatum*, is British. It is however a rare animal; and although occasionally found in other places, is most commonly caught off the Shetlands: hence it is called the Shetland Argus. (Forbes, *British Star-Fishes.*)

ASTUR. [FALCONIDÆ.]

ASUNCION, the capital of the department of Asuncion and of the republic of Paraguay, in South America, is situated on the eastern or left bank of the river Paraguay, in 25° 16′ S. lat., 57° 47′ W. long., at a short distance above the mouth of the Araguai branch of the Pilcomayo. The city, which stands upon a commanding spot, was built in 1535 by a colony of Spaniards under Juan de Salazar; and from the convenience of its situation speedily became a place of some consequence. It was nearly destroyed by fire in 1543, the greater part of the houses being built of wood. From this calamity it speedily recovered; and in 1547 was a place of sufficient importance to be erected into a bishop's see. It contains a cathedral, three parish churches, and four convents and monasteries. It once contained a college of Jesuits. Properly speaking the town consists of only one street surrounded by several lanes and a great number of houses which stand apart and are surrounded by groves of orange trees. Even in the principal street most of the houses are small and consist merely of a shop with two or three apartments attached to it. Few of the houses have flat roofs; the greater part are covered with tiles. The best buildings in the city are those mentioned above. The inhabitants are of European and Indian descent with the addition of a few negroes; their number is estimated at 10,000. Asuncion carries on a considerable trade in the export of hides, tobacco, sugar, and maté or Paraguay Tea, which is largely used all through South America. Great numbers of horned cattle, horses, mules, asses, sheep, and goats are bred by the farmers, who grow wheat, maize, sugar, tobacco, cotton, mandioc, potatoes, and other vegetables. Honey and wax are produced in abundance; and the rivers supply large quantities of fish.

The air in and about Asuncion is generally temperate and genial; for the greater part of the year the wind blows from the south.

The policy of the late Dictator of Paraguay, Dr. Francia, in prohibiting all intercourse with foreigners and with the surrounding states, preserved the republic from the miseries of constant civil and political commotions so characteristic of the neighbouring American republics; but was very detrimental to the trade of Asuncion and of the republic generally. By treaties however concluded with the President of Paraguay in March 1853, the subjects of Great Britain, France, Sardinia, and the United States are free to navigate the rivers of Paraguay, and to settle and trade in any of the towns of the republic. In the dry season vessels drawing 6 feet water and in the wet season vessels drawing 12 feet can sail up to

Asuncion, above which the river Paraguay is navigable for vessels of considerable size for 600 miles.

ATHAMANTINE. [CHEMISTRY, *S.* 2.]

ATROPINE. [CHEMISTRY, *S.* 2.]

ATTACHMENT OF DEBTS. A creditor who has recovered judgment against his debtor, may now, on obtaining a judge's order to that effect, attach the debts due to the judgment debtor by third parties; then either by a summary application to a judge at chambers, or where the debt is disputed by the garnishee (the person in whose hands the attachment has been laid), by proceedings similar to those in an ordinary action, enforce payment of these debts to himself, in discharge of his own claim; such payment operating as a discharge to the debtor. ('Common Law Procedure Act,' 1854.)

AUCKLAND. [ZEALAND, NEW.]

AUCKLAND, GEORGE EDEN, 2ND LORD AND 1ST EARL OF, eldest surviving son of the 1st lord, was born in 1784. After receiving his education at Eton and Oxford, he entered the House of Commons as M.P. for Woodstock, but was soon removed to the House of Lords by his father's death. He formed a part of the Whig administration as President of the Board of Trade, and was appointed First Lord of the Admiralty by Lord Melbourne in 1834. In the following year he went out to India as governor-general. His administration is marked by the ill-advised Afghan war (1838-39.) The Earl of Auckland was recalled to England in 1842, having been previously advanced to an earldom: the final settlement of the Afghan affairs was left for his successor, the Earl of Ellenborough. Lord Auckland died suddenly, January 1st, 1849.

AUCKLAND ISLANDS, named after Lord Auckland, lie in 51° S. lat., 166° E. long., about 900 miles S.E. from Van Diemen's Land, and 180 miles S. from New Zealand. The group, which was discovered in 1806 by Captain Briscoe, consists of one large island and several smaller ones. Auckland, the largest of the group, is about 30 miles long and 15 miles broad, and contains about 100,000 acres. The entire group is of volcanic formation, composed of greenstone and basalt, and has a wild and picturesque appearance. The highest hill, situated on Auckland Island, is estimated at about 1350 feet above the level of the sea. There is a marked difference between the west and east coast of Auckland Island, the west coast presenting towards the sea a line of precipitous cliffs, whereas the east coast exhibits here and there a fine sandy beach, upon which the sea scarcely breaks, and is intersected by numerous streams and inlets; while the elevated land from the sea-beach to the summit is clothed with luxuriant vegetation and covered with a thick layer of vegetable manure, producing an abundant growth of large ferns. The eastern coast contains two principal harbours, formed by inlets of the sea, which reach to within two or three miles of the western coast, and are only six miles from each other. Port Ross, at the western extremity of the island, is protected from all winds except the south-east, and has a good tenacious clay bottom. Port Ross contains an upper inlet called Laurie Harbour, about four miles wide, and perfectly landlocked; while the steep beach on the southern side of the harbour affords great facility for clearing and reloading vessels.

The climate has been described by Sir James Ross, Captain Briscoe, and other navigators who have visited the islands, as mild, temperate, and salubrious. The temperature in the valleys is scarcely ever lower in winter than 38°, or higher in summer than 78°. The weather is generally good, but there are occasional high winds and heavy rains. Auckland Island is abundantly supplied with small streams. The soil is very productive. The hills, except a few of the highest, are thickly covered with large trees. The elevated ground is covered with moss and a kind of tall grass. Dr. Hooker notices the Auckland Islands as remarkable for the variety of their vegetable productions, eighty flowering plants having been found; and no less than fifty-six of them, till then unknown, have been noticed for their beauty and novelty. The only animals found on the island are goats and rabbits. Pigs were left on Auckland Island in 1807 by Captain Briscoe, on his second visit, and these animals have greatly increased in number. In the woods three or four species of small singing-birds were found. On the heights petrels breed in considerable numbers. Hawks, gray ducks, snipes, cormorants, and the common shag also inhabit the islands. Fish are plentiful on the eastern coast of Auckland Island, and the rocks are covered with limpets; while the whale fishing carried on in the neighbouring seas may yet become very valuable. Sir James Ross mentions that while he was in Laurie Harbour many sperm-whales came into the anchorage.

The Auckland Islands were granted by government to the Messrs. Enderby on advantageous terms, in consideration of the services rendered by their father to this country, as also for the more recent discoveries of the southern continent by Captain Briscoe whilst in the employ of the Messrs. Enderby. A company to which the Messrs. Enderby ceded their privileges, obtained a charter of incorporation on the 16th of January, 1849, for the purpose of prosecuting the whale fishery from the Auckland Islands; and Laurie Harbour was chosen as the head station of the company, from the superior facilities it affords to whaling vessels. The islands were uninhabited until the Southern Whale Fishery Company, under the conduct of one of the Messrs. Enderby, made a settlement there in 1849.

AUDOUIN, JEAN VICTOR, was born at Paris on the 27th of April, 1797. His early education was intended to fit him for the law, but his inclinations were towards the study of organic nature, and he accordingly gave up the law for the study of medicine. His mind was early directed to the study of the natural history of insects. The first paper which he published was a description of an animal belonging to the class *Insecta*, in 1818, and from this date to the time of his death, his labours in this branch of study were incessant. The results of most of his investigations were published in the form of contributions to the various journals or in the Transactions of societies. These papers were numerous, and they are all valuable.

His early papers on the anatomy of the *Insecta*, and especially those on the *Annelida*, introduced him to the notice of Cuvier, Geoffroy St. Hilaire, and Latreille, with whom he lived on terms of intimacy, and from whose instruction he obtained those enlarged views of the relations of the animal kingdom which are so conspicuous in all his writings. In 1826 he became connected with M. Milne-Edwards in researches upon the *Crustacea* and *Annelida*, which resulted in a great addition to existing knowledge on the subject of the minute anatomy and functions of these animals. In the same year he became assistant to Lamarck and Latreille in the Jardin des Plantes, Paris, and on the death of the latter he was appointed professor of entomology in the museum attached to that institution. In his lectures here he paid particular attention to those insects which were injurious to vegetation. His investigation of the economy of insects was very extensive, and only a small portion of the matter he had collected was published before his death. He left behind him fourteen quarto volumes of manuscript on this subject, with numerous drawings. Audouin, at the request of the government of France, prepared and published a work, entitled 'Histoire des Insectes nuisibles à la Vigne, et particulièrement de la Pyrale qui dévaste les Vignolles des Départemens de la Côte-d'Or, de Saône-et-Loire, du Rhône, de l'Herault, des Pyrénées-Orientales, de la Haute-Garonne, de la Charente-Inférienre, de la Maine, et de Seine-et-Oise.' It came out in six parts quarto. The first part appeared in 1840, but the last did not appear till some time after the author's death, in 1843. The work treats not only of the natural history of these insects, but also of the means of preventing their increase and of destroying them. It is illustrated with beautiful plates, after drawings by the author, and, whether regarded as an example of careful observation, and the application of science to a practical subject, or for the beauty of its illustrations, is probably one of the most valuable ever contributed to entomology.

Audouin fell an early victim to the pursuit of his favourite science. In the summer of 1841 he visited the south of France, for the purpose of investigating the habits of the insects which injure the olive-plantations. Here he exposed himself to wet and cold, which brought on an attack of apoplexy, of which he died on the 9th of November, 1841. On the day of his funeral orations were delivered at his tomb by M. Serres, president of the Academy of Sciences; M. Chevreul, director of the Museum of Natural History; by M. Milne-Edwards, and M. Blanchard. Audouin had collected a fine museum, not only of individual insects, but of specimens illustrating their economy. These were exhibited after his death at the museum of the Jardin des Plantes. His library was large, and when sold by public auction at his decease realised 20,000 francs.

It would be unjust to Audouin to regard him as a mere entomologist. He was a comparative anatomist and naturalist, whose power of acute observation peculiarly adapted him for the study of the habits and the structure of insects. In all his more important papers on entomology, it is evident that he did not regard insects as the end of his inquiries, but that he looked upon them as a great class of phenomena, illustrating the general laws that were deducible from the study of the whole animal kingdom. With him external forms were only regarded as dependent on an internal structure, which in its development, and the functions it performed, stood closely related to the whole animal kingdom. It was thus that he was led to investigate the annulose subkingdom of animals, and succeeded in adding to science so many important facts which assist in indicating the true relation of these animals to one or the other division of the animal kingdom.

(Abridged from the *Biographical Dictionary of the Society for the Diffusion of Useful Knowledge.*)

AUDUBON, JOHN JAMES, an eminent American naturalist, was born in Louisiana, in the United States, on the 4th of May, 1780. Both his parents were French. His father, who was an ardent admirer of the beauties of external nature, endeavoured from his earliest years to foster in him a similar taste, and especially directed his attention to the many tribes of birds which inhabited that part of the state in which they resided. The boy's passion for the study of birds and everything connected with them, soon outran his father's promptings. While still a child he obtained possession of several of the splendid-plumaged specimens of American birds, and cherished them as his choicest treasures. At this period, when any of his birds died, his chief regret was that he could no longer, either himself retain what had been so bright, or convey to others a notion of the departed brilliance. His father having placed under his eyes a book of ornithological illustrations, the boy determined to become a draughtsman himself.

Feeling his deficiency in the elements of drawing, he applied himself with great assiduity to acquire the ability to draw well. At length, when he was about fourteen, his father took him to Paris, and placed him in the studio of the celebrated David. Here, though he neglected the study of the higher principles of art, he became a skilful draughtsman; and satisfied with having obtained the competency necessary to his views, he threw aside the lessons of the famous master; and, at the age of seventeen, returned to the 'Birds of America.'

In 1798 his father gave him a farm in Pennsylvania, near the river Schuylkil, but he sadly neglected his agricultural duties. Of his occupations here, he says, "my rambles invariably commenced at break of day, and to return wet with dew and bearing a feathered prize, was, and ever will be, the highest enjoyment for which I have been fitted." About this time he married a very interesting and accomplished young lady, who shared his after honours. For nearly twenty years he now pursued commerce (nominally); and his success was what may be easily supposed. He removed westward to Louisville, and there first met Wilson, whose example excited still more a zeal that needed no spur. In 1810 he sallied forth on a great exploring expedition, and sailed down the Ohio with his wife and child, bird-sketching as he went. In the next year he explored Florida. Finding the joint pursuit of business and science impossible for him, he at length abandoned his nominal business altogether.

On the 5th of April 1824, he visited Philadelphia, where Dr. Mease, his only intimate friend in the place, introduced him to Charles Lucien Bonaparte, prince de Musignano, himself an ardent ornithologist, and who, as is well known, published a splendid continuation of 'Wilson's Ornithology.' The prince warmly encouraged him in his plans, and he now began seriously to contemplate publication. From Philadelphia he went to New York; and thence, taking the Hudson for his high-road, penetrated into the pathless forests. It was now he projected, in a methodical manner, his famous publication of illustrations, which he divided into numbers, to each number five plates, according to the size of the objects. All Audubon's illustrations are of the dimensions of nature; and very often they are presented also in the most capricious attitudes, but with the strictest fidelity to nature.

After a ramble of eighteen months, he returned to his family in Louisiana; explored all the surrounding forests, and then sailed to Europe. Without the means of publishing his great work, the third part of which, when it appeared, cost 40*l.* per copy to the purchaser, he landed at Liverpool in 1826. His letters of introduction procured him a cordial, and even enthusiastic, reception in that town, in Manchester, and in Edinburgh, where he commenced the publication of his illustrations and descriptions of the 'Birds of America.' The work, however, was quickly transferred to the hands of London artists. In September 1828, he once more visited France, where he was rapturously welcomed by the scientific world. Baron Cuvier pronounced a panegyric of him before the Institute. Charles X., Louis Philippe, and the Duchess of Orleans, the Duke of Messina, Cuvier, Humboldt, the Institute, and others, joined his subscription list. By the 25th of November 1828, the eleventh number of the work, and 100 plates, had appeared.

He now determined to revisit America for the purpose of refreshing some of his drawings, and of bringing his wife back with him to Europe. On the 1st of April he set sail, and in about a year he returned with Mrs. Audubon. Having again gone back with his wife to America in August 1831, he proceeded to Florida, explored the forests of Maine, made a voyage to the Gulf of the St. Lawrence and the coast of Labrador, and visited Newfoundland and Nova Scotia. On the 28th of April 1833 he held at New York, where now the greatest honour was paid to him, an exhibition of his illustrations of American water-birds. In 1834 he again went to Florida, and thence to Texas. The scientific fruits of Audubon's romantic rambles had procured him many tokens of respect. He became a Fellow of the Linnæan and Zoological Societies of London; of the Lyceum of Natural History at New York; of the Natural History Society at Paris; of the Wernerian Society of Edinburgh; honorary member of the Society of Natural History at Manchester, of the Royal Scottish Academy of Painting, Sculpture, and Architecture, and other less important associations. Audubon's book was the largest and grandest which had been published on Ornithology. Every sort of bird is engraved, male, female, and young. The drawings are admirable; and the descriptions are second in merit to those of Wilson only. Audubon's peaceful and enthusiastic life of exploration and study was prolonged to the ripe age of 71. He died on the 27th of January 1851, at Minniesland, near the city of New York.

AUSTRALIA. In the article AUSTRALIA, of the 'Penny Cyclopædia,' a brief narrative has been given of the successive discoveries of the various exterior portions of the continent, and also of the most important surveys of the coasts. The principal journeys of exploration of the interior which had then been made were conducted by Wentworth, Hume, Cunningham, Oxley, and Sturt, and the information acquired is embodied in the article above-mentioned.

Further Progress of Discovery. Captain Sturt, in 1828, had discovered the river Darling, and traced it downwards to 30° S. lat., where he was obliged by want of water to abandon it. At the end of 1829 Captain Sturt was again sent into the interior, to trace the farther course of the rivers. He proceeded to the south of Sydney, and intersecting the Murrumbidgee, passed thence to the Murray. Sir Thomas Mitchell, in 1835, traced the Darling from the point where Sturt had left it in 1828 down to 32° 26′ S. lat. In 1836 Sir Thomas Mitchell followed the course of the Lachlan downwards, and crossing from that river to the Murrumbidgee, from it gained the banks of the Murray, and, following its course, reached the Darling at its confluence with the Murray.

In 1837-38-39, Captain George Grey conducted two expeditions in north-west and western Australia, and made some important discoveries in Western Australia between Cape Cuvier, 24° S. lat., and Swan River 32° S. lat.

In 1838 Captain Sturt led an exploring party overland from New South Wales along the banks of the Murray. He commenced his journey at the ford where the Hume intersects the road to Port Philip, and in so doing connected the whole of the waters of the south-east angle of the Australian continent.

In 1839 Mr. Eyre fitted out an expedition, and tried to penetrate northwards into the interior; but having descended into the basin of Lake Torrens, he was baffled at every point. He therefore went to Port Lincoln, whence he proceeded along the line of the south coast to Fowler's Bay, the western limit of the colony of South Australia. He then left the coast, and pushed boldly forward to the N.E. for Mount Arden along the Gawler Range, but was unable to advance farther than 29° 30′.

In 1840 Mr. Eyre again conducted another expedition towards the central part of the continent. He was unable to penetrate to the north, but steadily advancing westward, after a journey of excessive difficulty and privation, established the startling fact that there is not a single watercourse to be found on the south coast of Australia from Port Lincoln to King George's Sound, a distance of more than 1,500 miles.

Whilst these attempts were being made to penetrate towards the interior from the south, Captain Wickham, in Her Majesty's naval service, was actively engaged on the northern coast. In command of the Beagle, he carried on a survey of the intertropical shores of the continent, which led to the discovery of two considerable rivers—the Victoria, in 14° 26′ S. lat., 129° 22′ E. long, and the Albert, in 17° 35′ S. lat., 139° 54′ E. long. Captain Stokes succeeded Captain Wickham in the command of the Beagle, and penetrated nearer to the centre than had been done before.

Captain Sturt, in his last journey, left Adelaide on the 15th of August, 1844, and following the course of the Murray as far as its confluence with the Darling, then struck northwards. Crossing vast tracts of barren ground and the great stony desert, on the 8th of September, 1845, he reached 24° 30′ S. lat., 138° E. long. He arrived at Adelaide on his return, Jan. 19, 1846.

Sir Thomas Mitchell spent the year 1846 in an exploring journey into the interior of tropical Australia, making his way immediately to the westward of the mountain range which bounds the country to the west and north of Moreton Bay. He had to pass over a great deal of dry and barren land, but he also discovered a large extent of singularly beautiful and rich country, especially about the head of a river which he discovered near 25° S. lat., and which he named the Victoria. It trended to the north-west. Mitchell, however, was unable to continue his way to the head of the Gulf of Carpentaria, the main object of the journey; but as he was strongly of opinion that the Victoria would be found to fall into the Gulf of Carpentaria, Mr. Kennedy, after the return of the expedition, was despatched to continue the search along its banks. He found that the Victoria, called by the natives the Barcoo, soon turned to the south-west towards the interior. He followed it for about 100 miles beyond the point where it was left by Mitchell, and until it dwindled away and was lost in the sand in 26° 15′ 9″ S. lat., when, owing to the failure of water, he was compelled to return. Making his way homeward by a route much to the west of that by which he as well as Mitchell had before proceeded, he discovered a wide extent of rich and well-watered pastoral country.

Dr. Leichhardt started on his overland expedition from Moreton Bay to the north coast, at the end of September, 1844, and reached Port Essington, at the end of the year 1845. In this journey Dr. Leichhardt crossed a large extent of beautiful and fertile country. At the end of 1846 he started on a still more difficult and perilous journey, from the eastern coast to the western, across or on the skirts of the great desert which had been partly explored by Sturt in 1844, 1845, and 1846. In this last and fatal journey he found a country of remarkable beauty and fertility—a discovery which he, with characteristic ardour, returned 300 miles to the nearest frontier station to report. The richness of this part of Australia is therefore well established; and although the frequent failure of the streams is at present a complete bar to any successful squatting settlements, little appears to be wanting for the development of its resources besides the construction of dams, by which the channels of many of the streams might be at once converted into canals for the reservation of the water, and of reservoirs, for which the undulations of the land afford peculiar facilities. Dr. Leichhardt, in this last journey, was accompanied by Mr. Lynd, whose name has been given to one of the rivers on the east coast. Dr. Leichhardt has not since been heard of, and there seems to be hardly a doubt that he and all his party have perished in the great central desert.

The latest expedition to the interior of Australia was that of Mr. A. C. Gregory, from the north coast, which was organised at Moreton Bay, and proceeded by sea to the mouth of the Victoria River. The horses were landed at Point Pierce, in Sept. 1855; and to the 9th of May, 1856, the party was employed in preliminary details, and in the exploration of the country to the south of the Victoria River, having penetrated the interior deserts to 18° 20′ S. lat., 127° 30′ E. long. On the 21st of June Mr. Gregory left the encampment on the Victoria River, accompanied by six persons. The arid nature of the country compelled them to increase the latitude to 15° S., after which they kept parallel to the coast as far inland as water could be found in the rivers, the greatest distance from the sea not exceeding 100 miles. Proceeding thus they reached the Albert River, Aug. 30, and left it Sept. 3, and made some ineffectual attempts to proceed to the south-east. Want of water compelled them to pursue a route parallel to the coast, to 17° 20′ S. lat., when the Gilbert River enabled them to follow a south-east course. Crossing the head-waters of the Lynd in 18° 40′ they reached the Burdekin, Oct. 16. Their route was then along the right bank of that river to the junction of the Suttor River, which was followed up to the Beylando. Tracing that river to lat. 22° they then pursued a south-east course to the junction of the Comet and Mackenzie Rivers, whence their course to the Dawson brought them, on the 22nd of November, to the farthest station of the settlers, whence they proceeded to Brisbane.

Surface, Hydrography, &c.—The Australian Alps, which occupy the south-eastern angle of the Australian continent, rise to an elevation of 7000 feet above the sea, and their summits are perpetually covered with snow. In the rest of the mountain-range which flanks the eastern coast, the loftiest summits seldom exceed the elevation of 4000 feet, though there are some which rise to 6000 feet.

North of 33° S. lat. the principal valleys are transverse, and the course of the rivers is consequently west and east. The Hunter river runs about 140 miles in that direction, declining, however, considerably towards the south. Its entire length from its source in the Liverpool range is above 200 miles. It is navigable for small vessels up to Morpeth, about 35 miles from its mouth. Its two principal tributaries, the William and the Patterson, both of which join it on the left, are navigable for a somewhat greater distance. At the mouth of the Hunter is the town of Newcastle, the chief shipping-town of the Hunter coal district. In the vicinity are extensive beds of good coal, which are largely wrought. Much of the copper from the Burra Burra and other South Australian mines is smelted here. Up the Hunter the land is much more fertile than along the coast, and the towns of East and West Maitland and Morpeth are the centres of thriving agricultural districts. The Manning River to the north of the Hunter, and the Hastings, which falls into Macquarie Bay, still farther north, also run nearly east and west: neither exceeds 100 miles in length. Port Stephens, about 20 miles north of the Hunter, is a bar-harbour, but convenient for small coasting vessels, and the outlet of the produce of the Australian Agricultural Company, a part of whose extensive territory stretches along its northern bank, and for a considerable distance up the river Karuah, of which it is the estuary. The estuary of the Hastings forms the small harbour of Port Macquarie.

North of Port Macquarie the country changes greatly in character. The mountains are very lofty, some of them attaining an altitude of 6000 feet, while the formations are granitic, trappean, and schistose. The streams are numerous and among them the Bellengen, the Clarence, the Richmond, and the Tweed, are navigable for coasting vessels. The vegetation is more luxuriant, assuming more and more of a tropical character as we proceed northward. The timber is of a larger and more useful character. Moreton Bay especially is characterised by its pines, of which the finest are the Moreton Bay Pine (*Araucaria Cunninghamii*) and the Bunya Bunya (*A. Bidwellii*). The cedars are also in great repute for the beauty of their wood, and the chestnuts are much valued. Cotton, coffee, sugar, and tobacco grow vigorously in this part of Australia; except tobacco, however, they are little cultivated, in consequence of the impossibility of obtaining labourers. Moreton Bay is a fine harbour, 60 miles long from north to south by from 3 to 20 miles wide. The islands Moreton and Stradbrooke stretch across its mouth, leaving on the south merely a narrow passage navigable only by boats, but on the north there is an entrance sufficiently wide and deep for ships of the largest size. Between the islands lies a dangerous sand-bar. The navigable rivers Brisbane and Logan, with several smaller streams, fall into the bay. The Brisbane is a large and important river, having its farthest source in the coast range near 152° E. long., and being fed in its course by numerous tributaries. It is navigable by vessels drawing 16 feet of water 20 miles from its mouth, where the ship navigation is stopped by a rocky shoal, but boats ascend 40 miles higher. The Moreton Bay district and the country northward appear to be free from the droughts which are so destructive in the southern parts of the country.

North of Moreton Bay the mountains recede to the west, and abont 25° S. lat. become mnch lower, losing in fact, in a great measure, the character of monntains, and permitting a comparatively easy access to the extensive pastoral regions which Sir Thomas Mitchell and Dr. Leichhardt here discovered in the interior. On this part of the coast, near 22° S. lat., is Port Bowen, near Broad Sonnd, the ontlet of the Nogoa and some other streams. Port Bowen is well adapted for steam navigation, and appears likely some day to become an important harbour. The country northward is almost unknown. The entire north-eastern coast, from 23° S. lat., is bordered by small islands and rocks forming what is known as the Great Barrier Reef.

We now return to the south and west coasts. To the west of Wilson's Promontory and the Australian Alps rise several chains of hills with intervening fertile plains and valleys. The chief are the Pyrenees, the Grampians, and the Victoria Range. The Grampians, which stretch north and south near 142° 20′ E. long., are the loftiest of these western monntains, the highest snmmit being Mount Williams, 4500 feet. From this chain descend several rivers. The most considerable of these is the Glenelg, which descends from the western slopes; it has a large body of water, but on acconnt of sand-hanks is unnavigahle. The Wimmera and other streams which flow northward from the Grampians are lost in shallow lagoons, which are formed in the barren sands of the northern part of Victoria. The Yarra Yarra, which rises in the monntains east of Melbourne, flows past that city, below which it is navigahle. The country north of these mountains, which forms the north-western portion of the province of Victoria, was named hy Sir Thomas Mitchell, who first explored it, Australia Felix, on account of its apparent fertility. This tract affords very fine and extensive cattle-runs, bnt between it and the Murray is a dry and barren tract.

West of the Glenelg, in the colony of Sonth Anstralia, near the coast, are low ranges of wooded hills and grassy plains, with more extensive and very rich plains farther inland, together with lnxuriant forests, which extend to the foot of the Burr Mountains, the highest of which are 1000 feet above the sea. An isolated mountain, Mount Gambier, has an extinct crater on its summit. Between this and the Murray are low ranges of hills generally running parallel to the shore, and separated from each other by level plains, which are suhject to inundations, hnt afford excellent pastures. Between the Murray and the Gulf of St. Vincent are several ridges of mountains, extending from Bryan Range in the north to Wakefield Range, which terminates in Enconnter Bay. Mount Brown, near the head of Spencer's Gnlf, is 3000 feet high. Beyond the mountains, and curving round their bases, is the remarkable depression known as Torrens Lake. At least a third of the tract between the Mnrray and the Gulf of St. Vincent is computed to he harren. In the narrow tract between the mountains and the eastern shore of the Gnlf of St. Vincent stands the city of Adelaide. On the western shore of Spencer's Gulf is Port Lincoln, the best harbour in Sonth Australia, and around it is mnch fertile country. Off the entrance of Spencer Gulf lies Kangaroo Island. West of this, to Streaky Bay, is a monntainons tract, known as Gawler's Range, the summits of which increase in height towards the west, where they attain an elevation of 2000 feet. West of Streaky Bay, and extending into Western Australia, is a waste and dreary country, covered merely with scrub.

The whole of the western end of the continent is inclnded in Western Anstralia. The coast from Port Lincoln to King George's Sound forms the Great Anstralian Bight, and presents a very remarkable appearance; from Streaky Bay to Cape Arid, abont 600 miles, there is an unbroken line of cliffs from 300 to 500 feet high. The interior here, as far as it has been explored, consists of apparently interminahle plains: no river is visihle and no fresh water procnrable. Immediately west of the Great Australian Bight lies the Archipelago of the Recherche. Abont King George's Sonnd, at the mouth of which is the town of Albany, the country improves considerahly. The surface is much broken, and there are lofty hills and rapid streams. From the south-west angle of the island a lofty range, called the Darling Mountains, which terminates there in Point D'Entrecasteaux and Cape Leeuwin, runs northward as far as Shark Bay, at a distance of from 50 to 100 miles from the coast, and rising from 800 to 3000 feet above the sea. Portions of these connected mountains are known as the Gairdner's, Moreshy's, Herschel, and Victoria ranges. The highest snmmit, Tnlbanop, is said to attain an elevation of 5000 feet. The formations are chiefly of red sandstone or limestone. They are mostly barren, bnt at some distance inland near the Blackwood River, which falls into the sea at the western angle of Flinders Bay, Mr. Roe found considerahle forests of timber-trees fit for naval pnrposes; he also discovered good coal in two or three places. East of the mountains towards the interior are sandy deserts. Swan River has a har at its month, bnt within it is navigable for some distance. The bed of the river rises rather rapidly from its month, and some distance inland the channel is frequently dry. Perth, the capital of Western Anstralia, is built at the month of Swan River.

Along the north-western coast the conntry differs considerahly from any part of the continent hitherto described. Instead of a lofty range of hills rising at a short distance from the shore, the coast from North-West Cape along the Dampier Archipelago, to Roehuck Bay, and thence along Bnccanier Archipelago up to the rocky promontory, near Prince Regent's River, is a low sandy level, covered with salsolaceous plants. Near Prince Regent's River the coast is hroken into hold granitic head-lands, some of which are 800 to 1000 feet high. Nnmerons islands, some of them hasaltic, line the coast, and the scenery is wild and striking. Mounts Trafalgar and Waterloo rise to the height of 900 feet, and numerons streams flow from them. Thence around the coast as far as Cambridge Gulf, are low hills. At Cambridge Gulf a river of some importance falls into the sea. It was named the Victoria by its discoverer, Captain Stokes, R.N., who traced it npwards for 140 miles, to a range of low hills, which he called the Fitzroy Range. In its lower conrse the Victoria flows through low, sandy, mangrove flats, which at its month have been cnt into nnmerous islands, covered during floods; but higher np, its banks are hilly and very fertile. The Fitzroy range rises in one or two places to the height of 840 feet. From the Mosquito Flats a connected range, from 700 to 800 feet high, runs off to the north-east. Stretching away from the river towards the interior Captain Stokes saw apparently interminahle plains.

North-east from the Victoria and the Fitzmaurice rivers is the Macdonald range, which consists of hills averaging from 400 to 600 feet in height. Nearer the shore, between Camhridge Gnlf and the Gnlf of Carpentaria, these hills become lower, and terminate generally in sandstone cliffs, seldom exceeding 50 feet in height. But abont Melville Bay granite occurs. At Cobnrg Peninsnla, where was the now ahandoned colony of Port Essington and the town of Victoria, the cliffs are of red sandstone; the interior of the peninsula, the surface of which is broken by low hills, consists of a continnous forest.

The shores of the great Gulf of Carpentaria are almost invariably low and flat, and generally covered with mangroves. The banks, which are of clay or sand, are seldom more than from 10 to 30 feet above the heach. On the eastern sides there are more small trees, but the shore is one wide, low, level, sandy waste. The rivers which fall into the gulf are few and nnimportant. One or two inlets which appear to he the months of rivers, have indeed not hitherto been explored, bnt there is nothing to lead to the helief that they differ from those which have been followed up. The chief of the rivers in the Gnlf of Carpentaria are the Flinders and the Albert, bnt like the others they consist merely of short and narrow streams opening into wide shallow estnaries. The Albert was ascended by its discoverer, Captain Stokes, in a boat for abont 50 miles from its month. He found it hordered hy open woodlands of acacias and gum-trees. When unable to ascend the river higher, he made a journey for some distance towards the interior of the conntry, and found it to consist of vast and apparently boundless grassy plains, relieved by occasional clumps of gum-trees; he named them the plains of Promise. Another river which he ascended, and named Disaster River, was bordered by rich allnvial flats, evidently snbject to considerahle floods. Beyond the river valley were wide plains as before. It was in endeavouring to explore Cape York Peninsnla, which forms the eastern bonndary of the Gulf of Carpentaria, and the north-eastern angle of the continent of Australia, that the adventurons Kennedy was murdered hy the natives.

The farthest point to which the interior has yet been explored is 24° 30′ S. lat., 137° 59′ E. long. Here Captain Sturt found a boundless arid plain, covered with bare ridges of drift sand sometimes 100 feet high, running in parallel lines as far as the sight could reach. The dryness and the heat were almost intolerable. In the midst of this plain, near 26° 33′ S. lat., 139° 30′ E. long., was a remarkable stony and quite sterile désert, which extended, as far as he could ascertain, about 80 miles in length and 35 miles in width. Near 27° 35′ S. lat. Captain Sturt discovered a sheet of water which he called Cooper's Creek, extending east and west for nearly 80 miles, and ending on each side in arid sands. It has been supposed that this creek may be in seasons of flood connected with the singular horse-shoe shaped depression known as Lake Torrens, which as already mentioned in part encompasses the mountains at the head of Spencer's Gulf, and that on the other side it might unite with Sturt's Stony Desert. Lake Torrens, it may be as well to mention, though called a lake, is not filled with water, but is merely an extensive depression, the bed of which is for the most part dry, with occasional unconnected pools and muddy holes. In seasons of great floods it would no doubt be filled with water, which it is possible may find an outlet in Spencer's Gulf. In a country where rain was abundant Lake Torrens would of course be a permanent lake, according to the ordinary accentation of that term.

Generally it may be said of the continent, that the ranges of mountains mentioned as stretching along the south-eastern and eastern coasts, in some places come close down to the shore, but elsewhere permit wide, fertile, and thinly wooded plains, with occasional sandy tracts, to extend between them and the sea. Towards the interior, beyond and nearly parallel with the mountain ranges, are undulating downs of moderate height and great extent, such as the Darling Downs discovered by Mr. Cunningham, the Fitzroy Downs discovered by Sir T. Mitchell, the Goulburn, Bathurst, Maneero or Brisbane Downs, and the New England district, with vast fertile plains, lying along and between the great rivers. These downs afford the chief sheep runs, the plains the cattle pastures. Farther inland are wide-spread marshes and worthless jungle, and enormous barren, arid, and sandy, or stony deserts wholly uninhabitable, and which have hitherto baffled all attempts to explore them. No dense forests have been found; the densest are those which occur in the Moreton Bay district and in tropical Australia. The trees are almost invariably light of foliage and very marked in character. The herbage is thin; the grasses are nutritious, but generally grow in detached clumps.

The river system of Australia, as far as known, is peculiar. Many of the rivers of the interior are lost in the sands, others are subject to immense overflows so as to convert in the wet season a large portion of the adjacent country into vast swamps, while in the dry season their channels are in many places quite dry and they are converted into a number of scarcely connected lagoons. Few of the rivers which fall into the sea are navigable, and nearly all have bars or other encumbrances at their mouths.

The Murray is an exception to the other known streams of the Australian continent. The basins of this fine river are in the deepest recesses of the Australian Alps. The headwaters of its immediate tributaries extend from the 36th to the 32nd parallel of latitude, and from 146° to 148° of longitude. It reaches the lowlands near 36° S. lat., 147° E. long., not far from the rising town of Albury. Its course from this place is exceedingly tortuous, the curvatures being short, abrupt, and very numerous. The whole of the upper course is obstructed by sand shoals, and snags formed by trunks of trees, and other objects which have caught in the bed of the stream; but there appears to be no insuperable obstacle to the clearance of the channel if there were sufficient intercourse to render it profitable. It would however be a costly and tedious process, and useless also unless an embankment was formed, as the river is subject to annual overflowings, when the country for a considerable space on both sides is converted into a swamp. These floods prevent agricultural operations being carried on along the banks of the Murray, above the junction of the Murrumbidgee. Attempts have been made to raise wheat on the sandy heights, but they have not been successful. On its left bank the Murray receives in this part of its course the Ovens, the Goulburn, the Campaspe, and several other streams; on its right is the vast impassable tract known as Murrumbidgee, which lies between the Murray and the Murrumbidgee rivers. No river here falls into the Murray on the right bank, but there are numerous creeks which pass from the Murray to the Edward River, which is a great arm of the Murray which runs between the main stream and the Murrumbidgee for many miles, and receives near its eastern end the Billibong River. A large portion of the level country between the Murray and the Murrumbidgee is a swamp; much of the remainder is cut up by the Edward, and the many connected channels, and the innumerable lagoons, or 'billibongs' as they are called by settlers. Many of these lagoons have on the top a thick crust of salt; indeed the whole of the Murray district is rich in this mineral. The soil is generally a gray clay. The Murray receives the Murrumbidgee in about 143° E. long. The river is here about 350 feet broad, from 12 to 20 feet deep, and flows at the rate of 2½ miles an hour. In 141° 30′ E. long. it is joined also on the right bank by the Darling, which is here 100 yards wide and rather more than 12 feet deep. As far as the junction of the Darling the Murray continues to flow to the west-north-west, but afterwards it passes between some limestone cliffs and its course is changed to the west, and the river is considerably increased in size. After passing the meridian 140° it trends to the south; and in this direction it flows without receiving any tributary of consequence till it expands at its mouth into the Lake Victoria, which is 50 miles long and 40 miles broad, but generally very shallow. The water of the lake is brackish, and it communicates with the sea at Encounter Bay by a passage impracticable even for boats. The river Murray however is navigable for vessels of considerable burden, being for 50 miles from the head of the lake 350 yards broad and from 20 to 25 feet deep. It appears certain indeed that it is navigable for steamers of light draught up to its junction with the Darling; and recent explorations have shown that it is probably navigable for a much greater extent. Following the course of its windings, the length of the Murray is probably not less than from 1300 to 1500 miles. Little influenced by the sudden floods to which the other Australian rivers are subject, its rise and fall are equally gradual. Instead of stopping short in its course, as they do, and terminating in a marsh or exhausting itself over extensive plains, its neverfailing fountains have given it strength to cleave a channel through the interior desert, and carry its broad and transparent waters to the sea.

The Murray receives the first addition to its waters from the eastward in the month of July, and rises at the rate of an inch a day till December, in which month it attains a height of about seventeen feet above its lowest or winter level. As it swells it fills in succession all its lateral creeks and lagoons, and ultimately lays many of its flats under water. As it rises, so it falls, gradually. No river falls into the Murray after its confluence with the Darling, nor does any fall into the Darling from the west after it reaches the low lands of the interior at about 30° S. lat., 140° E. long.

Geology, Mineralogy, &c.—We possess so few facts, comparatively, respecting the geological structure of Australia, beyond an enumeration of a somewhat limited number of localities in which granite, limestones, sandstones, and other rocks, distinguished only by their mineralogical characters, occur, that it would be of little use to attempt to give a general description, or even to institute comparisons with the known European deposits. Here we shall do little more than enumerate the principal varieties of rocks—merely stating as a general law that, as far as known, the geological formations are almost entirely of the kinds commonly termed primary and tertiary. Secondary rocks are scarcely anywhere met with. It is however premature to draw general conclusions. The mineralogy of Australia is exciting at present an extraordinary amount of attention, and the geology is also being with more or less care and skill investigated, so that additions are almost daily being made to our previous store of information. The results will be more conveniently given in our notices of the several colonies.

The direction of the mountains and the strike of the rocks of which they are composed are almost invariably north and south; the only important exception being on the north side of the continent, where there is an inclination to the east and west. Granite forms the axes of the ranges of mountains described as occupying the south-eastern and eastern portions of the island, having frequent masses of metamorphic rocks in connection with it. Much of the granite is highly quartziferous; in other extensive formations the felspar and hornblende so largely abound as to modify the granitic type; in some places the hornblende predominates, and frequently, as between Arnprior and Braidwood, the granitic passes into sienite and porphyry. Examples of all these varieties are met with in the Australian Alps, about the sources of the Murray, in Mooneroo, in the Currambenya Range, the Araluen and the Main ranges, Mount Victoria, and many other parts of this vast tract of country. Trap rocks prevail very widely, and vary as usual very much in their mineralogical structure. Very commonly they consist of basalt, greenstone, and various amygdaloids, and have an overlying deposit of conglomerate grit and sandstone. The trappean region of Maneero, which may be taken as illustrative of the trappean regions of the south-eastern portion of Australia, is of this character. According to the Rev. W. B. Clarke, the government commissioner, "the physical features of this region are precisely similar to those of the Grampians and Lammermuir Hills in Scotland. Each occupies a trough between granite mountains (here the Snowy and the Coast mountains), which it has filled up, sending its streams of subaqueous lava to considerable distances on each side of the general line of the axis of eruption. In Maneero this axis has a north-west and south-east direction, and ranges from the head of the Towamba towards the principal bead of the Murrumbidgee, at the northern extremity of the Snowy Mountains, or Australian Alps. Connected with this general trend of the trappean formation, which has produced the plateau or 'plains,' as bare tracts occupied by basalt, &c., are improperly locally designated, are various outlying hills and ranges, insulating patches of the schistose rocks, or piercing and transmuting the larger masses of that system. But the disposition of these local exhibitions of igneous agency, their texture, structure, and composition, prove them to have a common relation with each other, and with the great development which has occasioned the remarkable connection between the Snowy ranges to the west and the Coast ranges to the east, and the no less remarkable anticlinal division between the waters flowing on the northern side to the Murrumbidgee, and on the southern to the Snowy River. It is to the trappean outburst, which is undoubtedly of considerable antiquity, that the broken and disturbed condition of the present surface of the counties of Beresford, Wallace, and Wellesley is in a considerable measure due; it has directed the principal drainage of the country in two opposite courses, and has produced innumerable physical disarrangements."

A large portion of the basin of the Murrumbidgee is occupied by quartz porphyry, which is also largely developed in many other places. Porphyritic and basaltic dykes are very frequent. Very fine examples of columnar basalt occur at Cooroo and elsewhere on the great dividing range, and not unfrequently in other parts of the great mountain district. Serpentine, soapstone, pitchstone, and a fine red jasper are frequently met with in the trappean districts. Laminated, compact, and fossiliferous limestones are found in numerous places. In the ridges of the gullies running into the Shoalhaven, a little below Glenrock, the limestone is seen passing into statuary marble, white and crystalline; black marble occurs in strata in Borough Creek. A bed of limestone, which appears to range with considerable thickness both north and south of Bathurst, has been termed carboniferous. The coal and associated bed of sandstone and shell, which occur extensively on the eastern coast from Port Stephens to Botany Bay, occasionally ranging into the interior, have been considered equivalent to the coal-measures of Europe, merely from their mineralogical characters. What the age of this Australian coal deposit may be we have no means of accurately judging; but it is worthy of remark, that a fossil plant (*Glossopteris Browniana*) detected in it is also discovered in the Damuda coal district in India. The coal itself appears to be abundant and generally of good quality. Coal also occurs in great quantities on the Warranbungall Mountains and elsewhere in the mountain district of New South Wales. Mr. Roe in 1848 discovered coal by the mouth of the Fitzgerald River, about 149° 40′ E. long., 34° 10′ S. lat., and by the Phillips River some distance to the west, both places being in or near to Doubtful Island Bay and easy of access. It has also been met with in several other parts of the continent.

Sandstone rocks extend very generally through the mountain district. Sydney is built upon a sandstone deposit, which extends as far inland as Mount Victoria, and forms the bulk of the Blue Mountains. Its southern limit is Port Stephens. The sandstones are of various kinds, fossiliferous, ferruginous, silicated, argillaceous, and calcareous. In parts they appear very similar to those of the old red-sandstone formation of England. Found in conjunction with fossiliferous limestones and conglomerates they closely resemble those of the Devonian system. Both the limestones and sandstones are of exceeding value for economical purposes. Sandstone and limestone are the prevalent rocks of the shores of Western Australia. In North Australia is a great sandstone plateau rising 1800 feet above the level of the sea.

The slate and other schistose rocks are numerous and important. A quartziferous schist is the predominant rock of the country between the Canobolas and the Wellington Valley, and it prevails extensively throughout New South Wales and the eastern part of Victoria. The soil which covers this rock is generally poor, but the rock itself is rich in minerals. The slates are commonly gray, bluish, and yellowish; good roofing-slates are found in many places. The slates are not unfrequently intersected by veins of quartz and trap. Gray or brownish-white, soft or hard, felspathic beds of schist occur in conjunction with the slates, passing "into a true grit or sandstone, and becoming occasionally very quartzose, bands of quartz and transversely fibrous veins of quartz traversing them." Clay-slates and other argillaceous deposits are also general. The clays and other tertiary deposits occupy a wide area; in fact, it is probable that the whole interior is formed of horizontal tertiary deposits, broken here and there by hilly tracts rising out from them, like islands from the bed of an inland sea. Good brick and pottery clay is found.

Australia was not until lately considered rich in minerals. The discovery of the valuable Burra Burra copper mines in 1845, and still more the extraordinary discoveries of gold in 1851, however led to investigations which have gone far to show that Australia is mineralogically one of the richest countries in the world. The first official mention of gold being discovered in Australia was in a despatch to the Secretary of State from Sir George Gipps, lieutenant-governor of New South Wales, dated 2nd of September, 1840, in which is inclosed a report from Count Strzelecki, stating that he had discovered in the vale of Clwydd, in 1839, a small quantity of gold in an "auriferous sulphuret of iron, partly decomposed." No further notice was taken of this communication. Sir R. I. Murchison, however, in the course of various statements respecting the Ural Mountains, which he read to the Geological and Geographical Societies of London between 1841 and 1843, called the attention of men of science to the fact of the similarity of the formation of the Australian to those of the Ural Mountains, and asserted his belief that gold must exist in Australia. No steps were taken to pursue the inquiry practically, and Sir Roderick in 1846 addressed a letter to the Geological Society of Cornwall, urging unemployed Cornish miners to emigrate and search for gold in the drift and débris of the Australian Alps. In 1848 Sir Roderick addressed a letter to Earl Grey, the then Secretary of State for the Colonies, stating his reasons for believing that gold would be found in Australia in large quantities, but no notice was taken of his communication. Meanwhile efforts had been made to attract attention to the subject in Australia. Small quantities of gold had been found by a shepherd and sold in Sydney. About 1841 gold was found in the bed of the Macquarie by the Rev. W. B. Clarke of St. Leonard's, near Sydney, a gentleman of considerable scientific acquirements, who somewhat later announced the fact in the Sydney journals, and asserted his belief of the extensive prevalence of gold in the colony, on the ground that the strata of the Australian mountains running north and south through Victoria and New South Wales were of the same formation as those of the Ural Mountains in Russia, namely, granite mixed with quartz and schistose slate; and also, as was subsequently pointed out, as the Sierra Nevada in California. But it was not till 1849 that a Mr. Smith communicated to the governor, Sir C. A. Fitzroy, that he had found gold in a particular place, produced a specimen, and offered to discover the locality for a certain reward; and somewhat later Mr. Lancellott forwarded a specimen weighing 3½ ounces, which he had found in the river Turon, near its junction with the Macquarie, with a similar proposal. Sir Charles declined these offers, and the matter dropped till April, 1851, when Mr. Hargraves, who had returned from gold-seeking in California, wrote to Governor Fitzroy, announcing that he had been seeking for and had found gold, and offering to discover the localities on being assured of a reward. The governor replied that any such discovery would meet with a reward, but declined assuring him of any beforehand. Upon this Mr. Hargraves disclosed the places where he had found gold—namely, Lewis Ponds, Summerhill Creek, the Macquarie River, and another in the districts of

Bathurst and Wellington, about 150 miles west of Sydney. When the government officer was sent in May to examine the places, he fonnd persons already working them. The governor immediately issued a proclamation claiming the gold for the Crown, and forbidding any person to dig for it on his private account. But this it was found at once to be quite impracticable to prevent, and on May 22nd instructions were given by the governor to grant licences at the rate of 30*s.* per month. By May 25th there were 1000 persons employed in digging and washing at Summerhill Creek and its neighbourhood, which took the name of Ophir. In July gold was found in two or three places within the colony of Victoria; and from that time the discoveries of fresh localites still richer in gold have been made almost without intermission. On the 3rd of June the governor ordered a reward of 500*l.* to be paid to Mr. Hargraves, who snbseqnently received a temporary appointment as assistant commissioner; in 1852 a further sum was awarded to him, making his reward in all amonnt to 5000*l.* Policemen were appointed to the various stations, and escorts fnrnished for bringing the gold from the diggings to the ports of Sydney or Melbourne. An assay-office was snbseqnently established at Adelaide, and a mint has been established at Sydney. The effect of the gold discovery on the colonists was most extraordinary. In a short time the towns and villages were deserted, all the nsnal avocations abandoned, the ships in harbour left unmanned, and every one capable of labour repaired to the diggings, so that serious apprehensions were entertained that the growing crops wonld be left ungathered, the wool of the numerous flocks remain unshorn, and the flocks themselves be destroyed by being nntended. These evils were for the time fortunately averted: the colonists exerted themselves to obtain assistance, and on the news that gold was to be had for gathering being made known in England, an immigration ensued almost without a parallel. It is computed tbat in 1852 not less than from 90,000 to 100,000 persons left England for Sydney and Melbourne, and it was found difficult to provide ships to convey them. The emigration from England dnring 1853 was on an eqnally large scale, but has since somewbat diminished. [Emigration, *S.* 2.] In the meantime the price of provisions rose greatly, particnlarly at tbe diggings, which are usually in remote districts, to which there are no roads; the sheep instead of, as previously, being shorn and their carcasses boiled down for tallow, were driven to the diggings for food, and the wool and skin thrown away. The effect on tbe pnblic revenue is shown in a striking manner by a comparison of that of the colony of Victoria in the first three quarters of 1851 and 1852. In the three quarters ending September, 1851, the total revenue was 226,181*l.* 9*s.* 1*d.*, while in the three quarters ending September, 1852, it was 979,476*l.* 3*s.* 1*d.*, being an increase of 753,294*l.* 14*s.* The revenne of Victoria in 1857 was upwards of 3,000,000*l.* From the first discovery of gold in Victoria up to 5th February, 1853, the quantity of gold found in the colony of Victoria alone is stated by colonial authorities to have amonnted to 5,166,234 ounces, of tbe estimated value of 19,373,377*l.* The gold exported from Victoria during the year 1857 amounted to 2,582,793 ounces, valued at more than 10,000,000*l.*

The places where gold has been fonnd now extend from the Grafton range, New Sonth Wales, in 26° S. lat., 149° E. long., to Ballarat in Victoria, 37° S. lat., 144° E. long.; while two small gold fields have been discovered abont 27 miles from Adelaide, South Anstralia, 35° S. lat., 139° 30′ E. long. What may be called the main gold region of New South Wales alone, including no portion of the northern district, where gold has been fonnd in considerable quantities, and of course wholly omitting the valuable gold-fields of Victoria, has been officially estimated by the government commissioner, the Rev. W. B. Clarke, after several surveying jonrneys, to embrace an area of 16,000 sqnare miles; and this he says, in a snbseqnent report, "is strictly within tbe limits of trutb, and very far witbin them." The gold is found generally among tbe mountains, in creeks and gnllies, and the otber water-courses, and on the flanks far above the water level, but nsually at elevations not exceeding 3000 feet above the level of the sea. It is found in granite, wherever qnartziferous schist occurs, throngbout the trappean formations, and largely in bands of argillaceous iron ore.

Copper, as has been mentioned, had been fonnd in large quantities in Sonth Australia some years before gold began to be sought for. The Kapunda mine, the first of any consequence, was discovered and opened with great profit in 1842. In 1845 the Burra Burra mine, apparently one of the richest in the world, was discovered. The total quantity of ore raised from tbis mine up to September, 1851, was 79,765 tons. Tbe mine occnrs in the clay-slate formation; the lode runs from east to west. Many other copper and some lead mines have since been opened in the colony, with more or less snccess. The gold excitement has for a while almost entirely suspended all other mining operations; but the careful examinations which have been made of the gold regions, especially those undertaken by the government geological snrveyors, have made known the existence of numerons and widely-spread metalliferous veins, of considerable richness, which may, when the present excitement has passed away, lead to most important mining operations. The value of some of these regions may be estimated from the Report of Mr. Clarke to the governor-general respecting a portion of country termed Quedong near the junction of the Slanghter-House Creek with the Delegate River, abont 37° S. lat., 149° E. long., near the boundary of New Sonth Wales and Victoria. The district is occupied by slates, traversed by quartz and trap, with occasional patches of granite; but, he says, "what renders this locality so interesting and full of promise is the fact, that in addition to the fonr metals, gold, iron, lead, and copper, existing in so narrow a compass, there is also abnndance of excellent limestone to serve as a flux in case of its reqnirement, and abundance of water in the ever-flowing Delegate River, together with wood upon the ranges at no considerable distance." The whole basin of the Murrumbidgee, from near Bullanamang to the jnnction of the Qneanbayan River, is also said by Mr. Clarke to exhibit "not only metalliferons formations, but in some places veins of lead, copper, and iron," in conjnnction with abundance of limestone: qnartz porphyry is here the prevalent rock. And in other districts the metals have been found nnder eqnally promising circnmstances.

Lead has been fonnd in Sonth Anstralia, and worked successfully at Yattagolinga mine, where tbe average yield is said to be 75 per cent. of lead and 18 to 20 oz. of silver to the ton of ore; it is also worked at some other mines. In the great mountain ranges of Victoria and New Sonth Wales, as we have seen, lead is said to occur in many places; it has also been fonnd in the Darling Range and near Murchison River in Western Australia.

Iron ore abonnds on the eastern coast of New South Wales, where also good coal is fonnd in large quantities; whence we may conclnde that at no very distant period the eastern side of Australia may be stndded with iron fonndries, distributing their products over Southern Asia and among the numerons islands of the Indian and Pacific oceans. Iron has been recently fonnd in conjnnction with coal in the Warranbungall monntains. Argillaceons iron ore occurs extensively in the regions of the Australian Alps. In South Anstralia iron-ore is said to abound in the monntains on the East of Spencer and St. Vincent gulfs; at Rapid Bay, Enconnter Bay, and in tbe ranges from Cape Jervis to Blackrock Hill. No iron works have however, we believe, been yet established.

Native silver has been found in small qnantities. Tin occurs in several places. Blacklead is said to have been found near Adelaide, at Mount Torrens, and in the Belvedere Range, South Australia. Manganese and sulphur are also reported to have been found. Indications of qnicksilver have been met with in the vicinity of the Ophir gold-field.

In the recent explorations of the mountain regions it has been found that the precions gems exist in many parts of New Sonth Wales, Victoria, and South Anstralia. The snrveyor-general Sir T. L. Mitchell brought with him, on his recent visit to England, a diamond which has been pronounced by competent jndges to be of the very finest water. Mr. Stnchbury, the government geological surveyor of New South Wales, reports having seen a small but beautifully crystallised diamond from the Turon River, and topazes, garnets, rubies, sapphires, chrysoberyl, chrysolite, and cairngorm, from various localities in the same district; to which may be added from otber anthorities and different parts of the conntry the hyacinth, amethyst, jasper, carnelian, agate, and opal.

Coal appears to exist in Western Anstralia, South Anstralia, and Victoria, as well as in New South Wales; but the finest beds yet discovered are those abont the Hunter River, in the last-mentioned colony, which are extensively and profitably worked.

Salt is fonnd over a large part of the country, and the salt-works are nnmerous and extensive.

Large tracts of limestone occur on the eastern and south-eastern side of the continent; clays fitted for the economical purposes of life are common in many places; there are numerous sandstones which seem well adapted for ornamental buildings; gypsnm is found abundantly in the clay or marl, extending from Bathurst to Hunter's River, and in the vicinity of Swan River; and there is roofing-slate both in the eastern and western parts of Australia.

Climate.—The climate of Anstralia differs considerably from that of other conntries. The most remarkable as well as the most unfavourable characteristic is the long droughts which occasionally prevail. Captain Stnrt says:—"The year 1826 commenced the fearful droughts to which we have reason to believe the climate of New South Wales is periodically subject. It continued the two following years with unabated severity. The surface of the earth became so parched up that the minor vegetation ceased upon it. Culinary herbs were raised with difficulty, and crops failed even in the most favourable situations. Settlers drove their flocks and herds to distant tracts for pasture and water. The interior snffered equally with the coast, and men at length began to despond under so alarming a visitation. It almost appeared as if the Anstralian sky was never again to be traversed by a cloud." These seasons without rain appear to occur every 10 or 12 years. They are succeeded by excessively long rains, but afterwards the rains decrease gradually year after year until they again wholly cease for a time.

Another peculiarity is the quick transition from heat to cold. There are instances of the thermometer having varied 25 degrees in 50 minutes. This is owing to tbe sudden change of the winds. The north-west winds blowing over the great sandy deserts in the interior attain such a degree of beat, that they become too scorching to be pleasant to men and animals, or to be favourable to vegetation. The thermometer then rises suddenly from 80° to 110° in the shade. On the other hand, the south-eastern winds are often cold and piercing, especially when there is a sudden shift from a hot north-western: on such occasions the thermometer in South Anstralia often falls 40 degrees in a quarter of an hour.

But in spite of snch occnrrences, which are to be considered as exceptions, the climate over most of the settled part of the conntry, though somewhat too dry, is commonly delightful, and the evenings and mornings as pleasant as in southern Italy. Even the great heat which occurs does not produce relaxing and enfeebling effects on the constitution. On the lower part of the coast the thermometer ranges in summer (from September to March) between 36° and 106°, its mean elevation being 70°; and in winter (from March to September) between 27° and 98°, its mean being 66°.

In the interior and to tbe west of the mountain ranges the wet season commonly takes place during the summer; on the coast it commences in the beginning of the winter. Dews are very frequent and heavy, and sometimes they fall like a drizzling rain. Hail-storms are common in December and January.

On the low coasts frost is very little felt, but in the hilly districts it is freqnent, and very keen on the high terraces on the western side of the mountains, especially on the plains of Bathurst and the plains contiguous to them: these districts are 2000 feet above the sea. It is likewise observed that in these parts of the conntry the seasons are nearly a month later than on the low district on the coast. The snow lies on the tops of the mountains and occasionally also in the valleys for many days together, but it is absolutely unknown in the neighbourhood of Sydney and other parts of the coast. In his explorations of Tropical Australia, Major Mitchell experienced much frost, the thermometer being on the 24th of June 17° Fahr., or 15 degrees below freezing point: no discomfort however was experienced by any of the party, a circumstance which he attributes to the great dryness of the atmosphere.

The climate on the eastern coast is very favourable to health; and endemic diseases are not known with the exception of ophthalmia, which occurs in the months of October and November, and is produced by the winds which prevail at that time. These winds in general are not unpleasantly warm, but they resemble in some measure the English easterly winds which blow in April and May: like them they occasion blights in vegetation, and are considered as the cause of the then prevailing ophthalmia The conntry north of the Hunter River appears to be much less liable to droughts, and the wet and dry seasons occur with considerable regularity; bnt the temperature is hotter on the whole, and the climate less healthy than farther south.

Soil, productions.—The soil of so extensive a country and one where the geological formations are so varied differs of course very greatly in different parts, and the productions of the agriculturist vary in an almost equal measnre. For a notice of the usual crops and productions we refer to the several colonies; here it will be snfficient to observe that almost every variety of grain is raised, and generally of excellent quality. The colonies of New Sonth Wales, Victoria, and South Australia are those which best repay the labonrs of the agriculturist. The soil of Western Australia is of inferior quality. In New South Wales and Victoria, although the cultivation of the soil is very far from being neglected, the breeding of sheep and cattle is the chief occupation. Sonth Australia is especially a grain-growing colony: wheat of the finest quality is raised, and the crops are very large. Maize, which succeeds excellently in New South Wales, seldom succeeds well in Sonth Australia. Barley and oats are much grown for grain crops. Rye is not very extensively raised. Tobacco is grown largely in the Hunter River district of New South Wales. Cotton and coffee are cultivated in North and South Brisbane. Hops are grown in various places. Nearly all European vegetables are cultivated; potatoes form important crops in cool and moist localities. Although Australia was almost entirely without indigenous edible fruits, the fruits of almost every country and climate are now successfully raised there; and the grape and the olive appear likely to take rank among the most valuable of its productions. The vineyards of New South Wales are already extensive, and wine of excellent qnality has been made in sufficient qnantities to show that tbe culture may be profitable. Good oil has also been produced.

Native Tribes.—The number of the native tribes of Australia is not great, and it is steadily decreasing; several tribes have already wholly disappeared. Many efforts have been made to protect them, and to induce them to adopt settled and industrious habits, but without much success. Schools have been established by the government, but the young people almost invariably, when passing out of childhood, throw off tbeir clothes, and return to their native haunts and habits. A few girls become house servants, but they are easily induced to leave for the woods. Of late there has, however, been a somewhat important change. The impossibility of obtaining a sufficient number of white shepherds and labourers caused many stock-keepers to offer good money wages to the natives, instead of merely giving them food and clothes, as was before the custom, and to adapt the service to their feelings. The result is said to bave been very generally beneficial. They show little inclination, or rather considerable dislike, for manual labonr; bnt they make very good hut-keepers, are careful and gentle as shepherds, and make excellent stock-keepers; and large numbers are now so employed, as well as in wool-washing, and other work connected with sheep and cattle farming. It remains to be seen, however, whether it will be possible to overcome to any extent their migratory habits, which have heretofore always prevented any permanent settlement. The government land commissioners, in their official reports, speak highly of the conduct of the aborigines, where employed either as shepherds or stockmen; instances are mentioned where ten or twelve of them have remained steadily under one employer from a year to three years, and even longer. Some of the large cattle and sheep-holders in New South Wales had not, in 1852, a single white man in their employment. In some cases natives have been receiving 20*l.* a year, and the commissioners seem to be agreed in stating, that "both the disposition of the aboriginal native to work, and of the settler to make use of his labour, is decidedly increasing. The system of paying them by a money wage has tended greatly to produce this cbange in the habits of the native; and as the settlers are now fully alive to the fact, there can be no doubt that the practice will be continued." (Report of Mr. Commissioner Merewether.) This statement is confirmed by the fact, that in districts where the system of money payments has not been adopted, the settlers still find great difficulty in retaining the natives as servants, and complain of their idleness and misconduct. In Victoria the reports are hardly as favourable as in New South Wales; but in South Australia there seems to be much satisfaction felt at the change in the aborigines. The 'Protector of the Aborigines' in that colony states that upwards of 200,000 sheep were in June, 1852, under the sole charge of native shepherds. A training institution for aborigines has been established at Adelaide, chiefly by the exertions of Archdeacon Hale, who resides on the establishment. He says that even his "own sanguine expectations did not lead him to anticipate a success so complete and triumphant as that which has attended our efforts, nor so rapid an increase in the number of onr inmates." Besides the school-room, mess-room, &c., there are 20 huts occupied by native married couples. There is also a small farm, the work of which, with herding, cattle-keeping, &c., is done by the inmates of the institution, who are also tanght brick-making, building, and other nseful occupatious. In New South Wales a "native police corps has been established," which the Governor-General reports to have "done mnch in maintaining order among the aborigines. There appears," he adds, "to be no difficulty in recruiting for this force, as the young men of the different tribes are found anxious to enlist." Quarterly reports respecting the condition of the aborigines are made by the district commissioners to the governors of the several colonies, by whom they are regularly transmitted to the Secretary of State for the Colonies.

Divisions, Government, &c.—The entire island of Australia is a British possession. It is divided by the British government iuto the colonies of New Sonth Wales, Victoria, South Australia, Western Australia, and the district of North Australia. New South Wales occupies the south-eastern portion of the island, extending from the shores of the Pacific to 141° E. long., and northward to 26° S. lat. Victoria is separated on the north and north-east from New South Wales by the Murray River, and a line carried from its source on the Australian Alps in a south-eastern direction to Cape Howe. Its southern boundary is the Southern Sea; on the west it is divided from South Anstralia by the meridian of 141° E. long. South Australia extends from 141° to 132° E. long., and northward to 26° S. lat. Western Australia occupies the entire conntry west of 132° E. long. North Australia occupies the entire country north of 26° S. lat. and east of 132° E. long. The population is chiefly collected abont the south-eastern coast in the colonies of New South Wales and Victoria; Western Australia is very thinly peopled. North Anstralia is not colonised, the settlement of Port Essington having been abandoned; on this coast there are consequently no European inhabitants, but a considerable nnmber of Malay fishermen have settled upon it. The total population (exclusive of natives and Malays) in 1850 was 335,107, of whom 265,503 belonged to New South Wales and Victoria, 63,700 to South Australia, and 5,904 to Western Anstralia. It has since very rapidly increased, owing to the immigration consequent on the gold discoveries.

On August 5th, 1850, an Act of the Imperial Parliament received the royal assent, by which represeutative coustitutious were given, as distinct colonies, to New South Wales, Victoria, Sonth Anstralia, and Western Australia (as well as to Van Diemen's Land); with power to form other districts if necessary, and also powers of modification. The details of the constitutions will be found under the heads of the several colonies. The governors of Victoria, South Australia, and Western Australia have the title of lieutenant-governor; the governor of New South Wales has the title of governor-general, but there is no seat of supreme government in Anstralia, all the colonies being placed on an equality. Six bishoprics have been founded in Australia, Sydney (metropolitan), Newcastle, Adelaide, Melbourne, Tasmania, and Western Australia. In 1856 a new bishopric was created at Perth, in Western Australia.

(*Narratives, Journals, &c., of Voyages, Travels, Journeys, &c, in Australia*, by Flinders, Brown, King, Earle Cunningham, Frazer, Nind, Pérou, Sturt, Oxley, Hunter, Grey, Eyre, Field, Breton, Bennett, Clarke, Melville, Roe, Wentworth, Macgillivray, Mossman and Banister, Lancellott, Gerstaecker, Stokes, Leichhardt, Strzelecki, Jukes, Darwin, &c.; the *Geographical Journal; Parliamentary Papers*, &c. For a clear and comprehensive view of the physical featnres of Anstralia, as far as known, the reader should consult Arrowsmith's *Great Map of Australia*, published in 1853; and that also by Arrowsmith which is attached to the *Parliamentary Blue Book* entitled *Further Papers relative to the Recent Discovery of Gold in Australia*, 1853.)

AVARS, or AVARES, a tribe of people of Mongolian descent, who made their first appearance in large numbers in the country around the Don, the Caspian Sea, aud the Volga, in the 6th century, after having been driven from their own conntry by the Turcomans. They are generally supposed to have been of the same stock as the Ugrians or Huns. They had many chiefs, who are called by the Greek writers χαγανος, or Chaganus, evidently the same as the better known title of Khan. A part of them remained in the mountainous regions of the Caucasus, bnt the greater part, about 555, penetrated to the Danube, and settled themselves in Daria. While here many of them served in the army of Justinian; they also materially assisted the Longobards to conquer aud destroy the Gepidæ, and by the end of the century, under their most famous chief Khan Bajan, they had possessed themselves by degrees of the whole of Pannonia. They afterwards conquered Dalmatia, penetrated with devastating armies into Germauy as far as Thuriugia, and also into Italy, where they fought with the Longobards and Franks. They extended their domination over the Slavonians on the Danube and to the north of that river; over the Bulgariaus as far as the Black Sea, and in 610 besieged Constantinople. The Emperor Heraclius succeeded in repnlsing them, but they retired loaded with booty. The Slaves or Sclaves, aud Bulgarians, whom they had cruelly oppressed, making them serve in their armies, and transporting them to various parts of their dominion for the pnrpose of weakening their strength (Gibbon says they settled some of the Tchecks in the Camarus, where they are yet to be traced), at length rose agaiust them in 640, and drove them out of Dalmatia, but they still retained Pannonia. Here they were conquered by Charlemagne in 796, aud after 827 their name disappears from history, but, according to the received belief, their descendants are the Szeklers, who appear to have been anti-Magyars though they now speak the Magyar tongue.

AZADITINE. [CHEMISTRY, *S.* 2.]

B

BAIL, in ERROR, in civil causes, is now regulated by the Common Law Procedure Act, 1852; no practical change having, however, been effected by this statute.

BAILLIE, JOANNA, was born at the manse at Bothwell, near Glasgow, in 1762. She was the sister of Dr. Matthew Baillie. The history of her uneventful life is soon told. The daughter of a Scottish clergyman and professor of divinity, and of a mother in whose family superior intelligence seemed a common property, Joanna, while trained in the strict manner usual in a Scottish manse, not only received an excellent education, but from her childhood was brought into constant intercourse with people likely to call into activity her own mental gifts. Her career through life was quiet, unobtrusive, domestic; her tastes were all studious; her disposition was gentle, kindly, and benevolent. At an early period she removed to London, where her brother, Dr. Baillie, was settled as a physician. After a time, she, with her sister Agnes, took up her residence at Hampstead, which, while from its proximity to the metropolis it allowed her to enjoy ready intercourse with the many friends her literary fame drew about her, insured her at the same time a certain amount of retirement; and here the rest of her lengthened life was spent. She was known and esteemed by the most eminent of her contemporaries of more than two generations, and for very many years, even from the New World, visitors, attracted by the charm of her poetry, came to obtain her acquaintance and to listen to her conversation. Those who visited her out of admiration returned adding to that sentiment feelings of affection and respect. She died at Hampstead on the 23rd of February, 1851, in her 89th year, having retained her faculties to the last.

Though Joanna Baillie possessed in a large measure that keen and sensitive interest in all that developed the feelings or touched the destinies of others, and that sensibility and sympathy which are the special heritage of dramatic poets, yet these sentiments had in her instance more of pensiveness and of speculativeness than of fire, and made her seek and find events in her own thoughts rather than in action and experiment. Adventure may be, and has often been, the school of poetry for men; but a woman, and especially one of Joanna Baillie's feminine and modest disposition, must invoke the muse with a serener and more gentle worship. A close and penetrating observer, and gifted with no common genius, yet not favoured with the highest, nor endowed with the inspiration of 'many-mindedness,' which makes poetry of the first order bear to philosophy the same relation that intuition bears to calculation, Joanna Baillie early in life conceived a literary project based on a principle essentially erroneous, but which led to the production of her greatest works, the celebrated 'Plays on the Passions.' The principle on which all these plays were constructed was to select some one of the more powerful passions that agitate mankind, and to exhibit it in full action, by making the hero of the drama completely subjected to it, and by evolving out of the promptings to which he is represented as paying undivided and uninterrupted allegiance, every incident and situation. Admitting fully the noble poetry with which these plays are filled, and even the deep interest of many positions and events, it is evident that such characters must have a constrained, morbid, and unreal aspect; since in life, as in the dramatic creations of the highest genius, we constantly see that the dominant passion is turned aside or suspended by, it may be transient, but for the time irresistible, counter-thoughts or the force of circumstances; and this is a main reason why her plays have only achieved a partial and temporary success on the stage. Yet the one master passion is often admirably exhibited—laid bare in its most secret workings—subjected to a keen and searching analysis.

It was in 1798 that Miss Baillie published the first volume of her 'Plays on the Passions.' She was then thirty-six years old. As a book the production met with great success; and a second edition was called for in a few months. In 1802 she published a second volume. Two years later, appeared her 'Miscellaneous Plays.' Among these was the 'Family Legend,' a tragedy, which she used to term "her Highland play." It was acted for the first time at Edinburgh, in January 1810, with brilliant but not durable success. The prologue was written by Sir Walter Scott, who interested himself most ardently in its production on the stage; and Mrs. Siddons sustained the principal female part. In 1812 appeared the third volume of the 'Plays on the Passions.' In 1836 she published three more volumes of dramatic poetry. Previously to this, her tragedy of 'De Montfort,' perhaps the finest of her productions, had been brought out in London; and for eleven nights John Kemble sustained the character of the hero. Again, in 1821, this play was put on the stage for Edmund Kean to perform the same part. The 'Separation,' one of the Miscellaneous Plays, and 'Henriquez,' one of those on the Passions, and both tragedies, have also been acted.

Notwithstanding the originality of conception of Joanna Baillie's great dramatic poems, and the fire and inspiration with which passages in all of them are composed, no perfect idea could be gathered of the writer's powers from these performances alone. Her fugitive pieces, her ballads, her occasional lines, and her songs, taken together, afford the true measure of Joanna's powers, and the fairest proof of her versatile genius. They are bright, fresh, simple, and genuine; often humorous; sometimes highly pathetic; occasionally homely; never low, common-place, or gross. We must add that, along with all these natural gifts of the true poet, she possessed those acquired advantages, which nothing but severe and constant labour can bestow. Among her lighter effusions, the 'Woo'd and Married and a,' 'The Kitten,' 'To a Child,' 'The Weary Pund o' Tow,' and 'Tam o' the Linn,' are singularly illustrative of her style, so varied, yet always so simple and so arch.

In the year of her death, her works, which began to appear before the close of the 18th century, being still young in public esteem, she herself superintended their collective publication, prefixing a vigorous and able introductory discourse. Her works have been reprinted since her death in a single volume with a brief memoir.

BAINES, EDWARD, an eminent example of the success of industry, good conduct, integrity, and of unceasing endeavours to make his talents beneficial to his fellow-men as well as useful to himself, was born Feb. 5, 1774, at Walton-le-Dale, a village about a mile from Preston, in Lancashire, of a respectable but not wealthy family, long settled at Marton-le-Moor, near Ripon, in Yorkshire. He was first sent to the free grammar-school at Hawkshead, the master of which was Edward Christian, afterwards Downing Professor of Law in the University of Cambridge, whence he was removed when eight years old to the free grammar-school of Preston. His father had commenced business as a cotton-weaver, and wished to bring his son up to that business, but he preferred a more intellectual employment, and at the age of sixteen was apprenticed to a printer in Preston. After serving about four years and a half, during which time he had seen something of the management of a country paper, his master's business falling off, he transferred his services to Leeds, where he finished his time in the office of the 'Leeds Mercury.' During his apprenticeship he sedulously cultivated his mind. He invited several of his companions to join him in forming reading and debating societies, in the latter of which he is said to have distinguished himself by his liberal opinions, his toleration, and his plain good sense. In September 1797, the day after the expiration of his apprenticeship, he began business for himself in connection with a partner, from whom he separated in the course of the following year. From the political circumstances of the time the dissenters from the Church of England were the most liberal in their political opinions. Mr. Baines, from their consonance with his own, was thus brought into association with many of the most influential among them; and at length joined the body as an Independent. In July 1798 he married the daughter of Mr. Matthew Talbot, an excellent and pious woman, and continued by his industry and attention to business to win the confidence of the dissenting body and to increase his means. In 1801, assisted by some of the wealthier members of that body, he purchased the copyright and the printing materials of the 'Leeds Mercury,' of which he immediately became editor as well as printer. By judicious

H

but not sudden improvements he gradually increased its circulation, and extended its influence, while his good taste and temper led him to abjure all grossness and bitterness of altercation; and he promoted as far as lay in his power all local schemes for the amelioration of the position of his poor fellow-townsmen, by advocating the establishment of hospitals, friendly societies (savings-banks had not yet been established), and the extension of education. A large part of the influence he acquired arose from his being among the first who introduced 'leaders' or original editorial dissertations on political subjects into a provincial paper; these leaders being distinguished by the moderation of their tone, their independence, their fearless advocacy of the opinions he entertained, the force of their style, and their general good sense. In the severely contested election for Yorkshire in 1807, he took an energetic part in support of Lord Milton in opposition to Mr. Lascelles, although he differed in opinion from Lord Milton respecting the desirableness of peace on proper terms, and a reform in parliament, both of which he advocated, while there were few more earnest in supporting the dignity of England when threatened by France, and his appeals to the inhabitants of Leeds to join the volunteers when an invasion was feared, had a most remarkable effect. But we are not about to narrate all the incidents connected with Mr. Baines's conduct of his paper, which was carried on with a strict adherence to the same principles until the close of his life; we shall only say that he was the principal means, in his paper, of developing, in 1817, the conspiracy of Oliver and Castles, the paid emissaries of the government to foment insurrections in the northern counties, and that after his exposure there were no more plots. In 1815 he made his first prominent appearance as a public speaker at a meeting at Leeds to oppose the enactment of the Corn Laws, and in 1817, at another in favour of parliamentary reform. In 1814 he commenced the publication of 'The History of the Wars of the French Revolution,' which met with such success that he continued it under the title of a 'History of the Reign of George III.,' the whole being a compilation of considerable impartiality and talent. In 1822 and 1823 he wrote and published 'The History, Directory, and Gazetteer of the County of York,' in two thick volumes; and in 1824-5 a similar work for the county of Lancaster, subsequently expanded into a 'History of the County Palatine and Duchy of Lancaster,' which was not completed till 1836. In 1834, on a vacancy being made in the representation of Leeds by the appointment of Mr. T. B. Macaulay (now Lord Macaulay) to be one of the commissioners in India, Mr. Baines was chosen member in opposition to Sir John Beckett, after a severe contest. In the House of Commons he maintained the character he had acquired as a journalist, and though not a brilliant speaker, his integrity, independence, industry, and conciliatory manners, with his close connection with the dissenting interest, made him an influential member. In January 1835 he was re-elected, and again in 1837. Though generally supporting the Whig party, he was opposed to them in their schemes for public education, which he always contended would be best effected by voluntary subscriptions, and he deprecated the assistance of the State as tending to give an undue domination to the Established Church. In 1841, his health having suffered from the sedulous performance of his parliamentary duties, he retired from the representation, and proposed Mr. Hume as his successor, who however was defeated. In September of that year his former constituency presented him with an elegant silver service as a testimony of their recognition of his services. From that time he retired to some extent from public life, but continued to take an active part in local affairs, both as a magistrate and a poor-law guardian, in both capacities promoting social improvements as far as lay in his power; and he was always ready to interpose as mediator between the men and their employers in the many strikes that took place in the north, representing to the men the folly of their having recourse to violence in endeavouring to effect their object, and to employers the desirableness of placing the men in as comfortable a position as the circumstances would allow. In 1845 the 'Leeds Mercury' warned the speculators of the danger attending the railway mania, though fully acknowledging the advantages of the railway system. He saw that though the facility of communication was a great good, yet that if it became a mere traffic for premiums, it was likely to produce much distress. In 1846, though he had declined to accept the office, his fellow-townsmen chose him for alderman as a mark of their respect, but he immediately resigned the office. In 1847 he again opposed Lord John Russell's scheme for state education of the poor, and the opposition of the dissenters was so strong that the plan was withdrawn. On August 3, 1848, after a long life of usefulness, and after a short illness, he died, and was honoured by a public funeral.

BALBI, ADRIEN, was born at Venice, April 25, 1782. At an early period of his life he was appointed professor of geography and also of natural philosophy in his native town. In 1820 he took up his residence in Portugal. Here, from the archives of the kingdom, he procured the materials for his 'Essai Statistique sur le Royaume de Portugal et Algarve, comparé aux autres États de l'Europe,' published in Paris in 1822. After having settled in Paris, and employed himself in collecting rich and varied materials for many years, he published in 1826 the first volume of his 'Atlas Ethnographique du Globe; ou, Classification des Peuples anciens et modernes d'après leurs Langues.' This work first made the French public acquainted with the researches of Adelung and other German philologists. Balbi however improved their arrangement, and added much information gathered from the accounts of such travellers as A. von Humboldt, Freycinet, and others, as well as from linguists such as W. von Humboldt, Remusat, Champollion, Klaproth, &c. This work attained a deservedly high reputation. Under the administration of Martignac, Balbi received from the government such pecuniary assistance as rendered his circumstances easy. He had previously published, with the assistance of others whose help he has scrupulously acknowledged, statistical tables of the kingdoms of France, Russia, and the Netherlands. After finishing his 'Abrégé de Géographie, rédigé sur un Plan Nouveau,' which work has been translated into most of the principal languages of Europe, he quitted Paris in 1832, and settled at Padua, where he died March 14, 1848.

We have mentioned the works on which Balbi's reputation rests, but he produced several others, among them are:—'La Monarchie Française comparée aux principaux États de l'Europe,' 1828; 'L'Empire Russe comparée aux principaux États du Monde,' 1829, and 'The World compared with the British Empire,' 1830.

BALBRIGGAN, county of Dublin, Ireland, a seaport and post-town in the parish of Balrothery, and barony of East Balrothery, is situated in 53° 46′ N. lat., 6° 10′ W. long.; and distant by the Dublin and Drogheda railway, which has a station here, 21¼ miles N. from Dublin, and 10¼ miles S. from Drogheda. The population in 1841 was 2959, in 1851 it was 2310. The harbour is formed by a pier of 200 yards in length, at the extremity of which is a lighthouse. Although dry at low water, the harbour has been found very useful as a place of refuge. Balbriggan supplies the neighbouring district with coals and other heavy articles of import, and has a brisk trade in the manufacture of cottons, and of a very fine description of hosiery. Many of the females are employed in the embroidery of muslins. There is a considerable fishery, for which Dublin is the market. The constabulary and the coast-guard have each a station here. Quarter and petty sessions are held, and there is a savings bank. Fairs are held on April 29th and September 29th.

BALDOCK. [HERTFORDSHIRE.]

BALLINA, county of Mayo, Ireland, a seaport and post-town, and the seat of a Poor-Law Union, in the parish of Kilmoremoy and barony of Tyrawley (with the suburb of Ardnaree, in the parish of Kilmoremoy, barony of Tirera, and county of Sligo), is situated on the Moy River, 7 miles above its embouchure in Killala Bay, in 54° 7′ N. lat., 9° 10′ W. long.; 159 miles N.W. by W. from Dublin. The population in 1841 was 7012; in 1851 the population was 5230 (being 4647 in Mayo, and 583 in Sligo county); besides 1339 inmates of the Union workhouse. Ballina Poor-Law Union comprises 20 electoral divisions, with an area of 150,414 acres, and a population in 1841 of 52,234, in 1851 of 33,611.

The two bridges which cross the Moy at Ballina are the leading means of communication between the county of Sligo and the northern baronies of Mayo. The situation is also favourable for the export of agricultural produce. The town is modern, well built, and clean. On the Mayo side it consists chiefly of one street, running parallel to the river, with cross streets diverging on the roads to Crossmolina and Killala. There are here a court-house, and chapels for Baptists and Wesleyan Methodists. On the Sligo side are the parish church and a spacious gothic Roman Catholic chapel, which serves as a cathedral to the Roman Catholic diocese of Killala. A brisk trade is carried on in the export of agricultural produce. There is a very productive salmon fishery. A fever hospital and a dispensary are in the town. Ballina has a station of the constabulary force. Quarter and petty sessions are held; there are fairs on May 12th and August 12th. The surrounding scenery is remarkably fine, having a fertile and very extensive plain towards the sea, bounded on the south and east by the range of the Ox Mountains in Sligo, and on the west by Nephin Mountain (2646 feet), and the highlands of Erris. Ten miles north-east of Ballina, near the shore of Killala Bay, is the ruined castle of Leacan, now called Castle Forbes, remarkable as having been the patrimony of the Mac Firbises, who held it in virtue of their office as hereditary scribes and historians of the ancient Irish territory of Hy-Fiachra.

(*Tribes and Customs of Hy-Fiachra, Published by the Irish Archæological Society*, Dublin, 1844; Thom's *Irish Almanac.*)

BALLINROBE, county of Mayo, Ireland, a market and post-town and the seat of a Poor-Law Union, in the parish of Ballinrobe, and barony of Kilmaine, is situated on the Robe River, 2 miles from its embouchure in Lough Mask, in 53° 37′ N. lat., 9° 9′ W. long; distant 141 miles N.W. by W. from Dublin, and 4 miles S.W. from Hollymount on the leading road from Tuam to Castlebar. The population in 1841 was 2678, in 1851 it was 2162, exclusive of 2301 inmates of the Union workhouse. Ballinrobe Poor-Law Union comprises 18 electoral divisions, with an area of 144,888 acres, and a population in 1841 of 52,113, in 1851 of 37,285.

Ballinrobe is picturesquely situated chiefly on the left bank of the river Robe, and has on the whole a clean and neat appearance. It has now little trade, having in this respect much declined from its former importance. In the town are the parish church, a large chapel for Roman Catholics, a chapel for Protestant Dissenters, a market-house, a dispensary, a bridewell, and the Union workhouse. Quarter and petty sessions are held, and in the town is a barrack station and a station of the county constabulary force. A market for agricultural produce is held weekly, and fairs on Whit-Monday and December 5th.

BALLOTA, a genus of plants belonging to the natural order *Labiatæ*, and the tribe *Stachydeæ*. It has the anthers approximating in pairs, the cells diverging, bursting longitudinally. The upper lip of the corolla is erect, concave, the lower three-lobed, the middle lobe cordate. The calyx is funnel-shaped, with five equal teeth. There are two British species of this genus, *B. fœtida* and *B. ruderalis*. *B. fœtida* is the most common plant, and goes by the name of Horehound. The White Horehound is the *Marrubium vulgare.* [MARRUBIUM.]

BALLYMENA, county of Antrim, Ireland, a market and post-town, and the seat of a Poor-Law Union, in the parish of Kirkinsiola and barony of Lower Toome (with the suburb of Harryville in the parish of Ballyclug and barony of Lower Antrim), is situated on the right bank of the Braid River, 2 miles above its junction with the Maine, in 54° 52′ N. lat., 6° 15′ W. long., 33 miles N.N.W. from Belfast by the Belfast and Ballymena railway, and 118 miles N. from Dublin. The population in 1841 was 5549; in 1851 it was 6136, besides 357 in the Union workhouse. Ballymena Poor-Law Union comprises 23 electoral divisions, with an area of 160,853 acres, and a population in 1841 of 74,120, in 1851 of 71,123.

Ballymena stands in the midst of a very densely-populated district, extending from the neighbouring town of Broughshane on the east to the river Bann on the west. The population here unite the manufacture of linen with the pursuits of agriculture, and Ballymena which is their chief market possesses a very considerable and flourishing trade both in linens and agricultural produce. The town is built of stone, and has a respectable appearance. There are an Episcopal, a Roman Catholic, a Wesleyan Methodist, and three Presbyterian places of worship; a market-house with a spire, the Union workhouse, a dispensary, and a bridewell. Quarter and petty sessions are held, and the town is the head-quarters of the county constabulary. Saturday is the market day. Fairs are held on July 26th and October 21st. In the vicinity are extensive bleach-greens. The surrounding district, although divided into very small holdings, is cultivated to advantage, and presents a rich and pleasing landscape.

BALLYMONEY, county of Antrim, Ireland, a market and post-town, and the seat of a Poor-Law Union, in the parish of Ballymoney and barony of Upper Dunluce, is situated on the leading road from Belfast to Coleraine, 3 miles E. of the river Bann, in 55° 4′ N. lat., 6° 31′ W. long., 18 miles N.W. by N. from Ballymena, 8¼ miles S.E. from Coleraine, and 140 miles N.N.W. from Dublin. The population in 1841 was 2490; in 1851 it was 2581, exclusive of 373 in the Union workhouse. Ballymoney Poor-Law Union comprises 23 electoral divisions, with an area of 127,115 acres, and a population in 1841 of 50,710, in 1851 of 42,418. The town is irregularly built on a small stream which runs into the river Bann. It contains a church of the Establishment, a chapel for Roman Catholics, several chapels for Presbyterians, a town-hall, a dispensary, the Union workhouse, and a bridewell. Quarter and petty sessions are held, and there are here stations of the constabulary and the revenue police. Ballymoney has a small trade in linens. A market for linens and dairy produce is held monthly, and fairs are held on May 6th, July 10th and October 10th.

BALM. [CALAMINTHA, *S.* 1; MELISSA, *S.* 1.]

BALSAM. [BALSAMINA; IMPATIENS.]

BALZAC, HONORÉ DE, a French novelist, was born at Tours, May 20, 1799. He was the son of a clerk under the government of Louis XV. At the college of Vendôme, where young Balzac was sent early, he gained the character of an idle and disobedient student, and was removed to a private academy. On leaving school he was placed with a notary in Paris, but he almost immediately commenced writing articles for the journals. These are said to be rather testimonies of his perseverance than monuments of his genius. Between 1821 and 1827 he had published a number of tales, none of them exciting or deserving much attention, under the assumed name of Horace de St.-Aubin. In 1826, in connection with one Barbier, he commenced business as a printer and bookseller, and among other things published an edition of Fontaine's works, with a notice of Fontaine, written by himself, and commenced the 'Annales Romantiques.' His speculation was altogether unsuccessful. In 1829 he appeared before the public for the first time, under his own name, with the novel of 'The Last Chouan;' the scene of which was laid in La Vendée, which district he had visited.

It was not however till the publication of his 'Peau de Chagrin,' in 1829, also under his own name, that the Parisians became alive to the piquant originality and lively fancy that distinguished his works. From that period he was a general favourite in France, and many of his productions have been translated into most of the languages of Europe. He was indefatigable in supplying the public craving under the title of 'Comédie Humaine.' He planned a series of compositions that was to embrace every phase of human society; and at this he worked for twenty years. Among the most popular were 'La Femme de Trente Ans,' and 'Le Père Goriot.'

On the publication of the 'Médécin de Campagne,' in 1835, Balzac received a complimentary letter from the Countess Eveline de Hanska, the wife of a Polish nobleman, possessing large estates in Russian Poland. Balzac replied, and an intimate correspondence ensued. To this lady his novel of 'Seraphita' was dedicated. The countess became a widow, and a few months after the revolution of February 1848 Balzac quitted Paris to bring her back as his wife. He inhabited a large house near the Champs-Elysées, which he adorned with a multitude of chefs-d'œuvres of art, and in which he hoped to find happiness and peace. But even before his journey he had been attacked by a disorder which it was found impossible to cure or to postpone—disease of the heart—of which he died, August 20, 1850. He was buried in the cemetery of Père-la-Chaise, an immense crowd attending the funeral; and Victor Hugo pronounced a critical eulogium over his grave. In that eulogium, he says, Balzac "chastised vice, dissected passion, fathomed and sounded man in his soul, his heart, his feelings, his brain—the abyss of each in its very essence." There is more asserted here than an English reader can concur in. Balzac had a rich fancy, but not a pure taste; he was an acute observer, but wanted poetic elevation; he was often extravagant, and sometimes wearisome. His 'Contes Drolastiques'—thirty short tales—are written in an antiquated form, a sort of resemblance to the 'Heptameron Français' of Margaret of Navarre. The 'Contes Philosophiques et Romantiques' are much inferior to the tales of Marmontel or of Voltaire, of which they are in some degree imitations. His dramas, of which he wrote a few, were failures.

(*Nouvelle Biographie Générale.*)

BANAGHER, King's County, Ireland, a post-town in the parish of Reynagh and barony of Garrycastle, is situated in 53° 13′ N. lat., 7° 54′ W. long., on the left bank of the river

Shannon, which is here crossed by a bridge leading to Galway by way of Eyrecourt; distant 2¼ miles S.S.W. from Shannon harbour, where the river is connected by the Grand Canal with Ballinasloe on the west, and Dublin on the east, and 82 miles W.S.W. from Dublin by the high road. The population in 1841 was 2827, in 1851 it was 1846. The town is built on the intersection of the Birr and Eyrecourt road with that leading from Shannon harbour to Limerick. The old bridge of 18 arches was removed in 1843, and a new bridge of 6 arches of 60 feet span each, with a swivel arch of 45 feet span for the passage of vessels, was erected in its stead by the Irish Board of Works. At the eastern end of the bridge are a barrack and a magazine, and there are batteries which command the bridge and its approaches on both sides of the river. The trade consists chiefly in milling and distillation. Prior to the Union, Banagher was a corporate town, and returned two members to the Irish Parliament. Petty sessions are held here. Fairs are held on May 1st, September 15th, October 28th, and November 8th. The adjoining district is flat, and in the immediate vicinity of great tracts of bog, but it is well cultivated.

BANBRIDGE, county of Down, Ireland, a post-town and the seat of a Poor-Law Union, in the parish of Seapatrick and barony of Upper Iveagh, is situated on the left bank of the river Bann, on the leading road from Newry to Belfast, in 54° 20′ N. lat., 6° 16′ W. long., 13 miles N. by E. from Newry, and 76 miles N. from Dublin. The population in 1841 was 3324, in 1851 it was 3301, exclusive of 478 inmates of the Union workhouse. Banbridge Poor-Law Union comprises 23 electoral divisions, with an area of 124,929 acres, and a population in 1841 of 87,100, in 1851 of 74,844.

The principal part of the town is built upon an eminence, having a steep declivity towards the river. To obviate this inconvenience, the centre of the main street, which was of width sufficient to admit of the alteration, was lowered to a depth of fifteen feet, leaving elevated causeways on each side. In carrying this arrangement into effect, it was necessary to remove the old market-house which formerly stood in the middle of the street on the summit of the hill: a viaduct connecting the opposite terraces now occupies the site. The town consists chiefly of this main street, and is substantially and neatly built, but has no building of pretension except the new market-house and the church. The church is pleasingly situated on a level green adjoining the bridge, on the right bank of the river. The Wesleyan Methodists have one chapel, and the Presbyterians have three chapels. Petty sessions are held here, and there is a station of the constabulary force. Twelve fairs are held in the course of the year. The linen trade in all its branches is carried on with great activity in the immediate neighbourhood. The line of the Bann, from a distance of several miles above the town to the border of Armagh, presents an almost continuous succession of bleach-greens. At Huntley Glen, a little below the town, is a large thread-spinning factory; and at Seapatrick an extensive establishment for weaving union cloth by machinery. A bridge has stood at this point of the Bann from a very early period. In the itinerary of King John, A.D. 1210, the place is mentioned under its present name.

(Fraser, *Handbook for Ireland; Original Communications.*)

BAND-FISH. [Cepola.]

BANKRUPTCY. The numerous statutes relating to bankruptcy have been consolidated by the Bankrupt Law Consolidation Act, 1849; which has been amended in one or two particulars by the statute 17 & 18 Vict. c. 119. The class subject to these laws, *traders*, has been further defined and extended, and the proceedings in court simplified. They are commenced by a petition either by the trader himself, or by a creditor or creditors; upon which an adjudication is made, and after notice, gazetted; there being an appeal to the Lords Justices of the Court of Appeal in Chancery, as coming in place of the Court of Review, and from them to the House of Lords. Meetings for the examination of the bankrupt and proof of debts follow at stated intervals [Bankruptcy, *S.* 1, p. 171], the property of the bankrupt being in the mean time vested by the adjudication in an official assignee; and on a choice being made by the creditors, in him and their assignees jointly, the control of the Court being exercised throughout on the collection and distribution of the estate. Companies incorporated by Charter or Act of Parliament (7 & 8 Vict. c. 111), insurance companies, and banking companies of more than seven partners (7 & 8 Vict. c. 113), may be made bankrupt. Joint Stock Companies, with limited liability, are wound up, when necessary, in the Courts of Bankruptcy; and the Court of Chancery may send the winding-up of companies, whose liability is unlimited, to this tribunal (19 & 20 Vict. c. 47; 20 & 21 Vict. c. 14; Blackst. Comm., Mr. Kerr's ed., v. ii. p. 484. See also Insolvency, *S.* 2).

The bankrupt laws of Scotland have been consolidated to some extent, and the procedure in a sequestration simplified and cheapened by the statute 19 & 20 Vict. c. 79.

A similar observation applies to Ireland. The laws relating to bankrupts and insolvents in that part of the kingdom have been consolidated, and the administration thereof committed to a new court called 'The Court of Bankruptcy and Insolvency' (20 & 21 Vict. c. 60).

BANWELL. [Somersetshire.]

BARBERRY BLIGHT. [Æcidium.]

BARBUS. [Barbel.]

BARHAM, REV. RICHARD HARRIS, was born December 6, 1788, at Canterbury, where his family had resided for many generations. He was an only son, and his father, who died in 1795, left him a small estate. In 1802 his right arm was severely shattered by the upsetting of the Dover mail, in which he was travelling to St. Paul's School, London. His life was despaired of for some time, but he ultimately recovered, and regained the use of his arm. From St. Paul's School he removed to Brasenose College, Oxford, where, during a short but severe illness, he first entertained the thought of entering into the church, though he had previously to this intended to become a lawyer, and did afterwards become for a short time a pupil to a conveyancer. Having passed his examination for holy orders, he was admitted to the curacy of Ashford in Kent, whence he removed to Westwell, a few miles distant. Mr. Barham married in 1814, and shortly afterwards was presented by the Archbishop of Canterbury to the rectory of Snargate, and he obtained at the same time the curacy of Wareham, the former in Romney Marsh, Kent, a district much frequented by smugglers, and the latter on the verge of it. The breaking of one leg and the spraining of the other by the overturning of a gig, gave him occasion to employ himself in the composition of a novel, entitled 'Baldwin,' which was published without attracting any notice. Soon afterwards he became a candidate for a vacant minor canonry in St. Paul's Cathedral, and though his friends thought he had no chance of success, he was duly elected in 1821. He thenceforth devoted much of the time not required by his professional duties to contributions in prose and verse to the periodical publications of the day. He wrote 'My Cousin Nicholas' in 'Blackwood's Magazine,' and about one-third of the articles in Gorton's 'Biographical Dictionary' were written by him. 'My Cousin Nicholas' has since been published in a separate form, in 3 vols. 8vo.

In 1824 Mr. Barham received the appointment of a priest in ordinary of the Chapel Royal, and shortly afterwards was presented to the rectory of the united parishes of St. Mary Magdalene and St. Gregory by St. Paul, London.

Till the year 1837, when the first number of Bentley's 'Miscellany' appeared, Mr. Barham had been an anonymous and comparatively unknown writer; but the 'Ingoldsby Legends,' a series of humorous tales in verse, which appeared in rapid succession in that work, brought him so much reputation, that his pseudo name of Ingoldsby no longer concealed him, and he became generally known as the author. In 1842 he was appointed divinity reader in St. Paul's Cathedral, and he was permitted to change his living for the more valuable rectory of St. Augustine and St. Faith, London.

On the 28th of October 1844, when the Queen visited the city to open the new Royal Exchange, Mr. Barham, who was a witness of the procession, caught a severe cold, from which he never recovered. He died June 17, 1845.

Mr Barham was personally acquainted with Theodore Hook, the Rev. Sydney Smith, and several other of the distinguished wits of his day, and was, like them, a frequent diner-out, a sayer of good things, and a teller of droll stories; but he never neglected his more serious duties, and was much respected by those who knew him.

The 'Ingoldsby Legends' have been published in 3 vols., post 8vo. 'A Memoir of the Rev. Richard Harris Barham,' by his son the Rev. R. H. D. Barham, precedes the Third Series.

BARKER, THOMAS, was born near Pontypool, Monmouthshire, in 1769. His father was by profession a barrister, but being a man of desultory and expensive habits, he failed to obtain practice, and, having wasted his property, he took to painting portraits of horses, &c. Thomas Barker early imbibed a passion for art; and some of his drawings so much pleased a Mr. Spackman, a wealthy coach-builder at Bath, where the family then resided, that he took the youth under his protection and kept him for several years in his house, affording him at the same time the means and opportunity of pursuing his artistic studies. When young Barker had arrived at the age of 21, his generous patron sent him to Rome to complete his studies, furnishing him with ample funds to maintain himself while there in something like luxury.

Mr. Barker established himself as an artist in Bath. He painted chiefly landscapes and rustic figures; but he occasionally essayed, though with less success, a more ambitious class of subjects. He speedily obtained popularity and patronage in Bath, and indeed throughout the western and midland counties. He only occasionally sent pictures to the London exhibitions, but his name was well known in the metropolitan art-circles. Perhaps no contemporary painter resident in the provinces (Bird excepted) gained so wide a measure of celebrity. One of his pictures—the Woodman—formed one of the most popular engravings of the day; and the Woodman's well-known figure was reproduced in ruder prints, upon jugs and plates, and nearly every variety of earthenware, upon snuff and tobacco-boxes, pocket-handkerchiefs, and almost every kind of article upon which a design could be painted or printed. Others of his designs were also very extensively employed by manufacturers. As a painter, Mr. Barker displayed in his own peculiar walk great originality, a vigorous though somewhat rude style, considerable powers of colouring, and, above all, the art of rendering his intention plainly perceptible to the general spectator, and of impressing the sentiment strongly upon all. His walk of art was not the highest, but his homely story was unaffectedly and forcibly told, and seldom failed to carry its simple lesson along with it.

Mr. Barker always found ample and liberal patronage; and, having amassed a fair amount of wealth, he erected for himself a handsome mansion at Sion Hill, Bath, filling its apartments with a choice collection of sculpture, pictures, engravings, and other productions of taste and elegance. But the decoration which he specially prized was a large fresco, 30 feet long by 12 feet high, which he painted upon the wall of one of the rooms: it represents the Inroad of the Turks upon Scio, in April 1822, and is a most elaborate composition. His friends and admirers describe it as the noblest of his productions; but neither the character of his mind nor his training as an artist qualified him for a painter of history. Mr. Barker died December 11, 1847, in the 79th year of his age.

BARRHEAD, Renfrewshire, Scotland, a small manufacturing town of recent growth, in the parish of Neilston, 3 miles S.E. from Paisley and about 8 miles S.W. from Glasgow. It is connected with Glasgow and Ayrshire by the Glasgow, Barrhead, and Neilston Railway. Spinning, weaving, and bleaching works are carried on here. The town, in addition to its neat railway station, possesses a chapel of ease and two meeting-houses, one for a congregation of the Free Church, and the other for United Presbyterians: the population of Barrhead in 1851 was 6069.

BARRISTER. [BARRISTER.] In order to be called to the Bar of England it is now necessary either to attend certain public Lectures in the Halls of the Inns of Court, which are delivered by Readers or Lecturers appointed by the Benchers for that purpose, or to pass an examination conducted by these Readers, who are paid partly by the Inns of Court and partly by fees levied from every person admitted to any one of these Inns. To encourage students to submit to examination, three studentships or bursaries of fifty guineas are given away annually to the student who has best answered the questions of the examination.

In Scotland, a preliminary education test, in the shape of an examination in classics and arts, has been imposed on persons applying for admission to the Faculty of Advocates.

BARROW, SIR JOHN, was born at Dragley-Back, near Ulverstone, Lancashire, June 19, 1764. Having passed through the Town Bank Grammar School, young Barrow was placed when about fourteen years old as clerk and overlooker in an iron-foundry at Liverpool, but quitted this situation two years afterwards to make a voyage in a whaler to Greenland. Having removed to London, he for a while was employed as mathematical teacher in a school at Greenwich, when he obtained in 1792, through the influence of Sir George Staunton, to whose son he had given lessons in mathematics, the appointment nominally of comptroller of the household to Lord Macartney in his celebrated embassy to China; but really to take charge of the various philosophical instruments carried out as presents to the emperor of China. Of this journey he published an account some ten years later in a thick quarto volume, entitled 'Travels in China.' In this embassy Mr. Barrow secured so far the good-will of Lord Macartney, that his lordship made him his private secretary on being appointed Governor of the Cape of Good Hope in 1797; and when Lord Macartney quitted the Cape in 1798 he left Mr. Barrow in the post of auditor-general of public accounts. During his stay at the Cape Mr. Barrow devoted his leisure hours to the study of the geography and natural history of South Africa, and made several journeys into the interior. On his return to England he published the results of his investigations in a quarto volume entitled 'Travels in Southern Africa.' In 1804 Mr. Barrow was appointed by Lord Melville to the responsible post of second Secretary to the Admiralty, the duties of which he continued to discharge for a period of forty years under thirteen administrations. In this office Mr. Barrow was earnest and indefatigable in the promotion of every project which commended itself to his judgment as calculated to advance the progress of geographical or scientific knowledge. Especially did he labour by every possible means to commend to the various governments under which he served, and to the country, the prosecution of the various voyages to the Arctic Regions which have so characterised the naval history of England during the forty years of his connection with the Admiralty; and though his services had been fitly commemorated by associating his name with the point of land, Cape Barrow, yet such was the sense entertained of them by those officers who had been engaged in those voyages, that, on his retirement from his secretaryship, they presented him with a costly candelabrum, bearing a suitable inscription on the pedestal.

Mr. Barrow was a man of untiring industry. The leisure hours afforded by his official employment were devoted to literary and scientific pursuits; and his literary labours would in extent have seemed not unworthy of one whose whole time was given to literature. Neither in literature nor science would he be regarded as having attained a high place, but for many years he held a distinguished position in the literary and scientific circles of the metropolis. He was for a long period a member of most of the leading learned societies of London. In 1805 he was elected a Fellow of the Royal Society; in 1830 he took a leading part in the foundation of the Geographical Society, of which some years later he was chosen president. In 1835 he was created a baronet.

In the beginning of 1845 Sir John Barrow, then in his eighty-first year, resigned his office at the Admiralty, and retired from public life. He had as early as 1806 received in consideration of his various public services, the grant of a pension of 1000*l.* per annum, to be deducted from the emoluments of any place he might hold under government. He died almost suddenly on the 23rd of November, 1848, in the eighty-fourth year of his age. Besides the works mentioned above, Sir John Barrow published a 'Life of Earl Macartney;' 'Life of George Lord Anson;' 'Life of Lord Howe;' 'Life of Drake;' 'Memoirs of Naval Worthies of Queen Elizabeth's Reign;' 'Chronological History of Arctic Voyages;' 'Voyages of Discovery and Research within the Arctic Regions;' 'Sketches of Royal Society and Royal Society Club;' the 'Life of Peter the Great;' and the 'Mutiny of the Bounty' in the 'Family Library;' and his 'Autobiographical Memoir,' written in his eighty-third year. He was also for a long series of years a frequent contributor to the 'Quarterly Review,' having in all furnished 195 articles to that journal, and he wrote some papers for the 'Encyclopædia Britannica,' as well as for one or two other periodical publications.

(*An Autobiographical Memoir of Sir John Barrow*, Bart.; Sir G. T. Staunton, *Memoir of Sir John Barrow*, edited by J. B. [John Barrow, son of the subject of the above article].)

BARRY, MARTIN, an eminent physiologist, was born at Fratton, Hampshire, in March 1802. The strong bent which he early manifested for scientific pursuits, led his parents to give up their scheme of a mercantile life for their son, and he studied in the universities of Edinburgh, Paris, Berlin, and other places in Germany, and in the medical schools of London. He entered warmly into the proceedings of the societies of the Scottish metropolis, and spent most of his holidays in geological and botanical excursions on foot among the lakes and mountains. He took his degree of M.D. at Edinburgh in 1833, and in the following year, after a term of study at Heidelberg, he rambled through Switzerland to Chamouni, where, though past the middle of September, too late in the season, as was thought, for success, he went to the summit of Mont Blanc. This was the sixteenth ascent; and Humboldt was so pleased with the narrative of the adventure published by Barry in 1836, that he personally requested him to translate his 'Two Attempts to ascend Chimborazo' from German into English.

Martin Barry has the merit of being one of the few physiologists who devoted their attention to the difficult question of animal development and embryology. He began by making himself well acquainted with the literature of the subject; and in the museums and laboratories of Wagner, Purkinje, Valentin, and Schwann, he brought his knowledge to the test of observation, and acquired that mastery over the microscope which afterwards appeared in the importance and value of his own researches.

Having published in the 'Edinburgh Medical and Surgical Journal' for 1836, a translation of the first part of Valentin's 'Manual of the History of Development,' he commenced his investigations into the development of the mammalian ovum and embryo, at that time, as truly described, "the darkest part of embryological science." The results, communicated to the Royal Society of London, were printed in the 'Philosophical Transactions' under the general title of 'Researches in Embryology.' These, as well as his papers 'On the Corpuscles of the Blood,' 'On the Formation of the Chorion,' 'On Fibre,' &c., will be found in the 'Philosophical Transactions' from 1838 to 1842. The most important—the discovery by which he will be best remembered—'Spermatozoa found *within* the Ovum,' appears in the volume for 1843. The Royal Society recognised the value of Barry's researches by awarding him their royal medal in 1839, and electing him a Fellow in the following year.

The 'Researches in Embryology' exhibit proofs of the author's skill in the grouping and selection of his facts, and of the perseverance by which they were demonstrated. He explains the formation of the ovum in the rabbit and dog, and in some of the oviparous vertebrate classes from the bird to the fish. He determined the order of formation of different parts of the ovum, and the nature and mode of its growth from the ovisac; and showed that the so-called 'disc of Von Baer' contained a retinacula, or peculiar species of mechanism, by which, as he supposed, the passage of the ovum into the Fallopian tube was regulated. He described the changes that take place in the ovum while on its passage—changes before unknown; and Barry was the first to throw light on this interesting process of animal development. Not till his paper appeared in 1839, was it known that the segmentation of the yelk which had been observed in Batrachian reptiles, was also true of mammals. It was an important discovery; and not less so that published in 1840—the penetration of the ovum of the rabbit, by spermatozoa, through an aperture in the zona pellucida. This at first was doubted; but he confirmed it by further observation in 1843; and it was eventually corroborated by the observations of Nelson and Newport, accounts of which are also published in the 'Philosophical Transactions;' and Professor Bischoff, who had denied the truth of Barry's conclusions, at last satisfied himself of their accuracy, and accepted them in full.

The views expressed by Barry in his paper 'On Fibre,' are disputed by physiologists. He assumed a spiral structure for muscular fibre and other organic tissues, and brought speculative arguments to bear in favour of his opinions; but other investigations show one and the other to be fallacious. His speculations have however tended to stimulate physiological research. Whatever may have been Barry's feeling for his own favourite ideas, his character as an amiable and benevolent man is beyond question. Ample private circumstances placed him above the need of practising his profession; and he devoted much of his time to the poor, chiefly as house-surgeon to the Royal Maternity Hospital in Edinburgh. From 1849 to 1853 he lived on the Continent to recruit his health and eyesight, both having suffered from long and severe study. At Prague he renewed his examinations of fibre conjointly with Purkinje; with what result may be seen in Müller's 'Archiv.' for 1850. In 1852 he returned to Scotland, suffering much from neuralgia; and having gone to reside at Beccles, in Suffolk, he died there on the 27th of April, 1855. He was a member of the Society of Friends.

Barry was a member of the Royal Society of Edinburgh, of the Wernerian and other societies, and the College of Surgeons in that city. Some of his papers and translations are printed in the 'Edinburgh New Philosophical Journal,' and others in the works and periodicals already mentioned.

BARTON, BERNARD, was born in London in 1784. His parents were members of the Society of Friends, and to the tenets of that sect Bernard Barton always adhered. In 1806 he went to Woodbridge in Suffolk, and there in 1810 he entered as a clerk the banking-house of Messrs. Alexander, in whose employment he continued almost to his death. Bernard Barton first claimed public attention as a poet in 1812, by the publication of a volume of 'Metrical Effusions.' This was followed in 1820 by a volume of 'Poems,' and thenceforward as long as he lived he continued to issue at intervals either brief occasional pieces, or, though much more rarely, a poem of greater length and loftier pretensions.

Bernard Barton attracted an amount of attention and popularity far beyond that to which his poetic merits would seem to have entitled him. This was perhaps mainly owing to his presenting the then unusual phenomena of a Quaker poet—the title indeed by which he came to be commonly known; but it likewise no doubt was partly due to the evidently unaffected tone of simple religious earnestness which pervades all his writings. He wrote with ease; and like most easily written poetry, his verses are more characterised by fluency than power. But though often diluted almost to feebleness, there is a vein of natural feeling and quiet unobtrusive benevolence running through his verses, which render them pleasing to all but the more critical class of readers. Barton was a man of refined habits; a lover of nature, and fond of paintings and other works of art to a degree then very uncommon among members of his sect. His moral character was blameless, and few men in his position of life won so wide and general a share of esteem as did Bernard Barton. Some years before his death he received, through the instrumentality of Sir Robert Peel, the grant of a pension of 100*l.* per annum. He died suddenly of spasm in the heart, February 19, 1849. Besides the works noticed above, Barton published 'Napoleon and other Poems,' 1822; 'Poetic Vigils,' 1824; 'Devotional Verses,' 1826; 'Household Verses,' 'New Year's Eve,' and numerous occasional verses and poems published separately, and in magazines, annuals, &c.

(*Memoir*, prefixed to his Poems; *Gentleman's Magazine*, 1849.)

BASEVI, GEORGE, an eminent architect, was born at Brighton, in 1794. He was placed as a pupil with Sir John Soane, R.A., in whose office he remained for six years. He then made a professional tour through Italy and Greece for three years. He commenced practice as an architect in 1819. During his comparatively short career Mr. Basevi was employed in the construction of various descriptions of buildings, scarcely any one of which is without manifest evidence of careful study and well-cultivated taste. Among the more extensive of his works may be mentioned Belgrave-square, which was erected entirely from his designs. The churches at Brompton, Twickenham, Hove, &c., show his acquaintance with the requirements of ecclesiastical architecture. St. Mary's Hall at Brighton may also be mentioned among his more successful efforts. But his great work is the Fitzwilliam Museum at Cambridge, one of the most ornate yet chaste and effective classical edifices erected in England during the present century. It was not quite finished at his death, and, like the Conservative Club-House, St. James's-street, another of his latest works, executed by him in conjunction with Mr. Sidney Smirke, it shows that he was rapidly throwing off the trammels of precedent, and giving his fine taste and attainments fuller and freer play. But his career was suddenly cut short by a lamentable accident. Whilst examining, in company with the Dean of Ely, the works in the Bell Tower of Ely Cathedral, the restoration of which was being conducted under his direction, his foot caught against a nail in a beam from which the flooring had been removed, and he fell through an aperture on to the top of the arch under the tower, a distance of 40 feet. He died almost instantly, October 16, 1845, aged 51. The Fitzwilliam Museum was finished under the direction of Mr. Cockerell.

BASSE. [LAURAX.]

BASTIAT, FREDERIC, was born at Bayonne, June 29, 1801. He was the son of a merchant, by whom he was early destined to a commercial career. After receiving a good education at the College of St. Sever, he was placed in the counting-house of an uncle at Bayonne. Here he applied himself sedulously to the study of the principles of trade; and, having to visit Spain and Portugal on business in 1840, he availed himself of the opportunity of studying the commercial regulations of these two countries, lagging behind even those of France at that time. The result of his thoughts was at length communicated to the public by M. Bastiat, in 1844. It appeared in the 'Journal des Economistes,' under the title 'L'Influence des Tarifs Français et Anglais sur l'Avenir des deux Peuples.' In this the author avowed himself as the adversary of the principle of protection to trade—a principle at that time universally acted upon in France, and almost as universally recognised as just and expedient. Bastiat, however, gained adherents, and time and truth, with the example of England, carried his principles forward till they were to some extent acknowledged and adopted by the government of France, and appear likely to be extended still further. In 1845, after a visit to England, where he had made the acquaintance of Mr. Cobden, he translated, under the following title, many of the addresses of the Free-Traders, preceding them by an introduction:—'Cobden and the League; or the English Agitation for the Freedom of Exchange.' In this he adduced all the inconveniences of a prohibitive system. He became secretary in Paris of a society for promoting the freedom of trade, and editor of a journal devoted to the same cause. While thus advocating sound commercial principles, he was opposed to the doctrines of Socialism, and the pretended right of every one to be supplied with work. After the revolution of 1848 he sat for some time in the Legislative Assembly, but his health failing, he proceeded to Italy in hopes of improving it, and died at Rome, December 24, 1850.

M. Bastiat wrote many works besides those mentioned, but all on the same leading subject. Though valuable and novel in France at the time of their appearance, they contain little that had not been before enunciated in England; but the views, although not original, are placed effectively before the reader.

(*Nouvelle Biographie Générale.*)

BATHS AND WASHHOUSES, PUBLIC. In the article BATH ['P. Cyc.' vol. iv. p. 31] it was said "There are but few baths in London, and those established there would not suffice for a small fraction of the population, if bathing were a common practice. Still of late years baths have increased both in London and England generally." The baths here spoken of were private ones of a comparatively expensive character. There were indeed a few public swimming-baths, but no public establishments, where, for a trifling sum, the labouring man might enjoy the use, or the luxury, of a warm, a tepid, or a cold bath.

But if baths of any kind were rare, public washing-houses were quite unknown. In olden days, indeed, the English were not wholly, or perhaps generally, home-washers. The housewife or the laundress carried the linen down to the nearest convenient spot by the side of a stream, where "the shore was shelvy and shallow," like that which the whitsters [washers] of Windsor resorted to, by Datchet Mead, where Falstaff was so unceremoniously slighted from the buck-basket. It is on record that the corporation of Reading, upon the suppression of monasteries, petitioned for the grant of the Friary in that town, for a town-hall, because their old hall stood by the river Kennet, near the spot which was used by the townswomen for washing clothes; and the corporation say in their petition that the noise of the women's clappers caused great interruption to the transaction of public business. These clappers were, of course, wooden ones. Washing in cold water, they used wooden battledores to beat their clothes, just as the *blanchisseuses* of the Seine do still. In the present day, washing by the river-side is, we believe, nowhere to be seen in England, but it is common enough in Scotland, Wales, and Ireland; and, as is well known, the Parisian laundresses pretty generally resort to washing-boats on the Seine. In Pepys's day, London families would seem to have sent their linen to be washed by their servants at some washing establishment; for that most valuable of diarists tells us, that on August 12th, 1667, he dined all alone, "my wife and maids being gone over the water to the whitster's with their clothes, this being the first time of her trying this way of washing her linen." Again he notes (August 19th, 1668), "This week my people wash over the water, and so I little company at home;" by which we may suppose that Mrs. Pepys was satisfied with her trial of "this way of washing her linen," as she continued to practise it for above a year.

It was reserved for our own day to establish public baths and laundries for the community generally, and for the poorer portion of it in particular. The practical philanthropist early saw that the sanitary improvement of the condition of the poor in our larger towns was a work loudly calling for accomplishment. Medical men, clergymen, city missionaries, parochial officers, and all whom either professional duty or benevolence had led to enter the dwellings of the very poor, however their opinion differed in other respects, were at least unanimous in declaring that those dwellings exhibited a degree of dirt and squalor with which health and morality were alike incompatible. Many remedies for the evil were suggested, and several carried into execution. One little knot of practical men resolved fortunately to give their special attention to the matter of personal cleanliness. It had been allowed by all who were really acquainted with the homes of the very poor, that in their crowded and wretched dwellings cleanliness was impossible. In such places not only were there scarcely the means for personal cleanliness, but to wash and dry clothes properly was quite impracticable. It was proposed, therefore, to see whether the establishment of places where, for a small charge, a warm bath could at any time be had, and where all the conveniences for washing and drying clothes should be provided free of charge, or at a trifling cost per hour, would not be gladly accepted by the classes most requiring such conveniences.

The movement was practically initiated by the holding of an influential meeting at the Mansion House, under the presidency of the Lord Mayor, in September 1844; when resolutions were passed for the formation of an 'Association for Promoting Cleanliness amongst the Poor;' and an active subscription was commenced. The first experiment was made in a wretched locality near the London Docks, where in an open court, called Glasshouse Yard, Rosemary Lane, an old but spacious building, which had for some time been occupied by 'sleeping-berths for the houseless poor,' was rented and converted into the first 'Free Baths and Wash-houses,' and opened in May 1845. A portion of the building was adapted, as well as it could be at a small expense, to the purpose, and furnished with a due supply of tubs and boilers, and with a few baths in various out-of-the-way recesses; and soap and soda, as well as hot and cold water, were provided gratuitously. The number of persons who availed themselves of the establishment was, in the first year, 27,662 bathers and 36,577 washers; in the second year there were 84,584 bathers and washers. This, though the first establishment of the kind in London, was not the first in England; a very small one having been previously started, and with much success, in Liverpool, though without the knowledge of the London Committee. The Glasshouse Yard establishment owed its success solely to its usefulness. There was nothing extrinsic to render it attractive. It was placed in one of the worst spots in the metropolis; the building itself was as little suited to the purpose as any building well could be; the accommodation was of the most ordinary kind. Yet it at once proved—if proof were needed—that the poorest in that wretched neighbourhood would gladly be clean when the means were attainable. In August 1846, a second, and much superior establishment, was opened in George Street, Euston Square; a plot of ground having been liberally offered by the New River Company, near one of their reservoirs, with the additional advantage of a free supply of water for the first six months. In the first year there were here some 113,000 bathers and 20,000 washers. This establishment, in which the baths are more varied in price than elsewhere, still flourishes.

The establishment third in point of date was, however, the first in importance and in the value of the consequences which resulted from it. In this the committee first fairly developed their plans. Although the building in Glasshouse Yard was opened gratuitously, it had been desired that the institution should as soon as practicable be rendered self-supporting by means of a small charge to each person who used it. The committee hoped too, to see the system extended throughout the country; and they rightly thought that nothing would so effectually and speedily further that object as to be able to show a Model Establishment, which, while it contained all the conveniences and appliances which those who availed themselves of it could desire, should be in itself all that science, combined with practical skill, could effect in the economy, suitableness, and completeness of its arrangements. Accordingly, architects and others were invited to send in designs for baths and laundries, and all the information which could be obtained was collected. The Model Establishment was then erected on a site which had been purchased in Goulston Square, Whitechapel, a very poor and crowded neighbourhood, but of ready access. The arrangements being almost entirely novel caused a very large original outlay, and many changes have been subsequently made; but as a whole they had been so carefully considered, and were so judiciously designed by Mr. Prichard Baly, the committee's engineer, that no material alteration has since been found necessary; indeed, in a recent Report of the Committee, we are told that "the general arrangements and mode of construction have been almost universally followed in London and the country."

In general character, then, these establishments are pretty much alike. The exterior is usually a plain brick building, with stone quoins and dressings; having a basement, and, in front, a story above it, with a lofty square ventilating and chimney-shaft, somewhat like a campanile in appearance. A brief sketch of the interior of any one will serve to give a general conception of all, it being understood that there are differences of detail in each.

The baths for males and females are on opposite sides of the building, and separated in Goulston Square by the washing-room, in some others by the plunging-baths. In both sides are first and second class baths. The apartment in which these are placed is spacious and lofty, covered by an open roof, and lighted in the day by ample skylights, by gas-lights at night. Each bath-room is a distinct compartment, somewhat more than six feet square, shut in by walls of painted slate, which are carried up to the height of some ten feet: but the top is open, so as, while insuring privacy, to admit of thorough ventilation. The bath, in some establishments sunk in the ground, in others placed as usual above it, is either of iron enamelled, or of zinc. The first and second class rooms are usually alike in every respect, except that the fittings in the first-class rooms are of a superior kind, and more complete than in the second. On each door is a porcelain knob, having a number painted upon it; a similar number is painted inside. An index outside enables an attendant to let in either hot or cold water, as the bather may direct. The charge for a first-class warm bath is sixpence, for which two towels, flesh and hair brushes, and a comb are allowed. For a second-class bath the charge is only twopence, but only one towel is allowed, and the bather most provide his own comb and brushes. The baths are in all respects alike, the same quantity of water (in most places forty-five gallons, but at St. Martin's much more) is allowed, and the bath is invariably cleaned after each person. The most perfect cleanliness is indeed observed in every respect. For a cold bath the charges are respectively threepence for a first and one penny for a second class bath: the regulations are the same as with the warm baths. The baths on the female side are similar to the others, but there is a little more taste in the first-class fittings. At Goulston Square there are only warm and cold baths. At St. Martin's a shower-bath is added. At George Street there are also vapour-baths; and at the more recently constructed establishments there are plunge or swimming baths filled with tepid water. For these swimming-baths the charge is usually fourpence for the first, and twopence each person for the second-class. At the larger of the recent establishments there are two swimming-baths—a first and a second class; the smaller places have only one large bath, using it three days a week as a first, and the other three days as a second-class bath.

The baths have everywhere proved exceedingly popular. The second-class baths are, in the summer particularly, always well attended, and of an evening there are generally many waiting for their turns, which are always strictly in the order of arrival.

The number of baths varies, of course, according to the requirements of the locality, and the size of the building. The number of first-class baths, for example, at St.-Martin's-in-the-Fields is, twenty-four men's, five women's; of second-class, thirty-three men's, and eight women's. At Goulston Square, there are ninety-four first and second class baths. At St. James's, Marshall Street, there are only about fifty of both classes; but there is a swimming-bath. The number of bathers at Goulston Square in the year is above 150,000; at St. Martin's-in-the-Fields the number is above 200,000.

The Wash-houses are more remarkable than the bathing-rooms, because entirely unlike what is seen anywhere else. Along the centre, on one side, and at the ends of a large and lofty room, are ranges of little doorless and roofless compartments, the walls being of unpainted slate, and some six or eight feet high: these are the washing-places. At convenient points are the wringing-machines. Along one side of the room (at Goulston Square) is what looks like a range of wide but shallow deal drawers, turned up endways, the handles being one above the other—that is the drying apparatus. A long flannel-covered board is furnished for ironing on. In some of the latest wash-houses a mangle is provided.

Each washing compartment is six feet long by three and a half feet wide. At the end are two wooden troughs, which serve as a washing-tub and a boiler; these are furnished with taps for hot and cold water, for steam, and for letting off the waste water, so that the tubs are filled and emptied without any more trouble on the part of the washer than turning the tap, and without moving from her standing-place. The water in the boiler is made to boil by the admission of steam into it, which, as we said, the washer can do whenever she pleases. The ventilation is so arranged that the steam from each compartment is at once drawn upwards, and carried off to the great ventilating shaft.

The Wringing-Machine is in effect a sort of wide but shallow colander, the sides, instead of the bottom being perforated, or rather formed of galvanised wire, so arranged that the meshes are about a quarter of an inch apart. When the wet clothes are put in this, it is set in rapid motion by a handle which works a few connecting wheels; the clothes at once by centrifugal force arrange themselves around the sides, and the water is rapidly driven out between the wires, and carried off by water-pipes: an opening at the foot of the machine shows when the water ceases to flow, and when consequently the 'wringing' is completed, and then the pressure of a lever at once stops the machine. The machine has rather a heavy look, but the turning of it is really very light work, and by it three minutes suffice to rid even a thick blanket of its moisture. The Drying-Chamber is a long chamber, heated by hot air to a temperature above 212°, and divided into numerous smaller chambers, so as to separate the clothes of the washers. Each division of the chamber contains a clothes-horse or maiden, one being allowed to each washer. In ten minutes, or a quarter of an hour, the clothes, unless very heavy or numerous, are quite dry. The Committee have published a table in their Report to show the rapidity with which the drying is accomplished. Some of the results are curious. We may take a single instance as an illustration of the processes we have been following. Three large dirty blankets weighed before being washed 9 lbs. 1 oz.; after washing, they weighed 24 lbs. 14 oz.; after leaving the wringing-machine, 12 lbs. 3 oz.; after being dried, 8 lbs. 12 oz. These blankets took twenty-five minutes to dry, at a temperature of 210°. In all other cases the results were similar, establishing the fact that "the articles when taken from the drying-chamber contained decidedly less moisture than they did when they were received for the wash." To show the "satisfactory working of the drying-chamber at the Model Establishment, and also its great advantage in the economy of time, trouble, and expense, to those of the labouring classes who resort to it," the committee give a return of the articles dried there in one week ending January 24, 1852. It is too full for us to copy; but we may state that the number of articles of all kinds, from counterpanes, jackets, and trousers, down to shirts and stockings, was 36,844, belonging to 1373 washers, who occupied 2999½ hours in washing, drying, and ironing them; and that the drying consumed only 282 bushels of coke, which cost under 4*l*.

In most of the establishments there is only one class of washers; but in some there are both first and second classes, the difference being that the first class have a somewhat larger compartment allotted to each washer, and a third or rinsing-tub. The charge for the use of all the apparatus we have described is now generally 1½d. an hour, though in a few places it is only 1d. an hour. Where there are both classes, the charge is 2½d. an hour first-class, and 1½d. second. Soap, soda, &c., have to be found by the washers. The number of washing compartments varies, of course, according to the size of the establishment; at Goulston Square there are 84 of them, at St. Martin's 56. The average time occupied by each washer at the Model Establishment is two hours and a half; and this is the general average time in London; in some country towns it differs considerably. In

London it seems pretty well established that the active wife of a labouring man can at one of these places wash and dry the clothes of her family in two or three hours. The ironing, at least in part, is generally done at home.

Let us now look a little at what has been accomplished. In August, 1846, the royal assent was given to an Act to encourage the establishment of public baths and wash-houses, which, as amended in the session of 1847, empowered parish vestries and borough councils to establish such institutions, and, with the sanction of the Treasury, to borrow money for the purpose on the security of the borough fund or poor's rates. A schedule directs, among other very excellent rules, that baths must be provided in them at 1d. for cold, and 2d. for warm baths; and that the wash-houses shall be furnished with necessary conveniences at a charge not exceeding 3d. for two hours. Baths and wash-houses of a higher class are to be charged as the council and commissioners respectively think fit. The baths and wash-houses "for the labouring classes" in any such establishment, must be not less than twice the number of those of any higher class. This Act at once gave the system a firm standing; and both boroughs and parishes have availed themselves of its powers to a considerable extent. Of course, it is not always easy to persuade vestrymen to permit an addition to be made to their parochial rates for a purpose that does not promise advantage to themselves; but as it has become year by year more evident that these institutions may be made self-supporting, and in due time repay the amount expended on their foundation, so there has been a growing readiness to found them. In London and the suburbs, besides the Model Establishment in Goulston Square, and that in George Street, Hampstead-road, there are several large parochial establishments, some of which are fitted up in an extremely complete manner, while all are well attended by both washers and bathers. Manchester and Liverpool have each several baths and wash-houses, and almost every other large town throughout the country is either provided, or taking measures to be provided with similar establishments; and the example has been followed by several of the smaller towns. Nor have the good effects of the movement been confined to this country. The Committee for promoting the Establishment of Baths and Wash-houses for the Labouring Classes, were able at the end of 1852, to state in the Report before quoted, that the governments of France, Norway, and Belgium, the municipality of Venice, and the authorities at Hamburg, Turin, Munich, Amsterdam, Lisbon, and New York, had applied for, and been furnished with information on the subject; and in some of these countries the example of England has since been followed in providing similar establishments for the labouring classes.

It is evident that the institution has become firmly established. In London alone, the bathers number little short of two millions a year; while the washers exceed half a million. The constantly increasing number of bathers and washers shows that the system is commending itself to a large section of the population. The experience of twelve years has proved that, with proper attention and economy, the establishments may be rendered self-supporting; and the observations of all who have watched them in particular localities, vouch for their beneficial influences. The point in which they appear to have failed, is in reaching the very poorest. That portion of the community for whom the institution was primarily intended, seems to have been scarcely touched by it. Everywhere those who avail themselves of the benefits offered, are of a class above the poorest. The most profitable section of the establishment is found to be the "first class." Whether availing themselves of the hint, the managers of these establishments might not, by furnishing a yet higher class bath (though still at a moderate price), provide the means by which they might support one of a cheaper kind than they have at present been able to afford, and so extend the benefits of the system both upwards and downwards, is a question perhaps deserving of more attention than it has hitherto received.

BATHYANI, COUNT LOUIS, was born at Presburg in 1809. At the age of sixteen he entered the Austrian army as a cadet, and was stationed at Venice. He subsequently travelled in the East and in Europe with his wife, the Countess Antonia Zichy. On his return to his native country, he became at once a leader on the liberal side, a distinguished orator, and a favourite with the public. From 1840 to 1844 he opposed openly the Austrian chancellor Apponyi, in favour of Hungarian commerce and industry. At this time he was alike opposed to Kossuth, with whom however he afterwards allied himself. When, in consequence of the events of March 1848, the Archduke Stephen was created Palatine of Hungary, Count Louis, an old friend of Stephen's, was named chief minister. He strove earnestly in this capacity to maintain the political union between Austria and Hungary. After the invasion of Jellachich, and some fruitless negociations with Austria, he resigned his functions on September 11; the next day he was commissioned to form a new ministry, but this effort failed.

After the dissolution of the Diet, and the murder of Count Lambert, he repaired to Vienna to endeavour to prevent the ill-effects of this crime, and if possible to form a new administration. His exertions were in vain, and he returned to take a part in the hostile struggle now become inevitable. In November 1848 he went to Pesth, to take his seat in the Diet, and was named one of a deputation sent to treat with General Windischgratz, the Austrian general, who was approaching Pesth with an army. The deputation was not received. The Hungarian government removed to Debreczin, but Count Louis remained at Pesth, where, on the arrival of Windischgratz on January 8, 1849, he was arrested. After being transferred to Ofen, to Olmutz, and to Laybach, he was at length brought back to Pesth, where he was condemned by a council of war to be hung. He endeavoured to escape the ignominy of the sentence by destroying himself with a poignard. He did not succeed, but at length the sentence was changed, and he was shot, Oct. 6, 1849. His estates were confiscated, and his wife and children were exiled.

(*Nouvelle Biographie Générale.*)

BATRACHOSPERMEÆ, a tribe of plants referred by some writers to the order *Fucaceæ*. It is regarded by Harvey as an aberrant group of *Chlorospermeæ* leading through *Ectocarpaceæ* to *Melanospermeæ*. [ALGÆ.] The species have a polysiphonous frond composed of a primary thread, surrounded by parallel accessory ones. The vesicles are terminal or lateral and clustered.

The principal genus of this family is *Batrachospermum*, which have got this name from *βάτραχος*, a frog, and *σπέρμα*, a seed, on account of their gelatinous fronds giving them the appearance of the ova of the *Amphibia*. The species are flexible, and have a gelatinous character. The surface is covered with innumerable little hairs, looking like cilia, which give them a very beautiful appearance under the microscope. They mostly inhabit pure and running waters where the force of the stream is not considerable. On removing them from the water the hairs, which are expanded whilst immersed, collapse, and they appear like masses of jelly without any traces of organisation.

Several species of this genus have been described by Dr. Hassall as inhabiting streams in the neighbourhood of London. *B. moniliforme* is figured in Lindley's 'Vegetable Kingdom,' p. 20; and Hassall has figured some of his new species in his 'British Fresh-Water Algæ.'

BAVIAN, a small hamlet in Kurdistan, situated on the left bank of the Ghazir, opposite to the village of Khinnis, which stands on the right bank of the river in about 36° 42½′ N. lat. 43° 28′ E. long. The place has become celebrated in connection with the Assyrian rock sculptures discovered near it by the late M. Rouet, French consul at Mosul, and since visited and described by Dr. Layard in his 'Nineveh and its Remains,' and in his 'Nineveh and Babylon.' The sculptures are carved in relief on one side of a narrow rocky ravine in the Missouri hills, on the right bank of the Gomel, a brawling mountain torrent which joins the Ghazir from the north-west just above Bavian. The sculptures are cut in the face of a limestone cliff that rises perpendicularly from the bed of the torrent. The face of the cliff has been smoothed down into several compartments or tablets, each inclosed in a frame of the living rock, and protected by an overhanging cornice from the water that trickles down the precipice. The bas-reliefs, which are of colossal size and admirable execution, are of the true Assyrian type, and represent gods, kings, warriors, sacred symbols, and mythic animals. They have suffered much from the effects of the atmosphere, but still more from the excavation of tombs in the [ready-scarped] rocks, by some people who occupied the country after the fall of the Assyrian empire. Across three of the tablets are inscriptions in the cuneiform character, which were copied by Dr. Layard, and have been translated by Dr Hincks. These inscriptions recount the exploits of Sennacherib, and are considered to be of considerable historical importance.

BEAM-TREE. [PYRUS.]

BEAUFORT, REAR-ADMIRAL SIR FRANCIS, K.C.B., F.R.S., &c., late Hydrographer to the Admiralty, is the son of the Rev. Daniel Angustns Beanfort, rector of Navan, connty of Meath, Ireland, and autbor of a Map of Ireland, pnblished with a memoir, in 1792, as well as of some theological publications. Francis Beanfort entered the navy, in June 1787, as a volunteer on board the Colossus 74, stationed in the Cbannel. He was made midshipman in June 1790, and while holding that rank saw mnch active service, assisting among other dnties in the capture of several vessels. In May 1796 he was created lieutenant, and whilst acting as first lientenant of tbe Pbaeton, 38 guns, he, having under his orders a barge and two cutters, hoarded and took the San Joseph, a Spanish polacre-rigged ship of 14 guns and 56 men, wbich lay moored nnder the protection of five guns of the fortress of Fuenzirola, near Malaga, supported by a French privateer. Lieutenant Beaufort in this hrilliant affair received a wound in his head, and several slugs in his body and left arm; hut was recompensed hy obtaining, as a recognition of his skill and courage, a commander's commission. During a cessation from service afloat, he was engaged from November 1803 to June 1804 in superintending the construction of a line of telegraphs between Dnblin and Galway. In Jnne 1805 he proceeded as commander of the Woolwich 44 guns, to the East Indies, and tbence to the Rio de la Plata, of which river he made, during tbe campaign of 1807, a very valuable survey. He was afterwards stationed at the Cape of Good Hope, and in tbe Mediterranean. In May 1809 he was appointed to the command of tbe Blossom, and tbe following year with the rank of Post Captain to the command of the Fredericksstein frigate. During 1811-1812, he was engaged in making a minute survey of tbe coast of Karamania in Asia Minor, but was compelled in the latter year to retnrn home in consequence of wonnds inflicted on him by a fanatic Mussulman.

In the course of these services Captain Beaufort bad obtained a very high rank, as a scientific as well as a hrave seaman, and equally so as a hydrographer and geographer. He was now conseqnently called upon hy the Board of Admiralty to devote himself to working out and embodying in a series of charts, the results of his various surveys. Among other charts constructed by him were one of the Archipelago, three of the Black Sea, including the coast of Asia, and seven of Karamania, tbese last being accompanied with a 'Memoir of a Survey of tbe Coast of Karamania in 1811 and 1812.' In 1817 he pnblished in 8vo, a fuller and more elaborate work on the same district: 'Karamania; or a Brief Description of the South Coast of Asia Minor, and of the Remains of Antiqnity, &c., witb plans, views, &c.' His labours and scientific merits found their appropriate reward in his elevation, in July 1832, to the post of Hydrographer to the Admiralty, to which important office he imparted new honour by the manner in which he fulfilled its duties; and wbich he continued to hold till he retired full of years and honours on the 30th of January 1855, having very nearly completed his 68tb year of service. He was sncceeded hy Captain Washington. Admiral Beaufort died iu Dec. 1857. In April 1835, Captain Beanfort was appointed Commissioner for Inquiry into the Laws, &c. affecting Pilots; and in Jannary 1845 a Commissioner for Inquiry into the Harbonrs, Sbores, and Rivers of the United Kingdom. He was created Rear-Admiral, Oct. 1, 1846.

Admiral Beaufort, besides his memoirs on the coast of Karamania, &c., contribnted papers to the Geograpbical and other learned societies; and tbe important collection of Maps of the Society for the Diffusion of Useful Knowledge was executed under his supervision. He was elected a Fellow of the Royal Society in June 1814; he was also a Member of the Conncil of the Geographical Society, a Fellow of the Royal Astronomical Society, a Corresponding Memher of the Institute of France, &c.

BEAZLEY, SAMUEL, architect and playwright, was the son of a surveyor in Parliament-street, Westminster, where he was born in 1786. In early life Mr. Beazley served as a volunteer, and some of his adventnres in the Peninsula and France were, as related by himself, of a somewhat romantic character. Mr. Beazley's chief claim to remembrance as an architect arises from the fact of his having erected a larger number of theatres than any other contemporary architect in England, or probably in Europe. Tbe Lyceum (both the present one of that name, and the one on its site destroyed by fire in 1830), the St. James's and the City of London theatres in the metropolis were bnilt hy him; also two or three in the provinces, and two in Dnhlin. He likewise furnished the drawings for two in Belgium, one in Brazil, and one or two in India. The Strand front of the Adelphi and the colonnade of Drury-lane theatre were also erected hy him; and we helieve that he execnted other works in connection with theatres. His theatres, thongh not remarkahle for any high order of artistic design, have the very great merit of affording tbe whole of the auditory a tolerably good view of the stage, while their acoustic properties are considerably ahove the average. Among his other more important works may be mentioned Studley Castle. For some years hefore his death he had been very extensively employed in constructing the architectural works of the South-Eastern Railway Company. The terminus at London Bridge, the stations on the North Kent line, the New Town, Ashford, Kent, the Warden Hotel, and the Pilot Honse, Dover, &c., are among the chief of these works. Like his theatres, they are mostly well adapted to their pnrpose, and like them, they have little other merit.

But during his life Mr. Beazley was not merely known as an architect. He was also one of the most prolifio playwrights of the day, having written, it is said, npwards of a hundred dramatic pieces. They were mostly farces, and other light occasional pieces, which were forgotten by tbe end of the season in which they were produced: hnt one or two still occasionally occupy the stage. They have no literary pretensions; but, like his bnildings, they appear to have exhibited great mechanical dexterity, and a keen perception of the immediate requirements of the subject. Mr. Beazley wrote two novels, the 'Oxonians' and the 'Roué;' and furnished the words to the English versions of the 'Sonnambnla' and some other operas. Though apparently so constantly employed, Mr. Beazley was well known in society as a diner-out and a cheerful companion. He died snddenly at his residence, Tunbridge Castle, Kent, October 12, 1851.

BEBEERINE. [MATERIA MEDIOA, *S.* 2.]

BEDALE. [YORKSHIRE.]

BEDWYN, GREAT. [WILTSHIRE.]

BEECHEY, ADMIRAL FREDERIC WILLIAM, was the son of Sir William Beechey, the painter, and was born in London in 1796. Having entered the navy when only ten years old, he was engaged as early as 1811 in an action off Madagascar, resulting in the captnre of the French frigates Renommée, Clorinde, and Néréide. In 1818, when the Dorothea under Captain David Buchan, and the Trent under Lieut. John Franklin, were despatched in search of the north-west passage, Beechey sailed with Franklin, with the rank of lieutenant. Lieut. Beechey had already distinguished himself as an artist, and also by bis attention to natural history, and it was given to his charge to collect and preserve such objects as were practicahle, or make drawings of snch as were not. This voyage, though unsnccessful in its main object, contributed many nseful resnlts to science and to natnral history, and an account of them in a narrative of the voyage was published by bim in 1843. For the ability displayed as an artist in the voyage he was rewarded by a parliamentary grant of 200*l.* In 1819 Lieut. Beechey took part iu an expedition nnder the command of Sir Edward Parry (then commander), which penetrated to 113° 54′ W. long. within the arctic polar circle. In 1821 he was commissioned, together with his brother, H. W. Beechey, to investigate by land tbe coasts of Nortb Africa to the east of Tripoli. Of this undertaking he published a most interesting narrative, witb descriptions of the ancient Syrtis, Pentapolis, and Cyrenaica, with a valuable and detailed cbart of the coast, extending from Tripoli to Derna, or from 13° to 23° E. long. After his return home he was appointed to the command of the Blossom, with the rank of commander, and directed to endeavonr to penetrate the Polar Sea by the Pacific Ocean and Behring's Strait, while Franklin made the attempt overland from North America. Beechey sailed in 1825, and returned in 1828; the voyage having lasted two years and a half. The extreme point reached in boats was 71° 23′ of N. lat., and 156° 21′ of W. long. While at Barrow Point, Franklin was at Point Turnagain, thus they were only 150 miles apart, but not heing aware of each other's position, neither advanced. In 1827 Beechey received the rank of Post Captain, and during tbe snmmer of this year succeeded in discovering to the south-east of Cape Prince of Wales, and near to Behring's Strait, two most convenient barbours, to wbicb he gave the names of Port Clarence and Port Grantley. After this voyage Captain Beechey remained unemployed for some time, as his health had suffered; but he occupied himself in preparing and publishing accounts of the various voyages in which he had been engaged. In 1828, the year of his return, appeared 'Proceedings of the Expedition to explore the Northern Coast of Africa, from Tripoli eastward, in 1821 and 1822;' the 'Voyage to the North Pole' followed; in 1831 appeared the 'Narrative of a Voyage to the Pacific and Behring's Strait;' succeeded by the Botany and Zoology of the same voyage, in two expensive quarto volumes. He had also been employed between 1829 and 1839 in surveying the coasts of South America and Ireland. In 1854 he was created Rear-Admiral of the Blue. He died November 28, 1856.

BEES, ST. [Cumberland.]

BELFORD. [Northumberland.]

BELFORT. [Befort.]

BELL-METAL. [Chemistry, S. 1.]

BELLINGHAM. [Northumberland.]

BELLOT, JOSEPH RENÉ, was born at Paris, in March 1826. His father, who was in humble circumstances, removed to Rochefort when Joseph was five years old. Joseph was placed in the elementary school of that city, and so favourable a report was made by his schoolmaster at the close of his term of instruction, that the municipality at once granted him a demibourse at the College of Rochefort. Here his progress was equally satisfactory; so that when his college term ended, in his 16th year, and he proceeded to the naval school at Brest, the municipality of Rochefort continued to contribute a moiety of the expense. He was two years at the naval school, and on quitting it took rank as fifth on the list at the final examination. Having served six months in port, he received his commission as 'élève de marine' on board the corvette Bercean, bound for the Isle of Bourbon. It is worthy of remark, as characteristic of Bellot's excellent disposition, that, before leaving France, out of his slender salary he assigned to his family the sum of 20 francs a month.

Bellot remained abroad somewhat over three years, returning home in November 1847. During this time, while steadily pursuing his private studies, he had, by the diligent discharge of his official duties, secured the esteem and approbation of his superior officers. M. Romaine Desfossés, the commodore, to whom Bellot had acted as aide-de-camp, in his official despatch to the minister of marine, pronounced Bellot to be "the most distinguished élève on the station, ... and in every respect superior to his age and position." Distinguished merit in a young officer is seldom neglected by the French government. For his conduct and bravery in the expedition against Tamative, Madagascar, in July 1845, in which he had been wounded, he had been already promoted to be an élève of the first class, and, though under twenty, created a Chevalier of the Legion of Honour; and now on returning home with the high commendation of M. Desfossés, he was raised to the rank of Sub-Lieutenant.

The following summer Lieutenant Bellot sailed in the corvette Triomphante to South America, where he remained for about two years. His conduct here affords a fine lesson for the young officer, whatever service he may be in, and to whatever country he may belong. His strictly professional duties, and they were very onerous, were most carefully and sedulously performed, and he obtained, as before, the warmest commendations from his superiors. But his own time was carefully husbanded and admirably employed. He not only extended his knowledge, especially in hydrography and geography, but taught himself to speak English, Spanish, and German fluently; and withal gave up much time and thought to what he had come to regard as an important part of an officer's duty—the training of his subordinates. So far indeed did he carry this, that, both here and on the African station, his biographer informs us, "he gave on board the vessel a course of lectures on geometry and navigation for all those seamen who, being intended for masters of trading vessels, would have to pass on their return the examination in theory and practice required by the rules of the marine."

Bellot's thoughts were now turned to a new sphere of operations. The search after Sir John Franklin and his gallant comrades had directed general attention to the Polar Regions. When he found that his own government would not, as he had hoped, aid in the search, he asked for, and obtained permission to volunteer his services in the expedition fitting out, chiefly at the expense of Lady Franklin, under Mr. Kennedy. His services were gladly accepted, and he sailed in the schooner Royal Albert in the beginning of June 1851, holding no declared rank, but really second in command, with the understanding that he was to act as chief officer in case of Captain Kennedy's death. Of this voyage Lieutenant Bellot left a full and very interesting journal, which has been published under the editorship of M. de la Roquette, along with his memoirs. The Royal Albert was ice-bound in Fury Bay for 330 days, and was compelled to return without having obtained any tidings of Sir John Franklin; but the expedition was so far successful as to have ascertained that Sir John could not have proceeded in the direction indicated for their search, and every man was brought home alive and in good health.

Bellot had displayed in this, as on every previous service, the most intelligent and devoted attention to its duties, and had secured the hearty good-will of both officers and seamen. In England he was received with an amount of enthusiasm for which he was little prepared, and his own government marked its approbation by raising him a step in rank. But he was not disposed to rest on his laurels. He again obtained permission to volunteer in a new searching expedition, and in June 1853 set out in the Phœnix, Captain Inglefield. They anchored safely in Erebus and Terror Bay, where they found lying the North Star, but its commander, Captain Pullen, had been for a month away from his ship on an exploratory journey. Captain Inglefield resolved to set out in search of Captain Pullen, but the latter returned shortly after Inglefield's departure. It now appeared very desirable at once to forward, if possible, the despatches, which it had been a principal object of the expedition to convey, to Sir Edward Belcher. In the absence of his captain, Lieutenant Bellot volunteered to conduct this perilous undertaking. He accordingly set out with four sailors, a canoe, and a sledge. A few days later, on the 18th of August, while crossing the ice, about three miles from the shore, off Cape Bowden, they were caught in a gale, became separated, and Bellot, with two of his companions, drifted on a broken piece of ice towards mid-channel. After cheering his companions as well as he was able, Bellot crossed to the opposite side of the hummock to see how the ice was drifting. As he did not return, one of the sailors went after him; but he was not to be seen, and he was never seen again. His stick lay on the other side of a wide crack, into which he had no doubt been driven by the violence of the wind. His companions happily escaped.

Thus, at the age of twenty-six, was lost one of the most promising men who have adorned the French navy. The news of his sad end was received with general sorrow in both countries. In London a meeting was held, at which resolutions, expressive of admiration and regret, were moved and supported by the First Lord of the Admiralty, the President of the Geographical Society, and various eminent naval officers and scientific men; and a subscription was authorised for raising a testimonial to his memory. The testimonial took the form best calculated to do him honour. Out of the funds a handsome granite obelisk, bearing his name, was placed in the square of Greenwich Hospital, fronting the river; and to each of his five sisters a sum of about 300*l.* was appropriated. The French government provided for his two brothers.

(Lemer, *Memoir of Lieutenant Joseph René Bellot, &c.*)

BELLOWS-FISH. [Centriscus.]

BELO'NE, a genus of Fishes belonging to the family *Esocidæ* of the *Abdominal Malacopterygii.* It has a head and body greatly elongated, the latter covered with minute scales; both jaws very much produced, straight, narrow, and pointed, and armed with numerous small teeth; the dorsal fin placed over the anal fin. The species are remarkable for the green colour of their bones.

One species, the *Belone vulgaris*, is common on the British coast. It is known by various names, but more especially that of Gar-Fish. It was placed by Linnæus in the genus *Esox*, and being an inhabitant of the sea, it got the name of Sea-Pike. From the fact of its leaving the deep water in spring to deposit its ova near the shore in the months of April and May, and thus preceding the mackerel in their annual visit to shallow water for the same purpose, it has received the name of Mackerel-Guide. Its other English names, according to Yarrell, are Greenbone, Horn-Fish, Long-Nose, Gorebill, and Sea-Needle. The usual length of this fish is about 24 inches. It has elongated jaws, beset with numerous minute teeth. The eye is large. The body is uniform in depth to the anal fin, thence tapering to the tail. The dorsal and anal fins begin and end nearly on the same plane. The ventral fins are small. The tail is forked; the external long rays are nearly as long again as those of the centre. The upper part of the head and back is of a dark greenish blue; the sides and belly are silvery white; the pectoral, ventral, and anal fins white. This fish is taken off the coast of Berwick during the mackerel season, and Dr. Johnston says it is not unfrequently called a Sword-Fish. It is taken also on the Devonshire and Cornish coasts. The fish are brought into the London markets in the spring, and eaten in considerable quantities. The flesh has the flavour of mackerel, but it is drier. Great numbers are said to be caught off the coast of Holland, but they are only used there as bait. Mr. Couch says of the Gar-Fish, that it "swims near the surface at all distances from land, and is seen not unfrequently to spring out of its element; its vivacity being such that it will for a long time play about a floating straw, and leap over it many times in succession. When it has taken the hook it mounts to the surface, often before the fisherman has felt the bite: and then with its slender body half out of the water, it struggles with the most violent contortions to wrench the hook from its jaws. It emits a strong smell when newly taken." In the Ionian Islands, according to Mr. Tonna, it is caught by attaching several lines with floats to a raft. In this way a large number are taken in a very short time. Specimens of this fish have been exhibited in the Aquavivarium of the Zoological Society, in the Gardens, Regent's Park.

There are several other species, some of which are said to attain a length of eight feet, and to bite very severely. Their flesh generally is wholesome. (Yarrell, *British Fishes:* Cuvier, *Règne Animal.*)

BELPER. [DERBYSHIRE.]

BEM, JOSEPH, was born at Jarnow, in Austrian Galicia, in 1795. After having studied in the University of Cracow, in 1810 he entered the military school at Warsaw, directed at this period by the French general Pelletier; and from this school, at the end of two years, he issued as an officer of the horse artillery. In 1812 he served as lieutenant in the army under Davoust, and subsequently under Macdonald, with whom he was during the siege of Hamburg. Russia having violated the capitulation, he was forced to return to Poland, residing with his father, who had an estate near Kielce. When the kingdom of Poland was again constituted, Bem resumed his military duties. In 1819 he was created a captain, and became aide-de-camp to General Boutemps. He was next made professor in a school of artillery newly established at Warsaw. Here he introduced into the Polish army the use of the Congreve rocket, and published a work upon this instrument of destruction. Soon afterwards he solicited to be removed from this school, but the Grand-Duke Constantine, who treated this demand as an act of insubordination, had him brought to trial before a court-martial, which condemned him to prison. He was however released, but sent to Ketzk, and placed under the surveillance of the police.

After the death of the Emperor Alexander, Bem obtained his dismission, and went to reside at Leopol, in Galicia. There he devoted himself entirely to science, and commenced a work on the steam-engine. When the revolution of 1830 broke out, Bem immediately betook himself to Warsaw, where he was at once made a major in the Polish army; and shortly afterwards was appointed to the command of a battalion of horse artillery, in which capacity, in the face of a numerous enemy, he displayed all the knowledge of a tactician with the bravery of a soldier. After the defeat of the Polish army he led the remnant towards France, and here he remained for a considerable period in exile, gaining his living by teaching mechanics and mnemonics. He afterwards undertook to raise a Polish legion for Dom Pedro in his expedition to Portugal, but the attempt proved a failure. He himself repaired to Lisbon, where an attempt was made on his life; the ball aimed at him was arrested by a piece of money in his pocket.

On the commencement of the revolution in 1848, Bem at first attempted to organise the insurrection at Vienna, and afterwards joined himself to the Hungarian party. Charged with the command of an army to oppose the Austrians on the side of Transylvania, he at first experienced some checks, but in March, 1849, he made himself master of Hermannstadt, took Cronstadt, and repulsed the Austrian army, though joined by that of Russia, called to its assistance in the previous February. He also compelled the Austrian general, Puchner, to abandon the Banat and Wallachia. The Austrians and Russians rallied in Transylvania; and after attempting in vain to excite the Wallachians and Moldavians to rise, he was attacked and defeated at Segesvar by a greatly superior force under Lüders, the Russian general. He however succeeded in re-assembling his forces, and on August 5, 1849, he a second time possessed himself of Hermannstadt, which however he could not retain for want of reinforcements. At the desire of Kossuth he entered Hungary, and on August 8 took part in the battle of Temesvar, in which the Hungarians were defeated.

Bem then, with others, took refuge in the Turkish territories, embraced the Mussulman faith, was favourably received by the Sultan Abdu-l-Medjid, and was raised to the dignity of a pasha, with a command in the Turkish army. In November 1850 he exerted himself at Aleppo, where he and several other converts had been ordered to reside, in repressing the sanguinary excesses committed by the Mussulman population on the Christian residents. He died at Aleppo, Dec. 10, 1850.

(*Nouvelle Biographie Générale.*)

BEN-NUTS, the fruit of *Moringa pterygosperma*, from which Ben-Oil, much used in perfumery, is obtained. [MORINGA.]

BENINCASA, a genus of plants named by Savi, in honour of Count Benincasa, an Italian nobleman. It belongs to the order *Cucurbitaceæ*, and has but one species, *B. cerifera*. The fruit is described as covered with hairs and a glaucous bloom. It grows in the East Indies. Lindley, in the 'Vegetable Kingdom,' calls it the White Gourd, and says it is identical with *Cucurbita pepo*. Ainslie says that in the East it is presented at every native marriage feast, and is supposed to insure prosperity to the married pair.

BENSINGTON. [OXFORDSHIRE.]

BENTINCK, LORD WILLIAM GEORGE FREDERICK CAVENDISH, commonly known as Lord George Bentinck, was the third son of William Henry, fourth duke of Portland, by Henrietta, daughter and co-heiress of Major-General Scott, whose sister was married to the late George Canning. He was born on February 27, 1802, and though only a younger son, inherited a fortune from his mother that placed him above the necessity of adopting a profession. He however entered the army, and gradually attained the rank of major; but a period of profound peace was not calculated to open the way to any ambitious aspirations in that direction. He therefore, when his uncle Canning became secretary for foreign affairs in 1826, became his private secretary, for which he displayed an extraordinary capacity, was treated with great cordiality, had unbounded confidence reposed in him, and it was thought a brilliant political career was opening before him. In 1827, while his uncle was first lord of the treasury, he entered parliament as member for the borough of King's Lynn, and for that borough he sat till the close of his life. He however did not distinguish himself in parliament at this time, except by a very sedulous attendance: he spoke very seldom, and then not well; but he voted steadily on the side of what were known as moderate Whigs. He voted for Catholic Emancipation, but was not very warm in its favour. On Canning's death in 1827, Lord George gave an independent support (this means opposing them occasionally) to Lord Goderich's cabinet, in which his father was president of the council; but he declined voting in favour of Lord Ebrington's motion that defeated the Wellington cabinet. He however continued to support Lord Grey's government till the secession of Lord Ripon, Sir James Graham, and Lord Stanley (now Earl of Derby), to the latter of whom he was strongly united by the consonance of political opinions and the similarity of pursuits; both being strongly attached to the turf. On the accession of Sir Robert Peel in December 1834, he formed one of the small party nicknamed by O'Connell as the Derby Dilly, "carrying six insides." He however vehemently denounced the 'Litchfield House treaty,' by which it was asserted the adhesion of the Irish members was bargained for by the Whigs, and which ultimately led to the resignation of Sir Robert Peel in 1836, and the accession of Viscount Melbourne. From that time until 1841, when Sir Robert Peel again assumed the direction of the government, Lord Bentinck was one of his warmest supporters. On this occasion Sir Robert made him an offer of office, which he declined; but he was most unwearied in his support. It is related that after a late debate, he would travel by rail to Andover to hunt, and return in time to attend the sittings of the House in the evening; throwing a wrapping overcoat of some kind over his scarlet hunting-coat, and exercising indefatigably the office of 'whipper-in,' in the house, that is, bringing up the members to a division. But in 1843 the free-trade measures began to alienate many of Sir Robert Peel's supporters; and when in 1846 he wholly repealed the Corn Laws, Lord George went into the most violent and personal opposition. Sir R. Peel resigned, but Lord George abated but little of his animosity, although he opposed the Whig free-traders who had succeeded him. The country party, as it was termed, had been taken by surprise, and knew not where to look for a leader. At length they selected Lord George, who very unwillingly accepted the post, but having accepted it, he threw himself into the part with his accustomed energy in whatever he undertook. He commenced studying statistics, he spoke on every possible occasion, he inspired his adherents with boldness, he impeded the administration in their measures. But though clever, ardent, indefatigable, and too often unscrupulous, free-trade continued its march in spite of his efforts, seconded by those of his principal ally, Mr. B. Disraeli. He had during all these political avocations continned his attention to racing and race-horses, declaring on one occasion that the winning of the Derby was the 'blue-ribbon' of the turf. On the prorogation of the house in August 1848, he retired to Welbeck Abbey for relaxation; he however attended Doncaster races four times in one week, at which a horse of his own breeding won the St. Leger stakes, to his great gratification. On September 21 he left the house on foot soon after four o'clock in the afternoon, to visit Lord Manvers, at Thoresby Park, and sent his servants with a gig to meet him at an appointed place. He appeared not; the servants became alarmed; search was made for him; but it was not till eleven at night that he was found quite dead, lying on a foot-path in a meadow about a mile from the house. At the coroner's inquest it was proved that the cause of death had been spasms of the heart. A lengthy life of Lord George has been written by his friend and follower, Mr. B. Disraeli, in 8vo, 1851. (*Gentleman's Magazine*; Miss Martineau, *History of the Thirty Years' Peace*; B. Disraeli, *Life of Lord George Bentinck*.)

BERANGER, PIERRE JEAN DE, was born in Paris, August 19, 1780, of humble parentage, and in his earliest years was brought up by his grandfather, a tailor. He witnessed the taking of the Bastille, in 1789, and was then removed to the care of an aunt, who kept an inn at Peronne. Here he first learnt to read. At fourteen he was apprenticed to a printer in Peronne. Somewhat later he attended a primary school founded at the same place. At sixteen he returned to his father at Paris, and having attended some theatrical representations, resolved to attempt a comedy, and produced 'Les Hermaphrodites.' At eighteen he projected the writing of an epic, to be called 'Clovis;' this he proposed as the task of the succeeding twelve years. He also produced verses on sacred subjects, some of which have been given in the edition of his works edited by M. Perrotin and published in 1834. These performances did not improve his fortunes; and, reduced to great distress, he thought of proceeding to Egypt, where Bonaparte then was, and whose first successes had excited extravagant visions of glory and prosperity among the French population. The return, however, of some members of the expedition dissipated Béranger's dream, and he remained in Paris. It was at this period, when suffering from his disappointed hopes, and even actual indigence, that he seems to have resolved to be gay if he could not be happy, and he produced his 'Roger Bontemps,' 'Le Grenier,' 'Les Gueux,' and 'Le Vieil Habit.' They were not immediately successful; but in 1803 he sent some of his poems to Lucien Bonaparte, who promised to ameliorate his situation. Lucien was suddenly called to Rome. Béranger thought himself forgotten; when a letter came from Lucien, assigning to Béranger his income as a member of the Institute. He next obtained some employment as an editor, and in 1809 was appointed a clerk in the secretary's department of the Academy. His songs were now becoming popular in every quarter. During the 'hundred days' of Bonaparte, Béranger refused the lucrative office of censor. In 1815, when he published his first collection of songs, which were popular throughout France, he was informed that it would occasion his dismission from the office he held in the Academy. He wavered not, and was retained; but in 1821, when the second collection was published, he was at once discharged. He wrote more and more poignant satires upon the government; he was prosecuted, and was sentenced to three months' imprisonment and a fine of 500 francs. In 1825 he published his third collection, and in 1828 his fourth. For this last publication he was again prosecuted, and was condemned to nine months' imprisonment and a fine of 10,000 francs. Confined more strictly in the prison of La Force, the undaunted poet continued his attacks on the faults and follies of the government, and these remarkable lyrics aided not a little in accelerating the fall of the Bourbons.

In 1830 the revolution of July would have acted favourably for Béranger's fortunes if he would have given up his beloved independence. He says, "I was treated with as one of the great powers;" "nearly all my friends have become ministers;" "unfortunately I have no love of sinecures, and all compulsory labour has become insupportable." Béranger was convinced that France was not fitted at this time for a republican government, and he supported the establishment of a limited monarchy. In 1833 he published his fifth and last collection of songs, containing some of his most striking pieces. After the revolution in 1848 he was elected in April of that year a representative of the Department of the Seine in the Constituent Assembly, by more than 200,000 votes; but in May he sent in his resignation. It was unanimously refused; but a week afterwards he renewed it, and it was accepted.

Béranger continued to write, but did not publish. He was known to have a large collection of songs, and he employed himself also with a 'Biographie' of himself and his contemporaries. He resided partly in Paris and partly in the country, living quietly in retirement, and enjoying the society of a few friends. He died in Paris, July 16, 1857, and was buried on the following day in the cemetery of Père la Chaise, at the expense of the French government. Soon after his death Madame Colet published 'Forty-five Letters by Béranger, and Details concerning his Life' (Quarante-Cinq Lettres,' &c.). In October, 1857, M. Lapointe published 'Memoirs of Béranger' (Mémoires,' &c.); in November appeared 'Last Songs of Béranger' ('Dernières Chansons,' &c.); and in December was published 'My Biography, by P. J. de Béranger' ('Ma Biographie,' &c.).

The songs of Béranger have deservedly attained a high reputation, not only in France but throughout Europe. One charm is their complete nationality. The delicate wit, the subtle satire, the indignant denunciation, the vivid and correct pictures, the frequent comicality of situation—are all truly and exclusively French; and so are the faults that are sprinkled rather too frequently through them. His command of language is marvellous, and in the most difficult rhythms the words always seem to drop naturally into their places; but this result, as he states in his 'Biographie,' was attained by him only with great labour.

The whole career of Béranger is very remarkable. He had become a real power in the state, under the first Napoleon. Although he felt that there was no hope for the national freedom of his country while that despotism endured, he had a sincere admiration of the emperor's genius. Consequently there were no personal attacks in his early songs; and when a little gentle raillery upon externals was ventured—as in 'Le Roi d'Yvetot' and 'Le Sénateur'—it was laughed at and applauded even at court. Béranger is considered by his countrymen as a religious poet: this is not the impression which an Englishman would receive. But he certainly does not shock by impiety, however he may offend by levity and want of reverence. The songs for which he was prosecuted were not attacks on religion, but on its false assumption. Fined and imprisoned under the Bourbons, he still remained the conqueror. Béranger has little resemblance to our own song-writers. He has none of the deep passionate love depicted by Burns. He never contemplates the happiness of

"Loving and being loved by one;"

but—

"Takes, forsakes, retakes Lisette"

in a fashion that jars on English feelings of delicacy. The passion he describes indeed is rather that which has become appropriated in English to the French word 'amour.' His contrast to our patriotic singer, Dibdin, is also striking. Dibdin holds out few incentives to the sailors he addressed beyond a sense of duty, prize-money, a picture of domestic happiness with their Nancy, and Greenwich Hospital. Such encouragements find no place with Béranger. The glory of France is the most prominent inducement to fight and to die. To our other lyrical poet, Moore, he has somewhat more resemblance.

BERCHEMIA, a genus of plants belonging to the natural order *Rhamnaceæ*. Two species, *B. volubilis* and *B. lineata*, are used in medicine.

BERESFORD, WILLIAM CARR, VISCOUNT, the natural son of the first Marquis of Waterford, was born on October 2, 1768. He entered the army early, and while serving in Nova Scotia lost the sight of an eye from the accidental shot of a brother officer in 1786. He served at Toulon, at Bastia, at Calvi, and in the West Indies under Abercromby, and in Egypt under Baird. In 1806, having attained the rank of brigadier-general, he commanded the land forces in the expedition against Buenos Ayres, and was taken prisoner, together with his corps, but he contrived to escape shortly afterwards. In 1807 he commanded the force which obtained possession of Madeira. In 1808 he arrived in Portugal with the English forces, and to him was confided the organisation of the Portuguese army, including the militia. This he effected so completely, that the Portuguese troops, throughout the Peninsular war, showed themselves worthy of fighting by the side of their British allies. On May 4, 1811, he invested the fortress at Badajoz, and on the 16th defeated Soult at Albuera. At the battle of Salamanca, in 1812, he was wounded. He then commanded a division under Wellington, and took a distinguished share in the battles of Vitoria and Bayonne. On the 10th of April 1814, he attacked and carried the heights before Toulouse with great skill and bravery. For his services he had been created a Portuguese field-marshal, Duke of Elvas, and Marquis of Santo Campo; and he was now created a British peer by the title of Baron Beresford. In the same year (1814) he was sent on a mission to Brazil: he returned in 1815; and after a short visit to Portugal, he repaired to Brazil again. On his return he resumed the command of the army of Portugal, at the request of the Portuguese government, but resigned it at the end of a few years, not approving of the efforts then being made to establish a constitutional government. On his return to England in 1823 he was created Viscount Beresford. From 1828 to 1830 he was master-general of the ordnance. He continued to take an active part in politics, being strongly attached to the Tory party; and in 1826, in consequence of assisting in forwarding English troops for the support of Don Miguel, he was deprived of his rank as Portuguese field-marshal. In 1832 he had married Louisa, his cousin, the daughter of the archbishop of Tuam, and the wealthy widow of Thomas Hope the banker, but left no issue. He died at Bedgebury Park, Kent, on January 8, 1854. At the time of his death he was governor of the Royal Military Academy at Woolwich, and governor of the island of Jersey.

BERGERA, a genus of plants belonging to the natural order *Aurantiaceæ*. *B. Königii* possesses stomachic and tonic properties, and an infusion of the leaves is used against vomiting. The green leaves are used raw in dysentery; the bark and roots are stimulant.

BERKELEYA, a genus of *Diatomaceæ*, named by Greville, in honour of the Rev. M. J. Berkeley, distinguished for his researches in cryptogamic botany. It belongs to the suborder *Naviculeæ*, and is characterised by having linear frustules included within tubular submembranaceous filaments, which are free at one extremity, but have the other immersed in a gelatinous tubercle. *B. fragilis* is found parasitic on *Zostera marina*, and some of the smaller marine *Algæ* on the British coasts. *B. Adriatica* has been found on the coasts of the Adriatic at Trieste.

BERMONDSEY. [SURREY.]

BERTHOLETIA. [MATERIA MEDICA, *S.* 2.]

BERZELIUS (or BERZEL), JÖNS JACOB, one of the most distinguished of modern chemists, was born August 20th, 1779, at Wäsersunda, a village near Linköping, in East Gothland. Beyond the fact that he received the elements of learning from his father, who was parish schoolmaster—a functionary of some consideration in Sweden—and who died while his son was yet a boy, we know nothing of his early years. At the age of seventeen the youth entered on the study of medicine at the university of Upsal, and attended the dull lectures on chemistry delivered by Afzelius and Ekeberg. So little care was at that time taken to render scientific instruction clear to the mind, that Berzelius had to discover and investigate facts and draw conclusions for himself, and soon became remarkable for his diligence and discernment. As an instance of the way in which he was initiated into chemical manipulation, he used laughingly to relate in after life:—"Afzelius first gave me sulphate of iron to calcine in a crucible, for the preparation of colcothar. 'Any one may do work of this kind,' I replied; 'and if this be the way you are to teach me, I may as well stay at home.' 'A little patience,' answered the professor, 'your next preparation shall be more difficult.' On the next occasion I got cream of tartar to burn, in order to make potass; which so disgusted me, that I vowed never to ask for any further employment." But he continued to attend notwithstanding his vow, and soon frequented the laboratory every day, although by the rules pupils were entitled to admission but once a week, his masters offering no opposition. Ekeberg was, however, vexed at times that the young student pursued his tasks in silence, asking no questions. "I preferred," said Berzelius, "to endeavour to instruct myself by reading, meditating, and experimenting, rather than question men without experience, who gave me replies, if not evasive, at least very little satisfactory on the subject of phenomena which they had never observed."

In 1798, after two years' study, he left Upsal, and engaged himself as assistant to the physician-superintendent of the mineral springs at Medevi, a watering-place much resorted to by the Swedes. Here with his habitual diligence he analysed the waters, and in conjunction with Ekeberg published a paper embodying the results. This was the first of the long series of papers that remain to illustrate his fame.

In 1804 Berzelius returned to Upsal, and took his degree of Doctor in Medicine; and soon after published his 'Physical Researches on the Effects of Galvanism on Organised Bodies,' a work which exhibits much of his sagacious insight and painstaking. Davy, who was born in the same year with the illustrious Swede, had made known his experiments; and Berzelius, taking up the subject, then a wonder to scientific men, materially widened his applications. His growing reputation gained for him, on his going to reside at Stockholm in 1805, the post of assistant to Sparrmann, professor of medicine and botany, who had sailed as naturalist in Cook's second voyage of discovery. The emoluments were so scanty that Berzelius had at times to practise medicine to eke out his resources. In 1806 he succeeded to the chair, and in the the same year, jointly with Hisinger, he commenced the 'Afhandlingar i Fysik, Kemi, och Mineralogie,' to which during the twelve years of its existence, he contributed forty-seven original papers. This periodical was at once translated into German, and subsequently into French, and generally prized for its trustworthy elucidation of chemical principles. This however was but a small part of what Berzelius undertook: he set to work to revise the labours of his predecessors, accepting no conclusion that did not admit of the clearest demonstration. His skill as an analyst is described as 'consummate,' and when Dalton and Davy put forth their views he, by innumerable analyses, established the laws which regulate chemical combinations, and reduced them to a form so simple as to give them a twofold value. "When these laws were once well ascertained," says an eminent foreign savant, "it became possible to control the results of analyses—even to foresee a great number of combinations then unknown—and to carry into every operation an accuracy previously thought altogether unattainable."

By his elaborate examination, beginning with the salts and going through the whole range of elements, including the products of organised existence, Berzelius anticipated Dalton in some of his conclusions, and afterwards found a perfect agreement between his results and those of the Manchester philosopher. His knowledge of the laws of definite combinations enabled him to elucidate the nature of minerals, and to show at the same time, by the composition of the minerals, the universality of the laws. He helped indeed to bring the atomic theory to perfection, and to introduce it into science. He framed moreover an electro-chemical theory, and published 'Lectures on Animal Chemistry,' a work filled with rare proofs of original research and clear perceptions on a branch of science then least understood. On the publication of these lectures the Swedish government made him a grant of two hundred dollars a year, to enable him the better to prosecute his labours. In 1807 he joined with seven leading members of the profession in establishing the Medical Society of Sweden, now a flourishing institution; and in the following year he was admitted a member of the Royal Academy of Sciences of Stockholm. In 1810, being then at the age of thirty-one, he was elected President of the Academy; a striking proof of the estimation in which he was held by his colleagues.

Berzelius visited England in 1812, and while here learned how prelections could be made really interesting as well as instructive by attending Dr. Marcet's lectures at Guy's Hospital. In conjunction with Dr. Marcet he wrote a paper entitled 'Experiments on the Alcohol of Sulphur, or Sulphuret of Carbon,' which was published in the 'Philosophical Transactions' for 1813; and in the same year he was elected a foreign member of the Royal Society.

On his return to Stockholm Berzelius at once changed his style of lecturing, and with the happiest results. His dry readings became living discourses, illustrated by experiments, of which he greatly multiplied the number suitable for public exhibition by his quick imagination. Men whose names have since become famous attended his teachings. In 1815 he was made Chevalier, and afterwards Commander of the order of Wasa; and in 1818 he was chosen perpetual Secretary of the Academy, which distinguished post he held for the rest of his life. In the same year, at the coronation of Charles John, he was ennobled with permission, contrary to custom, to retain his name. In 1821, at the instance of the Academy, he commenced that series of annual reports on the progress of chemistry and physics, which, while contributing materially to the advancement of those sciences, confirmed and heightened his own reputation. Speculative philosophers charged him with jealousy and envy, because of his intolerance of unsubstantial theories. No theory was ever accepted or started by him that was not supported by a solid basis of facts. If "too cautious," as was often said, he studied but the interests of science; and if jealous, it was for chemistry, and not for himself. Regarding himself as a vidette ever on duty, he warned and alarmed whenever the occasion required, and confident in integrity, delivered his opinions with unqualified freedom. So faithful a censor will not be easily replaced.

In the hands of Berzelius the blowpipe became a most important instrument in the analysis of inorganic substances. A translation of his treatise on the subject appeared in English in 1822—'On the Use of the Blowpipe in Chemical Analysis and the Examination of Minerals.' There was scarcely a question that he did not bring to the test of experiment, and reduce to its proper place in science, as may be seen in his great work 'Lehrbuch der Chemie,' which has gone through five editions, and as many translations. The last was published at Paris, in six volumes, octavo, in 1845-1850.

In 1832 Berzelius resigned the professorship which he had held for twenty-six years; but still kept on with his scientific labours. He married about this time, and on the day of his wedding the king wrote to confer on him the dignity of 'Freiherr,' or Baron, observing that, "Sweden and the world were the debtors of a man whose entire life had been devoted to works as useful to all, as they were glorious to his native country." Subsequently he had the further honour of receiving the Grand Cross of the Royal Swedish order of the Polar Star. The directors of the Swedish iron-works awarded him a pension, in acknowledgment of his eminent services to their branch of industry. And in 1836 the Royal Society of London showed their sense of his merits by giving him their Copley Medal.

So the life of Berzelius flowed on in a tranquil current. He enjoyed all the honours his native land could give, had the satisfaction of seeing his name enrolled among the members of nearly all the scientific societies of the world, more than 100, and of knowing that foreign governments recognised his worth. As he approached the age of fifty his sight began to fail, and his memory to lose somewhat of its power. Infirmities now increased on the philosopher, whose health had never been robust. He was seized with paralysis of the lower extremities; but retained the serenity of his mind till death approaching, as one has said, "with slow steps, as a messenger who regretted his errand," closed his career on the 1st of August, 1848. His death was felt as a national calamity, and the scientific societies of his native land wore mourning for two months in respect for his memory.

BESSEL, FRIEDRICH WILHELM, was born at Minden, on the 22nd of July 1784. His father was a civil officer (justizrath) under the Prussian government; his mother a clergyman's daughter; and there being a family of nine children to rear on but narrow means, the future astronomer received only an ordinary education. Among his earliest manifestations was a dislike of classical literature, and a love for arithmetic. His quickness in calculation led to his being articled at the age of fifteen as clerk in a mercantile house at Bremen. Here he showed himself diligent to fulfil the duty that lay immediately before him, whatever it might be; and this remained his especial characteristic. The hope of being offered the post of supercargo on a foreign voyage was then his stimulus; and to qualify himself for this responsible office he began to study French and Spanish, and Hamilton Moore's old work on navigation. Dissatisfied with the rules and processes laid down for nautical reckoning, he sought for better information in a popular treatise on astronomy, and finding therein the means for overcoming his difficulties, he pursued the study with eagerness, till ignorance of mathematics brought him to a stand. Regarding the check as a call for greater exertions, he betook himself to a course of mathematical reading, and so interested did he become in this new study, that all his spare hours, chiefly in the night, were devoted to it. There was no longer the same charm in commercial pursuits, or in the hope of a voyage. And now appeared a trait that marked his character through life—turning theory or knowledge to positive and practical uses. With a rude wooden sextant, made by a carpenter, and a common clock, he began to make time-observations; and having observed the occultation of a star by the moon, he got therefrom, to his great joy, an approximate latitude of Bremen. This was one of the successes that gladden the heart of the student, repay his toil, and animate him to renewed exertions.

From this time his progress in astronomical studies was surprisingly rapid. While still a clerk in a counting-house, he had formed designs of original inquiry, such as are expected only from veterans of science. Harriott's and Torporley's rough observations of the comet of 1607 had been found by Baron Zach, while searching the collection of Harriott's papers in the possession of the Earl of Egremont, and these being the first instrumental observations of that comet —since known as Halley's—their reduction was a desideratum of first-rate importance. Bessel, when in his 20th year, undertook the task, and executed it in so masterly a manner, that Olbers, to whom he communicated the results, foreseeing his future eminence, praised him in the warmest terms, and sought to enlist him in the astronomical ranks. The reductions—Bessel's first published work—appeared in Zach's 'Monatliche Correspondenz,' and was speedily followed by a theoretical paper of great merit, 'On the Calculation of the True Anomaly in Orbits nearly Parabolic,' the beginning of a long series of contributions to the German scientific periodicals. "So expert had he become in cometic calculations," says one of his biographers, "that Olbers, having placed in his hands, on the night of the 1st of November 1805, four observations of the comet of that year, he returned them to him the next morning, with the elements, whose calculation had occupied him only four hours."

Bessel faithfully served his term of seven years; but no sooner was he free than, abandoning all pursuit of a commercial life, he, recommended by Olbers, succeeded Harding as assistant to Schröter at Lilienthal in 1806. He was now an astronomer to all intents and purposes; and well did he justify the anticipations of his friends. Not many years elapsed before his name stood among the foremost of modern astronomers.

One of his first tasks at Lilienthal was a series of observations on the sixth, or Huyghenian satellite of Saturn, with a view to determine the mass of the planet and ring, on which he wrote an able and elaborate paper (published in the 'Königsberger Archiv für Naturwissenschaften'), discussing all the phenomena of attraction and the disturbing causes. It formed a subject for examination in after years, when more perfect instruments were available. He observed also the comet of 1807, by which, on the publication of the elements with an examination of the perturbations, in 1810, he gained the Lalande prize of the Academy of Sciences at Paris.

Bessel was one who cared little for accumulating observations without getting from them some direct practical result. He says of himself, in the preface to his 'Untersuchungen,' "that he at no time felt any especial predilection for one rather than another particular branch of astronomical occupation; but that one idea was continually present to his mind —that of always working up to an *immediate* and *definite* object." He held, that an observer who "failed to deduce actual results from observations, with a distinct view to the improvement of knowledge," neglected an essential condition of success and usefulness: and his whole life exemplified his conviction.

The king of Prussia having resolved to establish an observatory at Königsberg, Bessel was appointed director in 1810, and removing thither, he superintended the building and the mounting of the instruments, fulfilling at the same time the associated duties of professor of astronomy and mathematics in the university. The establishment, which was finished in 1813, remains no less a monument of his skill and earnestness than of the munificence that founded it amid the distractions of war. Observations were published in the same year, and have been continued ever since with incalculable benefit to practical astronomers.

Settled in a congenial home, Bessel married. His wife was daughter of Professor Hagen: he had by her one son and two daughters. And now, what he had done for the comet observations of 1607, he—also at Olbers' suggestion—undertook for Bradley's Greenwich observations, which, first published in 1805, had been but little regarded by the astronomers of the day. He had begun the task of digestion and reduction in 1807, and applying himself to it as his numerous avocations admitted, brought it to a close in 1818. The results of this long-continued labour have been for many years before the world in a folio volume, entitled 'Fundamenta Astronomiæ.' This work, published when the author was in his thirty-fourth year, is of such a nature that even grave philosophers can scarcely speak of it in sober terms; and it is especially interesting to Englishmen, being based on the twelve years' observations of Bradley. The book indeed cannot be over-praised. In the words of a scientific report—"Besides elaborate determinations of all the principal elements of the reduction, the errors of the instruments, the height of the pole, refraction, parallax, aberration, precession, proper motion, it contains a catalogue of the mean places of 3222 fixed stars, observed between 1750 and 1762, with the best instruments in existence at that time, and reduced to the epoch of 1755, with a precision and accuracy of which there was no previous example. It now furnishes astronomers with the best existing means of determining all those data which can only be deduced from a comparison of observations made at considerably distant intervals of time, and may be considered in fact as having laid the foundations of the principal improvements which have been made in astronomy since the date of its publication." Schumacher's noteworthy remark, "One may almost assert that one exact and able calculator is capable of doing better service to astronomical science than two new observatories," in this case found its verification.

Bessel's reputation was established. In 1822 he was elected a foreign member of the Astronomical Society of London, and three years later of the Royal Society; and the scientific societies on the Continent hastened to enrol him among their associates. The king of Denmark conferred on him the order of the Dannebrog; and from his own sovereign, who through life was his steady friend, he received the order of Civil Merit and of the Red Eagle, with the title of Privy Councillor; and the Berlin Academy awarded him their prize for his paper on the precession of the equinoxes.

Bessel's labours have been so numerous that anything more than a bare enumeration of them is scarcely possible. He improved the method of finding longitudes. He determined the length of the seconds' pendulum at his own observatory, and so perfectly, as to establish an epoch in the history of pendulum experiments. He showed that in all former observations an essential cause of error had been overlooked, namely, the mass of air dragged by the pendulum in its oscillations; and that the amount of consequent disturbance would have to be calculated for every pendulum. He investigated all possible causes of error in astronomical instruments, leaving nothing unaccounted for, till he surpassed all his contemporaries in his knowledge of the theory of instruments. He was employed to determine the Prussian standard of length; and in connecting the geodetical surveys of Russia with those of Prussia, and of the west and south of Europe; and displayed in these, as in his other labours, rare ingenuity in devising new methods and avoiding causes of error. At the same time he measured an arc of the meridian of his own observatory. Then, as was his habit, taking the whole subject into view, he investigated the surveys of the British government in India and elsewhere, and of the French from the Belgian frontier to the Mediterranean, shrinking from no toil that might aid in the accomplishment of his object. An error made in the French triangulation had been calculated and allowed for by four independent geometers; but Bessel, not satisfied with this, "actually recalculated the whole of the work by his own method, producing a result agreeing with the mean of the four determinations alluded to, within a fraction of a toise." In 1837 he began and carried on for three years a series of observations on the star 61 Cygni, to determine if possible the annual parallax of a fixed star—a task which had been the opprobrium of science. Thanks to his marvellous skill and delicacy of perception, he ascertained the fact; and though the amount of parallax is almost inconceivably small, only 31-100ths of a second, astronomers agree in considering it as demonstrated. By observations of other fixed stars, Sirius and Procyon, he "thought himself authorised to announce the want of uniformity in their proper motions as a positive astronomical fact." And he threw out a speculation as to the cause: namely, that the stars in question are double stars, of which one is not luminous; hence we see the disturbances, but not the disturber.

A more trustworthy guide than Bessel could not be followed: to his example the present excellence of astronomical science in Germany is due. He was a copious writer; the more remarkable, as his writings exhibit proofs of as much profound research, as of variety of attainments. His 'Tabulæ Regiomontanæ,' which may be regarded as a supplement to the 'Fundamenta,' &c., appeared in 1830. Nearly two hundred papers, neither short nor unimportant, in the 'Astronomische Nachrichten,' bear his signature; and others are to be found in the 'Abhandlungen' of the Berlin Academy and in scientific journals, some of which are named above. He published also two volumes of 'Astronomische Untersuchungen,' and, as is said, left a third in preparation.

Bessel visited England in 1842, and was received and honoured in a way accordant with his desert. There is reason to believe that on his return he intended to investigate the problem which, in the hands of Adams and Le Verrier, led to the discovery of Neptune. The preliminary reductions were made; but grief over the loss of his son, a young man of great promise, who died in 1841, and the approaches of disease of a very painful nature upon the astronomer himself, stayed his inquiring spirit. His sufferings became severe, caused by a fungous growth in the abdomen. He died on the 7th March, 1846, at the age of sixty-two.

BETEL-NUT-PALM. [ARECA.]

BETHAM, SIR WILLIAM, was born in 1779 at Stradbroke in Suffolk. His father was the Rev. William Betham, author of 'Genealogical Tables of the Sovereigns of the World,' folio, 1795, and of a 'Baronetage,' in 5 vols. 4to, published in 1801-1805. Although young Betham appears to have inherited his father's tastes, he had to carve out his own career, having been placed by his father as apprentice to a printer in London. His first literary employment was in the revision of the 3rd and 4th volumes of Gough's edition of Camden's 'Britannia.'

In 1805 he went to Dublin as clerk to Sir Charles Fortescue, Ulster King of Arms. A few years later he became the deputy of Sir Charles; and he succeeded him as Ulster King of Arms in 1820. Mr. Betham was appointed Genealogist of the order of St. Patrick in July 1812, on which occasion he was knighted. He also received the appointment of Deputy Keeper of Records at Dublin; an office in itself of little emolument, but which placed under his control a large number of records, of which he availed himself to form an immense collection of historical and genealogical references extending to several hundred volumes, which has since served as an individual store-house in family, historical, and legal inquiries. Sir William also formed an index to the names of all persons mentioned in the wills deposited at the Prerogative Office, Dublin; a task which occupied a considerable portion of his time from 1807 to 1828, and extended to 40 large folio volumes. Sir William was likewise a diligent collector of old manuscripts connected with Irish history and antiquities: his collection was purchased by the Irish Academy in 1851.

Sir William Betham was elected in 1825 a member of the Irish Academy, and soon after became its foreign secretary, which office he held till 1840, when he resigned it in consequence of the council refusing admission in the 'Transactions' of the society to some of his philological speculations. He was a zealous but credulous antiquary, and some of his archæological and philological speculations were of a very singular and wholly untenable character. For a long series of years he devoted himself to the investigation of primeval Irish, or rather Celtic, antiquities, and he fancied that he had discovered traces of the connection of the Celtic races with several of the most remarkable nations of antiquity. His first separate antiquarian publication, 'Irish Antiquarian Researches, or Illustrations of Irish History,' 1826-7, contains many of his peculiar views; but they are more fully developed in his two principal works of this class, the titles of which will sufficiently indicate the character of his notions: the first of these was entitled 'The Gael and Cimbri; or an Inquiry into the Origin and History of the Irish, Scots, Britains, and Gauls, and of the Caledonians, Picts, Welsh, Cornish, and Bretons,' 8vo, 1834; but the full expansion of his opinions was not arrived at till some eight years later, when appeared his 'Etruria Celtica, Etruscan Literature and Antiquities Investigated; or the Language of that People compared and identified with the Iberno-Celtic, and both shown to be Phœnician,' 2 vols. 8vo, 1842. He also contributed numerous papers on Irish Antiquities to the 'Transactions of the Irish Academy,' which have their value unfortunately greatly lessened by his strange want of critical discernment. Sir William was elected a Fellow of the Society of Antiquaries, London, in 1825, but only two or three papers by him were printed in the 'Archæologia.'

In his own proper line of research Sir William was a far more trustworthy guide. Besides several genealogical memoirs, and a valuable work on 'Parliamentary and Feudal Dignities,' Sir William published in 1834 an able and learned treatise on 'The Origin and History of the Constitution of England, and of the Early Parliaments of Ireland.'

For many years before his death Sir William occupied a prominent place in the general and literary society of Dublin; and he was looked up to as a leader in most of the religious and charitable as well as the literary and scientific movements in the Irish metropolis. Kindly and courteous to all who sought his advice or assistance, and always ready to place his stores at the service of the historical or antiquarian inquirer, his death, though at a ripe old age, was generally regretted. He died at Dublin, October 23, 1853, aged seventy-four.

BETH'ANY, a village 2 miles E. from Jerusalem, on the road to Jericho, at the eastern base of the Mount of Olives, was the scene of the raising of Lazarus from the grave. It is now called El-Azariyeh (the Village of Lazarus). (Robinson, *Biblical Researches*; *Dictionary of Greek and Roman Geography*.)

BHOPAL. [BOPAUL.]

BICKERSTAFF, ISAAC, was born in Ireland probably about 1735. He was one of the pages of Lord Chesterfield, who became Lord-Lieutenant of Ireland in 1746. Afterwards he became an officer in the marines, in which service he continued until forced to quit under circumstances of a highly discreditable nature. He is known as the successful author of a number of light comedies and musical pieces, produced under Garrick's management, of which some yet retain possession of the stage. The principal are—'Love in a Village,' 1763; the 'Maid of the Mill,' 1765; 'Love in the City,' 1767 (since altered to the farce of 'The Romp'); 'The Hypocrite,' 1768; 'Lionel and Clarissa,' 1768; 'The Padlock,' 1768; 'The Captive,' 1769; 'He Would if he Could,' 1769. His last piece, 'The Sultan,' was produced in 1787. The music to many of these pieces was composed by Charles Dibdin. The time and manner of Bickerstaff's death are uncertain: all that is known is that he withdrew to the continent, and died in obscurity. (*Biographia Dramatica; Thespian Dictionary*.)

BICKERSTETH, REV. EDWARD, was born March 19, 1786, at Kirkby Lonsdale, Westmorland. He was the fourth son of Mr. Henry Bickersteth, a surgeon of that town, and the younger brother of the late Lord Langdale, Master of the Rolls. He received his early education at the grammar school of Kirkby Lonsdale, but was removed thence on receiving a clerkship in the post-office, London, at the age of fourteen. Here he remained for six years, when he was received into the office of Mr. Bleasdale, a London attorney, as an articled clerk. Having completed his term of five years, he entered into partnership with Mr. Bignold, a fellow clerk, whose sister he married, and commenced business as a solicitor at Norwich in 1812.

The business soon became a flourishing one, and Mr. Bickersteth's prospects appeared very favourable. But he had become deeply impressed with the importance of religious truths, and he soon took a prominent part in the various religious movements for which Norwich was becoming celebrated. The Norwich Church Missionary Society was founded by him, and he was active in promoting the operations of the Bible Society, and several other religious societies in that city. He also wrote and published, in 1814, 'A Help to the Study of the Scriptures,' which in its enlarged form has had an enormous circulation. His own strong religious feelings, aided perhaps by an acquaintance he had formed with Mr. Pratt, Mr. Budd, and some other leading clergymen of the 'evangelical' section of the church, led him to desire earnestly to devote himself to the ministerial office—a desire which those gentlemen strongly encouraged. Accordingly, Mr. Bickersteth was, December 10, 1815, ordained a deacon of the Church of England; the Bishop of Norwich having been induced to dispense in his case with the usual university training, in consequence of its being represented to him that the Church Missionary Society were anxious to obtain the services of Mr. Bickersteth to proceed on a special mission to inspect and re-organise the stations of the society in Africa, and to act afterwards as their secretary. A fortnight later the Bishop of Gloucester admitted him to full orders, and he almost immediately departed with his wife to Africa. He returned in the following autumn, having satisfactorily accomplished the purposes of his visit.

He continued in the zealous discharge of the duties of his secretaryship for the next fifteen years, organising new and visiting old branch associations, directing the studies of the missionaries, continually advocating the interests of the society in the pulpit and on the platform, as well as with his pen; and in the course of his frequent official journeys through all parts of the kingdom, acquiring a constantly increasing amount of influence and popularity in what is commonly designated the religious world. At the end of 1830 he resigned his office, and also his ministerial charge at Wheler Chapel, Spitalfields, upon accepting the rectory of Watton in Hertfordshire. At Watton, Mr. Bickersteth spent the remaining twenty years of his life. But his labours were by no means bounded by his parish. He was during the whole of that time in constant request as the advocate, by sermons and speeches, not only of the missionary, but of almost every other religious society connected with the church, or in which, as in the Bible Society, and the Evangelical Alliance (of which he was one of the founders), churchmen and dissenters associate. And he also produced during his residence at Watton a constant succession of religious publications, which were for the most part read in the circles to which they were chiefly addressed with the greatest avidity. Indeed it may be said that during most of these later years of his life Mr. Bickersteth was one of the most influential and generally popular clergymen of that section of his brethren among whom he was classed.

During this period he took a very decided part in all those measures which he regarded as having a direct bearing on the religious condition of the country. He was especially earnest in opposing the Maynooth grant, and in calling for its withdrawal; and he was equally zealous in denouncing the spread of what are known as Tractarian opinions in the Church of England; yet his opposition was free from all personal bitterness, and his influence was directed to softening the asperities of religious strife. In his later years he manifested a growing interest in the study of prophecy. The unfulfilled prophecies were made the frequent subject of his discourses, and he published several pamphlets and tracts and three or four elaborate treatises in elucidation of the prophetic writings.

His principal works besides the 'Scripture Help' already noticed, and a large number of sermons, tracts, &c., were:—'The Christian Student,' 'A Treatise on the Lord's Supper,' 'A Treatise on Prayer,' 'Family Expositions of the Epistles of St. John and St. Jude,' 'A Treatise on Baptism,' 'The Signs of the Times,' 'The Promised Glory of the Church of Christ,' 'The Restoration of the Jews,' 'A Practical Guide to the Prophecies,' &c. His collected works have been published in 16 vols. 8vo. Among his literary labours ought to be mentioned the Hymn-book which he compiled, and the 'Christian Family Library,' which he edited, and which extended to fifty volumes.

Mr. Bickersteth was in 1841 attacked by paralysis, the result of too prolonged mental exertion. He recovered from this, and resumed his labours. In 1846 he was, when proceeding to a meeting of the Evangelical Alliance, thrown from his chaise under a heavily laden cart, the wheels of which passed over him; but though dreadfully injured he was after a time restored to health and activity, and survived till February 24, 1850, when he died of congestion of the brain, aged sixty-three.

(Birks, *Memoir of the Rev. Edward Bickersteth.*)

BIELA, WILHELM, BARON VON, was born at Rosla, near Stolberg, in the Harz Mountains, in Prussia, his patrimonial estate, on March 19, 1782. When he was born, Stolberg was an independent state, and he entered young into the Austrian army. He had taken an early predilection for astronomy, as an amateur, and while serving with his regiment at Josephstadt in Bohemia, in 1826, he became distinguished by the first discovery of the comet since called after him. Retiring from the military service, he continued to take an interest in the science of astronomy, and corresponded with many of the most eminent men of science. He died on February 18, 1856, at Venice.

BILL OF LADING. The indorsement of a Bill of Lading now not only transfers the property in the goods therein mentioned, but also all the rights and liabilities *inter se* of the original parties thereto. It is also conclusive evidence as against the master of the shipment therein mentioned (18 & 19 Vict. c. 111).

BILL OF SALE. A Bill of Sale of *personal chattels* must be registered within twenty-one days after the making thereof in the judgment office of the Queen's Bench, otherwise it will, as against assignees in bankruptcy or insolvency, or creditors, be null and void (17 & 18 Vict. c. 36.)

BILLBERGIA, a genus of plants belonging to the natural order *Bromeliaceæ*, named after Billberg, a Swedish botanist. Several species are cultivated in our stoves. They are all natives of South America. One of the species, *B. tinctoria*, yields a colouring matter, which is used for dyeing in Mexico.

BILLERICAY. [ESSEX.]

BIMANA, the first order of the class *Mammalia*, which includes the single genus and species *Homo sapiens*—Man. [MAN.]

BINNY. [BARBEL.]

BISHOP, SIR HENRY ROWLEY, was born in London in 1780. He received his musical education under Signor Bianchi, who was then settled in London as composer at the Opera House. In 1806 Mr. Bishop obtained the appointment of composer of ballet music at the opera, a post he occupied for some time; but little more than the titles of the pieces written by him have been preserved. The first of his long series of English operas, 'The Circassian Bride,' was produced at Drury Lane Theatre on the 23rd of February, 1809, with great success; but on the following evening the theatre was destroyed by fire, and the score of his opera perished in the flames. For the next sixteen or seventeen years he wrote almost incessantly for Drury Lane and Covent Garden theatres, at the latter of which he for several years held the office of composer and musical director. During this period he is said to have produced upwards of seventy operas, ballets, and musical entertainments. Of these many are forgotten; but others are still repeated, and, on account of their flowing melodies and animated style, are, when tolerably played, always heard with genuine pleasure. Those which best illustrate his style are 'Guy Mannering,' the 'Slave,' the 'Miller and his Men,' 'Maid Marian,' 'Native Land,' the 'Virgin of the Sun,' the 'Knight of Snowdon,' the 'Englishman in India,' &c., in all of which there is true musical power. He also 'composed and adapted' Mozart's 'Barber of Seville,' 'Marriage of Figaro,' &c. But the incessant calls upon him begot a hasty careless manner, and he frequently, in the later years of his connection with the theatres, contented himself with crude rifacimentos of the scores of foreign composers; and his fame in consequence gradually declined. At length, aroused by the production of Weber's 'Oberon' at Covent Garden Theatre, in 1826, he composed 'Aladdin' in direct rivalry to that famous work, and brought it out at the same time at Drury Lane. But instead of trusting to his own genius, 'Aladdin' was a direct attempt in the German style, and it proved an entire failure. Mortified at his loss of popularity, he never again composed for the stage. Besides his theatrical pieces, he composed three or four shorter pieces for a series of oratorios, which he conducted about 1819-20. He arranged also several volumes of the 'National Melodies;' and he composed and arranged all Moore's 'Melodies' subsequent to Stevenson's secession from that publication.

Sir Henry Bishop was knighted in acknowledgment of his musical eminence by the Queen soon after her accession to he throne. He was one of the first directors of the Philharmonic Society, and conductor of the Concerts of Ancient Music. He was also Reid professor of music at Edinburgh; and in 1848 was elected professor of music at Oxford University. He died April 30, 1855, aged 75. Sir Henry had heavy domestic trials, and he was not prudent in money matters; so that his later years were clouded by much anxiety and suffering.

Bishop was one of the first English composers of modern times. Had he written less he would have written better; but as it is, though few if any of his operas are likely to retain a permanent place on the stage, and his elaborate imitative philharmonic cantatas have long been forgotten, much of his chamber and concert music—married as it so often is to immortal verse—will long continue to delight the public ear, and will indeed most likely be still popular when many far more pretentious pieces of foreign as well as home growth shall have passed away with their novelty. Many of his songs and glees have the truest inspiration of that class of music—flowing, vivid, graceful, and free from all affectation.

(*Dictionary of Musicians; Athenæum*, 1855; *Gentleman's Magazine*, 1855.)

BISHOP'S AUCKLAND. [AUCKLAND, BISHOP'S.]

BITLIS, a town in Turkish Armenia, situated at the southern extremity of a long rocky ravine which separates the Kerku Mountains from the Nimrud-Dagh in a deep valley traversed by the Bitlis River, one of the head waters of the Tigris, at a distance of about 120 miles S.E. from Erzerum, and 12 miles S.W. from the western angle of Lake Wan. Three ravines each traversed by a stream open into the valley, one already mentioned from the north-west, another from the west, and a third from the east; and at their junction with the main valley the town is situated at an altitude of 5156 feet above the sea. In the centre of the town rises an abrupt rock 50 or 60 feet high, on the summit of which are the ruins of a castle, the residence of the former Begs of Bitlis. The only access to the castle is by a narrow steep passage, strongly defended by gates. The external wall which runs round the edge of the rock, and is 30 feet high above its level platform, is solidly built and loopholed, but within this inclosure there is nothing but a heap of ruins. At the eastern base of the castle rock are the bazaars, which are low, dark, ill-built, and dirty, but well stocked and generally much crowded, as Bitlis is one of the chief marts for the imports and exports of Armenia and Kurdistan. The bazaars are lighted only by perforations at intervals in the roof, which is terraced over and used as a highway for foot passengers. Near the bazaars and on the banks of the river are the slaughterhouses, haunted by mangy dogs, and reeking with offensive effluvia. The streets run along the streams and up the ravines, giving an irregular and straggling form to the town, which covers a considerable area, as the buildings are interspersed with numerous orchards and gardens, which smile in singular contrast with the bare limestone mountains that rise on every side to the height of about 2000 feet above the valley. The streams are crossed by single-arched bridges sufficiently numerous to afford a ready passage from one part of the town to another.

The houses are all built of stone and flat roofed. The best of them stand high up the declivities, and are ornamented with large arched windows, trellis-work, and porticoes. The stone used in building is a soft volcanic rock which abounds in the neighbourhood, especially in the north-west ravine; it is cut into square blocks which are cemented with mud; only a few of the houses are pointed with lime cement. There are two good khans for the accommodation of merchants, three mosques with minarets, twelve tekíyehs, or convents of Howling Dervishes, and four Armenian churches. The population of the town consists of about 2000 Mohammedan, 700 Armenian, and 40 Jacobite families. The principal building in Bitlis is the fortified residence erected by Sherif Beg in 1836, on the level summit of a mountain spur that runs half way across the mouth of the eastern ravine, and is 5475 feet above the sea. It is a rude but extensive structure, consisting of a quadrangle two stories high, built round a court which contains a copious fountain. The ground-floor is used for stables and store-houses; the upper rooms are entered from an open gallery overlooking the court, and are used as sitting and receiving rooms, harem, &c. The windows are all on the outer walls of the building, and command extensive views. From this frowning castle which commands the town on the west and the eastern ravine, Sherif Beg held Bitlis and its territory (containing 80 villages, and forming about one-third of the pashalic of Mush) in defiance of the Sultan for several years. The position of this fortress as given in the 'Royal Geographical Journal,' vol. x., is 38° 23′ 54″ N. lat., 42° 4′ 45″ E. long.; on the map in Dr. Layard's 'Nineveh and Babylon,' the town is placed 8′ or 9′ farther east.

In point of trade Bitlis is an important place. The exports are chiefly galls, honey, wax, wool, and gum tragacanth from the mountains of Kurdistan and Armenia, carpets and cotton stuffs woven in the town and neighbourhood, and dyed here in most brilliant colours. The dyes of Bitlis are celebrated for their brilliancy; they are made from mountain herbs, and from indigo, yellow berries, and other materials which are imported. The raw cotton used in their manufactures is brought from the districts of Kharzan and Shirwan (which also supply madder), and some of it is imported from Khoi, in Persia. It is spun by hand; and several hundred thousand short heavy calico pieces are manufactured throughout the country, of which Bitlis is the centre, and sent here to be dyed. The favourite colours among the Kurds are a dull deep red, and a bright yellow mingled or striped with black. The carpets are of a rich soft texture, with patterns displaying considerable elegance and taste; they are much esteemed in Turkey. Manchester goods, including unbleached calicoes, shawls, and prints; gay-coloured silks and satins, some woollen clothes and coarse cutlery are comprised in the list of British goods sold in the bazaars. The manufactures of Damascus, Aleppo, and Diyar-Bekr are more extensively used.

Bitlis is said to be an ancient place. Until lately it was governed by Kurdish Begs, who were but little under the control of the Porte. Sherif Beg, the last of these lawless chiefs, was exiled to Constantinople in 1849, after the so-called subjugation of the Kurds by Reshid Pasha, and the town is now governed under the Pasha of Mush.

BIVALVE, a name applied to those forms of Shell-Fish which have two shells, or valves, in contradistinction to those which have one shell, and which are called *Univalve*. [MOLLUSCA.] Before the structure of the Invertebrate Animals was as well known as it is at the present day, the Barnacles and Sea Acorns, which have several external valves, or shells, were referred to the *Mollusca*, under the name of *Multivalves*.

BLACK JACK, the name given by miners to the Sulphuret of Zinc. [ZINC.]

BLADDER, DISEASES OF, [SURGERY, *S.* 2.]

BLAINVILLE, HENRY MARIE DUCROTAY DE, a distinguished zoologist, was born at Arques near Dieppe, September 12, 1778, of a noble and ancient family. He went first to the military school at Beaumont-en-Ange, being destined for the army; but left it suddenly in 1792, and, as is said, shipped on board a channel cruiser, and took part in sundry engagements with English vessels. Afterwards he entered the École de Genie at Paris, and was drawn for the conscription of 1798, but obtained exemption through a partial stiffness of the right arm caused by an accident. He remained at Paris without any definite plan of life, occupying himself in a desultory manner by attending lectures on the natural sciences, and by drawing and painting, in which he became very expert. He had reached the age of twenty-seven, when, having heard one of Cuvier's eloquent lectures at the Collège de France, he resolved on devoting himself to the science of comparative anatomy, and at once entered as student in the School of Medicine. Here he took his degree of Doctor of Medicine in 1808, after three years of study; and chose as the subject of his inaugural dissertation, the influence of the eighth pair of nerves in respiration, as demonstrated by his own experiments.

The science of anatomy now became De Blainville's sole pursuit. His remarkable skill as a draughtsman led to his merits being recognised by Cuvier, who employed him as practical anatomist and artist at a salary of 2000 francs a year; and the great zoologist was so impressed by his assistant's ability, that he intrusted to him the delivery of a part of his course of lectures on zoology at the college. It was De Blainville's ambition to become professor, and in 1812 he competed with other candidates for the chair of zoology and physiology at the Faculty of Sciences. Having won the honourable post, he defended his well-known thesis 'On the Natural Affinities of the Ornithorhynchus Paradoxus.'

A flattering political position, obtained through his influential family connections on the restoration of the Bourbons, was offered to De Blainville: but he resisted the allurements of public life for his favourite science. He came to England in 1816, and during a short stay, made diligent use of his opportunities for adding to his zoological knowledge, and carried away drawings of the rare *Mollusca* in the British Museum, and of anatomical specimens in the museum of the Royal College of Surgeons. Some of his papers, published in the 'Bulletin de la Société Philomatique,' bear testimony to the good use he made of his sojourn in this country.

In 1825 De Blainville was elected a member of the Academy of Sciences at Paris. On the retirement of Lamarck in 1830, he was appointed to the chair of the natural history of *Mollusca* and *Radiata* at the Jardin des Plantes; and on Cuvier's death in 1832, he was appointed to succeed that great anatomist as professor of comparative anatomy in the same establishment. Thus in twenty-eight years after his resolve on a life of scientific study, he found himself as the result of his persevering labours, in the chair of his master, and acknowledged head of one of the most important branches of science. In the same year he was elected a foreign member of the Royal Society, and subsequently of the Geological Society of London. He was also a member of other scientific societies on the continent.

De Blainville availed himself of his new position to commence what has since been recognised as his great work: 'Ostéographie, ou Déscription Iconographique comparée du Squelette et du Systéme Dentaire des Cinq Classes d'Animaux Vertébrés récents et fossiles,' &c. Twenty-three parts of this magnificent work had been published, and the author had corrected the twenty-fourth part (*Camelus*), when on the arrival at Rouen of a railway train in which he had taken a place, he was found in a state of apoplectic insensibility. This was the 1st of May 1850. On the previous day he had delivered his usual lecture; "exhibiting," says M. Prévost, "a freshness of ideas, and facility of expression, which bore no marks either of fatigue or apprehension. Some threatening symptoms had been experienced during the year past, but, with a force of character peculiar to him, he had sought to conceal them from all, even from himself." All attempts at resuscitation proved unavailing, and he died a few minutes after his removal from the carriage.

De Blainville's writings are to be found in the 'Dictionnaire d'Histoire Naturelle,' the 'Bulletin' above-mentioned, the 'Annales' and 'Mémoires du Muséum,' the 'Annales des Sciences Naturelles,' the 'Révue Zoologique,' and other scientific periodicals. Of separate works may be mentioned his 'Dissertation sur la place que la Famille des Ornithorinques et des Echidnés doit occuper dans la Série Naturelle,' 4to, Paris, 1812; 'Sur les Ichthyolites,' &c., 8vo, Paris, 1818; 'Malacozoaires et Poissons de la Faune Française,' 8vo, Paris, 1820-30; 'Principes d'Anatomie Comparée,' 2 vols. 8vo, Paris, 1822-23; 'Mémoire sur les Belemnites,' 4to, Paris, 1827; 'Cours de Physiologie générale et comparée,' 3 vols. 8vo, Paris, 1833; 'Manuel d'Actiuologie et de Zoophytologie,' 8vo, Paris, 1834.

The fact that De Blainville's writings number nearly 200 in the whole, will best give a notion of his activity and devotion to science; they comprise researches in all branches of zoology. His 'Ostéographie' and 'Manuel de Malacologie,' are elaborate treatises which alone would employ the labour of a life. The former includes extinct as well as living animals, and is of rare importance to palæontologists.

De Blainville had a public funeral in Père-la-Chaise. Prévost, Chevreul, and Milne-Edwards each pronounced a discourse over his grave. A passage from the former presents a concise view of what he accomplished. "It was the great object of his life," says M. Prévost, "to establish in all his works, especially in his 'Osteology,' the doctrine that the whole series of organic beings was intimately related, the links of one great chain, ascending from the most simple of organisms to that which occupies the highest place; in other words, from the sponge to man. But while he endeavoured to refer all groups and every variety of animal form to one and the same plan, he never embraced the plausible hypothesis that each higher grade had been improved in the course of ages out of a lower one by transmutation; on the contrary, he saw in the whole animal creation one single operation, one great harmonious and divine idea, the various changes being neither due to chance nor to the influence of external circumstances, but being all the result of one and the same original conception."

BLAKEA, a genus of plants belonging to the natural order *Melastomaceæ*, named by Dr. Patrick Browne in honour of Martin Blake. The species are trees or shrubs, with large showy red flowers. The calyx is girded with from four to six broad scales; the coralla with six petals; the fruit a 6-celled berry, crowned with the calyx. The leaves have from three to five nerves. *B. quinquenervis*, Anblet, *B. triplinervis*, Linnæus, is a native of Brazil, Guyana, and Triuidad. It produces a large yellow berry, which is eaten in the countries where it grows. *B. parasitica* is a native of Guyana and Maranham, having red flowers. It is a climbing shrubby plant, rooting itself in other trees. It yields a colouriug matter, employed for dyeing red.

BLANCHARD, LAMAN, was born at Great Yarmouth, Norfolk, May 15, 1803. His father having removed to London, Laman was educated at St. Olave's school, Southwark. He commenced the bnsiness of life as reader in a printing office. From boyhood he had exhibited a great fondness for poetry, and considerable aptitnde in verse making; and his first ventnre in authorship was a small volume of poetry entitled 'The Lyric Offering,' pnblished in 1828. Before this, however, in 1827, he had received the appointment of secretary to the Zoological Society. This office he held till 1831, when he resigned it to become acting editor of the 'New Monthly Magazine.' From this tiιne till his death his talents were wholly devoted to writing for the periodical press, to which he was one of the most varied and prolific contributors. His contribntions cousisted of poems, essays, tales, sketches, and brief pointed paragraphs;—whatever in fact was most required for the magazine or journal with which he was at the time connected: and all of them displayed a lively and genial fancy and a ready wit. Mr. Blanchard edited the 'True Sun' newspaper during the whole of its career; the 'Constitutional;' and for a while the 'Conrt Journal,' and the 'Courier.' For some time previous to his death he had assisted in conducting the 'Examiner.' His death occurred nnder very painful circumstances. His wife, to whom he was mnch attached, became very ill about a year before his decease, and her illness ended in insanity. She rallied for awhile, but relapsed and died. Under the prolonged anxiety attending her long illness and its fatal terminatiou, his own health and spirits gave way. He was attacked by nervous paroxysms, and duriug or after one of these, pnt an end to his life, February 15, 1845. His death excited much sympathy, especially among his literary brethren, by whom he was greatly esteemed. His 'Essays and Sketches' have been collected and published, with a Memoir by Sir E. Bulwer Lytton.

BLESSINGTON. [WICKLOW.]

BLESSINGTON, MARGUERITE, COUNTESS OF, was born at Knockbrit, near Clonmel, Tipperary connty, Ireland, on the 1st of September, 1789, and was the third daughter of Mr. Edmund Power, who was of respectable family, bnt broken fortune and reckless habits. She was married in her fifteenth year to a Captain Farmer, but the marriage was a very unhappy one, and Mrs. Farmer after a time qnitted his house. He was killed by falling from a window in the King's Bench Prison, while in a state of intoxication, and within four months his widow was married to the Earl of Blessingtou, February 1818. After exhausting every means of eujoyment in England and Ireland, the earl and countess started in September 1822 on a contiuental tour, which, partly owing to the earl's property having become considerably encumbered, was prolonged till his death. At Paris they were joined by the Connt Alfred d'Orsay, who in 1827 married a daughter of Lord Blessington by his first wife. It was an nnhappy marriage, and a separation eventually took place; but Count d'Orsay contiuned after the death of Lord Blessington to reside with Lady Blessingtou duriug the remaiuder of her life. Lord Blessingtou died at Paris in May 1829. Lady Blessiugton on her return to London made her honse the centre of a brilliant circle of persons of social and intellectual eminence. She qnickly became one of the celebrities of London; and for nearly tweuty years the *salons* first of Seamore-Place and afterwards of Gore House, disputed the palm with those of Holland House, as the resort of the learned, the witty, and the famous of the day. But Lady Blessington aspired to be somethiug more than merely their hostess. She had in 1822 published a couple of volumes of 'Sketches,' and in 1832 she fairly entered upon her career of authorship by contributing to the 'New Monthly Magazine' a 'Journal of Conversations with Lord Byron.' She had become acquainted with Lord Byrou when residing on the contiuent, and as she repeated his remarks with little reserve, the 'Journal' excited considerable interest, and was soon repnblished in a separate form. From this time Lady Blessington continued to write for the press with little intermission. She wrote a great many novels, of which 'The Repealers' was the first in point of time: and the 'Victim of Society,' the 'Two Friends,' and the 'Belle of a Season,' were the most popular. When portraying the habits of fashionable society she was on familiar ground, and could write with effect; when she treated of subjects of more general interest, she lost her power. The majority of her novels and tales are of little literary worth, and none perhaps are likely to have a very long vitality. One of her most pleasant books, after the 'Conversations with Lord Byron,' is her 'Idler in Italy,' published in two volumes in 1839. The 'Idler in France' and 'Desultory Thoughts and Reflections,' are of inferior value. Lady Blessington also contributed slight tales, sketches, aud verses to the magaziues and annuals; and for several years she edited 'Heath's Book of Beauty' and the 'Keepsake; she also for a few years edited another annual called the 'Gems of Beauty.' She likewise for a time contributed to the 'Daily News' and 'Sunday Times' newspapers.

To this literary industry Lady Blessington was incited by pecuniary necessity, brought abont by her splendid style of liviug. But both her jointnre and her literary earnings proved insnfficient to meet her expeuditure; and when the famine in Ireland cut off in a great measure the returns of the Blessiugton property, it became uecessary in 1849 to dispose of the costly fittings and furniture of Gore House. Count d'Orsay had gone to Paris in the hope, as was understood, of obtaining a post uuder Louis Napoleon, with whom he had been on terms of much intimacy. Lady Blessiugton followed him in April 1849, and died at Paris almost suddenly on the 4th of Juue, 1849. Count d'Orsay died at Paris August 4, 1852.

(Madden, *the Literary Life and Correspondence of the Countess of Blessington.*)

BLETIA, a genus of plants belonging to the natural order *Orchidaceæ*. The corms of *Bletia verecunda* are said by Dr. P. Browne, to have a bitterish flavour, and when dry to be used with advantage as a stomachic.

BLOMFIELD, CHARLES JAMES, Bishop of London, was born in 1786, at Bnry St. Edmnnds, Suffolk, where his father was a schoolmaster. Having beeu first well-grounded iu classics, he proceeded to Trinity College, Cambridge, aud both there and in the uuiversity examinations he attained great distinctiou. He graduated in 1808 as third wrangler, and was senior medallist the same year; snbsequently he was elected fellow of Trinity College. The first pnblished specimen of his philological and critical abilities was an edition of the 'Promethens' of Æschylus, which appeared in 1810; this was followed by the 'Seven against Thebes,' 1812; the 'Persians; the 'Choephoræ; ' and the 'Agamemuou.' A valuable edition of Callimachns was published uuder his supervision in 1824. It is on these works that the fame of Bishop Blomfield as a classical scholar chiefly rests. But they are far from exhibiting the exteut of his labours in the academic field. In 1812 he edited, in conjuuction with Rennel, the 'Musæ Cantabrigieusis;' and in conjnnction with Mouk the 'Posthumous Tracts' of Porson, a work which he followed, two years later, by editing alone the 'Adversaria Porsoni.' But besides these he is known to have written numerons critical papers on Greek literature, some of them of a rather trenchant character, in the quarterly reviews and classical journals; and he compiled in 1828 a Greek grammar for schools.

His first preferment in the chnrch was in 1810 to the living of Warriugton; and in the same year he received that of Dunton in Essex. In 1819 he became chaplain to Howley, Bishop of Londou, aud very soon after he received the valuable rectory of St. Botolph, Bishopsgate, in the city of London, and was made Aιchdeacon of Colchester. From this time his career of active clerical influeuce may be dated. In 1824 he was raised to the episcopal bench as Bishop of Chester; and in 1828 on his friend aud patron Bishop Howley being translated to the see of Canterbnry, Bishop Blomfield was chosen to succeed him as Bishop of Londou. His Lordship ever afterwaιds took perhaps the most active and influeutial, if uot always the most prominent part, in the government of the established church, and a leading position in the discussion of all ecclesiastical or semi-ecclesiastical subjects iu the House of Lords. His condnct in the many important matters connected with the doctrines and ceremouial observauces and innovations which have vexed or interested the Church of England during the many years he held his important post, was much canvassed. But besides his watchful supervision of the general interests of the Church, Bishop Blomfield was a careful overseer of the clergy of his diocese, and prompt to support any proposition which appeared likely to improve the condition of the labouring classes in the metropolis. Nor in the briefest notice of Bishop Blomfield ought the amazing success of his efforts for increasing the number of churches to pass unmentioned. While Bishop of Chester he zealously set on foot efforts to erect new churches in places insufficiently supplied; but it is in his London diocese that success most abundantly crowned his labours. During the time that he held the see there were built in his diocese a number of churches beyond all comparison greater than in the presidency of any other bishop since the Reformation; yet one of his most recent public acts was to make an earnest appeal, seconded by a large subscription, to the affluent and liberal to endeavour by a vigorous effort to raise funds sufficient, if possible, to construct as many additional churches as the Census Report of the Registrar-General shows are still needed to meet the wants of the vast and rapidly increasing population of the metropolis.

The theological writings of Bishop Blomfield consist of 'Lectures on the Acts of the Apostles,' and of numerous Sermons and Charges.

Bishop Blomfield in 1856 resigned his bishopric, and was succeeded by Dr. Tait. He died August 5, 1857, at Fulham, near London.

BLOODSTONE, also called *Heliotrope*, is a deep green stone—a jaspery variety of quartz. It has obtained its name from being spotted with red so as to resemble drops of blood. In addition to silica, it contains oxide of iron and clay, which are mechanically introduced, and in this way the red spots are produced. In the royal collection at Paris there is a bust of Christ in this stone, so managed that the red spots represent drops of blood. (Dana, *Mineralogy*.)

BLOOD-VESSELS. The blood from which the tissues of the body obtain the material of their nourishment is conveyed from one part of the body to another by means of branched tubes which are named Blood-Vessels. It is carried along these vessels by the impulse given by the action of the Heart. [HEART.] The vessels which carry the blood from the heart are called Arteries. [ARTERY.] Those which return the blood to the heart are named Veins. [VEIN.] Whilst a very generally diffused net-work of Blood-Vessels exist, connecting the arteries and veins, which are called Capillaries. [CAPILLARY VESSELS.]

The Blood-Vessels, whatever may be their ultimate destination, seem to originate in the same manner. Observations on this subject have been made by Schwann and Kölliker in Germany, and by Professor Paget in this country. The observations of the two former were made on the development of the vessels in the germinal membrane of the egg, and on the capillary blood-vessels of the tail of the larva of a frog. Mr. Paget's observations were made on the tissues of the fœtal sheep. According to these observers it appears that these vessels originate from nucleated cells, similar to those which at first constitute the different parts of the embryo. The cell-wall or external envelope of these cells shoots out into slender pointed processes, such as is seen in the forms of stellate vegetable tissue. The projections from neighbouring cells encounter each other, and becoming organically united, the intervening walls between the two projections are absorbed, and thus a continuous tube is produced. In cases where new vessels are produced in the neighbourhood of old ones, the stellate cells are formed in the new part, and projections are formed in the old capillary vessels, which unite with the new ones, and thus the circulation is re-established. The projections when first united are solid and very slender, but eventually the intervening substance disappears and the vessels attain a uniform calibre. In growing parts where the web of vessels is kept up, new ones are constantly being added by the development of stellate cells in the interstices of the previous web. Whilst the capillaries early attain the development at which they remain, those vessels which are to become arteries or veins on either side of the capillary vessels go on increasing in size till they acquire the special membranes or coats which distinguish these parts of the circulating system. This explanation seems however only applicable to the smaller veins and arteries, as the observations of Kölliker would seem to show that the larger Blood-Vessels may take their origin in the same manner as the heart, in which organ there is first an agglomeration of cells, the interior ones of which become soft, and at last disappear, whilst the outside ones become firmer and constitute the outer walls. On this subject further observations are wanting.

(Sharpey, *Quain's Elements of Anatomy*; Schwann, *Microscopical Researches into the Accordance in the Structure and Growth of Animals and Plants*, translated by H. Smith; Kölliker, *Handbuch der Gewebelehre der Menschen:* Paget, *Supplement to Müller's Physiology*, by Baley and Kirkes.)

BŒHMERIA, a genus of plants belonging to the natural order *Urticaceæ*. The species were formerly comprehended under the genus *Urtica*. One of the species *B. nivea*, formerly *Urtica nivea*, is the Rheea of Asam, and yields fibres of remarkable fineness and tenacity. It appears from the investigations of Dr. Falconer, that the plant which yields the celebrated grass-cloth of China is identical with the Asam plant. Several specimens of these fibres manufactured into light articles of dress were exhibited in the Indian collection at the Great Exhibition of 1851. The *B. nivea* is a herbaceous plant, with broad ovate leaves, which are downy and white beneath, hence its specific name. It bears no sting.

BOERHAAVIA, a genus of plants named after the celebrated Boerhaave, belonging to the natural order *Nyctaginaceæ*. The species of *Boerhaavia* have generally emetic and purgative properties, and have been employed medicinally both by the natives of Peru and the East Indies, where the species grow. *B. tuberosa* is stated by Lindley to be the Yerba de la Purgacion of Peru, and that it is employed as a culinary vegetable. The root of *B. decumbens* is called Hog-Meat in Jamaica, and on account of its emetic properties it is sometimes called Ipecacuanha in Guyana. Sir Robert Schomburghk states that it is astringent, and is useful in dysentery. *B. decumbens* and *B. hirsuta* are also said to possess medicinal properties. (Lindley, *Vegetable Kingdom*.)

BOG-IRON-ORE, a loose earthy ore of iron, consisting of Peroxide of Iron and water. It is of a brownish-black colour, and occurs in low boggy grounds.

BOGMARUS, a genus of Fishes, to which the Vaagmaer, or Deal-Fish, is referred by Schneider under the specific title of *B. Islandicus*. [TRACHYPTERUS, S. 2.]

BOLDOA, a genus of plants belonging to the natural order *Monimiaceæ*. *B. fragrans* is the Boldu of Chili. It produces an aromatic succulent fruit, which is eaten by the natives. The wood is very fragrant, and makes a charcoal which is preferred by the smiths of Chili to that from any other wood. The leaves are also very fragrant. The bark is employed in tanning.

BOISSONADE, JEAN-FRANÇOIS, was born in Paris, August 12, 1774. Towards the end of the year 1792 Boissonade entered into the public service under the ministry of General Dumouriez; he was expelled from the administration in 1795, but was restored in 1801 by Lucien Bonaparte, who was then minister of the interior, and who made him secretary-general of the prefecture of the Haute-Marne. When Lucien retired from the public service, Boissonade retired also; and thenceforward devoted himself to literature, which had indeed previously occupied nearly all his leisure hours. He had from the year 1802 contributed numerous articles to the periodicals of the day. In 1809 he was appointed professor of the Greek language and literature in the Académie de Paris, but assumed only the title of assistant-professor, resigning the title of professor to Larcher, who retained it till his death in 1812. Boissonade then succeeded him, and also supplied his place in the Académie des Inscriptions et Belles-Lettres. On the death of J. B. Gail in 1828, Boissonade was appointed professor of Greek in the Collége de France. Other situations of honour and emolument were afterwards offered to him, but he declined to accept any of them.

M. Boissonade occupied a considerable portion of his time in the critical examination of Greek writers previously unedited, and published a very large number of works and fragments of works by Philostratus, Proclus, Tiberius the Rhetorician, Holstentius, Herodianus, Eunapius, Aristænetus, and several others.

In the period from 1823 to 1826 Boissonade published in 24 vols. 32mo, a 'Sylloge Poetarum Græcorum,' and in consequence of the discovery in 1839, in a monastery on Mount Athos, in Greece, of a manuscript which contained a large number of the lost Fables of Babrius, Boissonade published 'Babrii Fabulæ Iambicæ,' 8vo, Paris, 1844. [BABRIUS.]

Boissonade contributed to the edition of 'Athenæus' by

Schweighæuser, to the 'Euripides' of Matthiæ, and to the edition of Stephens's 'Thesaurus Græcæ Linguæ,' which was printed and published in London by Valpy. He also wrote several articles for Valpy's 'Classical Journal,' and he gave his assistance to the Paris edition of Stephens's 'Thesaurus,' printed by Didot. M. Boissonade was an indefatigable labourer not only in Greek but also in modern literature, having, for instance, published collections of the unedited letters of Voltaire, of the works of Parny, and having furnished a large number of the lives in the 'Biographie Universelle.' He died Sept. 12, 1857.

(*Nouvelle Biographie Générale.*)

BOLINGBROKE. [LINCOLNSHIRE.]

BOLITO'PHAGUS (Fabricius), *Eledona* of Latreille, Leach, and Millard, and *Opatrum* of some other authors, a genus of Coleopterous Insects, of the section *Heteromera* and family *Tenebrionidæ*. The principal generic characters are as follows:—Head short, partially hidden by the thorax, in the males sometimes armed with a horn or tubercle; antennæ very short and thick, the three or four apical joints much broader than the rest; maxillary palpi rather large and distinct, the terminal joint truncated, its length equalling that of the two preceding joints; labial palpi small; thorax coarsely punctured or rugose, the lateral margins more or less toothed; elytra deeply striated; legs short and thick, the anterior tibiæ compressed.

There are about six species of this genus known; they live in *Boleti*, and are of a small size, a short ovate form, and their prevailing colours are brown-black. In this country but one species has as yet been discovered, *B. Agaricola* or *Agaricicola*. It is of a brown colour, and about one-twelfth of an inch long. It is rather local, but where it does occur it is found in tolerable abundance.

BOLORETINE. [CHEMISTRY, *S.* 2.]

BOLTONITE, a native anhydrous Silicate of Magnesia. It occurs massive with a granular structure, or in yellowish or bluish-gray grains. The cleavage is in one direction; the lustre vitreous; transparent to translucent. It is found disseminated through limestone in the United States of America, at Bolton, Roxborough, and Nittleton, Massachusetts: and Ridgfield and Reading, Connecticut.

BONA NOTABILIA. [EXECUTORS.] The doctrine of *Bona Notabilia* has been abolished with the Courts whose jurisdiction depended on it, there being now but one Court of Probate for all England. [PROBATE, *S.* 2.]

BONAPARTE, CHARLES LUCIEN JULES LAURENCE, Prince of Canino, eldest son of Lucien Bonaparte, was born at Paris, May 24, 1803. He received a careful education, and always exhibited a much greater attachment to literary and scientific than political pursuits. As a naturalist the Prince of Canino acquired great distinction. In ornithology especially, he is generally regarded as one of the chief modern authorities; and he was elected a member of nearly all the principal learned societies of Europe and America. For some years the Prince resided in the United States, and it was by his writings on the Birds of America that he first made himself known to the scientific world. His chief publications are a continuation of Wilson's 'Ornithology of America,' in four folio volumes; and the 'Iconografia della Fauna Italica,' a splendidly illustrated work in three volumes folio. But besides these he published numerous essays and memoirs on particular portions of American ornithology, and on other branches of natural history in the scientific journals of the United States and Europe. The Prince was always the zealous friend and patron of the votaries of science, and for many years he was the chief promoter of the annual congresses of the scientific men of Italy. He died July 30, 1857, in Paris.

Prince Charles Bonaparte married at Brussels, June 29th, 1822, Zenaïde-Charlotte, daughter of his uncle Joseph Bonaparte, by whom he had ten children, of whom three sons and five daughters are living.

BONAPARTE, LOUIS NAPOLEON, the fourth son of Charles Bonaparte, and father of Napoleon III., was born at Ajaccio in Corsica, September 21, 1778. At an early age he entered the French army, and accompanied his brother Napoleon to Italy and Egypt. In Italy he distinguished himself at the passage of the bridge of Arcola, braving the fire of the enemy, and shielding the body of his brother and commander. When Napoleon became first consul, he was sent on a mission to St. Petersburg; but on arriving at Berlin he learned the news of the death of the Emperor Paul. He returned to Paris after remaining at Berlin about a year, and became a general of brigade, a counsellor of state, and afterwards a general of division. In 1802 he married Hortense Eugenie de Beauharnais, the daughter of the Empress Josephine.

When Napoleon became Emperor, Louis Bonaparte was promoted to higher honours, and was made governor of Piedmont, and afterwards commanded the army of the north of Holland. After the Batavian republic had been converted into a kingdom, the states of Holland in June 1806 sent an embassy to Napoleon, requesting that Louis might be their king, which was granted, and he immediately assumed the title of King of Holland. He strenuously exerted himself to better the condition of his people, and distinguished himself on several occasions by his personal humanity. His love for his people occasioned him to refuse without hesitation the offer made him by his brother of the crown of Spain; but his opposition to Napoleon's plans, which he thought were prejudicial to their welfare, gave great dissatisfaction at Paris. His wife was a most attached adherent of Napoleon's, and her inability to control her husband, the death of her eldest son in 1807, and the state of her health, induced her to repair to Paris, where a third son was born. She was afterwards sent by Napoleon in 1809 to induce Louis to comply with his wishes, but Louis refused. She then returned to Paris, where she resided in state as Queen of Holland, and Napoleon sent Oudinot with 20,000 men against Louis, who thereupon abdicated in favour of his son, which abdication Napoleon rejected; and on July 9, 1810, Holland was united to the French Empire. Louis retired to Gratz in Styria, where he lived three years under the title of Count de St. Leu, and his wife became wholly separated from him, though not divorced.

In 1813, when the allied armies appeared about to fall upon France, Louis offered his services to the Emperor, by whom they were accepted, and he proceeded to Switzerland, but he was not employed. On the downfall of Napoleon, when the Dutch threw off the French yoke, Louis addressed a letter to the provisional government from Soleure, asserting his claims to the throne, but they were rejected. He then commenced a suit at Paris for the restitution of his two sons, then living under the care of their mother, who had obtained a grant of the domain of St. Leu, with the title of Duchess, through the interest of the Emperor Alexander. The return of Napoleon put a stop to the suit, and the Duchess of St. Leu did the honours of Napoleon's court, and used her interest in favour of the unfortunate of all parties. After the battle of Waterloo she went to reside in Switzerland with her sons. Louis retired to the Papal States, where others of his family had assembled, and devoted himself chiefly to literature. He published 'Marie, ou Les Hollandaises;' 'Documens Historiques sur la Hollande,' 5 vols. 8vo, 1820, both of which have been translated into English; also, 'Mémoires sur la Versification;' an opera, a tragedy, a collection of poems, and a reply to Sir Walter Scott on his 'History of Napoleon.' He died at Leghorn, June 15, 1846; and at his special desire, which after some delay was acceded to, his body was buried at St. Leu in France, with those of his father and his first son, September 29, 1847.

BONE-BEDS. Accumulations of the bones of extinct animals, more especially of fish and Saurian reptiles, are not uncommon in various strata, and have had this name given them by geologists. They generally occur at the termination of one formation and the commencement of another. These Bone-Beds are local, and are not in any case very extensive. The thickest and most widely-distributed is that of the Lias, which seems to mark the commencement of the New Red-Sandstone epoch. The most remarkable Bone-Beds are the following:—

Bone-Bed at the base of the Lower Greensand at its junction with the Wealden; at the base of the Inferior Oolite, at its junction with the Lias; at the base of the Lias, at its junction with the New Red-Marl; at the base of the Mountain Limestone, at its junction with the Old Red-Sandstone; at the base of the Old Red-Sandstone, at its junction with the Ludlow Rock of the Silurian System.

(Brodie, *On the Basement-Beds of the Inferior Oolite: Proc. Geol. Soc.*)

BONGARDIA, a genus of plants belonging to the natural order *Berberideæ*, or *Berberidaceæ*. [BERBERIDEÆ.]

BONHILL, a town in the parish of Bonhill and district of Levenax or Lennox, Dumbartonshire, Scotland. The parish is divided in its length into almost equal parts by the south end of Loch Lomond, and the river formed by it, the Leven, from which the district derives its name, and which falls into the Clyde at Dumbarton. The population of the town of Bonhill in 1851 was 2327.

The town is situated on both banks of the Leven, about five miles above Dumbarton. A mile nearer this town, and on the right bank of the stream, is the thriving village of Alexandria, with a population of 3781.

The inhabitants are chiefly engaged in print-works and bleachfields on the banks of the Leven, the water of which, from its softness and purity, is peculiarly fitted for the processes of printing and bleaching. Coals, lime, and other articles required in manufactures are brought up the river in shallow broad-bottomed lighters, The extensive works on the river are generally the property of mercantile houses in Glasgow. The Leven is celebrated for its fine salmon and trout.

Besides the parish church of Bonhill there is a chapel-of-ease at Alexandria. At both places are chapels for Free Church and United Presbyterian Dissenters. There are also two chapels in Alexandria for Independents.

BONITO, the name of fishes belonging to the family *Scomberidæ*. They resemble the Tunny. The Bonito is the *Thynnus pelamys*, Cuv.; the Belted Bonito, *Pelamys Sarda*, Cuv.; the Plain Bonito, *Auxis vulgaris*, Cuv. [THYNNUS, *S.* 1.]

BOOTLE. [CUMBERLAND.]

BOOTTIA, a genus of plants belonging to the natural order *Hydrocharidaceæ*, the species of which are eaten as pot-herbs.

BORAGE. [BORAGO, *S.* 1.]

BORY DE SAINT-VINCENT, JEAN-BAPTISTE-GEORGE-MARIE, was born in 1780, at Agen, in the French department of Lot-et-Garonne. As early as his fifteenth year he had addressed some communications to the Annals of the Society of Natural History of Bordeaux. In 1799 he accompanied Captain Baudin, as a naturalist, in the scientific expedition which was sent out to Australia by the French government. In the course of the voyage, however, a disagreement took place between the captain and several of the officers and scientific men who accompanied him, in consequence of which Bory de Saint-Vincent and others abandoned the expedition at Mauritius, then named the Île de France. He was employed by the governor as one of the état-major of the colony, and provided with whatever was requisite for making a survey of the adjacent islands. His attention was particularly directed to the island of Bourbon, then named the Île de la Réunion, of which he constructed a good map. On his voyage back to France, he touched at and examined several of the islands in the African seas, especially that of St. Helena, of which also he made a map. After his return to France he published his 'Essai sur les Îles Fortunées de l'Antique Atlantide, ou Précis de l'Histoire Générale de l'Archipel des Canaries,' 4to, Paris, 1803, and his 'Voyage dans les Quatre Principales Îles des Mers d'Afrique,' 3 vols. 8vo, with Atlas, in 4to, Paris, 1804.

Bory de Saint-Vincent was afterwards promoted to the rank of captain on the staff of Marshal Davoust, and was present at the battles of Ulm and Austerlitz. When Marshal Ney was sent to Spain in 1808, Bory de Saint-Vincent accompanied him as one of his staff, and was promoted to the rank of major. He was afterwards attached to the staff of Marshal Soult, and was present with him at the final battle of Toulouse. He was included in the lists of proscription of July 24, 1815, and resided at Aix la-Chapelle, Maestricht, Magdeburg, and Brussels. While at Maestricht he examined the vast quarries which extend under the mountain called Petersberg, and published an account of them under the title of 'Un Voyage Souterrain,' 8vo, 1823. At Brussels he was engaged with others in the 'Annales Générales des Sciences Physiques,' 8 vols. 8vo. He returned to France in 1820.

In 1829 Bory de Saint-Vincent was placed at the head of the scientific expedition sent out by the French government to the Morea and the Cyclades, the results of which were published in the 'Expédition Scientifique de Morée,' 4to, with Atlas in fol., Paris, 1832. In this work, besides the assistance given to other departments, he furnished the entire section of the botany ('Partie Botanique'). His contributions to the periodical publications of Paris were very numerous, mostly on subjects of natural history. In 1838 he published a 'Resumé de la Géographie de la Peninsule,' 12mo, with maps. In 1839 he was appointed to the management of the scientific commission sent out by the French government to Algiers. He accompanied the expedition, and after the completion of the investigations returned to Paris. He died December 23, 1846.

(*Conversations-Lexikon; Nouvelle Biographie Générale.*)

BOSIO, FRANÇOIS JOSEPH, BARON, an eminent French sculptor, was born at Monaco, March 19, 1769. He went at an early age to France, where, under Pajou, he received his professional education. He acquired great celebrity under the empire, and was much patronised by the Empress Josephine as well as by Bonaparte. For the Emperor he executed busts of himself, of Josephine, his sister Pauline, the young King of Rome, &c. For Josephine he executed a fine marble statue 'l'Amour lançant des Traits.' The well-known bassi-rilievi of the column on the Place Vendôme are the work of Bosio. The restoration of the Bourbons did not interfere with Bosio's course of prosperity. The restored dynasty found employment for his chisel, and Bosio was equally ready to serve them. He was commissioned in 1817 to execute the equestrian statue of 'Louis XIV. triomphant' for the Place des Victoires. He also exhibited in the same year a marble statue of the Duc d'Enghien, and subsequently busts of Louis XVIII., the Dauphin, and Charles X. Under Louis Philippe his courtly chisel produced one of his best works, a bust of the Queen Marie Amélie. During all this period he was much engaged in the execution of various monuments, statues for public buildings, &c. Among the more important of his classical and poetic works may be named his 'l'Amour séduisant l'Innocence;' 'Hercule combattant Achélous metamorphosé en Serpent;' 'l'Histoire et les Arts consacrant les Gloires de la France,' &c. Bosio, despite the high position he occupied during his prosperous career, is not likely to take permanent rank among the great sculptors of France. He was a skilful workman, and had much facility in designing, but his works evince little of the higher order of inventive or imaginative power. Bosio was created a baron by Charles X.; he was also a member of the Institute. He died July 29, 1845.

BOTANY. The study of Botany may be divided and pursued under the following heads:—

1. The Chemistry of Plants, including a knowledge of the physical and chemical properties of the elements which enter into the composition of plants. [SECRETIONS, VEGETABLE.]

2. The Histology of Plants, including the facts connected with the origin of the vegetable cell, the various functions it performs, and its life in connection with others in the formation of organs. [CELLS, *S.* 2, HISTOLOGY, *S.* 2.; TISSUES, VEGETABLE.]

3. The Morphology of Plants, embracing the history of the origin and growth of the individual organs of plants, and the relation of all forms of organs to one another, and the laws which regulate the changes which the same organ undergoes in the same and in different families of plants. [STAMENS; PISTIL, *S.* 2; SEED; FLOWER; FRUIT; OVULE.]

4. The Organology of Plants, including the general phenomena of the entire life of the plant, and the consideration of the relations which animals bear to plants, and the way in which they take part in the great changes going on in the surface of the earth. [STEM; ROOT; LEAF.]

5. Systematic Botany, embracing the principles of classification and the arrangement of plants in groups, according to their relations to each other. This department of Botany has been only gradually developed. Under the heads of EXOGENS, ENDOGENS, and ACROGENS [POLYPODIACEÆ], will be found the subdivisions proposed by the most recent writers on systematic botany. In order however to facilitate the student in discovering the order to which any plant he may possess belongs, we give here an analysis of the orders contained in the 'Penny Cyclopædia' and its Supplements, upon the plan followed by Dr. Lindley in his 'Vegetable Kingdom.'

Class, EXOGENS.

Sub-Class, POLYPETALÆ. (Petals not united).

I. Stamens more than 20 (Polyandrous).

A. Ovary wholly or partly inferior

a. Stipules present

1. Carpels more or less distinct or solitary . . . : } *Pomaceæ.* (*Rosaceæ.*)

2. Carpels combined

Placentas central
Leaves opposite . . *Rhizophoraceæ.*
Leaves alternate . . *Lecythidaceæ.*
Placentas on the side . . *Homaliaceæ.*
b. Stipules absent
1. Carpels more or less distinct . *Anonaceæ.*
2. Carpels united
Placentas spread about . *Nymphæaceæ.*
Placentas on sides
Petals definite, distinct . *Loasaceæ.*
Petals indefinite, confused *Cactaceæ.*
Placentas in the centre
Leaves dotted
Ovary 1-celled . . *Chamælauciaceæ.*
Ovary more than 1-celled *Myrtaceæ.*
Leaves dotless
Petals numerous . . *Mesembryaceæ.*
Petals few
Petals narrow . . *Alangiaceæ.* (*Nyssaceæ.*)
Petals round
Style 1 . . *Barringtoniaceæ* (*Myrtaceæ.*)
Styles separate . *Philadelphaceæ.*
B. Ovary superior
a. Stipules present
1. Carpels more or less distinct or solitary
Stamens hypogynous
Carpel solitary . . *Leguminosæ.*
Carpels 00 . . . . *Magnoliaceæ.*
Stamens perigynous
Styles coming from apex of carpels
Carpel 1 . . . *Drupaceæ.* (*Rosaceæ.*)
Carpels more than 1 . *Rosaceæ.*
Styles coming from base of carpels . . . *Chrysobalanaceæ.*
2. Carpels united; placentas more than 1
Placentas on the side (parietal)
Leaves dotted, dots round *Flacourtiaceæ.*
Leaves dotted, dots linear and round, mixed . *Samydaceæ.*
Placentas in the centre
Calyx imbricated
Flowers unisexual . . *Euphorbiaceæ.*
Flowers hermaphrodite
Ovary 1-celled; sepals 2 *Portulacaceæ.*
Ovary 2 or more celled
Calyx double . *Chlænaceæ.*
Calyx single . . *Cistaceæ.*
Calyx valvate
Stamens monadelphous; anthers 2-celled
Stamens columnar . *Sterculiaceæ.*
Stamens not columnar *Byttneriaceæ*
Stamens monadelphous; anthers 1-celled . . *Malvaceæ.*
Stamens monadelphous; calyx irregular . . *Dipteraceæ.*
Stamens distinct . . *Tiliaceæ.*
b. Stipules absent
1. Carpels more or less distinct or solitary
Carpels immersed in a disk . *Nelumbiaceæ.*
Carpels not immersed
Stamens perigynous . . *Rosaceæ.*
Stamens hypogynous
Embryo in a vitellus . . *Cabombaceæ.*
Embryo naked, very minute Seeds with an aril . . *Dilleniaceæ.*
Exarillate; albumen fleshy
Flowers hermaphrodite *Ranunculaceæ.*
Flowers unisexual . . *Schizandraceæ.*
Exarillate; albumen ruminated . . . *Anonaceæ.*
Embryo nearly as long as seed
Calyx much imbricated
Fruit a legume . . *Leguminosæ.*
Fruit not a legume
Seeds smooth . . *Hypericaceæ.*
Seeds hairy . . *Reaumuriaceæ.*
Calyx little imbricated
Fruit not a legume . *Anacardiaceæ.*
Fruit a legume . . *Leguminosæ.*

2. Carpels united; placentas more than 1
Placentas parietal, in lines
Anthers versatile; juice watery *Capparidaceæ.*
Anthers innate; juice milky . *Papaveraceæ.*
Placentas parietal, spread over the lining of the fruit . . *Flacourtiaceæ.*
Placentas spread over dissepiments *Nymphæaceæ.*
Placentas central
Stigma broad and petaloid . *Sarraceniaceæ.*
Stigma simple
Ovary 1-celled . . . *Portulacaceæ.*
Ovary many-celled
Calyx much imbricated
Leaves compound . *Rhizobolaceæ.*
Leaves simple
Petals equal to sepals
Seeds few . . *Clusiaceæ.*
Seeds numerous; petals flat . *Marcgraaviaceæ.*
Seeds numerous; petals crumpled *Cistaceæ.*
Calyx little or not at all imbricated
Stamens perigynous; calyx tubular . . *Lythraceæ.*
Stamens hypogynous; calyx many-leaved . . . *Humiriaceæ.*

II. Stamens fewer than 20 (Oligandrous).

A. Ovary wholly or partly inferior
a. Stipules present
Placentas parietal . . . *Homaliaceæ.*
Placentas in the centre
Flowers unisexual . . . *Begoniaceæ.*
Flowers hermaphrodite
Stamens opposite petals . *Rhamnaceæ.*
Stamens alternate with petals
Leaves opposite . . . *Rhizophoraceæ.*
Leaves alternate . . . *Hamamelidaceæ.*
b. Stipules absent
Placentas parietal
Flowers unisexual . . . *Cucurbitaceæ.*
Flowers hermaphrodite . . *Grossulaceæ.*
Placentas in the centre
Flowers in umbels; styles 2 . *Umbelliferæ.*
Flowers in umbels; styles 3 . *Araliaceæ.*
Flowers not in umbels
Carpels solitary
Petals strap-shaped; stamens distinct . . *Alangiaceæ.* (*Nyssaceæ.*)
Petals very narrow; stamens growing on them . . *Loranthaceæ.*
Petals oblong; leaves hispid
Cotyledons convolute . *Combretaceæ.*
Cotyledons flat . . . *Haloragaceæ.*
Petals oblong; leaves balsamic *Anacardiaceæ.*
Carpels divaricating
Leaves alternate: herbs . *Saxifragaceæ.*
Leaves opposite: shrubs . *Hydrangeaceæ.*
Carpels parallel, combined
Calyx valvate; petals opposite stamens . . *Rhamnaceæ.*
Calyx valvate; petals alternate with stamens
Albumen none . . *Onagraceæ.*
Albumen copious . *Cornaceæ.*
Calyx not valvate
Stamens doubled . . *Melastomaceæ.*
Stamens curved
Leaves dotted . . *Myrtaceæ.*
Leaves not dotted
Parts of flower 4
Ovules ascending. *Onagraceæ.*
Ovules pendulous. *Haloragaceæ.*
Parts of flower not 4; seeds many
Leafy . . . *Escalloniaceæ.*
Scaly . . . *Monotropaceæ.*
Parts of flower not 4; seeds few . . *Bruniaceæ.*
B. vary wholly superior
a. Leaves stipulate

1. Carpels distinct or solitary
   - Anthers with recurved valves. *Berberidaceæ.*
   - Anthers with longitudinal valves
     - Style from the base of the carpel. *Chrysobalanaceæ.*
     - Style from apex of carpel; fruit a legume *Leguminosæ.*
     - Style from apex of carpel; fruit a drupe or capsule. *Rosaceæ.*
2. Carpels wholly combined
   - Placentas parietal
     - Flowers with appendages *Passifloraceæ.*
     - Flowers without appendages
       - Leaves with round and oblong transparent dots *Samydaceæ.*
       - Leaves dotless, circinate when young *Droseraceæ.*
       - Leaves dotless, straight when young; fruit capsular *Violaceæ.*
       - Leaves dotless, straight when young; fruit siliquose. *Moringaceæ.*
   - Placentas central
     - Styles distinct
       - Calyx in a broken whorl. *Elatinaceæ.*
       - Calyx in a complete whorl
         - Flowers unisexual *Euphorbiaceæ.*
         - Flowers hermaphrodite
           - Petals minute *Illecebraceæ.*
           - Petals large; stamens hypogynous; *Malpighiaceæ.*
           - Petals large; stamens perigynous; leaves opposite *Cunoniaceæ.*
           - Petals large; stamens perigynous: leaves alternate *Saxifragaceæ.*
       - Calyx valvate *Tiliaceæ.*
     - Styles more or less combined, gynobasic
       - Gynobase fleshy *Ochnaceæ.*
       - Gynobase dry; leaves opposite *Zygophyllaceæ.*
       - Gynobase dry; leaves alternate
         - Fruit beaked *Geraniaceæ.*
         - Fruit not beaked *Oxalidaceæ.*
     - Styles more or less combined, not gynobasic
       - Calyx in a broken whorl
         - Flowers spurred *Vochyaceæ.*
         - Flowers not spurred, calyculate *Chlænaceæ.*
         - Flowers not spurred, naked *Sapindaceæ.*
       - Calyx in a complete whorl
         - Leaves compound; sepals more than 2 *Staphyleaceæ.*
         - Leaves simple; sepals about 2 *Malpighiaceæ.*
         - Leaves simple; sepals 2. *Portulacaceæ.*
       - Calyx valvate or open
         - Stamens columnar *Sterculiaceæ.*
         - Stamens not columnar
           - Stamens opposite petals
             - Perigynous *Rhamnaceæ.*
             - Hypogynous *Vitaceæ.*
           - Stamens alternate with petals
             - Anthers porous *Tiliaceæ.*
             - Anthers slit; petals split *Chailletiaceæ.*
             - Anthers slit; petals undivided *Amyridaceæ.*

b Stipules absent

1. Carpels distinct or solitary
   - Anther-valves recurved *Berberidaceæ.*
   - Anther-valves longitudinal
     - Fruit a legume; radicle next hilum *Leguminosæ.*
     - Fruit a legume; radicle away from hilum *Connaraceæ.*
     - Fruit not leguminous
       - Carpels with 1 scale *Crassulaceæ.*
       - Carpels with 2 scales *Francoaceæ.*
       - Carpels without scales
         - Albumen abundant; embryo minute
           - Flowers unisexual *Lardizabalaceæ.*
           - Flowers hermaphrodite
             - Embryo in vitellus *Cabombaceæ.*
             - Embryo naked
               - Albumen solid. *Ranunculaceæ.*
               - Albumen ruminate *Anonaceæ.*
         - Albumen small or none
           - Carpels several
             - Enclosed *Calycanthaceæ.*
             - Naked *Menispermaceæ.*
           - Carpels solitary
             - Leaves dotted *Amyridaceæ.*
             - Leaves dotless *Anacardiaceæ.*
2. Carpels divided into a solid pistil
   - Placentas parietal
     - Stamens tetradynamous *Cruciferæ.*
     - Stamens not tetradynamous
       - Flowers with sterile stamens
         - Stamens and pistils on distinct flowers
           - Pistil-flower crowned *Pangiaceæ.*
           - Pistil-flower not crowned *Papayaceæ.*
         - Stamens and pistils together; placentæ lining the fruit *Flacourtiaceæ.*
         - Stamens and pistils together; placentæ in rows *Malesherbiaceæ.*
       - Flowers without sterile stamens
         - Disk of flower large; stamens indefinite *Capparidaceæ.*
         - Disk of flower large; stamens definite *Resedaceæ.*
         - Disk of flower small or none
           - Albumen large *Papaveraceæ.*
           - Albumen small
             - Calyx 5-leaved *Turneraceæ.*
             - Calyx tubular *Frankeniaceæ.*
   - Placentas covering dissepiments *Nymphæaceæ.*
   - Placentas central
     - Styles distinct
       - Calyx valvate *Vivianaceæ.*
       - Calyx in a broken whorl
         - Seeds hairy *Reaumuriaceæ.*
         - Seeds smooth; stamens polyadelphous *Hypericaceæ.*
         - Seeds smooth; stamens monadelphous, or free *Linaceæ.*
       - Calyx in a complete whorl
         - Carpels with a scale *Crassulaceæ.*
         - Carpels without scales
           - Carpels divaricating *Saxifragaceæ.*
           - Carpels not divaricating *Caryophyllaceæ.*
     - Styles united, gynobasic
       - Stamens arising from scales *Simarubaceæ.*
       - Stamens not arising from scales
         - Styles combined; flowers hermaphrodite *Rutaceæ.*
         - Styles combined; flowers unisexual *Xanthoxylaceæ.*
         - Styles divided; flowers irregular *Balsaminaceæ.*
     - Styles united, not gynobasic
       - Calyx in a broken whorl
         - Flowers symmetrical *Clusiaceæ.*
         - Flowers unsymmetrical
           - Flowers regular
             - Petals without appendages *Aceraceæ.*
             - Petals with appendages *Sapindaceæ.*
           - Flowers papilionaceous *Polygalaceæ.*
       - Calyx in a complete whorl

Carpels 4 or more; anthers porous
Embryo in the axis *Ericaceæ.*
Embryo at the base *Pyrolaceæ.*
Carpels 4 or more; anthers slit
Seeds winged

Stigma simple	
Stipules	*Cinchonaceæ.*
Without stipules	
Leaves opposite	
Stem square	*Galiaceæ.*
Stem round	*Caprifoliaceæ.*

Sub-Class, Apetalæ, or Incompletæ. (Without Petals, sometimes without Calyx.)

I. Without a Calyx (Achlamydeæ).

A. Stipules present	
Ovules numerous	*Balsamifluæ.*
Seeds winged	*Salicaceæ.*
Seeds comose	
Ovules solitary or very few	
Flowers with stamens and pistils	
Stamens unilateral	*Chloranthaceæ.*
Stamens whorled	*Saururaceæ.*
Flowers unisexual	
Carpel solitary; ovules erect	*Myricaceæ.*
Carpel solitary; ovules pendulous	*Platanaceæ.*
Carpels tricoccous	*Euphorbiaceæ.*
B. Stipules absent	
Ovules very numerous	*Podostemaceæ.*
Ovules single or few	
Flowers hermaphrodite	
Embryo in vitellus	*Piperaceæ.*
Embryo without vitellus	*Oleaceæ.*
Flowers unisexual	
Flowers naked; carpel single	*Myricaceæ.*
Flowers naked; carpel double	*Callitrichaceæ.*
Flowers covered; anther-valves recurved	*Atherospermaceæ.* (*Calycanthaceæ.*)
Flowers covered; anther-valves slit	*Monimiaceæ.*

II. Calyx present (Monochlamydeæ).

A. Ovary inferior	
a. Stipules present	
Flowers with stamens and pistils	*Aristolochiaceæ.*
Flowers unisexual; fruit in a cup	*Corylaceæ.*
Flowers unisexual; fruit naked	
Many-seeded	*Begoniaceæ.*
1-seeded	*Artocarpaceæ.*
b. Stipules absent	
Flowers unisexual, in catkins	
Leaves simple, alternate	*Myricaceæ.*
Leaves simple, opposite	*Garryaceæ.*
Leaves compound	*Juglandaceæ.*
Flowers unisexual, not in catkins	
Seeds in a pulp	*Cucurbitaceæ.*
Seeds dry	
Numerous	*Datiscaceæ.*
Solitary	*Helwingiaceæ.*
Flowers hermaphrodite	
Leaves dotted	*Myrtaceæ.*
Leaves not dotted	
Ovary 3-6-celled	*Aristolochiaceæ.*
Ovary 1-celled	
Embryo straight; cotyledons convoluted	*Combretaceæ.*
Embryo straight; cotyledons flat	
Albumen absent	*Haloragaceæ.*
Albumen fleshy	*Santalaceæ.*
Embryo curved	*Chenopodiaceæ.*
Ovary 1-celled; anthers many-celled	*Loranthaceæ.*
Ovary more than 1, but not 3 or 6-celled	
Embryo straight	*Haloragaceæ.*
Embryo curved	*Tetragoniaceæ.*
B. Ovary superior	
a. Stipules absent	
Flowers hermaphrodite	
Sepals 2	*Portulacaceæ.*
Sepals more than 2	
Carpels several, united	
Placentas parietal, in lines	*Papaveraceæ.*
Placentas parietal, diffused	*Flacourtiaceæ.*
Placentas in centre	
Ovules few	
Calyx short, with a gynobase	*Rutaceæ.*
Calyx short, no gynobase	
Embryo curved	*Phytolaccaceæ.*
Embryo straight	*Celastraceæ.*
Calyx tubular	*Penæaceæ.*
Ovules numerous	
Carpels 2, divaricating	*Saxifragaceæ.*
Carpels not divaricating; stamens hypogynous	
Leaves opposite	*Caryophyllaceæ.*
Leaves alternate	*Podostemaceæ.*
Carpels not divaricating; stamens perigynous	
Fruit 1-celled	*Primulaceæ.*
Fruit many-celled	*Lythraceæ.*
Carpels solitary or separate	
Carpels several	*Ranunculaceæ.*
Carpel single	
Anther-valves recurved, leafy	*Lauraceæ.*
Anther-valves recurved, scaly	*Cassythaceæ.*
Anther-valves slit	
Fruit a legume	*Leguminosæ.*
Fruit not a legume	
Calyx long or tubular	
Base hardened	*Nyctaginaceæ.*
Tube hardened	*Scleranthaceæ.*
Not hardened	
Stamens embedded in sepals	*Proteaceæ.*
Stamens not so	
Ovules erect	*Elæagnaceæ.*
Ovules pendulous	
Fruit 2-valved	*Aquilariaceæ.*
Fruit indehiscent	*Thymelaceæ.*
Calyx short	
Leaves with scales	*Elæagnaceæ.*

Leaves opposite . *Cunoniaceæ.*
Leaves alternate
Stamens alternate to sepals . . } *Rhamnaceæ.*
Calyx membranous . } *Ulmaceæ.*
Carpels solitary or separate
Calyx membranous . . *Illecebraceæ.*
Calyx herbaceous
Styles basal . . *Chrysobalanaceæ.*
Styles terminal, 1 to an ovary
Fruit a legume . *Leguminosæ.*
Fruit not a legume *Sanguisorbaceæ.*
Styles terminal, 3 to an ovary
Stipules ochreate . *Polygonaceæ.*
Stipules simple . *Phytolaccaceæ.*
Flowers unisexual
Carpels several, united
Flowers in catkins
Aril present . . . *Scepaceæ.*
No aril . . . *Betulaceæ.*
Seeds numerous . . *Lacistemaceæ.*
Flowers not in catkins . *Euphorbiaceæ.*
Carpel solitary
Cells of anthers perpendicular to filament . } *Stilaginaceæ.*
Cells of anthers parallel to filament.
Embryo straight
Albumen present . *Urticaceæ.*
No albumen . . *Artocarpaceæ.*
Embryo hooked
Albumen present . *Moraceæ.*
Albumen none . *Cannabinaceæ.*

Sub-Class, Dictyogens (Lindley).

Ovary inferior . . . . *Dioscoreaceæ.*
Ovary superior
Carpels distinct . . . . *Triuridaceæ.*
Carpels united
Placentas central
Flowers 6-petalled . . *Smilaceæ.*
Flowers 3-petalled . . . *Trilliaceæ.*
Placentas below . . . *Roxburghiaceæ.*
Placentas on the sides . . . *Philesiaceæ.*

Sub-Class, Gymnogens (Lindley).

Stem jointed . . . . *Gnetaceæ.*
Stem continuous
Leaves pinnate . . . . *Cycadaceæ.*
Leaves simple
Ovules in cones . . . { *Pinaceæ.* (*Coniferæ.*)
Ovules solitary . . . *Taxaceæ.*

Class, ENDOGENS.

1. Flowers complete (having distinct Floral Envelopes).

A. Ovary inferior
Flowers gynandrous . . . *Orchidaceæ.*
Flowers not gynandrous
Veins of leaves diverging from the midrib
Anther 1, with 1 cell . . *Marantaceæ.*
Anther 1, with 2 cells . . *Zingiberaceæ.*
Anthers 5 or 6 . . . *Musaceæ.*
Veins of leaves parallel with midribs
Stamens 3
Anthers turned outwards . *Iridaceæ.*
Anthers turned inwards . *Burmanniaceæ.*
Stamens 6
Leaves flat
Fruit 3-celled; sepals corolla-like.
Radicle remote from hilum *Hypoxidaceæ.*
Radicle next hilum . *Amaryllidaceæ.*
Fruit 3-celled; sepals calycine . . . *Bromeliaceæ.*
Fruit 1-celled . . . *Taccaceæ.*
Leaves equitant . . *Hæmodoraceæ.*
Stamens more than 6 . *Hydrocharaceæ.*
B. Ovary superior
Sepals calyx-like or glumaceous
Carpels separate, more or less
Placentas diffused . . *Butomaceæ.*
Placentas narrow . . . *Alismaceæ.*
Carpels in a solid pistil
Petals distinct from calyx
Placentas central . . *Commelinaceæ.*
Placentas parietal . . *Mayaceæ.*
Petals not distinct from calyx
Flowers scattered . . *Juncaceæ.*
Flowers spadicose . . . *Orontiaceæ.*
Sepals corolla-like
Carpels more or less separate
Seed solitary . . . *Palmaceæ.*
Seeds numerous
Anthers turned outwards . *Melanthaceæ.*
Anthers turned inwards
Parts of flower 6 . . *Butomaceæ.*
Parts of flower 2 *Philydraceæ.*
Carpels combined
Petals rolled inwards . . *Pontederaceæ.*
Petals not rolled inwards
Flowers with appendages . *Gilliesiaceæ.*
Flowers without appendages . *Liliaceæ.*

II. Flowers incomplete (Floral Envelopes not distinct).

A. Flowers in glumes
Stems hollow . . . *Graminaceæ.*
Stems solid
Carpel solitary; seed erect . *Cyperaceæ.*
Carpel solitary; seed pendulous . *Restiaceæ.*
Carpels several, distinct
Glumes only . . . *Desvauxiaceæ.*
Cup within glumes . . . *Eriocaulaceæ.*
Carpels several, combined
Placentas parietal . . . *Xyridaceæ.*
Placentas central . . . . *Restiaceæ.*
B. Flowers, or with a few verticillate leaves
a. Flowers on a spadix
Fruit a drupe . . . . *Pandanaceæ.*
Fruit berried; leaves in bud, convolute . . . . *Araceæ.*
Fruit dry; anthers clavate, on weak filaments . . . } *Typhaceæ.*
b. Flowers not on a spadix
Aquatic, with pendulous ovules
Pollen globose . . . . *Naiadaceæ.*
Pollen confervoid . . . *Zosteraceæ.*
Terrestrial; ovules erect . . *Juncaginaceæ.*
Aquatic; ovules erect . . *Pistiaceæ.*

Sub-Class Rhizogens (Rhizanthæ).

Ovules indefinite
Anthers opening by slits . . . *Cytinaceæ.*
Anthers bursting by pores . . . *Rafflesiaceæ.*
Ovules solitary . . . . . . *Balanophoraceæ.*

Class, ACROGENS.

I. With Stems.

A. No distinct axis of growth
Spores without elaters . . . *Ricciaceæ.*
Spores with elaters

Spore-case with valves . . .	Jungermanniaceæ.
Spore-case valveless . . .	Marchantiaceæ.
B. A distinct axis of growth	
Spores with elaters	
Spore-case with valves . . .	Jungermanniaceæ.
Spore-case in cones	Equisetaceæ.
Spores without elaters	
Spore-case on fronds	
Ringed	Polypodiaceæ.
Ringless	Danæaceæ.
Spore-case on edge of frond . .	Ophioglossaceæ.
Spore-case in an involucre . .	Marsileaceæ.
Spore-case naked	
Sessile in the axil of frond . .	Lycopodiaceæ.
Stalked	
Valves	Andræaceæ. (Musci.)
Without valves . . .	Bryaceæ (Musci.)

II. Without Stems.

Mycelium present	
Spores in fours	
Hymenium naked	Agaricaceæ. (Fungi)
Hymenium inclosed. . . .	Lycoperdaceæ.
Spore-case single	
Sporules naked	
Thallus obsolete	Uredinaceæ.
Thallus floccose	Botrytaceæ.
Sporules inclosed	
In asci	Helvellaceæ.
In a veil	Mucoraceæ.
Mycelium absent	
Aquatic	
Crystalline	Diatomaceæ.
Cellular or membranous	
Fresh-water chiefly	
Multiplied by zoospores . .	Confervaceæ.
Multiplied by spiral nucules .	Characeæ.
Salt water	
Multiplied by simple spores .	Fucaceæ.
Multiplied by tetraspores. . .	Ceramiaceæ.
Terrestrial	
Spores naked	Graphidaceæ.
Spores in asci	
Thallus gelatinous	Collemaceæ.
Thallus pulverulent . . .	Parmeliaceæ.

It will be seen that many of the orders are repeated in this analysis under different divisions; and this arises from the fact that this analysis is artificial, and only expresses the general characters of each order. Besides this, in the strongest orders, exceptions to some very general points of structure frequently occur. Thus we have apetalous and irregular-flowered plants in the polypetalous regular-flowered order *Ranunculaceæ*. With a little practice such an analysis as the foregoing will enable any one acquainted with the structure of plants to refer any particular plant to its right order, and on turning to the order in the alphabetical part of this work he will find a detailed account of its structure and properties.

BOTAURUS. [BITTERN.]

BOTTLE-GOURD. [LAGENARIA, *S.* 1.]

BOULDERS. Of the materials of which superficial deposits of the debris of ancient rocks are composed, some are of large size, and have been called Boulders or Erratic Blocks. The portions of smaller size are called Gravel. Boulders are generally found not far from the rocks from which they have been broken, whilst gravel is carried to a great distance. Instances, however, are not wanting in which boulders have been transported an immense distance. They have been transported from Norway and Sweden to the plains of Germany, and from the mountains of Scotland and Cumberland to the centre and south of England. So large are some of these boulders, and the obstacles such as intervening hills, valleys, and seas so great, that the mode of their transportation can be accounted for in no other way than by supposing that they have been floated across them in masses of ice, which as they have melted have dropped them in the places where they are now found when those places were at the bottom of a sea. The largest boulders seem to have drifted in all cases from northern and southern points towards the warmer districts in the temperate and tropical parts of the earth.

BOURMONT, LOUIS AUGUSTE VICTOR DE CHAISNE, MARSHAL COUNT DE, was born at Paris, or, according to other accounts, at the castle of Bourmount, in Anjou, in the year 1773. Having entered the army in 1788, at the age of fifteen, he served as an officer in the Royal French Guards until 1790, when he emigrated, and joined the army of the Prince de Condé. His sanguine disposition and earnest character recommended him so strongly to the emigrant leader, that he was immediately employed in fomenting the insurrection of the western provinces. In October 1793, he was despatched by the Prince to the head-quarters of the Viscount de Scépeaux, under whose orders he commanded one of the corps of the Vendean troops, and was promoted to the rank of major-general. At this time he was only in his 21st year.

In December 1793 he was sent to England to endeavour to prevail on the British government to assist the Bourbon cause, but his mission proved abortive. He had the satisfaction, however, of seeing the Count d'Artois, afterwards Charles X., who received him in the most cordial manner, knighted him, and authorised him to confer the same honour on other loyal gentlemen adhering to the monarchical interests, and more particularly on the Viscount de Scépeaux. He paid a second visit to England in 1796, exhibiting the greatest zeal in animating the French emigrants against the republic, and in collecting all the elements of civil war. Soon after he returned to France to share the perils of a new insurrection of the Vendeans, and commanded a division of the Chouans in 1799. On the 16th of October of the same year he forced his way into Le-Mans, the chief place in the department of Sarthe, committing, it is asserted, great cruelties, pillaging the inhabitants of nearly a million of francs, burning the post-office, the public records, and the library in the Hôtel-de-Ville.

About the period of the 18th Brumaire, when M. de Chatillon and other insurgent leaders found it necessary to submit to the consular government, the Count de Bourmont followed their example. He strove to induce Georges Cadondal to do the same: but that inflexible chief, far from complying, evinced his disgust at the proposal in 1801, by ordering Bourmont's brother-in-law to be shot. The activo mind of the young soldier indisposed him to a life of ease; he therefore offered his services to Bonaparte, and appears to have exhibited more eagerness than discretion in so doing. The ever-vigilant Fouché suspected his zeal; he caused the Count to be strictly watched. and, having discovered what he considered sufficient proof of intended treachery, he sent him a prisoner to the Temple, Paris, in 1803. From this prison he was transferred to the citadel of Dijon, and thence to that of Besançon. Having escaped from this last place of confinement, he went to Portugal, where he remained five years. The French army having become masters of that country in 1810, Bourmont made interest with the victorious general, was included in the capitulation, and returned to France with the army. He now submitted fully to the imperial government of Napoleon, and was offered the brevet of colonel, which he accepted. It must be observed, however, that in the vindication of his career, published in 1840 by his son, it is stated that when the Count made his submission he was at Nantes in France, and that he was allowed his liberty on condition of taking service in the army of Napoleon. His son goes so far as to assert that, in 1800, the First Consul offered him the post of lieutenant-general, which he declined.

From 1810 to 1814, Bourmont continued faithful to his new master; distinguished himself in several battles, especially at that of Nogent; and received no less than ten wounds, four of which were sabre cuts on the head. For this conduct he was rewarded with the rank of brigadier-general in 1813, and made a lieutenant-general the following year. When the fall of Napoleon tested the character of so many generals and marshals, Bourmont only followed the example of an almost universal defection. He did not betray Louis XVIII. in the spring of 1815; but offered him the use of his sword on the very eve of his departure from the Tuileries. After the flight of the King, he did not refuse to take service a second time under the powerful man, a single word from whom would have consigned his family to ruin. But he could not brook the despotism manifested in the Acte Additionnel, and tendered his resignation to the Emperor in consequence of it. Receiving no answer, he left the French army on the 15th June, 1815, after fully communicating his design to his successor, General Hulat, to whom he likewise explained every requisite detail of the service. Marshal Gerard, under whom he commanded a division during the campaign, and General Hulat, have, since then, exonerated Count de Bourmont from all imputation of treachery; whilst Napoleon, in his account of the battle of Waterloo, does not even accuse him.

After his second restoration, Louis XVIII. gave Count de Bourmont the command of a division, in the infantry of his Guards; and in this rank he served in the campaign of 1823, under the Duke of Angoulême in Spain; and on the return of the Duke to France, he appointed Bourmont to the command of the army of occupation. In 1829 the portfolio of the ministry of war was offered to him by Prince Polignac; but the Count declined the offer several times, recommended other generals in preference to himself, and was only persuaded to take office by the earnest request of the King. In 1830 the great expedition to Algiers was resolved upon, and the command of an army of 37,000 troops was conferred upon Bourmont. We have not space to follow his Algerine career. But it must be noted as somewhat remarkable that the man, who, in a few weeks, obtained for France this large and valuable colony,—the principal conquest she has retained during the present century,—should have been the object of so much aversion. The revolution of July added further bitterness to that dislike, and after Bourmont had been superseded in his command on the 2nd of September, by General Clauzel, a charge was brought against the deposed leader of having appropriated to his own use the treasures found in one of the captured towns. One of his sons had fallen in the campaign, and the custom-house officer at Marseille, after the landing of Bourmont, carried his zeal to such an excess, as to examine the corpse in search for the hidden gold. The Count bore this outrage patiently, but the Countess de Bourmont received so great a shock, that she never rallied afterwards.

From the year 1830 Marshal de Bourmont lived in exile; residing at various times in England, Holland, Germany, and other countries. He was at length allowed to return to France by Louis Philippe, and in 1840 he took up his abode with his family at the castle of Bourmont. Here he continued to reside in the greatest retirement until the day of his death, which occurred on the 27th of October 1846, at the age of 73. In France Bourmont is, of all the republican and imperial generals upon whom the charge of treason has been affixed, the most unpopular. Neither Moreau nor Pichegru, neither Bernadotte nor Marmont, has been so furiously pursued with the public odium. Grouchy himself is only his second in obloquy. After a careful examination of their real conduct, and due allowance being made for the circumstances of the time, it would not require an unusual stress of charity to remove much of the opprobium which now attaches to many of these great military names. But the time to do it effectually is not yet come; and public opinion must be respected even where most it appears to err.

(*Biographie des Contemporains;* Alison, *History of Europe;* Sarrut *et* Saint Edme, *Notice;* Feller, *Dictionnaire Historique.*)

BOURNE, HUGH, the founder of the Primitive Methodist Connexion, was born April 3rd, 1772, in the neighbourhood of Stoke-upon-Trent, in Staffordshire. He was brought up in the Wesleyan Methodist communion, and became an active and zealous preacher of that body. His zeal appears to have carried him beyond the bounds allowed by the leaders of the Wesleyan Conference, for when he was about thirty years of age he associated himself with William Clowes and some other preachers of the Wesleyan body in reviving open-air religious services and camp meetings, or great gatherings for preaching and public worship. These proceedings, although common enough in the early days of Methodism, and carried to very great lengths in America, were discountenanced by the Conference, which in 1807 passed a resolution to the following effect:—"It is our judgment that even supposing such meetings (camp meetings) to be allowed in America, they are highly improper in England, and likely to be productive of considerable mischief, and we disclaim all connection with them." This led to Mr. Bourne's separation from the Wesleyan Conference, and the establishment of the Primitive Methodist connexion, the first class (or local society) of which was formed at Standley, in Staffordshire, in 1810. This body, which in 1811 had two preachers and about 200 members, had increased in 1821 to 202 travelling and 1435 local preachers, and 7842 members. In 1853 the connexion numbered 1789 chapels and 3565 rented rooms, with 568 paid travelling preachers, and 9594 local preachers. The members at the same time had reached 108,926. The difference between the Primitive Methodists and the Wesleyan Methodists consists chiefly in the free admission of laymen to the conference of the former body.

Mr. Bourne, after he had organised the society in England, in which he was assisted by William Clowes, who had likewise been dismissed for similar irregularities from the Wesleyan body, made journeys in Scotland and Ireland for the purpose of forming religious societies in connection with his new organisation. In 1844 he visited the United States of America, where his preaching attracted large congregations. Mr. Bourne lived to fourscore years of age, and was much revered by the members of the Connexion. From his youth he was a rigid abstainer from intoxicating drinks, in which respect many of the preachers and members of the Primitive Methodist Connexion have followed his example. He died at Bemersley, in Staffordshire, October 11, 1852.

BOWERBANKIA, a genus of Ascidioid Polypes, or *Polyzoa*, belonging to the family *Vesiculariadæ.* It was named by Dr. Farre in honour of Mr. J. S. Bowerbank. The following character is given by Dr. Johnston in his 'British Zoophytes:'—Polypidom confervoid, matted or irregularly branched; the cells sessile, unilateral, irregular; the inflected portion with a spinous or filamentous rim. The polypes ascidian, with ten ciliated tentacula, and a strong gizzard. There is but one British species, *B. imbricata.* It has ovate or ovato-cylindrical cells, which are irregularly scattered on the polypidom in dense clusters. In its young state the polypidom is creeping and matted; but as it arrives at maturity it becomes arbuscular and erect. From this circumstance several names have been given to this species. It is found growing on the *Fuci* and corallines which are exposed at low water, and very generally distributed on the British coast. It grows in profusion on the chains of the steam-ferries at Southamptom and Portsmouth. (Johnston, *British Zoophytes.*)

BOWLES, REV. WILLIAM LISLE, a man of some importance as an English poet, but of still greater importance from the peculiar position he occupied in the history of English poetry, was born at King's Sutton, on the borders of Northamptonshire, on the 24th of September, 1762. His father was vicar of the parish in which he was born: his grandfather, Dr. Bowles, also a clergyman in the same neighbourhood, was of a Wiltshire family. His mother was one of the daughters of the Rev. Dr. Richard Grey, author of 'Memoria Technica,' and other works. When the boy was seven years old, his father was appointed to the living of Uphill in Somersetshire; and one of his earliest recollections was the journey of the whole family, consisting of the vicar, his wife, and seven children, with two maid-servants, in two lumbering chaises, preceded by a rustic in livery, on their way far westward to the new parish. In 1776, at the age of fourteen, he was sent to Winchester school, where his master was Dr. Joseph Warton. He was one of Warton's favourite pupils, and he himself expressed his obligations to Warton for the kindly care with which he instructed him in the principles of literary taste and criticism. It was probably on the recommendation of Joseph Warton that, on leaving Winchester School in 1782, after rising to be senior boy, Bowles chose Trinity College, Oxford, as the place of his farther education. Thomas Warton, Joseph's more distinguished brother, was then senior fellow of that college. Among his contemporaries at Trinity College, he seems to have taken a high place; gaining, among other honours, the prize for the chancellor's Latin poem in 1783. On quitting college, in 1787, at the age of twenty-five, he looked forward to some "independent provision in the church," which would enable him to marry a young lady to whom he was much attached. Dr. Moore, Archbishop of Canterbury, had been indebted, when a poor curate, to his maternal grandfather, Dr. Grey; and the young clergyman was led in consequence to expect some preferment from that prelate. None came however; and "worldly circumstances interfering," the engagement with the young lady was broken off. A second engagement also came to a melancholy close by the death of the young lady. After it had been determined not to wait any longer for "episcopal or archiepiscopal patronage," in great depression of spirits, Bowles made a tour through the north of England, Scotland, and some parts of the continent; and it was during this tour that he composed the 'Sonnets' which first made him known as a poet. The 'Sonnets' were intended for his own solace, and were not even committed to paper; but in 1789, when he had been some time back in England, it occurred to him, as he was passing through Bath on his way to Oxford, to write out as many of them as he could remember, correct them, and have them printed. Accordingly, he got Mr. Cruttwell, printer of a Bath newspaper, to strike off a hundred copies 4to, under the title of 'Fourteen Sonnets, written chiefly on Picturesque Spots during a Journey.' The expense of this modest publication was 5*l*. About six months after the publication he received a letter from Mr. Cruttwell, informing him that the 100 copies were all sold, and that he could have sold 500. Much encouraged (his father was just dead, and his mother was in somewhat reduced circumstances), he printed a second edition of 500, adding some new sonnets; and some time afterwards a third edition of 750 was called for.

It is curious now, looking back, to think that, in a year like 1789, when France was in the throes of revolution, the publication from a provincial press of 'Fourteen Sonnets,' by a young clergyman disappointed in love, should have been an event of any consequence in England; and yet so it was. A new literary spirit, and new notions of poetry, were beginning to be abroad; and young men were craving for something fresh and natural, even if but feeble, after the strong and fine artificialities, as they are called, of Dryden, Pope, and their followers. Bowles's sonnets came at the proper moment. Other young men of promise had already attempted, or were attempting poems in a new vein; but, both as the pupil of the Wartons and by reason of his natural susceptibility, Bowles was fitted to take the lead. His sonnets were read and read again by all academic young men of taste and poetical aspiration, including Coleridge, Wordsworth, Southey, and Lovell. "I had just entered on my seventeenth year," says Coleridge, when the sonnets of Mr. Bowles, twenty-one in number [this was the second edition], and just then published in a quarto pamphlet, were first made known and presented to me by a school-fellow who had quitted us [that is, Christ's Hospital] for the university. As my school finances did not permit me to purchase copies, I made, within less than a year and a half, more than forty transcriptions, as the best presents I could offer to those who had in any way won my regard. And with almost equal delight did I receive the three or four following publications of the same author." These "three or four following publications" of Bowles were short copies of verses on occasional subjects, published separately at Bath or Salisbury in 1789, 1790, and 1791. Thus in 1789 were published 'Verses to John Howard on his "State of Prisons and Lazarettos;"' and in 1790 verses 'On the grave of Howard.' In these, although not so conspicuously as in the 'Sonnets,' a tender and true spirit of poetry was visible, while the diction was far less artificial than had till that time been usual in poems. In short, though the revolution in British poetry had already broken forth in Cowper and Burns, and though it was to be completed in Wordsworth and Coleridge, Bowles's 'Sonnets' and other pieces, published in 1789 and the following years, were perhaps the first conscious insinuation of the new principles. Wordsworth and Coleridge soon proclaimed and illustrated them with greater power of genius; but all their lives these poets kept up a kind of dutiful allegiance to Bowles as their titular patriarch.

Hardly foreseeing all this, Bowles left Oxford finally in 1792, having taken his degree, and devoted himself to the duties of his profession. From an humble curacy in Wilts, which was his first appointment, he was transferred first to a living in the same county, and afterwards to another in Gloucestershire. In 1797 he married a daughter of the Rev. Dr. Wake, prebendary of Westminster. In 1803 he obtained a vacant prebend in the cathedral church of Salisbury; and in 1805 the long-expected patronage of Archbishop Moore at last visited him in the shape of a preferment to the valuable living of Bremhill in Wiltshire. Bowles was then forty-three years of age; but he continued to reside in his picturesque and elegant parsonage of Bremhill almost continually during the remaining forty-five years of his long life, discharging the duties of his parish in such a manner as to win the affection of his parishioners, varying his theological readings and his ecclesiastical business with continued exercises in literature, receiving visits from his friends, and happy in what he considered "the inestimable advantage of the social intercourse of such a family as that of Bowood" (Lord Lansdowne's). Subsequent ecclesiastical preferments, which did not interfere with the quiet tenor of his life as rector of Bremhill, were, his appointment in 1818, to be chaplain to the prince regent, and his appointment in 1828 to be canon of Salisbury cathedral.

Till 1804, Bowles was contented with issuing fresh editions of his 'Sonnets' and early poems (an eighth edition of the 'Sonnets' appeared in 1802), and with adding a few occasional pieces to the collection. In 1804 he published his longest poem, entitled 'The Spirit of Discovery,' in six books of blank verse; which was followed by his edition of Pope's works in 10 vols. in 1807. These two publications, together with his general fame as a writer of sonnets, were the ground for the well-known attack upon him in Byron's 'English Bards and Scotch Reviewers.' Notwithstanding Byron's onslaught, Bowles, like Coleridge and Wordsworth, retained his reputation, and went on republishing old and producing new poems. He and Byron met in a friendly way at Rogers's in 1812; and Byron in later life made amends for his satire by speaking of him with respect. Omitting minor productions, the following is a list of Bowles's poetical publications subsequent to the 'Spirit of Discovery:'—'The Missionary of the Andes,' in six books of heroic verse, published in 1815; 'the Grave of the Last Saxon, a Legend of the Battle of Hastings,' in six books, published in 1822; 'Days Departed, or Banwell Hill,' a descriptive didactive poem in blank verse, published in 1829; 'St. John in Patmos,' a blank verse poem of considerable length, first published anonymously in 1833; 'Scenes and Shadows of Days Departed,' a series of poems with a prose autobiographic introduction, published in 1837, in the author's seventy-sixth year; and the 'Village Verse-Book,' published in the same year, and consisting of simple hymns composed by him for the use of the children of his parish. After 1837 Bowles did not publish much. Nor had any of his poems since 'The Missionary,' which is considered on the whole the best of his large works, greatly added to his reputation. In all of them were discerned the same free taste, the same sensibility to the gentler beauties of nature, the same pathos, the same poetic fancy, and the same power of cultured expression which had distinguished his first sonnets; but it was felt on the whole that he was a kind of feebler Wordsworth, whose poetry, so long as he chose to write any, was rather to be received with respect and dipped into at leisure than eagerly read and appreciated.

But the whole virtue of Bowles's life did not lie in his poems. He was also a very busy prose-writer. If the list of his prose-writings is classified, it will be found to prove considerable versatility on the part of the author.

The 'Pope and Bowles Controversy,' which lasted from 1819 to 1828, if indeed it may not date from 1807, when Bowles's edition of Pope was published, has a permanent interest in our literary history. It was the battle, fought in prose, between the old or eighteenth century school of English poetry and the so-called new or nineteenth century school. Bowles, while doing justice as he thought to Pope's true excellences, had made some reflections on his moral character, tending to depreciate it; and had also, in an appended essay 'On the Poetical Character of Pope,' laid down this proposition, as determining the comparatively inferior rank of certain portions of Pope's poetry—"All images drawn from what is beautiful or sublime in nature are more beautiful and sublime than images drawn from art, and are therefore more poetical; and in like manner the passions of the human heart, which belong to nature in general, are *per se* more adapted to the higher species of poetry than those which are derived from incidental and transient manners." Byron in his 'English Bards and Scotch Reviewers' had pilloried Bowles for what he had said of the moral character of Pope; but it was reserved for Campbell, when preparing his 'Specimens of the English Poets,' in 1819, to offer the first distinct contradiction to Bowles' critical theory of poetry. Campbell vigorously defended the right of the world of the artificial to furnish images to poetry, and instanced 'ships' and the like to prove how beautiful and poetical such images might be. Bowles replied in his 'Letter on the Invariable Principles,' &c. Byron, then in Italy, wrote home to Murray that he was going "to plunge into the contest, and lay about him like a dragon, till he had made manure of Bowles for the top of Parnassus." He accordingly sent over two spirited letters for Pope and Campbell against Bowles, to which also Bowles replied. Other critics, including Octavius Gilchrist and the 'Quarterly Review,' took up the question on Campbell's side. Bowles manfully met them one after another, restating his real views in opposition to what he considered misrepresentations of them, and supporting these views by reasonings and examinations of the reasonings and examples of his antagonists. For some time he stood alone; but at last Hazlitt and the 'Blackwood' critics came to his assistance, and maintained that on the whole he had had the best of the argument. This view is now pretty generally acquiesced in. Bowles never said anything so absurd as that Pope was no poet—an opinion which has been ignorantly palmed on him by some who have engaged in the controversy; he only laid down some critical canons determining the *kind* of much of Pope's poetry, as compared with higher kinds, of which fine examples were found, he said, in other poems of Pope himself; and what he advanced on these points was founded on a right instinct, and was argued with much logical acumen, though not with any of that philosophical depth which distinguishes the similar reasonings of Coleridge and De Quincey.

Enjoying repose in his old age after this battle, and looking round on such men as Rogers and Wordsworth as his junior coevals, and on younger poets rising in the room of the departed Coleridges and Southeys, and Scotts and Byrons, whose births and deaths lay within his own protracted span of life, Bowles survived to find himself almost forgotten in the midst of new persons and themes and interests. He had a presentiment of this as early as 1837, when he wrote these words: "Many years after my gray head shall have been laid at rest in Bremhill churchyard, or in the cloisters of Salisbury cathedral, the reader of the memorable controversy with Lord Byron, in which I believe all dispassionate judges will admit that his lordship was foiled and the polished lance of his sophistical rhetoric broken at his feet, or perhaps some who may have seen those poems of which Coleridge spoke in the days of his earliest song so enthusiastically, may perhaps inquire 'Who was W. L. Bowles?'" The event thus anticipated came to pass on the 7th of April 1850, when Bowles died at Salisbury at the age of 88. His wife had died in 1844; and they left no family.

In his personal habits and manners Bowles was simple, genial, and kindly. He was also "famous," it is said, "for his Parson Adams-like forgetfulness." A life of him, the joint work of a relative and Mr. Alaric Watts, has been advertised as forthcoming; meanwhile we have gathered the above particulars from various notices, and from the autobiographical parts of his own writings. As we said at the outset, he will be remembered with interest on account of some of his poems, particularly his 'Sonnets,' and his 'Missionary' and his 'Village Verse-Book,' but with greater interest as a man occupying a position in our literary history entitling him in the opinion of some to be called the 'Father of modern English Poetry.' If the designation is accepted, it must be allowed that he has had some very rebellious sons.

BOYLE. [ROSCOMMON.]

BRACKEN. [PTERIS, *S.* 1.]

BRADNINCH. [DEVONSHIRE.]

BRAGANTIA, a genus of plants belonging to the natural order *Aristolochiaceæ*. One of the species, *B. tomentosa*, is said by Dr. Horsfield to be intensely bitter, and to be used as a medicine in Java.

BRAIN, DISEASES OF, [MEDICINE, *S.* 2.]

BRAKE, [PTERIS, *S.* 1.]

BRAKES ROCK, a common name for the *Allosorus crispus*, a plant belonging to the natural order *Polypodiaceæ*. *Allosorus* is known by its nearly circular sori, which are at length confluent, and are concealed by the reflexed margin of the frond. *A. crispus* has a slender very brittle stem, which attains a height of from 6 to 12 inches. It grows in stony places on mountains throughout Great Britain.

BRANTFORD. [CANADA, *S.* 2.]

BRAYERA, a genus of plants belonging to the natural order *Rosaceæ*. One of the species, *B. anthelmintica*, yields the anthelmintic remedy known by the name Cusso, Cabotz, or Kousso. Although its anthelmintic virtues have been long known, it has only been recently introduced into Europe. The plant is a native of Abyssinia.

BRAYLEY, EDWARD WEDLAKE, F.S.A., a laborious and an accurate topographer, was born in London (in the parish of Lambeth, Surrey), in the year 1773. He was apprenticed to one of the most eminent practitioners of the art of enamelling, but having from an early age been strongly addicted to literary pursuits, he gradually abandoned that business as a means of life, and devoted himself, a few years after attaining his majority, to the more congenial occupations of professional literature. His acquaintance with Mr. Britton [BRITTON, JOHN, *S.* 2,] had commenced before the expiration of his apprenticeship, and he also being desirous of exchanging a servile occupation for the pursuits of literature and the fine arts, the two young aspirants were associated in several literary undertakings of a minor description, until they united in projecting and in producing the well-known work on which their reputation was originally founded—'The Beauties of England and Wales,' the earlier volumes of which were written by them. This work greatly contributed to extend and gratify the zest for topographical history by which the early part of the 19th century was so remarkably characterised. The illustrations, chiefly copper-plate engravings, directed also by the authors, were the means by which many of the most eminent of our architectural and landscape draughtsmen and engravers became qualified for the execution of works of a higher grade in art. Mr. Brayley himself contributed also to the progress of the fine arts in another direction. Having become acquainted with the late Henry Bone, R.A., when that artist was endeavouring to elevate painting in enamel to the position it subsequently acquired in his hands, as an integral and a legitimate branch of accepted pictorial art, he had early begun to prepare enamelled plates for Mr. Bone's use. This he continued to do for some years after he had become eminent as a topographer, and the plates for the largest paintings in enamel which Mr. Bone executed—the largest ever produced until they were exceeded, in several instances, by those of the late Mr. Charles Muss—were not only made by Mr. Brayley, but the pictures also conducted by him throughout the subsequent processes of 'firing,' or incipient fusion on the plate, in the muffle of an air-furnace, requisite for their completion. He derived from the practice of enamelling and the preparation of enamel colours a certain interest in science and its pursuits, especially those of chemistry, mineralogy, and the allied departments of natural knowledge, which, though it scarcely rose above the character of an intelligent curiosity, was retained by him through life, and contributed to the care with which he introduced into country history—in 'The Beauties,' and in his subsequent works—the more characteristic or interesting features of the natural history of the localities described. He acquired also from the same early occupations, a skill in manipulation which in after-life he applied to good purpose in his archæological researches, in taking casts of sculptured ornaments impressions of inscriptions, rubbings of engraved monumenta brasses, &c. It may here be remarked, with reference to hi topographical works generally, that though there were bette geographers and historians, better architectural and recor antiquaries, better heralds, critics in art, and bibliographer there were probably few of his contemporaries—certainl none of his earlier ones—who could unite and apply a com petent knowledge of the subjects of all these branches literature and archæology to what is termed Topography, i a manner at once so useful and so acceptable to gener readers and the public.

In the year 1825 Mr. Brayley was appointed librarian an secretary of the Russell Institution, Great Coram-street, th third in date and in rank of the literary and scientific insti tutions established in London, which had been founded abo seventeen years before to meet the intellectual requiremen of the populous superior middle-class suburb which was the growing up on the estates of the Duke of Bedford and th Foundling Hospital, on the north side of the metropolis. H was the third librarian in succession of the Russell Instit tion, the first having been the late Nathaniel Highmore, LL.I and M.D. of Jesus College, Cambridge (author of 'Jus Eccl siasticum Anglicanum,' &c.). In this capacity Mr. Brayle greatly improved the library, and conducted with ability th general business of the institution, continuing however follow the pursuits of a topographer and antiquary. H produced several catalogues of the library (the last in 1849 which are not however remarkable in a bibliographic point of view, except perhaps for the extent to which th principle of the analysis of collections is carried. Having singular strength of constitution, neither the wear and tear these united official and professional vocations, nor the pr gress of age, sensibly impaired his faculties, either physic or mental, for many years. His most extensive, and, wi the exception of 'The History of Westminster Abbey,' pe haps his best work, was also his last, 'The Topographical History of the County of Surrey,' which he composed and produced between the ages of sixty-eight and seventy-six, during which period the history of the places and objects described was diligently and critically investigated in the localities themselves in very many journeys into the country. For a year or two prior to his decease, gradually increasing though slight weakness and liability to disease was observed in him by members of his family, but his intellectual powers remained unimpaired until the period of his death, which was occasioned by the consecutive fever of cholera, on the 23rd of September 1854, in the eighty-second year of his age; he having filled his official position for nearly twenty-nine years, and been actively engaged in the pursuits of historical and descriptive literature for about fifty-six years. Mr. Brayley became a Fellow of the Society of Antiquaries on the 19th of June 1823. His wife had predeceased him a few years: their surviving children are the eldest son and daughter.

The following is a list of Mr. Brayley's principal works and contributions to literature:—

'A Picturesque Tour through the Principal Parts of Yorkshire and Derbyshire, by the late Mr. Edward Dayes; with illustrative Notes by E. W. Brayley,' 1805: second edition, with additional notes, 1825. 'Views illustrative of the Works of Robert Bloomfield, accompanied with Descriptions; to which is added a Memoir of the Poet's Life,' 1806. 'Cowper: illustrated by a Series of Views; accompanied with Copious Descriptions, and a Brief Sketch of the Poet's Life,' 1810. 'Descriptions of Places represented in Middiman's Views and Antiquities of Great Britain,' 4to, 1813. 'Popular Pastimes: a Selection of Picturesque Representations, accompanied with Historical Descriptions,' 1816. 'Delineations, Historical and Topographical, of the Isle of Thanet and the Cinque Ports,' 1817. 'History and Antiquities of the Abbey Church of St. Peter, Westminster; including Notices and Biographical Memoirs of the Abbots and Deans of that Foundation,' 1818-23. 'The Ambulator, or Pocket Companion for the Tower of London and its Environs: twelfth edition, with an Appendix containing Lists of Pictures in all the Royal Palaces and principal Mansions round London,' 1819. 'A Series of Views in Islington and Pentonville, by A. Pugin; with a Description of each subject, by E.W. Brayley,' 1819. 'Topographical Sketches of Brighthelmstone and its Neighbourhood,' 1825. 'An Enquiry into the Genuineness of Prynne's Defence of Stage Plays, &c., together with a reprint of the said Tract, and also of Prynne's Vindication,' 8vo. 1825. 'The History and Antiquities of the Cathedral Church of Exeter,' 1826-27 (in Britton's 'Cathedral Antiquities'). 'Historical and Descriptive Accounts of the Theatres of London,' 1827. 'Londiniana; or Reminiscences of the British Metropolis,' 1829. 4 vols. 'Devonshire Illustrated, in a Series of Views of Towns, Docks, Churches, Antiquities, Abbeys, Picturesque Scenery, Castles, Seats of the Nobility, &c., &c.,' 1829. 'The Antiquities of the Priory of Christ's Church, Hants; accompanied by Historical and Descriptive Accounts of the Priory Church; together with some General Particulars of the Castle and Borough,' 1834. 'The Graphic and Historical Illustrator: an Original Miscellany of Literary, Antiquarian, and Topographical Information,' 1834. 'A Journal of the Plague Year; by Daniel De Foe: a new edition, attentively revised and illustrated with Historical Notes,' 1835. 'Illustrations of Her Majesty's Palace at Brighton, formerly the Pavilion; executed under the Superintendence of John Nash, Architect: to which is prefixed a History of the Palace by E. W. Brayley,' 1828. 'The Topographical History of Surrey,' 5 vols., 1841-48: the names of Mr. Britton and Mr. Brayley, jun., are inserted in the title-pages, but neither took any part in the work. The article 'Enamelling' in 'Rees's Cyclopædia,' vol xiii.; published before 1811.

'The Antiquarian and Topographical Cabinet,' a very popular and successful work, published by the well-known engravers Messrs. Storer and Gregg, was designed by Mr. Brayley, and the first number or two written by him, and produced under his direction.

In conjunction with J. Britton:—'The Beauties of England and Wales; or Original Delineations, Topographical, Historical, and Descriptive, of each County,' 1810-14. 'The British Atlas; comprising a series of Maps of all the English and Welsh Counties; also Plans of Cities and Principal Towns,' 1810. 'Memoirs of the Tower of London,' 1830. 'The History of the Ancient Palace and late Houses of Parliament at Westminster,' 1836.

In conjunction with William Herbert:—'A Concise Account, Historical and Descriptive, of Lambeth Palace,' 1806.

BREAST, DISEASES OF. [SURGERY, *S.* 2.]

BRIDGES. The requirements of railways have led, within the last few years, not only to the erection of stone and brick bridges and viaducts of unusual size and scale upon the ordinary system, but to a far more extensive use of iron, and the adoption, in connection with its employment, of new constructive principles, as well as the bolder, and often novel, application of principles already in general use. Of the stone and brick bridges and viaducts, important and beautiful as works of art, and interesting for their modes of construction, as many of them are, we do not intend here to speak. Our purpose is to notice some of those great iron bridges which have been constructed on novel or newly-applied principles since the publication of the 'Penny Cyclopædia' and 'Supplement.'

All the bridges we have to describe are applications of the beam or girder. Crossing indifferently populous thoroughfares, and navigable rivers and straits, as well as streams and ways which commercial traffic seldom visits, the railway bridge or viaduct must often be of wide span, and so constructed as neither to impede traffic nor interfere with the public safety and convenience. But to this end, neither the direction nor the level of the way can be materially altered, and the space to be crossed must be left as much as possible unbroken by divisions. The problem for the railway engineer, therefore, was to span the widest area with the least practicable encroachment upon it. The arch, even in its flattest form, was soon found to be unsuitable. The readiest mode was to return to the most primitive. One of the earliest artificial bridges, if not the very earliest, was no doubt a beam or girder,—whether that was the trunk of a tree or a plank matters not,—laid across the stream or place to be crossed, with its ends resting on the banks or on artificial supports. And after the invention of the arch, the beam continued to be used for bridges as well as for innumerable other purposes. In course of time, however, experience showed the weakness of the beam, except within very narrow limits, and various methods were invented fur strengthening it by the addition of diagonal and other bars or rods, technically known as bracings, stays, and trusses. Of these, *trussed girders*, as they are called, the general principles and applications, and the methods employed for determining their strength, ample accounts will be found in 'The Penny Cyclopædia' articles, TRUSSING, vol. 25, p. 318; ROOFS, vol. 20, pp. 144-147; and MATERIALS, STRENGTH OF, vol 15, p. 8.

Trussed-girders were very early employed for carrying railways across wide streets and streams. Among other instances, may be mentioned the bridge which carried the Blackwall Railway across the Minories, London; and several others on the same line, and some important ones on the North-Western Railway. At first, the girders were commonly made of cast-iron, flanges being added to give greater strength; but the fall of the cast-iron girder bridge over the Dee at Chester led to the abandonment of that material, and the substitution of wrought-iron. The best distribution of the material has likewise been made the subject of the most careful study, and the very ingenious and elaborate experiments which have been devised in the course of the searching and protracted investigations instituted, have resulted in placing in the hands of the engineer a body of formulæ, applicable to almost every purpose on which he can be called to exercise his skill.

The principal varieties of trussed girders which have been adopted for railway bridges are the trellised, the bow-and-string, and the hollow-beam, or tubular: the application of which will be sufficiently illustrated in the Crumlin and the Boyne viaducts; the Chepstow and the Saltash; the Newcastle High-level; and the Britannia and the Victoria bridges. We shall also notice an adaptation of the suspension principle to railway purposes in the Niagara Falls bridge.

The *Crumlin Viaduct* was constructed from the designs and under the superintendence of Mr. T. W. Kennard, to carry the Newport Abergavenny and Hereford line across the valley of Crumlin, in South Wales, and to connect the above line with that of the Taff Vale. With its approaches, the bridge is a third of a mile long. The bridge itself consists of seven spaces, each of 150 feet span, the roadway in the centre spans being at an elevation of 200 feet. The entire structnre is of iron. The piers which snpport the girders are composed of gronps of thin cast-iron colnmns, each of 17 feet high by 1 foot in diameter, and arranged in tiers of fonrteen colnmns each, cross-braced by wrought-iron ties and cast-iron struts. The central piers are 60 feet by 30 feet at the base, tapering upwards 24 feet by 16, and containing 140 columns, which are bound together by no less than 540 wrought-iron ties. At the top of each pier is a triangnlar frame of cast-iron, npon which rest the ends of the main girders. The girders themselves are strengthened by a complete series of diagonal wrought-iron ties and cast-iron struts, which it would be impossible to explain clearly without diagrams, but which forms an admirable system of trellis trnssing. There are fonr main girders to each span, to which six-inch planking is bolted for carrying the permanent way. The whole structnre has a remarkably light and symmetrical appearance, yet seems to be sufficiently strong not merely to snpport the heaviest traffic, but to withstand the most violent storms. It was opened in May, 1857.

Another admirable example of the trellis-girder bridge is the viaduct which carries the Dublin and Belfast Railway over the Boyne, near Drogheda, aud of which Sir John McNeil was the engineer. This noble work consists of a centre span of 264 and two side spans of 138 feet each. The height of the roadway above spring-tides is 90 feet. It was opened in April, 1855.

The High-Level Bridge, Newcastle-upon-Tyne.—Under Roor, 'Penny Cyclopædia,' vol. xx., p. 147, a cnt and description are given of the simplest form of bow-and-string rafter and girder; and nnder Trussing, p. 319, the application of the principle to girders of wronght-iron is noticed. For carrying railways over spaces of nnnsual width, or at a very obliqne angle, bridges of wronght-iron bow-and-string (or as they are by railway engineers nsnally called bow-string) girders were early found to be pecnliarly suitable. Among others of an important character, it may be snfficient to mention an excellent one, which carries the North-Western Railway across the Regent's Canal, near the Camden-town station; the great skew-bridge, by which the North London Railway crosses the Commercial-road at Stepney; and one, of rather peculiar form, on the Gloucester and Birmingham Railway at Cheltenham. But by far the most magnificent bridge erected on the bow-string girder principle, is the High-level Bridge which unites the towns of Newcastle-npon-Tyne and Gateshead.

When the Newcastle and Berwick Railway was planned, it was felt that a junction with the Newcastle and Darlington line conld be effected only by the construction of a very lofty bridge over the Tyne at Newcastle; because the banks of the river at that spot are very steep, and the general level of the railways wonld not permit of a crossing at a relatively small height above the water. It had long been wished by the inhabitants to have a 'high-level' bridge, since the old bridge was adapted only for the low or water-side districts of Newcastle and Gateshead; and Mr. Robert Stephenson boldly designed a scheme which shonld meet this requirement, as well as the requirement of the railway companies. His plan was to have a *double* bridge, with a railway line over a common road. The railway companies and the town corporations assented; an Act was obtained; the works were actively commenced about the beginning of 1847; and the bridge was opened by the Qneen in person in September, 1849.

The width of the river at this spot is 515 feet; bnt from the high ground in Gateshead to that in Newcastle the distance is above 1400 feet. The bridge is of six spans, each of 138 feet. Fonr piers of massive masonry rise from the bed of the river, and one from each bank; besides minor piers to support the roadway on either side. The superstrnctnre consists of two platforms, an npper, carrying three lines of rails; and a lower, which forms the public road. The lower platform is abont 90 feet above the high-water level; the upper is 20 feet higher. Each span or bay of the bridge is crossed by four main cast-iron arched ribs, with horizontal tie-bars. These ribs are disposed in pairs,—the two inner ribs being rather over 20 feet apart, the space between them forming the carriage road; while between the inner and outer ribs is a space of six feet, which is nsed for foot passengers. The upper, or railway, platform rests npon the arches, the lower roadway being suspended from them by wrought-iron rods. Each arched rib was cast in five segments, which, when put together, gives a span of 125 feet, with a rise of 18 feet. Besides the tie or tension bar, the ribs are braced by horizontal and vertical bracing frames, while diagonal bracings are inserted in the spandrels, or spaces between the arches and the girders which carry the railway. On the tops of the spandrel pillars, girders extend lengthwise, from which others stretch at right angles across the arched ribs. The whole has thus a perfectly rigid character, and is found to bear the heaviest weights withont deflection. Altogether, this bridge is one of the finest engineering works of onr time, though eclipsed in magnitude by the vast work, by the same engineer, which we are abont to describe.

Britannia Tubular Bridge.—The object of this bridge was to carry the Chester and Holyhead Railway across the Menai Strait, from Bangor to the Isle of Anglesey. As the Menai Strait is navigable by shipping, the Admiralty Commissioners refused to sanction the construction of any bridge which did not afford a clear way for ships at least 100 feet in height. Mr. Stephenson at first proposed to meet the reqnirements of the Commissioners by erecting an iron bridge of two immense arches; bnt his plan proposed that the arches should be 100 feet high at the centre, and only 50 feet at the spring of the arches, and the Commissioners refnsed to permit it to be executed nnless he raised the level so that the spring of the arches shonld be 100 feet above the water. As this wonld have compelled the height of the centres to be 150 feet, Mr. Stephenson abandoned his original intention, and boldly resolved to cross the channel by a girder bridge. He fonnd a site about a mile on the Caernarvon side of Telford's famons snspension bridge, which was admirably adapted for the kind of structnre he contemplated,—the opposite shores being bold steep rocks, and there being just abont mid-channel a rocky island, which would afford an excellent fonndation for a central pier.

The space to be crossed was 1100 feet wide, and each principal division of the bridge mnst be nearly 500 feet in span. It was necessary not merely to provide that the enormons beams, as yet nnapproached in bnlk, which were to be suspended at an altitude of a hundred feet above high-water, should be snfficiently strong to sustain their own immense weight, and that of a loaded railway train in rapid motion, bnt that they shonld be able to withstand the action of the fierce gales which are frequent in this locality. It was deemed advisable, therefore, to iustitnte an extended series of elaborate and costly experiments and investigations on the strength of iron, and the manner in which it might be arranged, so as most to conduce to the strength and rigidity of the bridge. These experiments, which were conducted by Mr. William Fairbairn and Mr. Eaton Hodgkinson, called into exercise a nnion of the highest mechanical and mathematical skill, and not merely sufficed for the immediate purpose, but have afforded a sure basis for the labonrs of succeeding engineers. The resnlt was the demonstration that the greatest amount of strength would be obtained by giving to the materials the form of a hollow quadrangular beam or girder, somewhat larger in section in the centre than at the ends, and making the top and bottom (or the floor and roofs) instead of being solid, to consist of shallow tubes or cells. Of these great hollow beams, it was decided to have two each npwards of a qnarter of a mile long, placed side by side, one for the down, the other for the np, traffic, the ends of which shonld rest upon abntments, the intermediate portions being supported across the strait by three massive and lofty stone piers or towers.

The bridge, then, as finally constructed, consists of four spans,—two principal spans, of 460 feet each, which are over the water, and two smaller ones, of 230 feet each, which are over the land. The central, or Britannia Tower, stands on the rock already mentioned, in the middle of the strait. It is constructed, with the exception of the inner masonry, which is of Cheshire red sandstone, of a hard carboniferous limestone, obtained from the Penmon quarries in Anglesea. Its height from the foundation is 230 feet, or nearly 30 more than that of the London Monument; its width at the base is 62 feet by 52 (the pedestal of the Monument being 20 feet square), and it tapers gently to 55 feet by 4[illegible] where it receives the tnbes. This tower contains 148,62[illegible] cubic feet of limestone, and 144,625 cubic feet of sandstone, in all near 20,000 tons; and 387 tons of cast-iron bars and girders are built into it. The east and west, or land, towers are similar in general construction to the Britannia Tower, but somewhat smaller, and only 190 feet high: they stand at a clear distance of 460 feet from the Britannia Tower. The east and west, or Caernarvonshire and Anglesey abutments, are situated inland, at a distance of 230 feet from th[illegible] east and west towers respectively, and are constructed of massive masonry.

Although the tubes form two continuous hollow beams or tunnels they consist in fact of eight pieces, four to each tube, which are joined end to end at the piers. The height of the tubes is 30 feet at the Britannia tower, and diminishes to about 23 feet at the abutments: the upper surface being slightly arched, but the lower horizontal. The clear internal height varies from about 19 feet to 26 feet. The external width is nearly 15 feet, and the internal about 14. The sides, top, and bottom are all formed of wrought-iron boiler plates, varying from 6 to 12 feet in length, from 21 to 28 inches in width, and from $\frac{3}{8}$ths to $\frac{3}{4}$ths of an inch in thickness. The plates (some of which weigh nearly 7 cwt. each) are laid lengthwise in the top and bottom, but vertically in the sides of the tube. The largest plates are in the bottom, where they are arranged in a double layer. The plates are joined together by rivets; and are stiffened and strengthened at the joints by T-shaped iron, both inside and out, which form vertical bars up the sides, at distances of two feet apart. The connexion of the top and bottom with the sides is made more substantial by triangular 'gusset-pieces,' rivetted in at the corners. The rivets in the entire structure are almost incredibly numerous; they are placed four inches apart in the top and bottom, and three inches apart in the sides. They are rather more than an inch in diameter, and were driven red-hot into the rivet-holes, which holes were made by a powerful machine that punched out forty holes in a minute. The whole bridge contains nearly 2,000,000 of these rivets. The rectangular tubes or cells, which form the top and bottom, are 14 in number: viz. 8 in the top, measuring 21 inches high by 21 wide; and 6 in the bottom, 21 inches high by 28 wide. The vertical sides of these cells are strongly connected to the plates of the top and bottom with L-shaped bars of wrought-iron. The two tubes contain 65 miles in length of T and L iron. The whole weight of wrought-iron in one of the large tubes is about 1600 tons, of which 600 tons are in the sides, 500 tons in the top, and 500 tons in the bottom.

The mode of constructing these tubes was not the least remarkable part of the operations. The short tubes (those between the abutments and the side towers) were constructed on platforms at their ultimate level; but the long tubes (those between the side towers and the Britannia tower) were constructed on floating platforms on the Caernarvonshire beach. The scaffolding for building the towers and the short tubes was among the finest ever yet formed. It consisted of whole 'balks' of timber, logs from 12 to 16 inches square, and some of them as much as 60 feet long; they were fastened together without nails, so as to be afterwards available without injury for other purposes. This beautifully formed scaffolding beneath the short tubes was about 100 feet in height; and round the Britannia tower it rose to a height of 250 feet. The span between the abutments and the side towers is 230 feet; but the short tubes are each 242 feet long, to allow space for resting on their supports. In like manner the span between the Britannia tower and the side towers is 460 feet; but the long tubes are 472 feet, to furnish supports at the ends.

The platforms on which the long tubes were constructed were made of whole balks of timber, and extended nearly half a mile along the Caernarvonshire beach; each of the four long tubes having a platform to itself. When finished, each tube was conveyed to the base of the tower on eight huge pontoons or close barges; each pontoon being capable of floating a weight of 400 tons. These pontoons were brought beneath the ends of the tube; and by taking advantage of variation of tide, they lifted the tube off the platform and supported its whole weight. They were then navigated, by enormous hawsers, cables, and capstans, to the Britannia rock, where the tube was brought as nearly as could be to its proper position. Each of the four long tubes as soon as it was finished was floated in a similar way to the Britannia tower, and placed across the river at the proper spot, where arrangements were made for supporting them until they were raised into their places.

The lifting of these tubes was a remarkable engineering effort. With the apparatus attached to it for aiding the lift, each of the four large tubes weighed 1800 tons; and this unparalleled weight had to be raised to a height of about 100 feet. It was effected through the medium of hydraulic pressure. Chains of enormous strength were fastened to the ends of the tubes and the upper ends of these chains were connected with hydraulic presses constructed on the tops of the towers: these presses, like many other parts of the apparatus, were larger and more powerful than any before constructed for any purpose. Two steam-engines of 40 horse power each worked the presses; the presses gradually drew up the chains, and the chains carried up the tube; when the masonry was built up under the tube, the end of which moved within a groove left for the purpose in the tower. When raised to their proper position, the tubes were brought into connexion, end to end, in the cavities left near the tops of the towers, and converted from independent into continuous tubes; and the mode of fastening them at these points greatly strengthened the whole structure, while space was left to allow for the expansion of the metal. Rails were laid down on the floor of the tubes, properly supported and strengthened; and oval windows were formed in the sides of the tubes.

The first stone of the Britannia tower was laid in May 1846, and on March 5, 1850, Mr. Stephenson himself drove the first train from shore to shore through the first tube. The second tube was completed and the bridge formally opened for traffic on the 21st of October, 1850. Subject to the severest tests with trains loaded to the extent of 300 tons, the tubes did not exhibit a deflection of more than $\frac{3}{4}$ of an inch; and they have now been subjected for more than seven years to the strain of traffic and the fury of the elements without any appreciable permanent influence having been produced upon them, or any perceptible increase of deflection. How fertile a principle the hollow-beam with cellular top and bottom has proved need hardly be pointed out: it is almost unnecessary to mention indeed as an illustration that it is to having been constructed on this principle, that the Leviathan steamer owes the enormous strength which has been so severely tested in the course of its protracted launch.

The *Conway Tubular* bridge is a repetition on a smaller scale of the Britannia bridge, but was constructed before it; every untried principle being first thoroughly tested in the smaller structure before it was applied in the larger. The Conway bridge consists of a single span of 400 feet clear, the platform of the tube being only 18 feet above the high-water level. The first stone of the masonry was laid in June, 1846; the whole was completed in November, 1848.

Victoria Bridge, Canada.—A more remarkable bridge as to size and in many other respects than even that over the Menai Strait of a similar superstructure is the Victoria bridge of the Grand Trunk of Canada railway, which is in course of construction across the St. Lawrence, near Montreal, and is expected to be completed in 1859. From shore to shore of the St. Lawrence, the Victoria bridge will be nearly two miles in length, being about five and a half times the length of the Britannia bridge, and seven times and a half the length of Waterloo bridge, London. The tubes, which are similar in construction to those of the Britannia bridge, will be supported on 24 piers, of which 14 were completed in December, 1857. The abutments have also been completed to the tube level. Of the tubular spans 24 will be each 242 long, the centre span being 330 feet, and 60 feet above the summer level of the St. Lawrence. The length of the bridge between the abutments is 8000 feet. The engineer is Mr. M. Ross.

Chepstow Bridge.—In this bridge, which carries the South Wales railway across the river Wye, near Chepstow, Mr. Brunel has employed two kinds of trussed girders, and also applied the rigid suspension principle. In one portion of the bridge wrought-iron girders 100 feet in span, and of the ordinary form, rest on cast-iron columns; while in the other portion, which is 305 feet in span, the trussed girders are sustained by chains, the tension of which is resisted not, as in an ordinary suspension bridge, by being fixed to the ground at either end, but by attachment to a horizontal wrought-iron column or strut, 9 feet in diameter and $\frac{5}{8}$ths of an inch thick, which rests on the towers at the ends of the bridge. The chain consists of three straight links only—its rigid form being maintained, and the flexure of the horizontal column prevented by vertical and diagonal bracings: the chain in effect is converted into the lower member of a rigid beam. The girders which carry the roadway have only two points of suspension, one at each end of the centre link of the chain, and they rest at each end on cast-iron columns. These girders are 87 feet above the ordinary low-water level, but owing to the remarkable rise of tide here, only 46 feet above high-water. The towers at the ends of the bridge present no peculiar features, but the middle one rests upon a pier formed by six enormous cast-iron

M 2

cylinders which pass through 50 feet of soil to the solid rock beneath. They were sunk to their positions by the removal of the mud, and the pressure of their own weight, (in the same way as the foundations of Rochester bridge were formed,) fresh cylinders being added as the previous ones sunk down. They were then filled up with concrete, and eventually carried up to a height of 190 feet, when they were bound together by the cast-iron frame work which supports the tower.

A somewhat similar combination of the rigid suspension bearing with the tubular form is being carried out in Mr. Brunel's *Royal Albert Bridge*, at Saltash, near Plymouth, which is intended to carry the Cornish railway across the river Tamar, in order to connect it with the South Devon line. The total length of this bridge is 2200 feet, the principal spans are each 455 feet, and the height of the railway above high-water level is 100 feet. The centre tower is built of solid granite to a height of 12 feet above high-water mark, upon this rest four octagonal cast-iron columns which carry the standards upon which one end of each tube rests; this tower rises to a height of 240 feet above the foundations. The principal side piers are of solid masonry, and carry the bed plates and rollers upon which rest the other ends of the tubes, and which permit their free expansion or contraction under the influence of variations of temperature. The tubes are similar in principle to those of the Britannia bridge, and like them after being constructed at the river side were floated out on pontoons to a spot between the towers, and thence gradually lifted by hydraulic pressure to their ultimate position.

Niagara Falls Suspension Railway Bridge.—The most remarkable application of the suspension principle yet made to railway purposes, has been made in the bridge constructed across the Niagara river, by Mr. J. A. Roebling, in order to carry the railway, and also the ordinary carriage and passenger traffic across that river. The space to be crossed was above 820 feet, and the level above the water 245 feet. From the nature of the locality it was necessary that the bridge should consist of a single arch or span, whilst the erection of scaffolding or the floating of portions of the structure to their place was impracticable, and hence a suspension bridge appeared to be the only available form of structure. But any other than rigid bridges had been shown to be unsuitable for railways, and it became necessary to overcome the flexibility inherent in suspension bridges of the ordinary kind. This the engineer has successfully accomplished, and the bridge which links the British possessions with the United States is, confessedly, one of the most remarkable achievements in modern engineering.

The bridge is a hollow beam, slightly curved in form, 25 feet wide at the bottom, and 24 feet at the top, 18 feet high, and 821 feet long from the centres of the towers. Along the bottom floor the ordinary passenger traffic is carried; along the top runs the railway. Separate systems of wire cables, two for each (and each 10 inches thick), support these two roadways, which are constructed of timber beams. The roadways are connected by double trusses so arranged that their resistance acts in opposite directions, upwards as well as downwards. The beams of the two floors are connected by posts which serve to transmit the depressive action of loads from one floor to the other. The posts are trussed together by diagonal rods. By these simple arrangements in combination with the tubular form of the bridge, a considerable increase of rigidity is obtained. To maintain horizontal stability the upper cables are braced laterally, and there are diagonal stays of wire above and below the floors. Fifty-six stays from the lower floor at the ends of the bridge are strongly anchored in the rocks. For the secure anchorage of the cables, expansion and contraction from variation of temperature, high winds, &c., it is needless to say careful provision is made. The railway traffic passes along the centre of the upper floor, the common waggon traffic along each side of the lower floor. The anchorage was commenced in September, 1852, the bridge was opened for traffic in March, 1855. The total cost was under 400,000 dollars. The bridge answers its purpose perfectly; but it must not be supposed that it has proved the suitableness of the suspension principle for railway bridges, except under peculiar circumstances. In this case the river being unnavigable, the engineer has been enabled to obtain stable rigidity by the use of an extended series of stays below the roadway, securely fastened to each shore, a means of course only available in exceptional cases. And although by the judicious application of the tubular form, and the use of a happy combination of trusses, girders, stays and weights, a remarkable amount of rigidity has been obtained, it is yet considered unsafe to allow the railway trains to cross the bridge at a higher speed than three miles an hour. At that rate when a train of 326 tons is passing over it, the bridge only cambers to the extent of 10 inches, and the roadway assumes its original level immediately the train has passed.

Londonderry Bridge.—The applicability of the suspension principle to railway bridges is about to be further tried by an English engineer. For some time this subject has been in various forms under investigation, and at the last meeting of the British Association (1857), Mr. C. Vignoles read a paper before the section of Mechanical Science, in which he stated that the suspension bridge which he erected in 1852 over the river Dnieper, at Kieff in Prussia, and to the platform of which he gave great rigidity by a careful system of bearings had not only effectually resisted the fierce hurricanes to which it had been exposed, but had successfully withstood the severest tests in the passage over it of Russian armies with heavy ordnance during the recent war in the east. As the result of his experience with this bridge, and of other inquiries, he had arrived at the conclusion that the adaptation of suspension bridges to railway purposes is quite practicable if the speed of trains when passing over them be moderate as compared with the ordinary speed on railways. The question as we said is about to be practically tried by Mr. P. W. Barlow, who is constructing a girder bridge, to be supported by suspension chains, for the purpose of uniting the Londonderry and Enniskillen and the Londonderry and Coleraine railways. The importance of the question in an economic point of view will be seen from the statement of Mr. Barlow, that while the span of the Londonderry bridge is about equal to one span of the Britannia bridge, the weight of iron in the span of the Britannia tube is above 3100 tons, whereas the weight of metal in the proposed Londonderry bridge will be only 432 tons—or only about one seventh of the former. In a paper which he read before the British Association on the subject, Mr. Barlow strongly urged the superiority of the suspension bridge under certain circumstances. The following summary presents the results of his investigations:—"That the deflection of the wave of a girder attached to a chain similar to the Londonderry bridge will not exceed one twenty-fifth of the deflection of the same girder not attached to the chain. That theoretically the saving of metal to give equal strength in a suspension bridge is only one-half of a girder; but as it can be made of great depth without practical difficulty, and as the deflection varies as the cube of the depth, a bridge, on the principle of such spans as the Londonderry bridge may be made, under average circumstances, with at least one-fourth of the metal of an ordinary girder bridge having equal rigidity."

Foundations of Bridges. To our notice of new principles applied in constructing the superstructure of bridges, it may be well to add a brief account of one or two of the most important of the new expedients adopted in forming the foundations. Until recently, in order to build the foundations of the piers and abutments of a bridge under water one of two plans was adopted: the first was to construct around the site of the pier, a *coffer-dam*, or wooden water-tight enclosure from which the water was pumped out so as to allow a firm and dry foundation to be laid—this was the plan adopted at London and Waterloo bridges and in many other bridges of an important character; the other, and much less costly, though less stable method, was to surround the platform on which the foundation of the pier was built with water-tight sides, and thus make a large water-tight box or *caisson*, the sides of which, when the platform was sunk to its proper level could be detached, the bottom or stage remaining as a foundation—this was the method used in constructing the piers of the old Westminster bridge. [COFFER-DAM, 'Penny Cyclopædia,' vol. vii. p. 324.] Coffer-dams and caissons were of course modified in form according to situation, and the method of construction according to the views of individual engineers; but wherever used they have been the same in principle. A more economical and less tedious system, and one which should be equally durable, has long been desired by engineers, and various plans have been suggested for supplying the requirement. Some of these have been successfully carried out in practice, as far as construction goes, while there seems no reason to doubt their permanent stability. Numerous bridges have in fact been erected both in this country and on the continent, where coffer-dams and caissons have been dispensed with. Piles and concrete, cased in ti ber, have been used in Brunel's railway bridge at Chepstow described above, and in various parts of the continent; and the same materials unprotected, have been used, as in the bridge at Rouen, and the bridges of Jena, Austerlitz, Alma, and Victoria, over the Seine. Cast-iron as an outer casing, in various forms, and with concrete or other materials as the filling, has been used in England and Ireland in numerous instances. In the Alma bridge over the Seine, having a length of 470 feet and three arches, the piers are founded on piles driven into the bed of the river over the whole area. The space between the piles is filled in with concrete and rough stones, the whole is enclosed by wooden sheet-piling, and is protected from the scour of the river by rough stones. The Suspension bridge at Chelsea was built by enclosing the area by piles and iron plates, driving wooden piles at short distances over the whole space, and filling in with concrete, and of course without using either coffer-dams or caissons; and the new bridge at Westminster is being built by the same engineer, Mr. T. Page, on a similar principle. In the Town bridge and the Railway bridge recently erected alongside of each other at Rochester, the piers are supported solely by a number of cast-iron cylinders, filled with brick-work and concrete. A description of the methods adopted by Mr. Page at Westminster bridge, and by Mr. Hughes at the Rochester bridges, will serve to indicate sufficiently the direction taken by civil engineers in this branch of their practice.

It having been decided,—partly on the score of economy in cost, partly on that of saving in time, but chiefly perhaps in order to avoid the excessive obstruction of the water way which would have arisen from building a bridge of several arches close against an old bridge of a still greater number of arches, the piers of which would not coincide in position with those of the new,—not to use coffer-dams in constructing the piers of the new Westminster bridge, the system proposed by the engineer, Mr. Page, was examined and approved of by the Bridge Commissioners. His plan, which is being carried out as rapidly as circumstances permit, was to drive a number of bearing-piles over the whole area, to a sufficient depth in the clay, but to leave them standing at some considerable height above the gravel, as the base of the pier; to enclose the area for the pier in a circuit formed with round hollow iron piles, and flat plates alternately, the former sustaining the latter by grooves, and all driven down to a sufficient depth; to dredge out in the spaces between the bearing-piles to the hard gravel; and to fill up all the spaces and area in the casing up to the level of the tops of the piles, with concrete made from Portland cement, which

PLAN OF HALF AT DIFFERENT LEVELS.

The letters refer to the same parts in Section and Plan.

has the property of setting under water, the concrete being deposited through the water by means of shoots. The casing was previously tied together, across the intended pier, by iron bolts. This system of construction was to terminate at or rather below low-water line. Blocks of granite were to be fixed over the piles, concrete to be again filled in, and the whole to be levelled off to receive a heavy bed of granite capping, or rather base course, above which the pier would be continued in brickwork faced in granite, to finally attain the level for the springing of the great iron ribs or arches of the bridge. The works in course of execution are of course retarded by the rise of the tide: but otherwise, though below water, they are conducted above it, except as to the requisite inspection, the attachment of the iron ties, and in similar cases where the diving-bell or the diving-dress is used.

The 145 bearing-piles in each pier of Westminster bridge are driven to an average depth of 29 feet 6 inches below low-water line; the 44 cast-iron piles, each 24 feet 9 inches in length, are driven 23 feet 9 inches below the same line, so that their heads stand somewhat above it; the 44 cast-iron plates or flat sheeting-piles, 15 feet in length, are driven down to 21 feet below low water, and to make up the height, they are surmounted by granite slabs, which, consequently with the upper part of the round piles, are part of the casing. The bearing-piles are thus 22 feet below the average level of the caissons of the old bridge, and the cast-iron piles and plates are respectively 16 feet 9 inches, and 14 feet below that level. Supplementary protection external to the pier is intended to be provided by a solid mass or bank of concrete round the pier; this concrete when set forming a kind of artificial rock, which is found to be harder than the stone of the old bridge. For this concrete a trench is dredged out to the clay, and it is proposed that it shall have a thickness of five or six feet; so that, should it endure, as the hardness and heaviness of the mass would make probable, the flat piles would be always underground, and at the junction at the feet of the granite slabs there could be no escape of the gravel. Mr. Page further proposes to dredge out the channel under the arch to a regular curve, commencing at three feet below low water at the piers, laying bare the clay at the centre, so as to give a low-water depth there of about 12 feet; and he believes from his observation of the flow of the stream of the tides, that the tendency would not be to scour at Westminster bridge, but that the first operation would rather be to silt up. The entire cost of constructing the foundations of Westminster bridge on Mr. Page's system is estimated at about 60,000*l.* less than by the employment of coffer-dams. A peculiarity in the construction of the new Westminster bridge is that, in order to save the usual expense of building a temporary wooden bridge when a new bridge is to be erected on the site of an old one, only one half of the bridge—the western —is in the first instance to be built along side of the old structure, which is during its progress to be used for the ordinary traffic. This half of the new bridge is then to be used for traffic, the old bridge is to be demolished, and the other, or eastern half of the new bridge erected on its site. This necessitates the construction of the piers, as well as of the bridge itself, in two parts, at intervals of time, and doubts have been expressed whether there are not in consequence likely to be unequal settlements in the completed structure. Mr. Page has, however, suggested arrangements for the formation of the piers, and for the introduction of peculiar bracings in the coupling together of the two parts of the superstructure which will afford sufficient provision for any inequalities of subsidence.

In the system of Mr. J. Hughes employed in forming the foundations of the Town and Railway bridges which cross the Medway side by side at Rochester, the piers are entirely supported on cast-iron cylinders, which were sunk down to the hard chalk by using each cylinder as a diving-bell. A somewhat similar principle has been applied to other bridges, and there are different claimants to the invention of the principle. In the original invention of Dr. Potts, the sinking of the cylinder was effected by the exhaustion of the air contained within it, but though that method has been adopted in some cases, it has not met with general success. Mr. Cresy and Mr. Hughes ascribe the first successful sinking of hollow cylindrical piles through sand by means of compressed air, to M. Triger, who thus sunk a shaft through a quicksand 65 feet thick, on the banks of the Loire. But the actual conversion of the cylinder into a diving-bell in which the workmen carry on their operations, the diving-bell then forming a part of the permanent structure, is an extension of the principle which is due to the ingenuity of Mr. Hughes.

The Railway and Town bridges are both borne on abutments at the banks, and two piers in the bed of the river. To sustain the abutment on the Strood side 30 hollow cylinders were used; for the Rochester abutment 12; and for each of the two piers 14; making in all 70 hollow cylindrical piles, each 7 feet in diameter. The piers are respectively 70 feet long and 17 feet wide, and the cylinders are set at distances of 9 feet apart lengthwise, and 10 feet transversely. The bed of the river was found by boring to consist of strata of soft clay, sand, and gravel, overlying hard chalk, which appeared at a depth of 44 feet below high-water level. On this hard chalk the cylinders were to be based. To reach it for the Strood pier a mass of hard stone, part of the foundation of the original wooden bridge, had to be passed through. The plan of sinking hollow cylinders by exhaustion was evidently impracticable here. To ensure a firm foundation workmen must excavate the stone, gravel, &c., in order to prepare a passage for the descent of the cylinders, and then to secure their stability fill them with brickwork as soon as they were in the positions they were ultimately to occupy.

The cylinders were in lengths of 9 feet each, the diameter as already mentioned being 7 feet. Operations were commenced by converting one of these lengths of hollow cylinder into a diving-bell, by securely bolting to one end of it a wrought-iron cover. Through this cover were two cast-iron air-locks (or chambers bearing a certain resemblance to the locks of a canal), with air-tight flaps or doors, through which the workmen entered and quitted the cylinder, the excavated materials were passed out, and the brick and concrete passed in. Separate cocks, one under the control of a workman inside, the other under the charge of a workman outside, permitted the passage at will of the buckets outwards or inwards, the filling of the chamber with compressed air, &c. There were besides a great number of ingenious appliances for the convenience of the workmen and to facilitate the various operations, which it would be out of place to describe here, but which are fully described and illustrated in Mr. Hughes's Memoir on the subject, and in the Supplement (1856) to Mr. Cresy's 'Encyclopædia of Civil Engineering.'

A substantial timber stage having been erected over the site of the pier, and steam-engines and air-pumps conveniently placed, the prepared cylinder was connected with an air-pump, and with its various apparatus was lowered to the proper position on the bed of the river. "The working of the apparatus commenced by setting the pumps in motion, the flap of one of the air-locks and the door of the other being closed, a few strokes compressed the air within the pile [or cylinder] sufficiently to seal the joints; and every subsequent stroke delivered an additional quantity, until the density was sufficient to expel the water, and leave the bottom dry. Fifteen feet of water was cleared out in five minutes; and whilst the pumping continued the workmen passed through the air-locks to their respective stations; and as the excavations proceeded, the material, sent up in buckets, was discharged into lighters placed alongside. During the time of shallow water, the pile descended as rapidly as the excavations below would permit it; but when the water was deep, and the weight of the pile and elasticity of compressed air contained in it were nearly in equilibrio, the excavation was carried down 14 inches below the edge of the pile, when it would at once descend through the whole space as soon as the pressure was removed." ('Cresy's Encyclopædia of Civil Engineering,' p. 1697). When the cylinder had thus sunk 9 feet, the cover, with the air-chambers, was lifted off, and another 9 feet length of cylinder was bolted on to the first, the air-locks being now fastened to the top of the upper cylinder. The air-pumps were again set to work, the excavating process was repeated, and the cylinder sank another 9 feet. These operations were repeated till the necessary depth had been reached, when the cylinders were filled up with brickwork and concrete. In the Strood pier nine lengths of cylinder were employed. The lowest rested on the hard chalk; that above it was surrounded by soft chalk; the third by Kentish rag stone; while about half of the fourth was above the bed of the river.

For forming the foundations of bridges, but more particularly of lighthouses, landing-stages, beacons, breakwaters, and other structures which have to be based upon sand or soft ground, hollow cast-iron *screw-piles*, the invention of Mr. Mitchell, have been extensively used. These piles have the lower end converted into an auger-screw, which enables the pile to be screwed with great facility through shingle, sand, &c.; while the upper part of the worm may be expanded into a disc, varying in breadth according to the character of the soil, thereby increasing greatly the firmness of its hold. The value of these screw-piles is very great in situations where the loose sandy soil is incapable of supporting any solid structure, or where the action of the waves quickly undermines any work based on ordinary piling.

BRITTANY. [Bretagne.]

BRITTON, JOHN, was born July 7, 1771, at Kington-St. Michael, near Chippenham, Wiltshire, where his father was a small farmer, and kept a village shop. His parents dying early, he was received as a servant by an uncle in London, who after a while apprenticed him to a wine-merchant. After having served six years, his health gave way, and his master agreed to cancel his indentures. Young Britton had in the village schools received a little rudimentary instruction, and during his apprenticeship he had become extremely fond of reading, but his reading was desultory and aimless. On reaching manhood he was still uneducated, and his mind quite unformed. At the close of his apprenticeship he found himself without connections, and without any definite pursuit. For some years he had to struggle hard with poverty, and was driven to a variety of shifts to earn a livelihood. Among other things, he engaged himself for a time to recite and sing at a kind of dioramic exhibition with the sounding title of Eidophusikon. During this unsettled course of life he formed the acquaintance of various persons connected with the humbler walks of literature, and he was induced to embark in a small way on authorship himself, by compiling some common street song-books, &c., and at length adventured on writing an 'Account of the Surprising Adventures of Pizarro.' Some short notices which he prepared for the 'Sporting Magazine' brought him acquainted with Mr. Wheble, its publisher, and to the connection thus formed Mr. Britton owed his introduction into the career which he so long and honourably pursued.

Mr. Wheble, whilst residing at Salisbury, had issued the prospectus of a work to be called the 'Beauties of Wiltshire,' but after having received some subscriptions for it, found himself unable to carry it on. But now, learning that Britton was a native of Wiltshire, Wheble proposed to him to compile the work he had announced. It is hardly possible to conceive of such a proposal being made to a person less qualified by previous pursuits or attainments, but among Britton's acquaintances was a young man named Brayley of about his own age, but somewhat better taught; they had assisted each other in their studies, and were prepared to enter upon a sort of literary partnership. In conjunction with his friend Brayley, Britton promptly undertook to 'get up' from ready sources an 'Account of Wiltshire,' and as their first preparation for it, the friends set out on a tour, not, as might be supposed, through Wiltshire, but through Wales. In due time however, the 'Beauties of Wiltshire' were completed in 2 vols. 8vo (1801), to the satisfaction of the publishers; and at their invitation the joint authors immediately set to work on the 'Beauties of Bedfordshire.' Eventually the 'Beauties' of all the other counties of England were published in 26 vols., but only the first nine volumes were written by the original authors. [Brayley, E. W., S. 2.] While compiling his 'Wiltshire,' Mr. Britton not only became conscious of his deficiencies, but endeavoured resolutely to supply them; and the criticisms and advice of various antiquaries and topographers with whom the work brought him into connection materially assisted his progress. Finding his publisher averse to the admission of antiquarian matter, he began to collect materials for another and more elaborate work, the 'Architectural Antiquities of England,' of which the first part was published in 1805, and which was above nine years in progress. It eventually formed five splendid quarto volumes. Henceforth Mr. Britton's course was one of laborious and persevering authorship in the path which he made for many years in a special manner his own —that of architectural and topographical description and antiquities. It would occupy too much space to enumerate his many publications, which in his own chronological list, in the second part of his 'Autobiography,' number eighty-seven distinct productions. The most important of them is the 'Cathedral Antiquities of England,' a magnificent work, which was commenced in 1814 by the publication in a detached form of the 'Antiquities of Salisbury Cathedral,' and ultimately embraced a series of elaborate illustrations of the entire cathedrals of England. In its completed form the 'Cathedral Antiquities' occupy 14 vols. fol. and 4to, 1814-35, with upwards of 300 highly-finished steel-engravings.

The production of these works was carried on throughout under Mr. Britton's immediate superintendence, many of the artists working in his own house, and being trained to their work by himself; and the facility he thus acquired in the production of this class of publications led to the preparation of many other works of a similar kind. Among the illustrated works of which he was either author or editor may be named—an 'Historical Account of Corsham House,' 1806; the 'Fine Arts of the English School,' 4to, 1812; 'Historical Account of Redcliffe Church,' 4to, 1813; 'Illustrations of Fonthill Abbey,' 1823; 'Historical Account of Bath Abbey Church,' 1825; the 'Public Buildings of London, from drawings by A. Pugin,' 2 vols. royal 8vo, 1825–28; 'Architectural Antiquities of Normandy, drawn by A. Pugin,' 1825-27; 'Picturesque Antiquities of English Cities,' 4to, 1830; 'A Dictionary of the Architecture and Archæology of the Middle Ages,' 4to, 1832-38; 'A History, &c., of the Ancient Palace and Houses of Parliament at Westminster,' jointly with E. W. Brayley, 8vo, 1834-36; 'Historical Account of Toddington, Gloucestershire,' 1841; 'Historical Notices of Windsor Castle,' 1842; &c. &c. But besides these Mr. Britton wrote on many subjects connected with general literature, either as distinct works or as contributions to literary journals, &c. In biography he published in 1845 a 'Memoir of John Aubrey,' and in 1848 an essay entitled 'The Authorship of the Letters of Junius Elucidated, including a Biographical Memoir of Colonel Barré, M.P.' Mr. Britton wrote the articles 'Avebury,' 'Stonehenge,' and 'Tumulus,' for the 'Penny Cyclopædia.'

In 1847 the literary and other friends of Mr. Britton gave the veteran author a dinner on his retirement from the active pursuit of his calling; and it being determined to mark their esteem for him by a permanent testimonial, a social gathering called the 'Britton Club' was organised to carry out the project. The form of the testimonial, at Mr. Britton's own suggestion, it was eventually agreed should be an 'Autobiography,' which he was to prepare and to print with the testimonial funds. Despite of his advanced age, Mr. Britton continued to labour at his self-imposed task; and some of the parts of his 'Autobiography' were published, but he died before the work was completed, January 10, 1857.

Mr. Britton was not a man of marked originality or great mental power, but as a careful and diligent writer in a branch of literature which had been cultivated chiefly by minute antiquarians, he did excellent service in calling the attention of the educated public to the long-neglected topographical and architectural antiquities of England; and there can be little doubt that his elegantly-illustrated works have been a chief exciting cause in bringing about the improved state of public feeling with reference to our national antiquities. The career of Mr. Britton was moreover an admirable illustration, as he himself describes it, "of what may be effected by zeal and industry, with moderate talents, and without academic learning."

BROCKVILLE. [CANADA, *S.* 2.]

BROMAL [CHEMISTRY, *S.* 1.]

BROMOFORM. [CHEMISTRY, *S.* 1.]

BROMLEY, ABBOT'S. [STAFFORDSHIRE.]

BROMUS, a genus of plants belonging to the natural order *Graminaceæ*, and the tribe *Festuceæ*. It has unequal many-flowered herbaceous glumes, the lower being 1-nerved, the upper 3 to 5-nerved. The flowers are lanceolate, compressed. The outer palea short, (usually) founded on three nerves from below the tip. The styles below the summit of the fruit lateral. The sheaths of the leaves divided half way down.

The species are generally known under the name of Brome-Grass. Four of the species are common in Great Britain.

B. erectus has an erect stem two or three feet high, and grows on dry sandy and chalky soils. It is known from the other species by the outer palea being indistinctly 7-nerved and one-third larger than the smaller glume.

B. asper has its outer palea hairy and 5- to 7-ribbed, with the leaves broad and hairy. The stem reaches a height of four or five feet. It grows in damp woods and thickets.

B. sterilis is a common plant in waste places, and is known by its outer palea having 7 distinct equidistant ribs. It has large flat broad pubescent leaves, and a stem from one to two feet high. It grows in waste places.

B. diandrus is remarkable for its erect panicle. It is a rare plant.

Some of the species, as *B. purgans* and *B. catharticus*, are purgative, whilst *B. mollis* is said to possess poisonous properties.

BROMYARD. [HEREFORDSHIRE.]

BRONGNIART, ALEXANDRE, an eminent chemist and mineralogist, son of the architect of the Invalides, was born at Paris in 1770. He received a good education, promoted by his father's care, and the friendship of Lavoisier and Franklin; and it is said, delivered a lecture on chemistry before he was fifteen. He pursued his earliest scientific studies at the École des Mines, and at the École de Médécine. At the age of nineteen he assisted in establishing the Société Philomatique, and in 1790 he visited England for a scientific examination of the mines and mining processes and pottery works of Derbyshire. One of the results showed itself on his return to France by his publication of a 'Mémoire sur l'Art de l'Émailleur,' in which improvements were suggested. He then became assistant for a time to his uncle, who was chemical demonstrator at the Jardin des Plantes.

By the requisition for military service which called every Frenchman to the frontier, Brongniart was attached as apothecary to the army of the Pyrenees, and for fifteen months he enjoyed opportunities, which he turned to good account, of studying the botany, zoology, and geology of the mountains. Having however been suspected of favouring the escape of the naturalist, Broussonnet, he was imprisoned; but the ninth Thermidor restored him to liberty. He returned to Paris, and was employed as engineer under the Agency of mines. Next he was chosen professor of natural history at the École Centrale des Quatre Nations; and in 1800 he was appointed director of the porcelain manufactory at Sèvres, which office he held for the rest of his life. He owed it to his paper on enamelling, which having been read by Berthollet, procured him the recommendation of that distinguished chemist.

In 1807, at the instance of the Imperial University, Brongniart published his 'Traité élémentaire de Minéralogie,' which is described as "one of the best, and in particular one of the clearest and most practical" then known. It became a text-book for lecturers; and it exhibits the originality and lucidity which had been remarked in the author in his early years. Pursuing his zoological researches, he studied the freshwater formations of Auvergne, and revisited England to study the corresponding formations of this country. It was he who established the four divisions of reptiles, and first gave the names *Saurians*, *Batrachians*, *Chelonians*, and *Ophidians*, by which they are now familiarly known. To him naturalists owe the name *Trilobite*, and a basis of classification for those singular *Crustacea*. It has been the starting-point for all subsequent works on the subject.

Brongniart's studies rendered him the congenial associate of Cuvier; he helped to classify the Montmartre fossils, and in 1810 appeared the joint publication 'Essai sur la Géographie Minéralogique des Environs de Paris.' It was reprinted in the following year, with important additions, and has ever since been recognised as the classical type of similar works. It confirmed Brongniart's reputation, and in 1815 he was elected a member of the Academy of Sciences of the Institute, and a foreign member of the Royal Society of London.

In 1817, accompanied by his son and one of his pupils, he made a scientific tour to Switzerland and Italy, during which, by his discoveries and generalisations, he strengthened his claim to be considered as "the legislator in fossil zoology." All the new results obtained were included in a third edition of the 'Essai,' published in 1822. In 1824 he travelled to Sweden, and with Berzelius for his companion and interpreter, laid down the first foundations of a classification of the most ancient fossiliferous formations, and gathered materials for a memoir on the erratic blocks. He afterwards put forth his clear and ingenious views on volcanoes, particularly of Vesuvius, and an original memoir on the 'Ophiolithes of the Apennines.'

With all this activity Brongniart did not neglect his duties as director of the national manufactory of porcelain; his journeys and labours to acquaint himself with the best processes and materials would alone have sufficed to occupy any ordinary man. The results of his long experience appeared in 1845 in his 'Traité des Arts Céramiques.' And carrying out his earliest researches on enamelling, he revived at Sèvres the almost lost art of painting on glass. He found time moreover for a diligent share in the affairs of the Institute, and in promoting the interests of science, and the views of scientific inquirers. He died on the 14th of October, 1847.

Brongniart was a foreign member of the Geological Society of London, and other learned societies. His writings are to be found in the 'Mémoires de l'Académie des Sciences,' 'Annales des Mines,' 'Annales de Chemie,' and 'Annales des Sciences Naturelles.' Many have been published in a separate form. Among them 'Essai d'une Classification des Reptiles,' 1805; 'Essai sur une Détermination et une Classification minéralogique des Roches mélangées," 1813; 'Mémoire sur les Corps organisés fossiles nommés Trilobites,' 1814; Histoire Naturelle des Crustacés fossiles sons les Rapports zoologiques et géologiques,' 4to, 1822 (jointly with Desmarest); 'Introduction à la Minéralogie,' 8vo, 1825; 'Tableau des Terrains qui compose l'Écorce du Globe,' 8vo, 1829; 'Premier Mémoire sur les Kaolins, on Argiles à Porcelaine,' 4to, 1839; 'Second Mémoire sur la Nature et l'Origine de cette sorte d'Argile,' 4to, 1841.

(*L'Institut.; Biog. Univ.; Proc. Royal Soc.; Journal Geo. Soc.*)

BRONTÉ, CHARLOTTE (MRS. NICHOLLS, better known by her pseudonym CURRER BELL), was born April 21st, 1816, at Thornton, in the parish of Bradford, in the West Riding of Yorkshire, of which her father, the Rev. Patrick Bronté, had then the living. He afterwards held the living of Haworth, also in the West Riding, about four miles from Keighley. Mr. Bronté removed from Thornton to Haworth, February 25, 1820. Charlotte Bronté and her sister Emily, in February, 1842, went to Brussels, in order, by acquiring a better knowledge of the French language than they already possessed, to qualify themselves for keeping a school. On the death of their aunt at the end of 1842, they returned to Haworth. Emily Bronté remained at home, but Charlotte returned to Brussels in the beginning of 1843. She was engaged as teacher of English in a school for young ladies, completed her education in French, made considerable progress in German, and returned to Haworth at the end of 1843. The novel entitled 'Jane Eyre, by Currer Bell,' published in 1847, was the first production of Miss Bronté's pen which caught public attention, but it was not her first venture in authorship. Her first essay was in a little volume of 'Poems by Currer, Ellis, and Acton Bell,' published in 1846. The poems passed almost unnoticed, but the success of the novel was immediate and extraordinary; and curiosity was for some time exercised not only as to its paternity, but as to the sex of its author; many separate passages and traits bearing manifestly the traces of a woman's mind, yet the general cast of thought, it was urged on many sides, was as evidently unfeminine. The appearance almost simultaneously of other stories, marked by the same peculiarities of thought and general style, with the names of Acton Bell and Ellis Bell as their authors, served to stimulate still further the public curiosity, and when it was confidentially announced that Currer Bell was the daughter of a clergyman in a remote part of Yorkshire, and that Acton and Ellis Bell were her sisters, there was a general feeling of surprise almost amounting to incredulity. In truth, 'Jane Eyre' is a remarkable work, and as the production of the daughter of a country clergyman, it would be still more remarkable if it were as necessary as sometimes seems to be supposed, to have a wide acquaintance with society to obtain intimate knowledge of the human heart, and to portray diversities of character. 'Jane Eyre' was followed in 1849 by 'Shirley,' and that in 1853, by 'Villette,' both marked by the same vigour of intellect, and keen, in fact morbidly keen dissection, of character and motives, though with less of that somewhat wayward originality which had in her first work called forth so much adverse criticism, but at the same time had excited such intense interest.

What is unpleasant, painful, morbid in these powerful novels may, there can be little doubt, be set down to the action of disease upon an overwrought and intensely susceptible mind. Young as she was at her death, she was the last survivor of the three gifted sisters, and in fact of all her father's children. Emily Bronté (Ellis Bell), the author of 'Wuthering Heights,' and next to Charlotte the most gifted of the sisters, died Dec. 19, 1848. Anne Bronté (Acton Bell), the author of 'Agnes Grey,' died May 28, 1849. Miss Bronté married in June, 1854, the Rev. Arthur Bell Nicholls, her father's curate; but pulmonary disease, the same insidious malady which had carried off her sisters, had already marked her as its victim. She died at the parsonage, Haworth, on the 31st of March, 1855; and was laid beside her sisters, in the crowded but quiet churchyard there. In 1857 appeared 'The Professor, a Tale by Currer Bell,'—a novel written in 1848, but laid aside and much of it recast to form 'Jane Eyre.' "The life of Charlotte Bronté," 2 vols. sm. 8vo., 1857, has been published by Mrs. Gaskell.

BROSSÆA, a genus of plants, belonging to the natural order *Ericaceæ*. The fruit of *B. coccinea*, like that of *Gaultheria procumbens* and *Arctostaphylos alpina*, is succulent and grateful to the taste, and sometimes used as food.

BROWN, CAPT. SIR SAMUEL, R.N., was born in London in 1776. At the age of eighteen he entered the navy, and served with distinction during the French war. He passed through the successive grades in his profession, rising to the rank of commander in 1811, and accepting that of retired captain in 1842.

It is however as a civil engineer that Sir Samuel Brown has claim to remembrance. To his ability and ingenuity may be ascribed the introduction into use of both chain-cables and suspension-bridges. The idea of substituting iron cables in the place of those made from hemp, first occurred to M. de Bougainville, whose account of a voyage which he made round the world was published in 1771. [BOUGAINVILLE, LOUIS A. DE.] But the idea was not put in practice; and though a patent was taken out by a Mr. Slater, a surgeon in the British army, in 1808, little was done until Captain Brown carried out a series of experiments, the results of which were deemed so satisfactory that the Board of Admiralty ordered iron chain-cables to be tried in the navy. Their use, it need hardly be added, has since become general. Iron suspension-bridges had, as is well known, been erected in several instances both in America and Europe before Captain Brown directed his attention to them. But they were generally regarded as insecure, except for crossing narrow streams, until Brown introduced his improved method of constructing chains for suspending the roadway. Instead of chains of the ordinary construction, he proposed to form them of long bars of flat or round iron, pinned together by short links and bolt-pins. He made a model of his invention in 1813, having however designed and prepared specifications for suspension-bridges much earlier, but he did not obtain his patent till 1817. Brown's plan was soon after adopted in principle by Telford (who had in the first instance proposed to use cables of merely the ordinary construction) in the erection of his magnificent bridge over the Menai Strait. The first extensive bridge erected wholly on Captain Brown's plan was the Union bridge which crosses the Tweed at Berwick, in which the length of the chord-line between the points of suspension is 449 feet: it was opened for use in July 1820. In 1821 Captain Brown commenced the construction of the Trinity suspension-pier at Newhaven near Edinburgh. He subsequently erected several other bridges and piers, but it may suffice to mention, as his great work, the suspension-pier at Brighton, which consists of four openings of 255 feet each, with a deflection of 18 feet. The Brighton pier has suffered considerable damage on two occasions in severe storms, but, as subsequently strengthened, it has successfully withstood others of excessive force.

Captain Brown was knighted in 1835. He died on the 15th of March 1852.

BRUCIA. [CHEMISTRY, *S.* 1.]

BRUNEL, SIR MARK ISAMBARD, was born on April 25, 1769, at Hacqueville, in the department of L'Eure, a few miles from Rouen. His parents, who were respectable agriculturists, had four children, of whom he was the eldest. From his earliest boyhood he showed a decided inclination for mechanical pursuits; and on being sent to the seminary of St. Nicaise at Rouen, preferred the study of exact science, mathematics, mechanics, and navigation, to the classics; and during the vacations, which he passed at home, he was never happier than when busying himself in a joiner's workshop. He familiarised himself with the tools and some of their applications, and when but twelve years old was already a proficient in turning and in the construction of models—ships, machines, and musical instruments. All this constructiveness was little gratifying to his father, who would have preferred to see his son in the church or in the merchant's office.

On leaving the seminary at the age of fifteen, Brunel passed some time in the family of M. Carpentier, a friend of his father, at Rouen; and went through a regular course of lessons in drawing, perspective, and hydrograpby. He took so mnch interest in the astronomical part of his nautical studies, that on his visits home he set himself to observe the stars, greatly to the astonishment of the villagers. He made an octant, guided by the one belonging to his tutor, and a treatise on navigation; and finding its results nnsatisfactory, he stndied the instrument, and constructed another of ebony, which enabled him to take trustworthy observations.

Inflnenced perhaps by M. Carpentier, who had been a trading captain, Brunel enlisted as a sailor in 1786, from which date up to 1793 he made several voyages to the West Indies. He was remarked for tbe skill, intelligence, and good humour witb wbich he discharged a seaman's duties; won good opinions from everybody; and astonished his companions by using instruments of his own construction, and by making a pianoforte while tbe ship once lay at Guadaloupe. During a visit to Paris after his last voyage in 1793, Brunel ventured to raise his voice in one of the political clubs against the ferocious doctrines there actively promulgated, and thereby endangered his personal liberty; bnt, obtaining permission from the minister of marine, he escaped to America, hoping to find employment for his abilities in a new country.

Brunel had not been long in New York wben he joined a party of his conntrymen who were about to explore the wild and nnsettled regions bordering on Lake Ontario, to snrvey the lands of a French company. The operations were carried on for two months, during which the party, seven persons in all, Brunel being leader, encamped in tbe woods, finding a charm in the adventurous natnre of their work. In 1794 Brunel was appointed, conjointly with one of his fellow-explorers, to snrvey for tbe canal wbicb now connects Lake Champlain with the river Hudson at Albany. With this task, in which his fertility of invention and readiness in overcoming difficnlties were strikingly manifested, his career as an engineer may be said to have begun. When designs for the houses of congress were called for he sent in one which, though acknowledged as the best, was rejected as too costly and magnificent for simple repnblicans. He afterwards acted professionally as an architect, and among other works bnilt and fitted up one of the principal tbeatres of New York. It has since been burned down. He was employed on the forts erected for the defence of the city, and in the establishment of an arsenal and foundry, where his ingenious contrivances for boring cannon and moving large masses of metal with facility, showed how snccessfnlly he could bring new ideas to bear on the work immediately in progress.

In the family of his friend Carpentier, at Rouen, Brunel had become acquainted with Miss Sophia Kingdom. This acquaintance, and a desire to work among the scientific engineers of Europe, drew him to England. He married shortly after his arrival; and to initiate his career in this country, produced an autographic machine, designed to copy drawings, maps, and written docnments. Soon afterwards, be snbmitted to government a plan for making block-pulleys for ships by machinery, and was employed to carry it into execution in the dockyard at Portsmonth. The ingennity of this contrivance is not less remarkable than the accuracy and economy with whicb its operations are performed. It comprises, so to speak, sixteen different machines, all driven by the same steam-power; seven of which cut and shape logs of elm or ash into the shells of blocks of any required size, while nine fashion stems of lignnm-vitæ into pnlleys or sheaves, and form the iron pin, which being inserted, the block is complete. Fonr men with this machine tnrn ont as many blocks as fonr-score did formerly, and at less cost. The supply has never failed, even in time of war, though 1500 blocks are reqnired in the rigging of a single ship of the line. Results so satisfactory produced a corresponding liberality on the part of government, and the inventor was rewarded beyond his expectations. The steam saw-mill in Chatham dockyard was erected by Brunel. Tbe success of the circular saws there introdnced led him to further improvements, by which in the cutting of veneers double the nsual number could be obtained. He invented a machine for making seamless shoes for the army, whicb, after two years' trial, was given up from an economical motive. Among other inventions may be enumerated a machine for making wooden boxes; for nail-making; to twist, measure, and form sewing cotton into hanks; for ruling paper; a contrivance for cntting and shuffling cards without the aid of fingers, produced in reply to a playful request of Lady Spencer's; a hydraulic packing-press; new metbods and combinations for snspension-bridges; and a process for building wide and flat arches without centerings. He was employed in the construction of the first Ramsgate steamer, and was the first to suggest the advantages of steam-tugs to the Admiralty. He constructed a machine for using carbonic acid gas as a motive power, and, assisted by his son, carried on a series of experiments, for more than ten years, in the endeavour to bring it to perfection. Most of the mechanical difficulties were overcome; bot although an intense power was obtained, and with a very low temperature, the economical advantages as compared with the cost of the vapour of water, did not appear to be snch as to compensate for the increased cost of the machinery, and the nsual difficulties in its use.

Brunel's works of engineering construction are to be found in different parts of the United Kingdom. That by which he is most popnlarly known is the Thames Tunnel. This great work, commenced in March, 1825, was successfully accomplished, notwithstanding the accidents, obstacles, and overwhelming disasters that hindered its progress. The water broke in more than once, and flooded the whole of the excavations. Brunel, however, proved himself equal to each emergency, and his persevering genius at lengtb triumphed. The tnnnel was opened to the public in March, 1843.

Brunel was elected a Fellow of the Royal Society in 1814, and was chosen on the council, and appointed vice-president in 1832-33. He was a member also of other scientific societies and institutions. The hononr of knighthood was conferred on him in 1841. With advancing years he became snbject to a disease of which he had felt the first approaches while completing the tunnel, and he died in December, 1849, having nearly reached the venerable age of eighty-one. His life is an example of what may be accomplished by genius, seconded by industry. The high character of his inventions, their essential nsefulness, give them especial claims to consideration. In the words of a French writer, these have gained for him "the celebrity tbat now distinguishes his name, the admiration of men of learning and of labour, and the affectionate remembrance of all those who, fortunate enough to know him personally, could appreciate his simple and noble character."

BRUSA. [BURSA.]

BRYDGES, SIR SAMUEL EGERTON, BART., was born November 30, 1762, at Wootton Court, Kent. His father was Edward Brydges, Esq., of that place: his mother was tbe daughter and co-heiress of the Rev. W. Egerton, LL.D., Prebendary of Canterbury, &c. Young Brydges was educated first at Maidstone Grammar School, and afterwards at the King's School, Canterbury, whence he proceeded to Cambridge, entering at Queen's College in October, 1780. He left the University without taking a degree; entered himself of the Middle Temple in 1782, and in 1787 was called to the bar. He never practised, however; but having married in 1786, devoted himself to literatnre, and especially to genealogical and bibliographical studies. His earliest appearance in print was as a poet, a volume of 'Sonnets and other Poems' being pnblished by him in 1785. Soon after the death of the last Duke of Chandos, in 1790, his uncontrolled imagination, excited perhaps by his somewbat superficial genealogical inquiries, a large share of vanity, and a passion for titles, led him to stimnlate his elder brother the Rev. E. T. Brydges, to prefer a claim to the barony of Chandos, alleging his descent from the first Brydges or Bridges, who bore that title. Litigation was protracted till June 1803, when the House of Lords decided that the petitioner had not made out his right to the title. Henceforth every thing which Sir Egerton Brydges wrote, was more or less a wail for tbe lost dignity, and after the death of his brother, he always wrote himself 'per legem Terræ Baron Chandos.' The worthlessness of his claim is amply shown in a 'Review of the Chandos Peerage Case, adjndicated in 1803, and of the pretension of Sir S. E. Brydges, Bart., to designate himself per legem Terræ Baron Chandos of Sudeley. By George F. Beltz, Esq., Lancaster Herald,' 8vo, 1834. By improvident expenditnre in the purcbase and improvement of the estate of Denton, Kent, Mr. Brydges had early become involved in his pecuniary circnmstances, and in 1810 he removed to Lea Priory, the seat of his son, where he amused himself by setting np a private press, and superintending the printing of various pieces in prose and verse of his own writing, and reprints of scarce old books. After several nnsuccessful efforts to get into parliament, he was elected in 1811 for Maidstone, which place he represented till 1818. In 1814 he obtained a patent of haronetcy. On losing his seat in parliament he retired to the Continent, where he remained till his death, which occurred at Compagne Gros Jean, near Geneva, September 8, 1837.

Besides the works above ennmerated, and several pamphlets on popnlation, wealth, &c., Sir Egerton Brydges wrote 'The Topographer,' 4 vols. 1789-90 (in which he was assisted hy the Rev. Stebbing Sbaw); the novels of 'Mary de Clifford,' (1792); 'Fitz Albini,' a kind of fictions autobiography (1798); 'Le Forester' (1802); "Coningsby' (1819); and 'The Hall of Hellingsey' (1821); 'The Censuria Literaria,' a hibliographical work of some value, 10 vols. 8vo, 1805-1809; 'The British Bibliographer,' written in conjunction with Joseph Haslewood, 4 vols. 1810-12; 'Restitua, or Titles, Extracts, and Characters in Old Books revived,' 4 vols. 1814-16; a new edition of 'Collins's Peerage,' 9 vols. 1812; 'The Ruminator,' and 'The Wanderer,' two series of essays, 1813, 1814; 'Occasional Poems,' 1814; 'Bertrand, a Poem,' 1815: 'Excerpta Tndoriana, or extracts from Elizabethan Literature,' 2 vols. 1819; 'Res Literariæ,' 3 vols. 1820-21; 'Letters from the Continent,' 1821; 'Letters on Lord Byron,' 1822; 'Gnomica, or Detached Thoughts;' 'Odo, Connt of Lingen, a Poem;' 'Theatrum Poetarum,' 1824; 'Recollections of Foreign Travel,' 1825; 'The Lake of Geneva,' 2 vols. 1832; 'Imaginary Biography,' 2 vols.; and 'The Antobiography, Times, Opinions and Contemporaries of Sir Egerton Brydges, K.T.' (per legem Terræ) Baron Chandos of Sndeley, &c., 2 vols. 8vo, 1834.

BRYONIN. [CHEMISTRY, *S.* 1.]

BRYOZOA, a name proposed hy Ehrenherg for those Zoophytes in which a higher organisation is indicated by the presence of separate orifices for the mouth and anus. The same naturalist has applied the term *Anthozoa* to those Polypes in which the month and vent have hut one orifice. The distinction between these two great families seems to have been observed by Mr. J. V. Thompson previously to the pnhlication of Ehrenberg's name, hence his designation for this family, *Polyzoa*, is more generally received. Other names have been given to this interesting family of Zoophytes. Professor Owen calls them Molluscan Zoophytes, on account of their structure being supposed to ally them to the *Mollusca*. For the same reason they have also been called Ascidioid Polypes (*P. Ascidioida*). Milne-Edwards has also called them Tunicated Polypes (*Polypes tuniciens*). Dr. Farre in a paper in the 'Philosophical Transactions,' 1837, proposes to call them *Ciliobrachiata*, in reference to the ciliated character of their tentacnla. Mr. Bnsk in his Catalogue of tbe Zoophytes in the Collection of the British Mnseum, adopts Mr. Thompson's designation of *Polyzoa* as prior to that of any others. [POLYZOA.]

BUCH, LEOPOLD VON, a distinguished geologist, was born on the 25th April, 1774, at Stolpe, in the Uckermark (Brandenhurg). He came of an ancient and noble family, which reckons among its members not a few anthors and statesmen. After the usual course of education, he became a student in the Prussian department of mines, and was marked for the earnestness of his scientific pnrsuits. In 1790 he entered the Miniog Academy at Freiberg, where he had Hnmboldt for a companion, and where Werner, its eminent founder, taught the then novel science of mineralogy, in a way so interesting and genial, as thoroughly to enlist the sympathy of his pnpils. Under his teachings grew np a school of young philosophers, destined to widen and confirm his repntation, and amend his errors, among whom Von Buch was one of the most conspicuous. In 1792 the pnhlication of his 'Mineralogical Description of the Carlshad region,' formed the first of that series of valnahle papers with which he enriched his favourite science for the rest of his life—all distinguished as mnch hy conscientious inference, as hy perfection of observation. Next appeared his 'Versnch einer mineralogischen Beschreibnng von Landeck,' describing a little-known part of the monntains of Silesia; followed shortly afterwards hy 'Versuch einer geognostischen Beschreibung von Schlesien,' with (for tbat time) a very advanced geognostical map of the conntry. These works are written in accordance with the views of his great master, in which the Neptnnian theory prevailed; and it is no small proof of the accuracy of the observed facts that they are now easy to be reconciled with the present more enlightened theory.

In 1797 Von Buch and Humboldt met in Styria, and spent some time in geological excnrsions among the Alps, and passed the winter together in Salzburg in observation and verification of natural phenomena. In the following year Von Bnch travelled alone, on foot, to Italy, and furnished to scientific periodicals descriptions of the geology of tbe conntries he traversed, in which, besides the clearness of perception, there hegan to appear donhts as to whetber the Wernerian doctrine were tenable in its integrity. He grew mistrnstfnl of his former views. Writing from Rome to his friend Von Moll, he says: "Make the finest and surest observations, and then go a few miles farther on, and you will find occasion, upon gronnds jnst as certain, to maintain the very opposite of your former cooclusions."

In February 1799, Von Bnch arrived at Naples, and hetaking himself to the stndy of Vesuvius, described the phenomena in that pictnresque and eloqnent style which among other qualities characterised his writings. In 1802 he visited the volcanic region of Auvergne. He revisited Italy, and was present at the eruption of Vesnvins in 1805. The results of these five years of observation were published in two volumes 'Geognostischen Beobachtungen anf Reisen dnrch Dentschland nnd Italien,' 1802-9, in which, thongh relnctant to throw donbt on Werner's conclusions, he abandons his view as to the action of water, and declares hasalt to he a rock of volcanic origin.

For the next two years, from 1806 to 1808, Von Buch travelled into Scandinavia, and made some of his most important geological discoveries. He was the first to establish the fact of the slow and continuons npheaval of the Swedish coast ahove the sea-level; and he made valuahle observations in climatology and the geography of plants, as may he seen in his narrative 'Reise durch Norwegen und Lappland,' two vols. 1810: of which an English translation was pnhlished with notes hy Professor Jameson in 1813.

The more interest attaches to these jonrneys as they were performed on foot. Few who met Von Bnch walking with unsteady gait, his head hent forward, wearing even in snmmer a great coat with numerons pockets to contaio maps, specimens, his hammer and note-hook, wonld have believed that they beheld one whom Humboldt describes as "the greatest geologist of onr age; the first to recognise the intimate connection of volcanic phenomena and their mntual interdependence in regard to their effects and relations in space." Possessed of snfficient means, Von Buch conld gratify his inclination for travel, and for the enconragement of others, especially youthfnl stndents, less fortunate than himself.

In 1815 he sailed from England (accompanied by the Norwegian botanist Christian Smith, who afterwards met with an untimely death in Tuckey's expedition to the Congo), for a geological exploration of the Canary Islands. In 1824 appeared the first geological map of Germany in forty sheets, of which Von Buch, thongh anonymous, was the compiler and anthor. He had visited the basaltic islets of the Hebrides and the Giant's Causeway on his retnrn from tbe Canaries, and in 1825 he pnblished 'Physikalische Beschreihnng der Canarischen Inseln,' with an atlas, of which the snhseqnent works, 'Ueher den Zusammenhang der basaltischen Inseln nnd Ueber Erhehnngs-Krater,' and 'Ueber die Natur der vnlkanischen Erscheinungen auf den Canariscben Inseln nnd ihre Verbindnng mit andern Vnlkanen der Erdoherfläche' may be regarded as snpplementary. These volcanic researches alone wonld snffice to estahlish his repntation. The science of volcanoes,—the fruitful sonrce of many later advances—is therein developed and placed on a sure basis. He shows how the phenomena of upheavals are traceable to craters of elevation, and demonstrates the action of fire; and states his conviction that "the ancient seas have not rolled away over the mountain chains, hut that the monntain chains have heen npheaved into the atmosphere, hnrsting throngh the series of strata in long lines—fissures—and that these npheavals have taken place at different geological epochs."

Von Buch's life is strikingly manifest by his labours. His papers in the 'Abhandlnngen' of the Berlin Academy of Science, would alone form several large volnmes. They exhibit the development of his scientific views from first to last. In 1806 he had snggested certain ideas in his paper 'Ueher das Fortschreiten der Bildungen in der Natur,' as to the progress of forms in natnre, and when past the age of fifty, he showed how the ideas had ripened in his mind by his papers on the *Ammonites, Cystideæ, Terebratulæ, Orthis, Productus*, and others, accomplishing for the geological branch of palæontology what Cuvier had accomplished for the physiological branch. In the words of the late Edward Forbes, it was Von Buch "who first developed the idea of the obronomorphosis of genera, the great leading principle of natural history applied to geology." He pointed the way moreover to a new field of fossil botany in the important conclusions which be shows to be deducible from the nervation of the leaves of fossil plants. And in his writings on climate, on hail, the temperature of springs, and the geography of plants—guiding principles apparent in all—he proves himself an able physicist as well as geologist.

In his many journeys Von Buch visited Sweden and Norway, and Auvergne a second time, and any excuse sufficed to draw him to Switzerland. He would leave his house in Berlin without telling any one of his intention, remain away for weeks or months, and return as unexpectedly. He liked to find out and make the acquaintance of geologists of eminence, and for this purpose he attended the meetings of naturalists on the continent and of the British Association in England. He was present at the Werner Festival, celebrated with so much pomp at Freiberg, in 1850. He never married, was somewhat eccentric in his habits, but always serious as regards science. When asked for his titles he was accustomed to reply, 'Royal Prussian Student of Mines.' He was created a baron, a knight of the Order of Merit (Berlin), and of the Red Eagle, and held the appointment of royal chamberlain in the court of Prussia. He was a member of the Academy of Sciences of Berlin, and of the chief scientific societies on the continent and elsewhere. In 1828 he was elected a foreign member of the Royal Society of London, and in 1840 was chosen one of the eight foreign associates of the French Academy of Sciences. He died at Berlin, after a few days' illness, on the 4th of March, 1853.

"Von Buch was a sower," says E. Forbes, in his anniversary address to the Geological Society. "He went about the world casting the seeds of new researches and fresh ideas, wherever his prophetic spirit perceived a soil adapted for their germination. The world of science has gathered a rich harvest through his foresight. He is the only geologist who has attained an equal fame in the physical, descriptive, and natural history departments of his science. In all these he has been an originator and a discoverer. In every subdivision of all three he has been a suggester—a high merit in itself."

The 'Abhandlungen' of the Berlin Academy of Sciences, Leonhard's 'Taschenbuch für Mineralogie,' and other German scientific periodicals, contain most of Von Buch's papers. Among his other works are—'On the Petrifactions collected by Humboldt in America'—'Die Bären Insel . . geognostisch beschrieben,' 4to, 1847; 'Ueber Ceratiten besonders von denen die in Kreidebildungen sich finden,' 8vo; besides those above-mentioned. A French translation of his 'Canary Islands' was published at Paris in 1836.

(Hoffman, *Geschichte der Geognosie; Monatsbericht, Acad. Berlin; Edin. New Phil. Journ.; Journ. Geol. Soc.*)

BUCHOLZITE, a mineral closely allied to Sillimanite. According to Thompson it is composed of—

Silica	46·4
Alumina	52·9

A specimen from Chester, Pennsylvania, gave Erdmann—

Silica	40·1
Alumina	58·9
Protoxide of Manganese	(a trace)

It is found at Fassa, in the Tyrol, and in several districts in the United States.

BUCIDA, a genus of plants belonging to the natural order *Combretaceæ*. One of the species, *B. Buceras*, yields a bark which is used in tanning.

BUCK. [DEER.]

BUCKINGHAM, JAMES SILK, was born in 1786, in the marine village of Flushing, near Falmouth, in Cornwall. His father had been a seafaring man, but then occupied a farm, and died while Buckingham was yet a boy. His mother sent him to school at Falmouth, and was desirous of bringing him up to the church, but he preferred going to sea, and made a few voyages to Lisbon, in the last of which the ship was captured by the French, and the crew made prisoners. After some delay they were set at liberty, but on their way home were impressed for the British navy. Buckingham however escaped from the press-gang, returned to Cornwall, and entered into an engagement with a bookseller at Devonport, in whose employ he remained about four years; and here he seems to have gained some knowledge of the trade of a printer. He however took to the sea again on board a king's ship, but deserted, returned home, tried the law, and abandoned that profession also. He married before he was twenty years of age. About this time his mother died, leaving him a considerable property in charge of trustees. He then commenced business as a bookseller, on borrowed money. One of his trustees robbed him of his property, his business proved a failure, and he was left destitute with a wife and female child.

Leaving his wife in the care of her friends, Buckingham then went to London, in the hope of getting an engagement as captain of some vessel; but having waited till he was almost in a state of starvation, he obtained employment in a printing-office, and was afterwards engaged at the Clarendon press, Oxford. At length he was appointed captain of a West-Indiaman, and continued four or five years in that trade. He afterwards was a captain in the Mediterranean trade, and made many friends at Malta and Smyrna. He then resolved to settle at Malta as a ship-owner and merchant, and having purchased a cargo of goods, he sailed from London in April 1813. When the vessel reached Malta, the plague had broken out there, and no persons were allowed to land; the cargo however was taken on shore, and the ship then proceeded to Smyrna. While he remained at Smyrna, many failures took place in Malta, and he among others lost all his property.

Buckingham then resolved to try his fortunes in Egypt, and left Smyrna for that purpose, August 30, 1813. He was well received at the British Embassy, and was introduced to Yuseff-Boghos, an Armenian, the principal agent of the pasha, Mohammed Ali, who was then absent on an expedition in Arabia. At this time there was much speculation about renewing the commerce with India through the Red Sea, and making a navigable canal from that sea to the Mediterranean. Buckingham had a despatch forwarded to the pasha, in which he offered his services to examine the Isthmus of Suez for an eligible track, and to trace as far as possible the course of the ancient canal. His offer, after some delay, was accepted, and having in the meantime ascended the Nile as far as the cataracts, he started from Keneh on the Nile, with a single attendant, for the purpose of travelling to Kosseir on the Red Sea. His attendant deserted him on the route, he was robbed of everything he possessed, and was left entirely naked. He was befriended by a poor Arab, who supplied him with some scanty covering, and at length reached Kosseir, whence however he was obliged to return to Keneh, and thence to Cairo, without effecting anything. At Cairo he was introduced to the pasha, Mohammed Ali, with whom he had some long conversations, and again set out February 15, 1814, for the same purpose as before; he reached Suez, and traced the ancient canal as far as it had not been filled up and obliterated. After his return to Cairo the pasha had changed his mind as to the canal, but gave him a commission to purchase ships for him in India, and to encourage a trade between India and Egypt.

Mr. Buckingham then left Cairo for the purpose of proceeding to Bombay by the Red Sea, and reached Suez, October 18, 1814, and Bombay April 6, 1815, having been delayed in Arabia. He found the merchants at Bombay distrustful of the pasha of Egypt, and unwilling to trade with him; he therefore accepted an engagement from the agent of the Imaum of Muscat as commander of a ship of 1200 tons burden, which was intended to trade to China on the Imaum's account. When this was made known to the civil authorities at Bombay, and also that he had no licence from the East India Directors to reside in India, he received an order to return to England, but, after much remonstrance on his part, was allowed to return to Egypt in one of the East India Company's ships, which was about to proceed up the Red Sea for surveying purposes. He accordingly sailed from Bombay June 27, 1815, was landed at Suez, and reached Cairo November 20, in the same year. After another interview with the pasha he received a firman and other assistance, by the aid of which he travelled overland to India through Syria, Mesopotamia, and Persia, dressed in Turkish costume, and speaking Arabic, which, he states, is more or less understood in all those countries.

From this period his proceedings in the East are imperfectly known. In 1816 he was in Calcutta, and established a journal there, but the boldness of his censures of the maladministration of Indian affairs led to his expulsion from the presidency of Bengal; his printing-presses were seized, and he was compelled to return to England.

After his arrival in London, Mr. Buckingham delivered many lectures against the monopoly of the East India Company, and in support of opening the trade to China. A liberal subscription was entered into to re-imburse him for the losses he had sustained by the suppression of his journal. He established in London 'The Oriental Herald,' which became the precursor of several similar journals, and 'The Athenæum,' which is now the leading literary journal among those which are published weekly. In 1822 he published his 'Travels in Palestine;' in 1825 'Travels in Arabia;' in 1827 'Travels in Mesopotamia;' in 1830 'Travels in Assyria and Media.' At a later period he made several tours through various parts of Europe and of North America. He published 2 vols. on Belgium, the Rhine, and Switzerland: and 2 vols. on France, Piedmont, and Switzerland. He was nearly three years in America, and traversed the United States in all directions, from Maine to Louisiana. His 'Travels' in America comprise:—3 vols. on the Northern States; 3 vols. on the Slave States; 3 vols. on the Eastern and Western States; and 1 vol. on Canada, Nova Scotia, and New Brunswick. Much of these volumes however consists of statistics, and a great variety of other matters of compilation. Their literary or other worth is very small.

In 1832 Mr. Buckingham was elected member of parliament for Sheffield, and he retained his seat till 1837. He was a supporter of liberal policy, and especially of social reforms. For many years his chief occupation was the delivery of public lectures in various parts of the country. His choice of subjects, style, and especially his manner, were popular and pleasing, and his lectures were always fully attended. In 1843 he was the chief agent in establishing a literary club called the British and Foreign Institute, of which he was appointed secretary, but which ceased to exist in about three years. In 1849 he published 'National Evils and Practical Remedies,' 1 vol., in which he expounded his views on many subjects connected with the public welfare. He was a zealous advocate of the temperance movement, and he was President of the London Temperance League formed in 1851. In 1855 he published the first two volumes of his 'Autobiography,' and he intended to publish the next two volumes in the course of the same year, but he closed his life of extraordinary vicissitude and adventure on June 30, 1855. The court of directors of the East India Company had made amends for their former ill-treatment by granting him a pension, which he enjoyed for a few of the last years of his life, and which is continued, we believe, to his widow, who is still living, having been his wife for fifty years. He had also for a few years a pension of 200*l.* a year from the civil list. The manuscript journals of his various travels occupy, as he states in his 'Autobiography,' 28 folio volumes, closely written.

BUCKLAND, THE VERY REV. WILLIAM, Dean of Westminster, an eminent geologist, was born at Axminster, Devon, in 1784. He was educated at St. Mary's College, Winchester, and from thence, in 1801, entered Corpus Christi College, Oxford, as scholar. In 1808 he was elected Fellow of this college. In 1813 he was appointed reader in mineralogy, and in 1818 reader in geology in Oxford University. His geological lectures were characterised by such clearness and comprehensiveness of description, and such apt illustration, that they met with brilliant success. Geology, as a science, was then in its infancy, and much of its subsequent vigorous advancement is due to Dr. Buckland's lectures.

The Geological Museum at Oxford owes its chief excellence to Dr. Buckland's industry in procuring and arranging specimens, particularly of the remains of the larger Fossil Mammalia, and other animals from the caves in different parts of England and Germany. He spared neither pains nor expense in travelling to make the collection worthy of the university and the science it was intended to illustrate, as exemplified in his 'Descriptive Notes,' with sections of 50 miles of the Irish coast, made conjointly with the Rev. W. Conybeare, dean of Llandaff, during a tour in Ireland in 1813, and published in the third volume of the 'Transactions of the Geological Society.'

In 1818 Dr. Buckland was elected a Fellow of the Royal Society. In 1820 he delivered a lecture before the university, which was afterwards published under the title 'Vindiciæ Geologicæ, or the Connexion of Geology with Religion explained.' The object of the lecture was to show that the study of geology has a tendency to confirm the evidences of natural religion, and that the facts developed by it are consistent with the accounts of the Creation and Deluge as recorded in the Mosaic writings.

In 1822 he communicated to the Royal Society an 'Account of an assemblage of Fossil Teeth and Bones of elephant, rhinoceros, hippopotamus, bear, tiger, hyæna, and sixteen other animals, discovered in a cave at Kirkdale, Yorkshire,' and for which in the same year the society awarded him their highest honour, the Copley medal. This paper was made the foundation of a treatise published in 1823 'Reliquiæ Diluvianæ, or Observations on Organic Remains attesting the Action of an Universal Deluge,' which proved of essential service in the promotion of geological science.

In 1825 Dr. Buckland was made canon of Christ Church, Oxford. He was president of the British Association at their second meeting at Oxford in 1832. Four years later he published his Bridgewater Treatise, 'Geology and Mineralogy considered with reference to Natural Theology,' 2 vols. 8vo. The discovery of new facts had materially advanced geological science; and modifying in this work the previous diluvial theory, Dr. Buckland brought the weight of his authority to support the views now generally received. One of the most able of his numerous geological writings, as subsequently testified by Murchison and Sedgwick, was a sketch of the structure of the Alps, published in the 'Annals of Philosophy,' in which he showed, for the first time, that many crystalline rocks of this chain are of no higher antiquity than our Lias, Oolitic, and Cretaceous Formations.

The 'Transactions of the Geological Society' contain highly valuable suggestive evidence of Dr. Buckland's skill as a field geologist, as well as a palæontologist, and among them, his description of the south-western coal district of England (1825) may be mentioned as an example. It has stood the test of more than thirty years, and is still appealed to as a standard work.

Dr. Buckland was chosen on the council of the Royal Society in 1827, and in subsequent years up to 1849. He was one of the earliest fellows of the Geological Society, having been elected in 1813, and twice filled the presidential chair. His anniversary addresses are printed in the society's 'Journal.' He was also a Fellow of the Linnæan Society. In 1845 he was made Dean of Westminster; and, coming to reside in London, he was appointed a Trustee of the British Museum in 1847, and took an active part in the meetings of scientific societies, and in the establishment of the Museum of Practical Geology in Jermyn-street. In the year 1850 he was obliged, in consequence of disease of the brain, to relinquish his favourite pursuits, and was never afterwards able to resume them. He died August 14, 1856.

BUFFALO, AMERICAN. [Bison.]

BUGEAUD DE LA PICONNERIE, THOMAS ROBERT, DUC D'ISLY, Marshal of France, was born at Limoges, October 15, 1784. He came of a good family, most of the members of which were among the emigrants of the first revolution. Young Bugeaud, however remained in France, and having chosen a military life, entered the army as a private in 1804. At Austerlitz he was a corporal; the following year he was made sub-lieutenant. He served in the campaign of Prussia and Poland, and was wounded at Pultusk, Nov. 26, 1806. Sent into Spain as adjutant-major he speedily caught the eye of Marshal Suchet, who in his despatches made frequent mention of Bugeaud's merits. He in consequence rose steadily in professional rank till he was made lieutenant-colonel, and appointed to the command of the 14th regiment of the line. On his return to France he was created colonel.

On the abdication of Napoleon I., Bugeaud gave in his adhesion to the restored dynasty; but, with most of the other officers, went over to the emperor on his return from Elba. During the Hundred Days he had the command of a small body of troops, and with it he succeeded in defeating a much superior Austrian force at l'Hôpital-sous-Conflans, June 1815. Upon the second restoration, Bugeaud retired to his estate, where he diligently cultivated the soil, till the revolution of July 1830 called him again into public life. He was elected a member of the Chamber of Deputies, and became an earnest supporter of Louis Philippe, whose confidence he quickly gained, and who made him marshal. In January, 1834, occurred a deplorable event, which caused great excitement in Paris, and rendered Bugeaud extremely unpopular: this was the death of M. Dulong, in a duel between him and General Bugeaud, arising out of some bitter remarks made in the Chamber of Depnties by Dulong in reply to Bugeaud, in a debate on the conduct of Marshal Soult. So great was the exasperation of the Parisians, that the goverument found it advisable on the occasion of Dulong's funeral to take precantions against an insurrection. A few months later Bugeaud's unpopularity was increased by the decisive measures he took for suppressing the various émeutes which broke out, and especially by having his name coupled with the massacre of the Rue-Transnonain.

In 1837 Bugeaud was sent to Algiers, where he concluded a treaty with Abd-el-Kader, which was mnch criticised at home, hnt which served the purpose for which Bugeand made it—that, namely, of enabling the French commander, by securing the inactivity of the only chief whose prowess and authority were really to be feared, to direct his whole strength against the disunited tribes, and reduce them snccessively to snhmission. Bugeaud returned to Paris to give an account of his mission. It soon appeared that Bugeand knew better how to deal with the Arabs than the officers previously sent; and in 1840, affairs appearing very unpromising, Marshal Vallée was recalled, and Bugeand was appointed governor-general of the French possessions in Africa. An outline of his proceedings has been given under Algeria, *S.* 1. It will be enough here to observe, that the maxim he was fond of repeating was that "to conquer the Arab you must first become an Arab," and that in accordance with this he set abont organising the Zonaves and other irregular soldiers, characterised by their capacity for acting independently as well as in masses, their celerity of motion, and their daring, and who have since become so important a part of the French army; and having established a chain of fortified posts, he was enabled to maintain incessant attacks and surprises, never permitting any body of armed natives to collect without immediately dispersing them, and never allowing any hostile tribes to carry on any of their ordinary agricultural avocations. From his energy and ruthlessness, there was no escape for the uncivilised natives. Attacked in detail, resistance was useless; there was only the choice of submission or destruction. In three years Bugeaud was able to annonnce that there was no longer an enemy in the field. Abd-el-Kader was a fugitive, and Algiers was formally annexed to the French crown. The Emperor of Marocco had ventured to oppose the progress of the French arms; but his coast-towns were ravaged, and at Isly, Bugeand, with a far inferior force, had destroyed his army. For this last achievement Lonis Philippe created Bugeaud Duc d'Isly; the Arabs gave him the more poetical title of Conqueror of Fortune. He retnrned to France in 1846; but in his absence Abd-el-Kader again collected an army, and the whole conntry was speedily in revolt. Bugeand was sent back, and with an iron hand quickly and effectually crushed the Arah rising.

At the outhreak of the revolution of February 1848, Bugeaud was in Paris, and on the night of the 23rd the command of the troops was given to him. He would have adopted energetic measnres, but the king shrank from shedding blood, and the military command was placed in other hands. Bugeaud was not again employed till Louis Napoleon became president, when he was named to the command in chief of the army of the Alps. He was also elected hy Charente-Inférieure representative in the National Assembly. But he enjoyed neither dignity long: he died of cholera, on the 10th of June, 1849. Bugeaud published memoirs on infantry manœuvres, on army organisation, on the establishment of military colonies, and on a variety of matters connected with the governance of Algiers.

BUGLOSS. [Anchusa, *S.* 1.]

BUHRSTONE is a quartz rock containing cellules. It is as hard and as firm as a quartz crystal, and owes its pecnliar value to this quality, and the cellules, which give it a very rough surface. Stoues for grinding wheat and other kinds of grain are formed of this rock, and those which are most valued have the cavities about equal in space to the solid part. The best stones for this purpose come from France, and are obtained from the Paris basin and adjoining districts. When used for grinding, the stones are cut into wedge-shaped parallelopipeds, which are called panes. These are bound together by iron hoops into millstones. The Paris Buhrstone is a tertiary formation. A Buhrstone is obtained in Ohio in America, which is in part a true sandstone, and contains fossils. It also contains lime, and Mr. Dana suggests that the removal of the lime hy solution may have given it its cellnlar character. It overlies the coal formation, and has an open cellular structure where qnarried for millstones. The quartz rock of Washington in the United States is in some parts cellular, and makes good millstones. Buhrstone also occurs in Georgia near the Carolina line, and in Arkansas near the cove of Wichitta. (Dana, *Manual of Mineralogy.*)

BULGARIA, a conntry of Turkey in Europe, is bonnded N. by the Danube, which separates it from the principalities of Wallachia and Moldavia, and from the Russian province of Bessarabia; E. by the Black Sea; S. by the crests of Emineh and Khojah Balkan; and W. by the principality of Servia, from which it is partially divided by the Timok, a feeder of the Danube. The area is above 32,000 square miles, and the popnlation according to the estimate of 1844 was about 3,000,000, the majority of whom are adherents of the Greek Church. The area is thns distributed, as nearly as we can ascertain:—Pashalic of Silistria, including the territory of Varna, 13,000 sqnare miles; pashalic of Nicopoli, 10,000 square miles; pashalic of Widdin, 4,500 square miles; and a portion of the pashalic of Sophia, 4,500 square miles. These divisions however do not coincide with the present Turkish divisions of Bulgaria, which are Widdin, Nisch, or Nissa, Sophia, and Silistria. We retain, however, the old divisions in our maps.

The Danube runs with many windings, but in the general form of a bow, with the convex side towards Bulgaria, all along the northern houndary to the mouth of the Sereth, whence it turns to the eastward and enters the Black Sea by several mouths. [Bessarabia; Danube.] Reckoning all its windings the river flows along the province for not less than 500 miles, and is navigable for steamers and large vessels all the way. It forms numerous small islands in its course and a delta at its month; and on both sides of the river at intervals are extensive marshes, which in the dry season are very unhealthy and infested by mosquitoes.

The Balkan Mountains, the ancient Hæmus, rise on the sonthern frontier to about 6000 feet above the sea. They sink down rapidly on the south side; on the north the slope is more gradual. The chain is traversed by many defiles and passes. [Balkan.] From its crest numerous ramifications extend northward to the plain of the Danube. These offsets are generally well wooded or covered with rich pastnre; and they are separated by valleys or small plains drained by feeders of the Dannbe. The principal of these rivers, commencing on the Servian frontier and proceeding eastward, are the Timok, the Ogust, the Skitul, and the Isker, which cross the pashalic of Widdin; the Wid, the Osma, the Jantro (which passes the town of Tirnova), and the Lom, which traverse the pashalic of Nikopoli, sometimes called the sanjak of Rustchuk; and the Drista, the Taman or Jemnrlu, and the Kara-Sn, which drain that part of the pashalic of Silistria which belongs to the basin of the Dannbe. The Kamtchik, which rises west of the Selimno Pass of the Balkan, flows eastward through a longitudinal valley between parallel ranges of the Balkan, and enters the Black Sea between Cape Emineh and the port of Varna. In the mountains that screen the valley of the Kamtchik on the north is the town and fortress of Shnmla. The most important of the other tributaries of the Black Sea in Silistria is the Parawadi, which passes through the marshy lakes of Devno and falls into the port of Varna. The Parawadi River is identified by General Jochmus in his 'Notes of a Journey to the Balkan' with the ancient Lyginos; and the site of Alexander's battle with the Triballi (B.C. 336) he considers to be the isthmus between the two lakes of Devno, a little west of the village Bnyuk-Aladin. Not far from the same spot, but nearer Varna, is the site of the great battle fought between the Sultan Murad and King Wladislaus in 1444. The site is easily identified hy two large mounds called Sandshak Tépé and Mnrad Tépé.

The coast of Bulgaria, or Silistria, from Cape Emineh, the eastern extremity of the Balkan, to Cape Kslakria or Gulgrad Burun, north of Varna, is generally high; to the northward of this last point the shore is for the most part flat, low, and marshy. The most important places along this coast are the city, port, and fortress of Varna, and the little town and roadstead of Kustenjeh, which is only about 30 miles distant from the point where the Danube makes the great bend to northward. It has been lately proposed to cut a navigable canal across the isthmus, in order to avoid the tedious navigation by the months of the Danube. Between the base of the Baba-Dagh, an elevated mass in the extreme north of Silistria and the sea lies the large lake of *Rassein*, or Razem, which is 35 miles long from north-west to south-east, and about 15 miles wide where broadest. It is separated by a narrow strip of land from the St.-George mouth of the Danube, from which a little arm called Dunavitz enters the lake. The lake itself communicates with the Black Sea by two principal channels called the Jalova and the Portitcha mouths. On the west shore of the lake is the town of *Baba-Dagh*, with 10,000 inhabitants, seven mosques, and extensive salt-works. The fishery of the lake is important. At the northern base of the Baba-Dagh range, and on the right bank of the Danube, is the fortress of Issatcha, near which the Russians in 1828, and Darius about 2300 years before them, passed the Danube. In consequence of the Russians having neglected to keep the Sulina month of the Danube in a navigable state, attention has been turned to the St.-George mouth, which belongs to Silistria, but is by treaty open to all trading vessels, and to the war ships of Austria and Russia. No vessel of any size however can easily enter it, owing to the banks of mud which have accumulated round its embouchure, and to the shallowness of the stream from the deposits of the river. It has however been lately surveyed with the view to make it navigable, and to free the trade of countries along the lower Danube from the vexatious regulations of the Russians.

A considerable portion of the sanjak of Sophia, and the pashalic of Nisch or Nissa, forms part of Bulgaria. This district of Bulgaria extends southward to the point where the Emineh Balkan, the Despoto-Dagh, and the Khojah Balkan meet near the source of the Isker and the Suln Derbend, or Pass of Trajan. The Isker here traverses a beautiful plain, in which stands the populous and well built city of Sophia, famous for its hot springs. Into the plain from the north-west a high valley screened by the Khojah Balkan and Mont Tesovitch opens; in its northern part stands the city of Nissa, in a fertile country watered by the Nissava, a feeder of the eastern Morava. Near Nissa is the Tower of Skulls erected as a trophy of victory gained over the Servians by the Turks under Kumnrgee.

The plains of Bulgaria are in general well cultivated, and the hill-slopes are covered with vineyards. On the Thracian side of the Balkan (excepting the valley of the Maritza) cultivation is generally confined to the immediate circuit of the villages; but in Bulgaria wide tracts are subdued by the plough, and large quantities of corn are produced by the industrious inhabitants. The largest quantities of corn are grown in Silistria and in the plains near the Danube. A good deal of flax, hemp, and tobacco are grown, large quantities of wine are made, and fruits are abundant. Roses are cultivated very extensively for making perfumes. Timber cut in the mountain forests is floated down the river for export to the towns on the Danube. For want of good roads however Bulgaria, like all other parts of the Turkish empire, has comparatively but a limited trade. The Bulgarians however seem to enjoy a rude abundance; it is rare to see a beggar, and their well-built dwellings, and neat fields and gardens present a most favourable contrast to the mud-plastered huts and wattles and the neglected or rudely cultured steppes on the Wallachian side of the Danube.

The soil of Bulgaria is in general fertile and well watered; the section between the town of Sistova and the Balkan, however, is deficient in water, although it yields grass abundantly. The best cultivation is seen in the districts extending from the western part of the pashalic of Silistria to the pashalic of Widdin: this region is inhabited chiefly by Bulgarians, a race always remarkable for industry and for their pacific disposition, notwithstanding their long oppression under the Turkish feudal system and the rapacity of the pashas. But the Tanzimat has now put the Bulgarian on a level in point of law with the Turk (in other respects he was always his superior), and the feudal system has been swept away; so that Bulgaria, at all times confessedly the best cultivated part of Turkey, will probably soon reach a high degree of prosperity and improvement.

That part of Silistria which skirts the Black Sea is sometimes called the pashalic of Varna, and is inhabited chiefly by Turks and Tartars, who barely raise enough of corn for their own consumption, and are chiefly occupied in rearing cattle. The fine plain south from the Baba-Dagh to the neighbourhood of Kustenjé is inhabited by Bulgarians, and by a goodly number of Russian colonists from Bessarabia, who raise large quantities of hard wheat of very superior quality. In the rest of Silistria the country is well cultivated throughout, and yields an abundant supply of provisions of all kinds. Hard wheat of two kinds, distinguished by the names of 'arnaut' and 'coloss,' is grown very abundantly. Barley also of fine quality is extensively grown. The other crops are maize, beans, and hemp, which in years of drought do not succeed so well. Several thousand oxen are slaughtered in the city of Silistria for the tallow, which is sent to Constantinople.

The eastern part of the pashalic of Nicopoli is well wooded as far as the neighbourhood of Rustchuk; it also possesses abundant pasturage, and, in ordinary years, when not visited by long droughts, it is very productive in corn. Wood for building, and oak planks of superior quality, are exported. Between Rustchuk and Sistova the plain of the Danube is occupied densely and solely by Bulgarians, and presents a fertile and pleasing aspect. Besides corn, the chief products are hemp, flax, attar of roses, and tallow. Sistova is considered the capital of the Bulgarians; it is one of the most important towns on the right bank of the Danube, and carries on a considerable trade with Wallachia. Westward from Nicopoli, and throughout the greater part of the pashalic of Widdin, the country is more thinly peopled, habitations being met with only where there is water, and agricultural produce is raised merely sufficient for the local consumption. The plain of the Danube here partakes of the nature of a steppe, and cultivation prevails more in the mountainous districts. Indeed the cultivation of corn for export was long effectually checked in this part of Bulgaria by a restrictive system, by which the farmers could not sell their surplus produce without the pasha's permission, and at a price fixed by him. Sometimes the pasha appropriated the surplus to himself, ground it at his own mills, and then forwarded it for sale to Constantinople. These regulations have been very injurious to the trade of Widdin, which, however, has a considerable commerce in manufactured goods imported from Austria.

The tallow trade causes the rearing of large numbers of cattle in Bulgaria. Large herds of oxen, to the number of 40,000 or more, are fattened during the summer months, and slaughtered during the autumn, in the neighbourhood of Varna, Silistria, Rustchuk, and other towns, for their hides and fat; for beef is seldom eaten by the Moslems, whose favourite animal food is mutton and goat. There is a depôt at Varna for the tallow and other products of the province. Owing to the difficulties, tediousness, and expense of the river navigation, and vexatiousness of the Russian quarantine regulations, the corn and other products of Bulgaria are generally brought by land carriage to Varna for export even from the plain of the Danube. Corn, however, for export to Constantinople is frequently conveyed in 'kirlaches,' or Turkish lighters, of from 30 to 100 tons, which are very numerous on the river, to Matzin, a small port opposite Brailoff, and there embarked in larger vessels. From the roadstead of Kustenjé also large quantities of corn are occasionally exported; but the exposed condition of this port since the destruction of its mole (built by Constantine the Great) is a great obstacle to its trade. Its position, however, has been at all times considered of great importance, as it is only 30 miles distant from Czernawoda on the Danube. A canal was projected in 1837 to unite the two points, and to give a short and direct route to the Danube trade, by avoiding the great northern bend of that river, and the intricate shoals and mud-banks in its mouth. This project has been recently revived, and will probably be one day executed.

Besides horned cattle, including buffaloes, Bulgaria rears a great many horses of inferior breed, sheep and goats in great numbers, and swine for the consumption of the Christian part of the population: pork to the Moslem, as to the Jew, is an abomination. The manufactures of the country are all of a coarse description, and for home consumption. The imports are manufactured goods, coffee, spices, sugar, salt, &c.

The principal towns of Bulgaria are—*Widdin, Nicopoli, Sistova, Rustchuk, Silistria, Rassova, Tirnova, Sophia, Varna, Kustenjé, Shumla, Nissa,* &c., of which the most important are described under their respective names.

Bulgaria comprises the greater part of ancient Mœsia, which was occupied in the time of Darius by the Getæ, and in the time of Alexander by the Triballi. It is a very interesting country for its historical associations, to illustrate which there is great need of enlightened exploration. General Jochmus, in the work already quoted, has thrown great light upon the history of the expeditions of Darius and Alexander in this country. He supposes Darius to have crossed the Balkan by the pass to the north-west of Mesembri, and to have marched northward to Issatscha by the same route that Marshal Diebitsch led the Russians in an opposite direction in the campaign of 1828. Alexander, he says, fought the action with the Thracians at the foot of the defile of the Balkan to the north of Aïdos; thence crossed the defile to the Lygiuos, near the town of Parawadi; and after his victory over the Triballi, before mentioned, marched in three days to the Danube, which he is supposed to have crossed at or near Silistria, for the purpose of attacking the Getæ. Bulgaria contains some Roman remains: the great Roman road connecting Trajan's Bridge over the Danube with Dyrrachium on the Adriatic crossed the valley of the Timok, the ancient Timacus, above Widdin, and is still in parts entire. On the road from Shumla to Rustchuk numerous ancient mounds, covered with forest trees, are passed at a place called Lazgaret, marking no doubt the site of some great ancient battle.

Mœsia was originally inhabited by a Scythic or Slavonic people. It was subjected by M. Licinius Crassus about B.C. 29 to the Romans, who built entrenched camps along the Danube; one of these is still visible near Widdin. In the 3rd century it was invaded by the Goths, whose incursions were not thoroughly checked till the time of Aurelian, who planted several Roman colonies in the province. It was next overrun by the Visi-Goths, to whom Theodosius I., after the defeat and death of Valens at the great battle of Adrianople in A.D. 378, ceded the country; and a part of those who settled in the western part of it are known in history as the Mœso-Goths. In the 6th century Slavonian tribes spread over Lower Mœsia, and in the 7th century Upper Mœsia was given by Heraclius to the Serbs and other Slavonic people, to protect the empire in that direction against the Avars.

The Bulgarians, a Tartar people from the banks of the Volga, subdued the Slaves of Lower Mœsia about the middle of the 7th century; but became in a short time so blended with the Slavonic part of the population, that before the commencement of the 9th century they had adopted the Slavonic language and customs, the name of the race which gave its designation to the country alone remaining. They were governed by kings who put themselves under the protection of the Greek emperors. This alliance however they renounced in 1185, their king Asan remarking that the Greek empire needed protection more than Bulgaria. Long wars with Hungary desolated the country between this and the 13th century, when Bulgaria was subjugated by Stephen IV. about the time that the Turks made their first appearance in Europe. In 1392 the Turks made the Bulgarian king Susman prisoner, and the people lost their independence. There are many Bulgarian colonies in Thrace and in the countries along the left bank of the Lower Danube.

During the Russian war of 1853-4 a portion of Bulgaria was seized and occupied by the Russian troops, and the fortress of Silistria was besieged by them, but was not taken.

(Arrian, i. 1-5; Herod. iv.; *Dictionary of Greek and Roman Biography*; General Jochmus, *Notes of a Journey to the Balkan*, 1853; Macgregor, *Commercial Statistics; Frontier Lands of the Christian and Turk*; Ubicini, *Lettres sur la Turquie*, Paris, 1853.)

BULLER, CHARLES, RT. HON., was born in August, 1806, in the city of Calcutta. His father was in the civil service of the East India Company, and belonged to a family which possessed great parliamentary influence in the south of Cornwall, where they had for a long series of years represented West Looe as a nomination borough. Charles Buller was educated at Harrow School, Middlesex, at the University of Edinburgh, and at Trinity College, Cambridge, where he took the degree of B.A. in 1828. He was returned in 1830 as member of parliament for West Looe, and in the following year became a barrister of Lincoln's Inn. He voted for the Parliamentary Reform Bill, which disfranchised West Looe, and in 1832 was returned for the borough of Liskeard, in Cornwall, which he continued to represent till his death in 1848. Mr. Buller, throughout the whole of his parliamentary career, was distinguished for the liberality of his principles, for soundness of reasoning founded on an extensive acquaintance with the details of his subject, and for a liveliness of imagination, which rendered his speeches attractive by sallies of pleasantry and wit. He was from the first a steady opponent of the Corn Laws, advocated triennial parliaments, was against a property qualification for members of the House of Commons, maintained the necessity of national education, and was a supporter of the Poor Law Amendment Act. He early distinguished himself by his speeches on colonisation, and by the ability with which he advocated improved principles and practice in colonial government. When the Earl of Durham was sent out in 1838 as governor-general of Canada, Mr. Buller accompanied him as secretary, and is known to have contributed largely to the Report which was presented to parliament by the Earl of Durham, and published in 1839. After his return from Canada, Mr. Buller commenced the practice of the law, in appeals from the colonies and from Hindustan, before the Judicial Committee of the Privy Council. In 1841 Lord Melbourne appointed him secretary of the Board of Control; and Lord John Russell, after he became premier in 1846, made him Judge-Advocate General, with an understanding, it is said (which however was not realised), that he was to act in some way as colonial minister, though not included in the department. In November 1846 he was appointed a queen's counsel, and in July 1847 was sworn of the Privy Council. Upon the remodelling of the Poor-Law Commission, with a president as head of the board, he was appointed to that office in Nov. 1847. He died in London, Nov. 28, 1848.

Mr. Buller was a ready extemporaneous speaker, but was accustomed, on important occasions, to write out his speeches in their whole extent. He also wrote largely for the periodical press, especially the 'Morning Chronicle' and 'The Globe,' and for the 'Edinburgh Review' and 'Westminster Review.' He also wrote for the 'Colonial Gazette' a series of papers on 'Responsible Government for Colonies,' afterwards published as a small volume.

BUMELLA, a genus of plants belonging to the natural order *Sapotaceæ*. Many of the species are used in medicine. *B. nigra* has a bitter and astringent bark, which is used in fevers. The wood is very hard. *B. retusa* has a milky fruit. The fruit of *B. lycioides* is austere, with some sweetness, and is said to be useful in diarrhœa. The flowers of *B. graveolens* have a heavy unpleasant odour. (Lindley, *Vegetable Kingdom*.)

BUNTINGFORD. [HERTFORDSHIRE.]

BURDOCK, the common name for the species of *Arctium*, a genus of plants belonging to the natural order *Compositæ*. This genus is distinguished by its globose involucre, the bracts terminating in hooked points, and imbricated, the flat receptacle with rigid subulate scales; the fruit compressed, oblong; the pappus short, pilose, and distinct. Two species of this genus are common in Great Britain. *A. majus*, the Greater Burdock, is characterised by its large subcorymbose heads and its cordate ovate leaves, the lowermost of which attain a very large size. *A. minus*, the Lesser Burdock, has small heads, which are racemose. The leaves are smaller than in the last species. They were both described as *Arctium Lappa* by Sir J. E. Smith.

BURNET. [SANGUISORBA; POTERIUM, *S.* 1.]

BURNEY, MISS. [D'ARBLAY, MADAME, *S.* 1.]

BURNTISLAND, Fifeshire, Scotland, a town, royal burgh, and sea-port, in the parish of Burntisland, on the north or left side of the Frith of Forth, is situated in 56° 4′ N. lat., 3° 13′ W. long., about 5½ miles nearly due north from Leith. The population of the royal burgh in 1851 was 2329, of the parliamentary burgh 2724. The burgh is governed by two bailies and ten councillors, of whom one is provost; and unites with Kirkaldy, Dysart, and Kinghorn, in returning one member to the Imperial Parliament.

Burntisland was made a royal burgh in 1568. At the General Assembly which met here in 1601 James VI. took the oath to the Covenant. The town was fortified in the reign of Charles I., and besieged and taken by Cromwell, who repaired and considerably improved the harbour. The town chiefly consists of two parallel streets terminated by the harbour on the west. The harbour is deep and well sheltered. Being now the principal ferry station, the town has much increased of late years. There is a good dry dock; and on the eastern pier is a lighthouse, the light of which may be seen a distance of seven miles. Burntisland formerly possessed a considerable trade. About 1656 there were twelve ports, including St. Andrews and the now extensive port of Kirkaldy, which were subordinate to Burntisland. For many years past its traffic has been confined to that arising from the curing of herrings and from distilleries in the neighbourhood. Ship-building is carried on. There is daily steam communication with Granton on the opposite coast, and the Edinburgh and Northern railway opens up a direct communication with the whole north-east of Scotland, the passage across the Frith being effected here by a floating railway.

The parish church was built in 1592. There are also a Free church, and chapels for Episcopalians and United Presbyterians.

North from the town, on the summit of Dunearn Hill, an eminence rising 695 feet above the sea, is a level space surrounded with a number of loose stones, which has been called Agricola's Camp, and supposed, very improbably, to mark the site of a Roman encampment. On another eminence overhanging the harbour stands Rossend Castle, erected about the 15th century.

BUTE, one of the islands which compose the county of Bute, Scotland, is situated in the Frith of Clyde, between 55° 42′ and 55° 56′ N. lat., 4° 58′ and 5° 10′ W. long., distant about six miles from the opposite mainland of Ayrshire, and about half a mile from Argyleshire, from which county it is separated by a narrow and crooked but picturesque channel called the Kyles of Bute. The population of the island in 1851 was 10,661. The island is about 16 miles long, and varies from three miles to four miles in breadth. To the north it is elevated, rocky, and barren; the central part is diversified by hills, valleys, and fertile tracts; and the south end is hilly and divided from the rest of the island by a low and sandy plain called Langal-chorid. The coast is rocky and indented by bays. The soil of the island consists of clay, loam, and sand, with moss lying on gravel. The greater part of the arable land is inclosed and cultivated; barley, oats, potatoes, turnips, and the artificial grasses are all cultivated with success. About the middle of the island are three small lakes—Loch Fad, Loch Ascog, and Loch Quein. The climate though damp, is mild and temperate, and the island is much resorted to by invalids, Rothsay being one of the favourite watering-places of the Clyde. The minerals are limestone, freestone, slate, and some indifferent coal. Beds of coral and shells, of considerable thickness, are found in several places half a mile from the sea-coast.

Bute island contains many remains of antiquity. Dungyle, or Dunnagoil, a vitrified fort, attributed to the Danes or Norwegians, and situated on a lofty crag in the south-west part of the island, is an object of interest and curiosity. In the southern extremity of the island are the ruins of an ancient chapel. Not far from the ruins are the remains of a circular erection about 30 feet in diameter and 10 feet high, known as the 'Devil's Cauldron;' the object for which it was erected has not been ascertained. Bute, and the adjacent islands, were long subject to the Norwegians. Haco of Norway in 1263 took possession of Bute, but after his defeat it returned to the allegiance of the King of Scotland. Edward of England held it till 1312, when it fell into the possession of Bruce. Robert III. and James III. made the island their occasional residence. It was garrisoned by Cromwell, and was the scene of the Earl of Argyle's unfortunate landing in 1685.

(*New Statistical Account of Scotland.*)

BUTEO, a genus of Birds belonging to the order *Raptores* and the family *Falconidæ*. It includes, according to Yarrell, two British species, *B. vulgaris*, the Common Buzzard, and *B. lagopus*, the Rough-Legged Buzzard. [FALCONIDÆ.] Various other species of the *Falconidæ* have been included under this generic name. (Yarrell, *British Birds.*)

BUTYRONE. [CHEMISTRY, *S.* 2.]

BUTYRYLE. [CHEMISTRY, *S.* 2.]

BYRSONIMA, a genus of plants belonging to the natural order *Malpighiaceæ*. The bark of the species is astringent, and is used extensively for tanning in the Brazils. The wood of some of the species, especially *B. verbascifolia*, is of a bright red. The bark of *B. crassifolia* is used in fevers. *B. crassifolia* is one of the thousand remedies for rattlesnake bites. It is called Chapera Manteca. The Alcornoco Bark is the produce of *B. laurifolia*, *B. rhopalæfolia*, and *B. coccolobæfolia*. The acid and astringent berries of *B. spicata* are said to be good in dysentery. (Lindley, *Vegetable Kingdom.*)

BYTOWN, Canada West, the chief town of Carleton County, is situated in a very beautiful part of the country on the Ottawa, near the junction of the Rideau Canal with that river, in 45° 20′ N. lat., 75° 42′ W. long.; distant 126 miles N.N.E. from Kingston, and 284 miles N.E. by E. from Toronto: the population of the town in 1851 was 7760. The lower town, which is the older part, is that in which business is generally carried on: the upper town is of more recent erection; it is situated about half a mile distant on a more elevated site, and consists chiefly of private residences. Considerable improvement has taken place in the appearance of Bytown of late years. Several handsome stone buildings have been erected. The town contains places of worship for Episcopalians, Presbyterians, Wesleyan Methodists, Baptists, and Roman Catholics; several schools, a commercial reading-room, a mercantile library association, a court-house, barracks, and a jail. Bytown is supported chiefly by the lumber trade, a term applied to the system of floating large rafts of rough timber down the rivers of America to the depôts and ports in the lower parts of their course. Timber cut on crown-lands and brought down the Ottawa River is measured at Bytown, and the owner gives bond to pay the duties at Quebec. The value of timber brought down the river in one year, 1844, was estimated at 341,756*l.* About three-fifths of the whole being cut on crown-lands was liable to duty, amounting to about 24,000*l.* Fairs are held at Bytown in April and September. Steamers ply between Bytown and Grenville on the Ottawa, and between Bytown and Kingston on the Rideau Canal.

C

CACHELOT. [WHALES.]

CACODYL. [CHEMISTRY, *S.* 1.]

CADDICE, CADDIS-WORM, or CAD-BAIT, the common name for the larvæ of the species of *Phryganea*, which reside in the water, in cases which they form of various substances, such as bits of stick, grains of sand, small stones, shells, &c., which are held together by a silken thread secreted in their bodies in the same manner as in the silk-worm. The case acts as a protection to the larva, and it is capable of drawing in its head or putting it out, according to circumstances.

CADET, LIQUOR OF. [CACODYL, in CHEMISTRY, *S.* 1.]

CAHIR. [TIPPERARY.]

CAISTOR. [LINCOLNSHIRE.]

CALAMOPHILUS, a genus of Birds belonging to the family *Paridæ* and the tribe *Incessores*, sub-tribe *Dentirostres*. *C. biarmicus* of Yarrell is the *Parus biarmicus* of Pennant and other writers. This bird is common in Great Britain, and is known by the name of the Bearded Tit. [TITMICE.] (Yarrell, *British Birds*.)

CALEDONIAN CANAL, a connected series of lakes and canals extending through Glenmore, or the 'Great Glen of Albion,' and connecting the Western Ocean with the North Sea. In 1773 the trustees for forfeited estates employed the celebrated James Watt to report on the practicability of a canal from sea to sea through Glenmore. Watt's report was most favourable; but the forfeited estates having been soon after restored to the families to which they had formerly belonged, the office of trustee was abolished, and the project dropped. In 1802 the scheme was revived, and government employed Mr. Thomas Telford, the civil engineer, to resurvey the district, and to report the result of his investigations. This report was in favour of the construction of the canal, and the work was immediately proceeded with under Mr. Telford's direction. Operations were commenced in 1803. In 1820 the eastern division of the canal was opened for navigation. The whole line was opened towards the close of 1823. The Caledonian Canal commences on the south-west on the shore of Loch Eil at Corpach near Fort William, in 56° 50′ N. lat., 5° 12′ W. long., and joins Loch Lochy by a cutting 8 miles in length; a short cutting of about 2 miles connects Loch Lochy with Loch Oich; a canal nearly 6 miles long continues the navigation from Loch Oich to Loch Ness from the north-east end of Loch Ness a canal of about 7 miles in length continues the passage to Clachnaharry near Inverness; whence by another short artificial cutting, it opens into the Moray Frith on the shore of Loch Beauly, in 57° 26′ N. lat., 4° 15′ W. long. The length of this communication between the west and east seas is in all about 60 miles, of which rather more than 37 miles are through natural lochs or lakes, and about 23 miles through artificial cuttings. The summit level is at Loch Oich, which is about 94 feet above high water on the east coast at spring tides. There are 28 lochs in the range, 14 being to the west of Loch Oich, and 14 to the east. The locks are about 170 feet in length and 40 feet in width, the rise at each lock being 8 feet. The width of the canal at water surface is 120 feet; at the bottom 50 feet; the depth of water is 17 feet. There were considerable engineering difficulties to be overcome in the construction of the canal. The object proposed in this national work was the avoidance of the tedious and often dangerous voyage by the Orkneys and Cape Wrath. From Kinnaird's Head on the east coast to the Sound of Mull on the west coast the passage by the Orkneys and Cape Wrath is about 500 miles, while by the inland navigation the distance is only 250 miles. By the Cape Wrath passage also many shipwrecks had occurred. A large amount of public money has been expended on the works. The returns have been very small in comparison with the cost; one chief source of expected revenue was indeed cut off by the act of the legislature in imposing duties upon the import of timber from the Baltic, in order to encourage the employment in this country of timber of Canadian growth. For a number of years after the opening of the canal, vessels were often detained in the lochs by calms and contrary winds: since 1847 this has been remedied by the establishment of steam-tug vessels, causing a considerable increase in the number of vessels using this line of navigation. The amount of public money granted by Parliament at various periods from 1803 to 1857 was 1,242,387*l.* 8*s.*; the amount received for canal dues, shore dues, &c., to 30th April 1857, was 95,048*l.*; for towages, 8152*l.* 6*s.* 4*d.*; for rent of houses, stables, lands, materials sold, &c., 11,318*l.* 15*s.* 3*d.*; for interest on Exchequer bills, interest from bank, &c., 11,767*l.* 16*s.* 7*d.* The cost of construction, repairs, management, law expenses, shipping, roads, &c., from 20th October, 1803, to 30th April, 1857, was 1,346,562*l.*; cost and maintenance of steam-tug vessels, 25,452*l.* The canal rates are in most cases one farthing per mile per ton for the whole passage, the rate for towage being similar. The charge on steam-vessels passing wholly through the canal is 2*s.* per register ton, whether laden or unladen. In 1848 the commissioners, with the view of inducing a greater number of the Baltic traders to use the passage by the canal, reduced the dues on trading sailing vessels exceeding 125 tons register to 1*s.* per register ton for the through passage; and to encourage the traffic connected with the fisheries, the towage rates on vessels laden with herrings or salt were reduced by one half. The opening of the Caledonian Canal has given rise to an increased intercourse and traffic between Inverness and Glasgow, and generally between the northern and western districts of Scotland. Much damage was sustained by the works of the canal in December 1848 and January 1849 by a severe storm and heavy rains. The damage was repaired with great skill and promptitude, and at less cost than was anticipated, under the direction of Mr. Walker, consulting engineer to the commissioners, and Mr. George May, their resident engineer. To cover the expense, Parliament granted 10,000*l.* to the commissioners in 1849.

(*New Statistical Account of Scotland; Fifty-Second Report of the Commissioners for Making and Maintaining the Caledonian Canal; Life of Telford, edited by* Rickman.)

CALENDULA. [ALAUDINÆ, *S.* 2.]

CALHOUN, JOHN CALDWELL, one of the most influential of the recent statesmen of America, was born on the 18th of March, 1782, at Abbeville, in South Carolina. His father, Patrick Calhoun, was by birth an Irishman, but he emigrated to America early in life, settled in Carolina, and took an active part on the American side during the war of independence. John C. Calhoun graduated with distinction at Yale College in 1804; and, having completed his legal studies in Connecticut, returned to his native place in 1807, to enter upon the practice of his profession. He was elected the following year a member of the South Carolina House of Representatives, where his clear vigorous intellect soon obtained for him considerable notice. In 1811 he was sent as representative to the United States Congress, and the rest of his life was spent at Washington. During the discussion of the important measures which in the course of the next five years excited the public mind, Mr. Calhoun played a prominent part, and his fervid eloquence, eagerly defending and stimulating the popular war-cry, won for him a commanding position. On Mr. Monroe's election to the presidency of the United States in 1817, he appointed Mr. Calhoun his secretary of war, a post he retained during the eight years of Mr. Monroe's tenure of office. His administration was marked by energy and judgment, and secured his position as one of the ablest public men of his time. On the next election, 1825, he was named as a candidate for the presidency, but withdrew his claim, and eventually he was chosen vice-president. To this high office he was re-elected in 1829, when General Jackson succeeded Mr. Adams as president; but he differed greatly from Jackson in policy, especially on the Tariff and Bank Charter questions; and in 1831 he resigned the vice-presidency, and was elected by South Carolina to the Senate of the United States. From the end of his term of six years he remained in retirement, until President Tyler, in 1843, appointed him secretary of state, an office he held till the election of President Polk in 1845. In that year he again became the representative of South Carolina in the senate. He had now come to be regarded as the great leader and representative of the southern states in Congress, and no man was listened to with greater attention by all parties. An intense and fervid republican, he was yet eminently conservative in spirit, a staunch defender of all southern rights, and the inflexible supporter of the 'institution' of slavery. In general and international politics, he commonly took the popular, or, as it is usually termed, the patriotic side. He died March 31, 1850. Many of Mr. Calhoun's speeches were printed as separate publications about the time of their delivery: and his collected 'Works' are now in course of publication at Charleston and Colombia.

CALIDRIS, a genus of birds belonging to the order *Grallatores* and the family *Charadriidæ*. It has the following characters:—Beak as long as the head, straight, slender, flexible, compressed at the base, with the point dilated and smooth; nostrils basal, lateral, narrow, longitudinally cleft in the basal furrow, which extends to the smooth point of the beak; wings of moderate length, pointed, the first quill-feather the longest; legs of mean length, naked above the tarsal joint; feet with three toes, all directed forwards, with a very small connecting membrane at their base. Gould, in his 'Birds of Europe,' regards the Knot (*Tringa canutus*) as a species of *Calidris*. With this exception, the only British bird which is a species of this genus is *C. arenaria*, the Sanderling. It is an inhabitant of most of the shores of Great Britain and Ireland. It obtains its food by probing the moist sands of the sea-shores, from which it obtains minute *Mollusca*, shrimps, annelides, &c. It visits the shores of Sweden, and is stated to breed still farther north. Sir John Richardson says it breeds on the coasts of Hudson's Bay. It does not appear to breed in the British Islands. (Yarrell, *British Birds*.)

CALIFORNIA, STATE OF, one of the United States of North America, is bounded N. by the United States territory of Oregon, N.E. by that of Utah, S.E. by that of New Mexico, and S. by the Mexican territory of Lower California. Its western boundary is the Pacific Ocean, along which it extends from 32° to 42° N. lat., its eastern boundary is defined by a line which runs along 120° W. long. from 42° to 39° N. lat., thence in a south-eastern direction till it intersects the Rio Colorado in 35° N. lat., whence it is continued down the mid-channel of that river to its month in the Gulf of California, 32° N. lat. The area is 160,000 square miles. The estimated population in 1856 was 507,067. The tract of country which now forms the State of California was, until lately, the coast section of the territory of Upper (Alta) or New (Nueva) California, the north-western part of the Mexican republic. It was ceded to the United States of North America by treaty in February 1848, and has since been admitted into the Union as a sovereign state. The extraordinary increase of its population will be seen by the following statement:—In 1802, Humboldt, from materials supplied by the padres at the head of the missions, estimated the entire population of Upper California, which included, besides the present State of California, the territory of Utah and (in part) that of New Mexico, at 16,862, of whom 15,562 were 'converted Indians.' The official return of persons resident in the missions of Upper California in 1823 was 23,105, of whom 18,763 were converted Indians. After the suppression of the missions the Indians became more scattered, and no official statement of the population was made. The first federal census after the cession of California to the United States was in 1850, when the State of California had a total population of 117,538. In 1852 a census was taken by the State authorities, when the agents' returns gave the population as 264,435; but the Secretary of State, in his official Report, states that all the census agents declare their inability to obtain the numbers of "the whole population of their respective counties," and he thinks it necessary, in order to render an approximately correct statement, to add one-sixth to the number returned. He therefore gives 308,507 as the population in 1852: of whom 210,858 were whites, little more than 30,000 being females, and 105,344 being citizens over 21 years of age; 2090 were negroes, of whom the females were under 300; 572 mulattoes; 33,539 domesticated Indians: and 59,991 foreign residents, of whom about 25,000 were Chinese. California sent in 1857 two members to the Congress of the United States, and like each of the other states two members to the Senate.

Coast-line, Surface, Hydrography.—The State of California owes its characteristic features to two great ranges of mountains, the Sierra Nevada and the Coast Range, which traverse it from north-west to south-east, having between them the splendid valley of the Sacramento and the Joaquin; on the eastern side wide sandy plains, and on the western the narrow slip of coast. The coast of California is generally rugged and precipitous. Beginning at its southern extremity, it makes a bold semi-circular sweep to the north-west as far as Point Concepcion. Off this part of the coast there are several small islands and rocks, and the coast-line is indented by several bays and harbours. The only valuable one of these is San Diego Bay (32° 41′ N. lat), which has an excellent natural breakwater at its mouth, formed by a narrow strip of shingle beach projecting into the sea. The bay itself is wide and spacious, and forms an excellent, though at present little-used, harbour. The harbours of San Pedro and Santa Barbara are also available for craft of considerable burden. From Concepcion Point the coast bears north-north-west to Point Pinos, the southern extremity of Monterey Bay, one of the safest and most capacious harbours on this coast; it is said to be capable of containing at one time the navies of the world. From Monterey Bay the coast continues as before for about 70 miles, in a direct line, to the almost unrivalled bay of San Francisco. The entrance, which is nearly in the centre of San Francisco Bay, is only about a mile wide, but the bay itself opens out for more than 30 miles both on the right and left; its entire length is 70 miles, with an average breadth of 8 miles, and it has a coast of 275 miles. By projecting points of land, several small inner bays are formed, the principal being San Pablo and Suisun bays. It is land-locked on every side, and quite safe within, but a bar at the mouth renders the entrance somewhat dangerous. This harbour is the natural outlet of the valleys of Sacramento and Joaquin, with their wondrous mineral riches and vast agricultural capabilities. Beyond San Francisco Bay is Port Bodega, where was formerly a Russian station. From thence the coast continues in the same north-west direction, but less broken than before, to Point Delgado, beyond which is the bold headland of Cape Mendocino, 40° 21′ N. lat., which forms the southern point of the Bay of Trinidad, in which the coast of California terminates.

The mountain masses which constitute the peninsula of Lower California extend undivided into the State of California as far north as the snow-capped peak of St. Bernardino, 34° N. lat., where they divide into the two great ranges already mentioned. These ranges both run in a north-western and generally parallel direction. The eastern range, called the Sierra Nevada, or Snowy Range, is by far the loftiest, many of its peaks being above the line of perpetual snow: the Saddle Peak is 7200 feet high, the Table Mountain 8000 feet, the Butte 9000, Mount St. Joseph above 10,000, and Mount Shasté at the northern extremity of the range (41° 34′ N. lat.) 14,390 feet above the sea. This range is traversed by few and those very elevated passes. North of 39° N. lat. its slopes, especially on the western side, have vast forests of pine, and lower down of oak. The distance of the Sierra Nevada from the coast averages about 200 miles. The Coast Range runs at a short distance only from the coast, to which it is generally nearly parallel. Its usual height varies from 2000 to 3000 feet: its highest peak, Monte Diavolo, at the head of San Francisco Bay, is 3700 feet above the sea. This range is broken near Monte Diavolo by the united Sacramento and Joaquin rivers; decreases in altitude towards the north; and finally re-unites with the Sierra Nevada near Mount Shasté. From this point northward the surface of the country is wholly mountainous and little known; the Sierra Nevada with its offsets and connected ranges occupying the entire breadth of northern California, and extending northward till it is lost in the cascade Range of Oregon. Between the highest mountains of the Sierra Nevada and the great valley is a line of lower mountains; and from both the Sierra Nevada and the Coast Range lesser lateral ranges and offsets diverge throughout California, forming numerous narrow valleys and ravines.

The basin included between the two main ranges, though really one geographical formation, bears the names of the Sacramento and Joaquin valleys, from the rivers which rise respectively at its northern and southern extremities, unite near the centre of the valley, and flow into San Francisco Bay. This fine valley is upwards of 500 miles long and 50 miles wide. It has evidently at some remote period been the bed of a vast lake of which the Sierra Nevada and Coast Range formed the margin. The water of this great lake has been drained by some convulsion of nature having broken a passage through the Coast Range at San Francisco Bay. At the southern extremity of the valley are the Tulare (Bulrush) Lakes, which during the wet season extend above 100 miles in length, but in the dry season have little water, and are fordable in many places. Within the last year or two a commencement has been made towards embanking these lakes and draining the rich tract of country hitherto subject to the annual floods. The soil and climate of this great valley vary considerably, but a large part of it is very fertile, including most of the eastern side, which is intersected by numerous streams, along which the land is extremely rich and productive. The surface of the valley is greatly diversified, being broken into rugged hills at its northern end, and in many places along its eastern side by well-wooded spurs from the Sierra Nevada. Towards its southern end by the Tulare Lakes, and along the banks of the two great rivers, it is low and level, rising gently at some distance from the rivers into undulating slopes, which break into low hills as they approach the bases of the mountains. The richest and most picturesque part of this fine valley is that central portion of it which incloses San Francisco Bay and the delta of the Sacramento.

The coast district west of the Coast Range—almost the only part of California inhabited previous to the American occupation, but now by no means the most populous part of the country—is full of narrow fertile valleys, the seats in former days of the mission stations, around which the industry of their occupants had caused most of the cereals and fruits of temperate climes to flourish abundantly. Along a good part of the coast the mountains come close down to the sea; but along a still larger portion there extends a tract of low sand-hills, which in some places reach many miles inland. The country east of the Sierra Nevada, and west of the Rio Colorado, comprising the remaining portion of California, is mostly level, and a good part of it is sandy and barren. It is however but little known, owing mainly to the superior attractiveness of the mountains and great valleys, and partly to its being occupied by hostile tribes of Indians. It is believed that while much of it is of comparatively small account, there are very extensive tracts of valuable and hitherto unappropriated land. The country along the Colorado is supposed to have a rich alluvial soil; but near its entrance into the Californian Gulf the country about it is dry and barren, and the climate extremely hot.

The two most important rivers of California are the Sacramento and the San Joaquin: the value of the Colorado remains to be fully ascertained. The *Sacramento* rises at the northern extremity of the valley of the same name; its head-streams issuing chiefly from Mount Shasté or some of its spurs. Its course throughout is generally south, and it receives on its left bank a great number of affluents from the Sierra Nevada. Most of these are mere mountain torrents; but several of them, as the Feather, the American, Cosumes, and the San Juan rivers are of some importance. Near Monte Diavolo the Sacramento receives the San Joaquin, and the united river turns abruptly to the west, and soon after expanding to a considerable width opens into San Francisco Bay. The entire length of the Sacramento is about 300 miles; its width for many miles above its junction with the Joaquin varies from 200 to 300 yards, and it is navigable at all seasons up to Sacramento city, 150 miles from its mouth. The Sacramento is subject to great floods during the wet season, and on the melting of the snow on the Sierra Nevada. The *San Joaquin* issues from the Tulare Lakes at the southern end of the great valley. Its course is north and north-west, and like the Sacramento it receives numerous tributaries from the Sierra Nevada. During the wet season the San Joaquin is greatly augmented, and apt to flood much the lowlands on its borders. It is navigable for vessels drawing 9 feet of water up to Stockton, 3 miles above its junction with the Sacramento, and for vessels under 15 tons up to the Tuolumne River. The San Joaquin abounds in fine fish, and the taking and curing of salmon afford employment to many persons. The banks of the river and its tributaries are generally extremely fertile, and agriculture is pursued with much diligence. The country watered by the San Joaquin and its affluents is becoming rapidly settled. The *Colorado*, the lower part of which drains the south-eastern portion of California, and which falls into the Gulf of California, belongs rather to New Mexico, under which it is noticed. Except during the wet season, this river, though draining a vast extent of country, is said to have a depth of only 6 feet of water for some distance above its mouth: that part of California which lies in its basin is almost unknown. Along the coast are numerous rivers which rise in the Coast Range and after a short course fall into the Pacific. Among these are the San Buenaventura, San Felipe, San Pedro, and the Smith; many of them are of considerable value for irrigation, and may at some future period be rendered available for mechanical purposes, but none are navigable.

Numerous roads have been formed in the state since its cession by Mexico in addition to those previously existing, and many bridges have been built and ferries established across the principal rivers; but the communications of the state are of course yet very incomplete. Of the railways in contemplation the most important is the great line from the Mississippi to the Pacific Ocean. The only line completed in California is that of the Sacramento Valley, 22 miles, the receipts of which in 1856 were 1,254,639 dollars.

Geology, Mineralogy, &c.—The Sierra Nevada, with its connected ranges, has for its substratum schistose or talcose slate; quartziferous rocks are the prevalent strata covering the slate. In many places a fine white quartziferous granite occurs. In the Coast Range quartz also abounds. Sandstone is found throughout the lower ranges of hills. Bituminous coal is worked in the neighbourhood of San Francisco Bay; it has also been found about San Diego Bay, and is believed to occur in various localities.

Sir Francis Drake, who visited California, which he named New Albion, in 1578, received such reports of the existence of gold from the natives that he declared it to be his conviction that there was "no part of this country wherein there is not some special likelihood of gold." Yet though his statement was often repeated in the subsequent collections of travels, and occasionally in geographical works, no search seems to have been made for the precious metal. The remarkable discovery of the auriferous wealth of California was at last made by mere accident in December 1847, by a Mr. Marshall, who was engaged in erecting some saw-mills on the estate of Captain Suter, a wealthy American settler on the Sacramento River. The effect of the publication of this discovery was most extraordinary. The rush of adventurers to the 'diggings,' and of immigrants into the country was quite without parallel in the history of the world. California was at this time occupied by American citizens, and its formal cession soon after to the United States happily placed it in the possession of a people as distinguished for capacity of self-government as for energy, instead, as it had hitherto been, of a singularly indolent and incapable race; thereby affording as it were opportunity for the full development of its marvellous capabilities, and at the same time providing against the frightful anarchy which might else have ensued. As it was, towns and cities as they were termed, though the houses were commonly only of wood or canvass, sprang up with a rapidity hitherto unknown; the magnificent San Francisco Bay was for the first time alive with vast fleets of merchant vessels, crowded with anxious adventurers from almost every part of the world. All ordinary labour was neglected in the rage for gold seeking, which seized indiscriminately on all classes, and the value of food and labour rose to almost fabulous prices. The quantity of gold discovered continued for a while to increase even beyond the proportion of new searchers for it. By the end of the year 1851 it was estimated that gold to the amount of nearly 150 millions of dollars had been found. No correct estimate is possible, as no official account has been taken of the gold obtained, but from what appear to be unexaggerated estimates the quantity found in 1849 was valued at 40 millions of dollars, and it is believed that the average yearly find has since increased to between 50 and 60 millions of dollars. The quantity of gold-dust and coin manifested and shipped on board steamers and sailing-vessels from San Francisco during 1852 was 46,256,574 dollars; but this does not show the entire amount exported, as large quantities are taken abroad in ships without being entered on the manifests. If 10 millions be added for this the total quantity shipped in 1852 from San Francisco would be about 56 millions of dollars. The quantity received at the mint of the United States and its branches up to September 30, 1852, was 136,747,935 dollars. Since that date an Act of Congress has been passed for establishing a mint in California. The total shipments of gold from San Francisco from April 11, 1849, to Dec. 31, 1856, inclusive, were valued at 322,393,856 dollars.

What is known as the Gold Region of California extends for some 500 miles in length, with a breadth of from 40 to 50 miles, following the range of the Sierra Nevada. It occupies the lower mountains of that range lying between the central mountains and the valley of the Sacramento and the San Joaquin. These mountains average from 4000 to 5000 feet in height, and the gold is generally found either in the gulleys and ravines, or in the sandy beds of the mountain streams on their way towards the two great rivers. The geological formation of this region is very similar to that of the gold mountains of Australia and the Ural Mountains of Russia. [AUSTRALIA, *S.* 2.] Wherever the gold has been found *in situ* it has been in connection with quartz; and the water-worn gold found in the debris of the rocks and the sands of the rivers in like manner shows, by its frequently being attached to small particles of quartz, that it was derived from a quartzose bed. The main gold region, as we have said, is the lower mountains on the western side of the Sierra Nevada, but gold has been also found in the loftier central heights of the Sierra Nevada, and on its eastern side. Gold is likewise reported to have been found in the Coast Range, especially in the narrow valleys on its western side, and also in the connected ranges. Indeed Drake's words seem now singularly applicable; for there appears to be hardly any "part of this country where there is not special likelihood of gold."

Nor is gold the only important metal which abounds, though it is the only one to which much attention is at present given. A mine of quicksilver has long been worked in the neighbourhood of San José, in which the cinnabar from which it is produced lies near the surface and is easily procured. But the metal is believed also to be widely spread and in valuable veins in other parts of the state. Silver ore of great richness has been found at Monterey and elsewhere. Copper, iron, and other of the more important metals are also believed to abound. Coal is profitably worked at San Francisco, and is supposed to exist in extensive beds in other parts.

Botany and Zoology.—The botany of California is of a peculiar and interesting character. It contains among other striking plants some noble pines, especially one called from its discoverer, the Douglas pine (*Pinus Douglasii*), which occurs on the mountains about San Francisco Bay, and grows frequently to the height of 240 feet, with a circumference at the base of the trunk of 60 feet. The cones are eaten by the Indians. The *P. Sabiniana*, *P. Lambertina*, and *P. nobilis* are of less magnificent but still very large dimensions, and great beauty. The live oak (*Quercus virens*) grows to a considerable size on the lower hills of the west side of the Nevada, and on it Fremont found unusually large quantities of mistletoe. The white oak is common in the valleys. The maple, ash, beech, and chestnut are the other more usual denizens of the Californian forests, which however do not generally extend south of 39° N. lat. Two or three kinds of *Arbutus* abound on the banks of the rivers and the margins of the forests. The *Scilla esculenta* grows everywhere along the coasts; its root is the quamash of the Indians, with whom it is a common article of food. The fibres of the *Helonias tenax* are made by the natives into a very tough cord for snaring deer, &c.; and the amole and samate are used by them for soap. Large numbers of *Polemoniaceæ*, especially some beautiful specimens of the *Leptosiphon* and *Gilia;* some curious plants belonging to the genera *Nemophila* and *Emmenanthe ;* several new genera of poppies, *Eschcholtzia*, lupines, *Calochortus*, *Cyclobothra*, *Calliprora*, *Brodiæa*, &c., stamp the vegetation with a character quite unlike that of any other part of America.

The black bear, the grizzly bear, and the barren-ground bear, the racoon, American badger, glutton, ermine, weasel, mink, martin, and skunk are common in many parts; as are also the beaver and the musk-rat about the mouth of the Sacramento: all of these are much sought after for their skins. Several kinds of wolves, foxes, and lynxes abound in the denser forests of the north, where they prey on the numerous deer and other animals which frequent those regions. Of the deer, the moose, the black-tailed, and the long-tailed or jumping deer, the elk, and the prong-horned antelope (*A. furcifer*) are the most plentiful. Mountain sheep abound. The bison is only occasionally met with.

Among birds the first place is due to the great Californian vulture (*Sarcoramphus Californianus*), which is inferior only to the South American condor in size, and very similar to it in its habits. The black vulture, the turkey buzzard, the golden eagle, the bald eagle, the peregrine falcon, the jer falcon, the osprey, and several other hawks and connected species as well as owls, are more or less common. Most of the ordinary European singing birds, swallows, woodpeckers, &c., or birds to which similar names have been given, also abound. The humming-bird is common in the south. Grouse are said to be more numerous and of more various kinds than have been found in any other country. The bays and inlets of the coast swarm with swans, geese, ducks, curlews, and most of the other ordinary wading and swimming birds. Large numbers of white pelicans frequent the coast, and albatrosses are sometimes shot, measuring 10 or 12 feet across the wings.

The coasts and rivers of California alike yield an astonishing number and variety of fish. In some of the rivers as many as 3000 salmon, many of them weighing from 20 to 30 lbs., are often taken in a single day. Salmon-trout and trout also largely abound. Sturgeons are sometimes taken in the mouths of the rivers measuring 8 or 10 feet long and weighing nearly 500 lbs. Mackerel, pilchards, and sardines swarm off the coast. The halibut, skate, turbot, bonito, &c. are caught. Oysters of excellent flavour and most other shell-fish are found. But though fish is so abundant, the fisheries are at present little heeded.

Climate, Soil, Agriculture, &c.—California has a dry and a wet season; the dry season lasting from about the middle of May to September or October, the wet season setting in early in November and lasting till May. But there are considerable variations, both in the temperature and in the amount of moisture in different parts of this extensive tract of country. In its northern part, north of 39° N. lat. for example, the air during the dry season is much less parched and rains occur earlier than in the southern districts. Along the coast the climate is much more temperate than in the great valley; while east of the Sierra Nevada the air is excessively hot and parching. In summer the coast is visited by heavy fogs, and a cold wind sets in regularly towards noon from the Pacific, and continues to blow with increasing force and keenness till late at night. Some few miles inland the cold is modified, and the temperature becomes equable and agreeable. Throughout the great valley of the Sacramento and San Joaquin, the mid-day heat is so great as to render labour in the open air everywhere unpleasant, and in many places impracticable.

The soil along the great valley is generally extremely rich. This valley has evidently been at some remote period the bed of a vast lake, and the rich alluvial soil only needs judicious irrigation to render it capable of producing almost every variety of crop. The banks of the rivers however require proper embankments to prevent the present often destructive floods, and to permit the full development of its agricultural capabilities. Tobacco, rice, maize, and most of the plants except cotton which grow in the warmer parts of the United States, flourish in the sheltered lateral valleys connected with this principal valley, while in the main valley itself most of the cereals produce extraordinary crops, and grapes, peaches, and nearly all other fruits of a moderately warm climate thrive admirably. The grasses are luxuriant and nutritious, affording excellent pasturage for cattle. North of 39° N. lat. are extensive forests of pine and oak. The valleys along the coast produce all the cereals, and all or nearly all of the fruits and vegetables of the temperate and colder parts of Europe. Onions are grown in large quantities; the produce from nine counties in 1852 was returned at 5,553,655 lbs. Tomatoes are extensively cultivated in parts of the great valley; 1,039,800 lbs. were raised in 1852 in Sacramento county alone, and in the same county 385 acres were planted with melons. In the county of Santa Barbara, on the southern part of the coast, 1370 barrels of olives were gathered; and in this and the adjoining county of Los Angeles 73,462 gallons of wine, and 73,056 gallons of brandy were made. Agriculture has however hitherto been comparatively neglected, but as more attention is being paid to it the various capabilities of the soil are becoming more apparent, and there can be little doubt that California is destined to take high rank as an agricultural country.

It is usual in taking the census of the various states of North America to ascertain the quantity and value of the various productions. In the state census of California for 1852 these returns are very incomplete, but they were sufficient to enable the Secretary of State to "take a comparative view of the position of California in reference to other states of the Union," which is at once so curious and interesting that it may be worth while to quote a few of the items. In barley California surpasses every other state in the Union except New York, and already raises half as much as is produced in the whole Union besides: in oats it cultivates more than three fourths of its sister-states; in wheat it surpasses ten of the states; of maize it produces less than any other; in potatoes it stands next to New York, and grows one-fifth of the quantity produced by the rest of the Union; in beans it surpasses nine of the states; in hay, though only half of the counties made returns, it surpasses nine states; and in fruit it exceeds all the states in variety, and one-half in quantity. In the number of horses it exceeds 15 of the states; of mules 26; of milch-cows 12; of work-oxen 8; of sheep 4, and of swine (though the returns of both these are very imperfect) 3. In live-stock it surpasses 22 of the states. In trade and merchandise it already exceeds half of the states. The number of horses returned in the state in 1852 was 64,773, mules 16,574, cows 104,339, oxen 344,457, sheep 82,867, hogs 38,976, poultry 96,230—of the last three the returns are from only 20 counties.

The vast and rapidly increasing extent of the commerce of the State of California, is partly shown by the statement of the number and tonnage of the vessels which entered and cleared at San Francisco in 1852:—

Entered—Sailing vessels	876	of	326,138 tons.
Steamers . .	127	„	118,876 „
Total .	1003		445,014

Of these, 40 vessels of 18,286 tons burden were British, and 594 vessels of 317,262 tons burden were American.

Cleared—Sailing vessels	1333	of	356,092 tons.
Steamers . .	158	„	127,047 „
Total . .	1491		483,139

Of these, 1121 vessels of 361,166 tons burden were American. In 1849 the tonnage of the vessels entered at San Francisco amounted to 313,351 tons, of which 247,417 tons belonged to the United States. The number of passengers arriving at San Francisco in 1849 was 41,709. In the year ending December 28, 1852, there arrived 64,190, of whom 5223 were females; and there departed 22,946, of whom 390 were females.

Of the manufactures we have no very exact account. At present, owing in a great measure to the high price of labour and the superior demands of other branches of industry, the articles manufactured are chiefly such as cannot be profitably imported. Bricks for example are now made in immense quantities to meet the enormous demand for new buildings: the county of Marin alone reported to the census agents the manufacture of 1,500,000 bricks a month during 1852, of the value in the year of 360,000 dollars; the total population of Marin county during the same year was only 1036.

Divisions, Towns, &c.—The state is divided into 35 counties. The original capital of the state was San José, next Vallejo, afterwards Benicia; it is now Sacramento City. The chief town is San Francisco [*S.* 2], on the bay of the same name; and next in importance to it is Sacramento City [*S.* 2], the capital of the 'diggings.' Numerous other towns and 'cities' have sprung up in various parts of the state, but most of them are built only of wood, or even canvass, and many of them disappear almost as rapidly as they arose. The following are among the more important and may require a brief notice:—

Stockton, on the Stockton Slough or Canal, formed by the junction of the Sacramento and Joaquin rivers, 100 miles E. from San Francisco by water, was founded in 1848. Population about 3000. It is the port of the southern mining district and of the valley of San Joaquin, and is likely to remain one of the first towns in the state. Vessels drawing 9 feet of water can discharge their cargoes alongside the shore. Constant steam communication is maintained with San Francisco. At present there is no public building of any consequence except an asylum for the insane. *San José*, population 1200, the original capital of the state, is pleasantly situated near the south extremity of San Francisco Bay about 50 miles S. from San Francisco city. It has some trade, but is chiefly agricultural. Near this town is the principal quicksilver mine. *Vallejo* is situated on the Napa Strait, 25 miles N.N.E. from San Francisco. It is merely an agricultural village. *Benicia* is an unimportant village on the west side of Suisun Bay, about five miles E. from Vallejo. *Monterey*, population about 1600, on the south side of Monterey Bay, was one of the largest and most frequented towns of Upper California prior to its cession by Mexico, and will eventually become again an important commercial place when the fine bay on which it stands is resorted to, as no doubt it will be, by shipping. At present being away from the mining districts it is comparatively deserted. *San Diego* is another old town which has fallen into neglect, but will doubtless again grow into importance. It stands on the safe and spacious bay of the same name near the southern extremity of the coast. Coal has been found near it. *Marysville*, on the Yuba, 98 miles N.N.E. from Vallejo, is a busy new town with a court-house, several hotels, mills, and stores, two newspapers each having 'tri-weekly and weekly issues,' and nearly 8000 inhabitants. *Oro City* on the Feather River, the capital of the Placer mining district, has 3000 inhabitants. *Placerville*, 112 miles N.E. from San Francisco, was one of the oldest and most flourishing of the gold district towns, but the 'diggers' have deserted its neighbourhood, its newspapers have ceased to be published, and the place itself is worn out and fallen into decay. In 1852 its population had decreased from 4000 to 2000. The state-prison is at *San Quentin*, 12 miles from San Francisco. Among the other towns which either have been, or are expected to be flourishing and important places, it must suffice to name Auburn, Downieville, Los Angeles, Mariposa, Napa, Nevada, Santa Barbara, Santa Cruz, San Luis Obispo, Shasté, Sonoma, Suisun, Tuolumne, Vernon, and Yuba: in all of these the population is constantly shifting, and a statement perfectly correct to-day would be wholly inaccurate in a month or two.

Government, Judicature, &c.—The constitution of California resembles in its general features the constitutions of the other states of the Union. Slavery is not permitted. The legislative power is in a General Assembly, consisting of a Senate of 16 members, elected for two years, and a House of Representatives of 36 members, elected for one year; the sittings of the General Assembly are held annually. The governor is elected for two years: his salary is 6000 dollars per annum. The receipts for the year ending June 30, 1856, were 723,289 dollars; the expenditure for the same period was 1,368,684 dollars. The total debt of the State, Jan. 1, 1857, was 4, 128.927 dollars.

The judicial power is vested in a supreme court and district and county courts. The supreme court consists of a chief justice, who has an annual salary of 8000 dollars, and two associate justices, each of whom has a salary of 6000 dollars a year. The justices are elected by the people for six years, and are so classified that one goes out of office every two years. The senior judge in office is the chief justice. The first judges of the district courts were chosen by the legislature, but all future judges are to be elected by the people: there are fifteen district judges, with annual salaries varying from 3000 to 7000 dollars. A county-court judge is elected in each county for four years.

The constitution directs that a superintendent of public instruction shall be elected, to hold office for three years; and that the legislature shall establish public schools, in which instruction shall be given during at least three months in the year: it also provides funds for their support. A Board of Education has been established, and the returns for 1856 from all but four counties exhibit 322 districts, 417 teachers, and 29,628 scholars from 4 to 14 years of age.

History.—California was discovered by Cabrillo in 1542. It was next visited in 1578 by Sir Francis Drake, who named it New Albion. It was first colonised in 1768 by the Spaniards, who established in various places, chiefly west of the Coast Range, military posts (presidios) and religious stations (misiones). There were four of these military stations and twenty-one missions; and while California remained subject to Spain the actual direction of the country was in the hands of the priests, the governor having scarcely any civil authority. The priests collected the native Indians in villages, and taught them to cultivate the soil, but gave them little other instruction either religious or secular. According to the latest account published by the priests there were above 18,000 of these nominally 'converted Indians,' who spoke twenty different languages. On the separation of Mexico from Spain the missions were broken up, and the Indians returned pretty generally to their native state. After the declaration of Mexican independence a good many Americans and other foreigners visited California for the purpose of hunting or traffic, and several Americans settled in the neighbourhood of San Francisco Bay. The governors appointed by Mexico were unable to maintain tranquillity in the province, and the discontent increased till, in 1836, it issued in a successful revolt, mainly excited it is said by the foreign residents. The government was overthrown without bloodshed, and the governor and other officials were put on board a schooner and shipped off to Mexico. The Mexican government agreed to permit the Californians to choose their own governors, and the country continued nominally subject to Mexico. It remained however in a state of anarchy, and for some time before its cession had become virtually under the control of American citizens. On the termination of the war between Mexico and the United States, California was, as already mentioned, formally ceded to the United States by treaty in February, 1848; and on its rapid growth in wealth and population, consequent on the gold discoveries, it was a year or two later admitted into the Union as a sovereign state.

(Colton, *Statistical Gazetteer of the United States*, 1853; *American Almanac;* Fremont, Wilkes, and various *Travels, Journeys, &c., in California; Visits to Gold Diggings, &c.*)

CALLIGONUM, a genus of plants belonging to the natural order *Polygonaceæ*, of which one species, *C. Pallasia*, yields in its roots an amylaceous gummy matter, on which the Calmucks feed in times of scarcity. The fruits and branches are acid, and are chewed by the same people to allay their thirst. This plant is destitute of leaves, and grows in great abundance on the sandy steppes of Siberia.

CAMBERWELL. [SURREY.]

CAMBORNE. [CORNWALL.]

CAMEROON, or CAMAROENS, a river of Africa, which discharges itself into the Bight of Biafra and into the same estuary as the Malimba, about 45 miles E. from Fernando Po. It has a bar across its mouth, with an average depth of from 15 to 18 feet water over it. Of this river little is known beyond a few miles from the entrance. Like other rivers on this coast, it has been long known to be a great mart for slaves. Palm oil and ivory are obtained here; the latter is considered very fine. The system of traffic is by barter. This river is separated from those to the westward by high land called the Cameroon Mountains, the highest peak of which rises to 13,000 feet above the sea, and is generally capped with snow. The name is derived from the Portuguese word for shrimp, of which there is a great abundance. Each side of the river is governed by a separate chief, whose friendship must be purchased by presents before any traffic is commenced.

CAMPDEN, CHIPPING. [GLOUCESTERSHIRE.]

CAMPHORA, a genus of plants belonging to the natural order *Lauraceæ*. This genus was constituted by Nees von Esenbeck for the *Laurus Camphorifera* of Kämpfer, the plant which yields the Camphor of commerce. It is known by its hermaphrodite panicled naked flowers; 6-cleft papery calyx, with a deciduous limb; 9 fertile stamens, 3 in a row, the inner row with two stalked glands at their base; the anthers 4-celled, the outer turned inwards, the inner outwards; the fruit placed on the obconical base of the calyx; the leaves triply nerved, glandular in the axils of the principal veins; the leaf-buds scaly.

C. officinarum, the Camphor Laurel, is a tree with lax smooth branches; the leaves are bright green and shiny above, paler beneath, and somewhat coriaceous, with a sunken gland at the axils of the principal veins, projecting at the upper side, opening by an oval pore beneath. This plant is a native of Japan and China, and is cultivated in most of the warmer parts of the world. The Camphor of commerce is yielded by this tree, which is cultivated most extensively in the island of Formosa, from whence it is taken to Canton, which is the principal market for Camphor. [CAMPHOR.]

CAMPION. [LYCHNIS, *S.* 1; SILENE.]

CAMPSIE. [STIRLINGSHIRE.]

CANADA.—*Lower Canada*, or *Canada East*, is divided into 36 counties, the names of which we give here with the population of each in 1851:—Beauharnois, 40,213; Bellechasse, 17,982; Berthier, 34,608; Bonaventure, 10,844; Chambly, 20,576; Champlain, 13,896; Dorchester, 43,105; Drummond, 16,562; Gaspé, 10,904; Huntingdon, 40,645; Kamouraska, 20,396; Leinster, 29,690; L'Islet, 19,641; Lotbinière, 16,567; Mégantic, 13,835; Missisquoi, 13,484; Montmorency, 9598; Montreal, 77,381; Nicolet, 19,657; Ottawa, 22,993; Portneuf, 19,366; Quebec, 61,526; Richelieu, 25,686; Rouville, 27,031; Rimouski, 26,882; Saguenay, 20,783; St. Maurice, 27,562; St. Hyacinthe, 30,623; Sherbrooke, 20,014; Shefford, 16,482; Stanstead, 13,898; Terrebonne, 26,791; Two Mountains, 30,470; Vaudreuil, 21,429; Verchères, 14,393; Yamaska, 14,748;—total population of Canada East, 890,261.

In *Canada East* are *Montreal* and *Quebec*. [MONTREAL; QUEBEC.] The other towns are Three Rivers, St. Hyacinthe, Sherbrooke, and Sorel. *Three Rivers* is prettily situated at the confluence of the St. Maurice with the St. Lawrence, and has a population of 4936. There are iron mines near the town. There is a considerable trade in pot- and pearl-ashes. Three Rivers is one of the depôts of the north-west traders, and is on the whole a place of some importance in a commercial point of view. *St. Hyacinthe*, population 3313, in St. Hyacinthe county, is situated on the left bank of the Yamaska River, about 30 miles E. by N. from Montreal. It is the seat of a college. *Sherbrooke*, population 2998, the district town of the eastern townships, is situated at the junction of the Magog with the St. Francis River. Its extensive command of water-power gives it great facilities for manufactures. The chief public building here is the court-house and jail. *Sorel*, or *William Henry*, population 3424, at the confluence of the Richelieu and the St. Lawrence, is likely from its advantageous situation to be of much greater importance than it has yet attained. By the Chambly Canal there is communication between Lake Champlain and the St. Lawrence, at Sorel. There is also a railway along the same line of route.

Upper Canada, or *Canada West*, is divided into 42 counties, as follows:—Addington, population 15,165; Brant, 25,426; Bruce, 2837; Carleton, 31,397: Dundas, 13,811; Durham, 30,732; Elgin, 25,418; Essex, 16,817; Frontenac, 30,735; Grey, 13,217; Glengary, 17,596; Grenville, 20,707; Haldimand, 18,788; Halton, 18,322; Hastings, 31,977; Huron, 19,198; Kent, 17,469; Lambton, 10,815; Lanark, 27,317; Leeds, 30,280; Lenox, 7955; Lincoln, 23,868; Middlesex, 39,899; Northumberland, 31,229; Norfolk, 21,281; Ontario, 30,576: Oxford, 32,638; Peel, 24,816; Perth, 15,545; Peterboro', 15,237; Prescott, 10,487; Prince Edward, 18,887; Renfrew, 9415; Russell, 2870; Simcoe, 27,165: Stormont, 14,643; Victoria, 11,657; Waterloo, 26,537; Wellington, 26,796; Welland, 20,141; Wentworth, 42,619; York, 79,719;—population of Canada West, 952,004. Total population of Canada, 1,842,265.

Canada West contains the cities of *Toronto*, at present the capital of the United Province, *Hamilton*, and *Kingston*. [TORONTO.] *Hamilton* is beautifully situated at the western extremity of Burlington Bay, near the shore of Lake Ontario. It was founded in 1813, and became an incorporated town in 1833; the population in 1851 was 14,112. The construction of the Burlington Canal, a short cutting which opens a clear navigation into Lake Ontario, and the improvements of the Desjardins Canal, five miles long, which connects Hamilton with the manufacturing town of Dundas, have much promoted the prosperity of the place. It is the district town of Gore district, and as such contains the court-house for the district and other public buildings. The streets are well laid out, and many of the houses are built of stone. There are two market-houses, one of them including an upper story used as the town-hall, a custom-house, a post-office, and a theatre. There are places of worship for Episcopalians, Presbyterians, Wesleyan Methodists, Independents, Baptists, Roman Catholics, and others; news-rooms; and a mechanics institute. Good roads extend in all directions from the city, and numerous stage-coaches keep up communication with the surrounding districts. Steam-vessels ply regularly during the season to Toronto and to Queenstown and Niagara. Hamilton has much increased in commercial importance of late years. *Kingston*, population 11,585, situated on lake Ontario, distant 199 miles S.W. from Montreal, and 177 miles E.N.E. from Toronto, was incorporated in 1838. It is advantageously situated at the beginning of the Rideau Canal and the Cataraqui River, and is important in a military as well as a commercial point of view, being the key of the central St. Lawrence, as Quebec is of the river's seaward extremity. In its neighbourhood is Navy Bay, a narrow and deep inlet of Lake Ontario, which is the chief naval station on the lakes. The market-house, which contains also the post-office, the town-hall, and several public offices, is a handsome stone building of considerable dimensions. There are places of worship for Episcopalians, Presbyterians, Wesleyan Methodists, Baptists, Roman Catholics, and others. There are here a Presbyterian college, an hospital, a mechanics' institute, and news-rooms. Ship-building is carried on. A bridge nearly 600 yards long crosses the river Cataraqui at Kingston. There are several mineral springs in the vicinity.

Of the towns of Canada West the following may be noticed:—*Amherstburg*, a garrison town on the Detroit

River, population 1880, is finely situated, the banks of the river in the vicinity of the town being very beautiful. The town received in 1845 a charter to hold a fair twice a year. There are Episcopal, Presbyterian, Methodist, Baptist, and Roman Catholic places of worship, a court-house, news and reading-rooms, and a market-place. British and American steamers frequently call. Several handsome dwelling-houses are in the neighbourhood of the town. *Barrie*, population 1207, commenced in 1832, is now the district town of Simcoe district. There are in the town a court-house, several places of worship, a mechanics' institute, and a jail. Steam-vessels ply on Lake Simcoe, which by the river Severn communicates with Georgian Bay and Lake Huron. *Belville*, population 4569, situated about 50 miles W. from Kingston on the Bay of Quinté, is a place of considerable trade. There are here a court-house for the district of Victoria, several places of worship, and some other public buildings. Steam-vessels call regularly at Belville. *Brantford*, population 3877, on the left bank of the Grand River, about 74 miles W. by S. from Hamilton, was commenced in 1830. A canal about 2½ miles long with three locks enables vessels of moderate draught to reach the town, thus avoiding the falls of the Grand River. There are chapels for Episcopalians, Presbyterians, Independents, Baptists, and Roman Catholics. Grist-mills, fulling-mills, soap-factories, and other establishments give considerable employment. *Brockville*, population 3246, situated on the river St. Lawrence, about 56 miles N.E. from Kingston, was founded in 1802; it is now an incorporated town. Most of the houses are built of stone, and the town has a handsome appearance. The court-house and jail, and the churches, of which there are several, are stone-buildings. Tanneries, saw-mills, a brewery, and other works employ some of the inhabitants. Steam-vessels call at Brockville on their passage. *Bytown.* [BYTOWN, *S.* 2.] *Chatham*, population 2070, on the left bank of the river Thames, 66 miles S.W. from London, and 50 miles E. from Detroit, is a thriving town, with an increasing trade. A steam-vessel belonging to the place maintains a regular communication with Detroit and Amherstburg. There are here saw-mills, tanneries, pottery works, &c. Several places of worship are in the town. *Cobourg*, population 3871, is situated on gently rising ground, on the bank of Lake Ontario, 103 miles W. by S. from Kingston, 72 miles E. by N. from Toronto. The town is well built, and has a good appearance. The harbour and lighthouse are of recent construction. There are churches for the leading denominations of Christians, a court-house, a mechanics' institute, &c. Victoria College, founded by the Wesleyan Methodists, but not exclusive in its management, is supported partly by a legislative grant. It has the power to grant degrees. There are here a large cloth-factory, mills, and other works. *Cornwall*, population 1646, situated at the termination of the Cornwall Canal in the St. Lawrence, was incorporated in 1834. There are many good stone dwelling-houses, several churches, and a court-house and jail. Some tanneries, a foundry, and other establishments give employment. *Dundas*, population 3517, a manufacturing town, about 5 miles N.W. from Hamilton, possesses extensive water-power, which has contributed much to its prosperity. The town is surrounded on three sides by high table-land, usually termed 'the mountain;' from this high land freestone and limestone are procured and exported. There are several chapels in the town. There is a mechanics' institute *Goderich*, population 1329, on Lake Huron, at the entrance of the Maitland River, was laid out in 1827 by Mr. Galt, who was at that time Secretary of the Canada Company. The town is finely situated on rising ground, more than 100 feet above the level of the lake. It is about 60 miles N. by W. from London. An expensive harbour was constructed, and a lighthouse was placed at the port, but the town has not been very successful. There are several churches, a court-house, breweries, tan-yards, &c. *Guelph*, population 1860, the district-town of Wellington district, about 42 miles N.W. from Hamilton, was laid out by Mr. Galt in 1828. It is pleasantly situated on elevated ground. The Episcopalians, Presbyterians, Wesleyan Methodists, Independents, and Roman Catholics have places of worship. *London*, population 7035, is finely situated at the junction of two branches of the river Thames, 85 miles W. by S. from Hamilton. It was laid out in 1826 by the crown, and was incorporated in 1840. London suffered severely from fire in 1844 and 1845, but the appearance of the town was much improved by the handsome streets of fine buildings which were subsequently erected. St. Paul's Episcopal church, erected by subscription to replace the edifice burnt down in 1844, is a beautiful gothic structure with a square tower surmounted with pinnacles. The court-house and jail, built of brick in the form of a castle; commodious barracks; two market-buildings; a theatre, and a handsome station of the Great Western railway are among the public buildings of the town. There are good roads in the vicinity. Machine-making, tanning, brewing, &c., are carried on. *Niagara*, population 3340, the district town of Niagara, 48 miles E. from Hamilton, is one of the oldest towns in Canada, and was for five or six years under the name of Newark the capital of the country. It has several churches, a town-hall, and a court-house. The Niagara Harbour and Dock Company, incorporated in 1830, have constructed in their ship-yards numerous barges, schooners, and steam-vessels. Considerable quantities of apples, peaches, and cider are shipped annually from the port of Niagara. *Ottawa.* [OTTAWA, *S.* 2.] *Perth*, population 1916, the chief town of Bathurst district, distant about 40 miles N.W. from Brockville, was laid out by the government in 1816. It stands on the river Tay, which is made navigable to the Rideau Canal by a branch canal about 11 miles in length. The town contains several places of worship, a court-house, and a jail, and many good dwelling-houses built of stone. White marble is found a few miles from the town. *Peterborough*, population 2191, occupies a beautiful situation on the Otonabee or Trent River, about 34 miles N.N.W. from Cobourg. It was commenced in 1826, is well laid out, and has a handsome appearance. Part of the town on the east or left bank of the river is called Peterborough East. Most of the places of worship are built of stone. On an elevated site behind the town is the court-house and jail, a handsome stone edifice. There are here woollen manufactories, fulling-mills, saw-mills, chair-factories, breweries, &c. *Picton*, population 1569, chief town of Prince Edward district, is finely situated on the Bay of Quinté. It is an old town and contains many good stone houses. Steamers call here on their passages between Kingston and Trent. There are several places of worship, a court-house, a jail, and a library. A good deal of trade is carried on. Wheat, flour, butter, leather, &c., are exported. *Port Hope*, population 2476, on Lake Ontario, about 8 miles W. from Cobourg, between Toronto and Kingston, is built on the side of a hill commanding interesting views of lake and inland scenery. It contains some handsome buildings, including four places of worship. Wheat, flour, and timber are the chief exports. *Prescott*, population 2156, on the St. Lawrence, about 12 miles N E. from Brockville, possessed considerable trade previous to the opening of Rideau Canal, but since then it has not made rapid progress. Among the buildings are four places of worship and a custom-house. At this place the river is about a mile and a quarter broad. A good deal of pot and pearl ashes is exported. *Sandwich*, population not given separately, on the Detroit River, is finely situated and well laid out. It is one of the oldest towns in Canada, and has assumed very much the appearance of an English country town. Many flower-gardens and orchards are kept by the inhabitants. The Episcopalians and Methodists have places of worship in the town. *Simcoe*, population 1452, the chief town of Talbot district, is situate near the shore of Lake Erie, about 24 miles S. by W. from Brantford. Grist- and saw-mills, a carding-machine and fulling-mill, with other establishments, furnish employment. *St. Catherine's*, population 4368, on the Welland Canal, about 12 miles W. from Niagara, occupies a beautiful situation, and possesses a good trade. Ship-building is carried on. Great quantities of flour are annually exported. There are six places of worship. *Woodstock*, population 2112, chief town of Oxford county in the Brock district, about 32 miles E.N.E. from London, is pleasantly situated. It is composed of East and West Woodstock, forming one street of about a mile long. There are six places of worship, a court-house, and a mechanics' institute. Considerable trade is carried on.

Of the population of Canada East, 890,261, as many as 669,528 are natives of Canada of French origin, and 125,580 are Canadians of other than French origin; 51,499 are of Irish origin; 14,565 of Scotch; 12,482 are from the United States of North America; and 11,230 from England and Wales. The remainder is composed of natives of the European continent, and of our own colonies.

In Canada West, the population of which is 952,004, the Canadians of French origin number 26,417, and the Canadians not French, 526,093: the Irish, 176,267; English and Welsh, 82 699; the Scotch, 75,811; natives of the United States, 43,732; natives of Germany and Holland, 9957.

With respect to the whole of Canada, of which the total population is 1,842,265, the seven principal items stand as follows:—Canadians of French origin, 695,945; Canadians, not French, 651,673; Irish, 227,766; English and Welsh, 93,929; Scotch, 90,376; natives of the United States, 56,214; of Germany and Holland, 10,116. At the time of the surrender of Canada to Great Britain, the population was chiefly French, and located in the lower province. Although this class has not been much increased by immigration, its numbers have in the course of 90 years increased about 1000 per cent. The progress of Canada West has been still more remarkable. In 1791, the date of the Constitutional Act, the population was 50,000; in 1811 it was 77,000; in 1824 it was 151,097; in 1832 it was 261,060; in 1842 it was 486,055; in 1851 it amounted to 952,004.

The amount of immigration into Canada is stated in a separate article. [EMIGRATION, *S.* 2.]

In January 1857, the total length of main railways in Canada was above 1000 miles. These railways consist of two principal lines, the Grand Trunk Line and the Great Western Line, which are united at Toronto, and form a continuous railway from St. Thomas, east of Quebec, to the western boundary of Canada, on Detroit River. The Grand Trunk Line proceeds from St. Thomas 49 miles to New Liverpool, opposite Quebec, and thence by Richmond (where it unites with the line from Portland, in the State of Maine) to Montreal 170 miles, throwing off a branch northwards from Prescott to Ottawa. From Montreal the line proceeds through Prescott, Kingston, and Toronto, to Stratford 421 miles; total 640 miles. The Great Western Line extends from Toronto through Hamilton and Chatham, to Windsor, opposite Detroit, 229 miles. There is also an independent line from Niagara Falls to Hamilton 34 miles. This gives a total length completed of 903 miles, exclusive of the Ottawa branch and other smaller railways.

The revenue and expenditure in each year, from 1848 to 1853, are as follows:—

	Revenue £	s.	d.	Expenditure £	s.	d.
1848	213,037	6	0	389,992	14	11
1849	421,998	4	0	370,613	15	2
1850	578,822	11	3	437,312	11	3
1851	692,206	4	9	521,643	11	3
1852	723,724	7	4	535,171	6	7
1853	982,334	10	2	611,667	16	5

The imports and exports in each year, from 1848 to 1853, are as follows.—

	Imports £	s.	d.	Exports £	s.	d.
1848	2,629,584	17	11	2,302,830	17	6
1849	2,468,130	6	9	2,193,078	0	3
1850	3,489,466	3	5	2,457,886	1	2
1851	4,404,409	0	2	2,663,983	14	4
1852	4,168,457	8	5	2,888,213	19	3
1853	6,571,527	19	9	4,523,060	19	1

Canada receives from the United Kingdom coals, metal, cordage, East India produce, and the various kinds of British manufactures; from the British West Indies, sugar, molasses, coffee, rum, and hard woods; from the United States, beef and pork, biscuit, rice, and tobacco. The exports of Canada are:—To the United Kingdom, pot and pearl-ashes, wheat and flour, and timber; to the West Indies, beef and pork, beer, grain, and flour; to the United States, forest produce, wheat, flour, butter, wool, livestock, &c.

CANNABINACEÆ, *Hempworts*, the Hemp Tribe, a natural order of Exogenous Plants. This little order which has been separated from *Urticeæ* embraces two well-known plants, the Hop (*Humulus Lupulus*) and the Hemp (*Cannabis sativa*). They are distinguished from the Nettle Tribe by having a solitary suspended ovule, and a hooked ex-albuminous embryo, with a superior radicle. [HUMULUS; CANNABIS.]

CANON LAW. In the university of Oxford, the common law has been substituted for the canon law. This is effected by stat. 17 & 18 Vict. c. 81, s. 45. The canon law still governs the court of the university of Cambridge.

CAPELLEN, GODERD ALEXANDER GERARD PHILIP, BARON VAN DER, a distinguished governor-general of the Dutch East Indies, was born at Utrecht on the 15th of December 1778. He lost his father, Alexander Philip van der Capellen, Heer van Berkenwonde, before he was nine years old. After studying at Göttingen under Martens and Blumenbach, with both of whom he continued in correspondence to the end of his life, he entered the public service of Holland, and became in 1809 Minister of Internal Affairs under King Louis Bonaparte, whom he strongly advised to defend the entrance of Holland by force against the armies of Napoleon; and when the French system was introduced into the country Jan. 1, 1811, he accompanied Louis to his retreat at Gratz in Styria. A coolness however arose on the part of the ex-king when he found that his late minister looked with no unfavourable eye on the rising in Holland to restore the house of Orange; and after the complete emancipation of Holland from the French yoke, Van der Capellen was in fact appointed Minister of Commerce and the Colonies, and on the 1st of August 1814 Governor-General of the Dutch East Indies. Owing to an important mission to the congress of Vienna, and the return of Napoleon, which gave Van der Capellen an admirable opportunity of showing his constancy and courage at Brussels on the day of Waterloo, he did not leave Europe for his post till October 1815, and a further delay occurred before he finally received Java from the hands of the English, agreeably to the arrangements made at the peace. He remained beyond the five years, which had been originally intended, and was recalled in disgrace in 1826, when he was universally censured in Holland for having effected a loan of fifteen millions of sicca rupees at Calcutta, at nine per cent., on the security of the revenues of the Dutch East Indies. It was said that of all measures that could be adopted the most unadvisable was that of pledging the Dutch possessions to the English. Van der Capellen had however shown no partiality to our nation; he had, on the contrary, strongly urged the Dutch government not to consent to the English establishment of Singapore. He had however followed up the arrangements made by Sir Stamford Raffles during the English possession of Java, and by that means an immense improvement was effected in the position and prospects of the country. He had also abolished the monopolies which under the old Dutch system pressed heavily upon the natives of Celebes and the Moluccas, made alterations and improvements much required in the coinage, and taken measures for the abolition of the slave trade and slavery. The most unfortunate circumstance connected with his administration was the outbreak of the great revolt of Diepo Negoro, a Javanese chief, which lasted many years, and which on his return to Europe he left still unsubdued. On the whole however, when his administration came to be reviewed, the unpopularity which had collected around him gradually cleared off, and his merits are now universally acknowledged. He was nominated to several high posts, among others to that of ambassador to England on the occasion of the Coronation of Queen Victoria, President of the Commission of Education, and President of the University of Utrecht. In February 1848 he was unfortunately on a visit to Paris, on an invitation from King Louis Philippe, who was a personal friend, when in the outbreak of the revolution he was struck on the head by a stone thrown by one of the mob. No outward injury appeared, but on his return to his seat at Vollenhoven he sunk into a deep melancholy, produced partly by his feelings at the events he had witnessed, and this was succeeded by an inflammation of the brain, attributed to the blow, which carried him off on the 10th of April, 1848.

CAPPOQUIN. [WATERFORD.]

CARAPA, a genus of plants belonging to the natural order *Meliaceæ*. *C. Touloucouna* yields the Tallicoonah or Kundar Oil, which has a reputation as an anthelmintic. It is said to be well suited for burning in lamps. The bark of the root of *C. obovata* is bitter and astringent. The bark of *C. Guianensis* is used as an anthelmintic and febrifuge.

CARBUNCLE. [GARNET.]

CARDIOSPERMUM, a genus of plants belonging to the natural order *Sapindaceæ*. The root of one of the species, *C. Halicacum*, is said to be diuretic, diaphoretic, and aperient. In the Moluccas the leaves are cooked and eaten.

CARDIUM. [CONCHACEA.]

CARDUELIS. [GOLDFINCH.]

CARIA. [KARIA, *S.* 2.]

CARLINGFORD. [LOUTH.]

CARLOS, DON (Count de Molina), Infante of Spain, and pretender to the Spanish throne, was the second son of Carlos IV. of Spain, and was born on the 29th of March 1788. Left chiefly in the hands of priests, to whom the superintendence of his education had been entrusted, Don Carlos remained in comparative obscurity during the domination of Godoy. On the first abdication of his father and the accession of his brother Ferdinand VII., Don Carlos was sent to meet Bonaparte, who had announced his intention to visit Spain. The young prince was inveigled beyond the Spanish provinces, and made in effect a prisoner, and Ferdinand, like his brother, soon found himself also in the hands of the French. Bonaparte next compelled the weak ex-monarch of Spain to proceed to Bayonne, and refusing to acknowledge his former abdication, forced him first to resume the crown, and then, for himself and his posterity, to "abdicate all claims to the Spanish kingdom in favour of his ally the Emperor of the French." In this renunciation, after a strenuous opposition, Don Carlos, as well as Ferdinand, was compelled to join. The brothers were sent to Prince Talleyrand's house at Vallençay, where they were detained prisoners, though treated with great respect, till 1813, when Napoleon restored them to liberty, and Ferdinand to the throne of Spain.

When, after the suppression of the constitutional party by the French invasion under the Duc d'Angoulême, Ferdinand appeared inclined to adopt a somewhat more moderate policy, the absolutists turned their attention towards Don Carlos, and determined if possible to raise him to the throne. A conspiracy of a formidable character was organised, and an insurrection broke out in Catalonia in 1825, but was repressed by the vigorous measures of the Count d'España.

Don Carlos had himself taken no open share in the insurrectionary movements of his partisans. He was heir to the throne, and it is probable he was anxious not to endanger his succession by a premature declaration. His hope of legal succession was however quickly dispelled. Ferdinand had been three times married without having any children, but by his fourth wife, Christina, he had in October 1830 a daughter, Isabella, the present queen of Spain. By the ancient laws of Spain females could inherit the crown in default of male issue; but the Salic law of France had been introduced with the Bourbons, and females continued to be excluded from the throne till 1789, when Carlos IV. abrogated the restriction, and restored the ancient rule of succession. In 1812 however the Cortes re-established the Salic law, and Don Carlos was therefore still the heir-presumptive to the throne. But Ferdinand now issued a decree which annulled the provision of the Cortes, and restored the order of succession in the female line. Don Carlos protested, but remained quiet. His partisans however throughout the kingdom prepared for the struggle which the weak state of the king's health showed to be not very distant. In September 1833 Ferdinand was believed by himself and those about him to be dying, and the feeble king, terrified at the mischiefs which he was assured would result from the measure which excluded his brother from the throne, and acting on the advice of his favourite minister Calomarde, signed a decree by which he restored the Salic law. Ferdinand however rallied, and was easily induced by his sister-in-law to destroy the evidence of his recent vacillation. He died a few days later, and his death was the signal for a general rising of the adherents of Don Carlos in opposition to Queen Isabella, who had succeeded to the throne of her father.

For full five years Spain was desolated by a civil war, in its early period at least one of the most atrociously cruel which has ever disgraced a civilised country. Carlos was supported by the great body of the priests, by a large portion of the country party, and by nearly the whole of the inhabitants of the Basque Provinces—the bravest and most devoted portion of the Spanish people. Had he been a man of more energy and ability, the great probability is that he would have succeeded. But he possessed in full the hereditary bigotry, weakness, and obstinate folly of his race, and he more often marred than followed up the successes which his generals achieved. Yet the energy and courage of his generals, Cabrera and Zumalacarregui, maintained the balance decidedly in his favour, till the valuable aid of the British legion under General Sir de Lacy Evans, and the death of Zumalacarregui, turned the scale. The defection of Maroto, and the surrender of his army to Espartero in August 1839, left Carlos no alternative but flight, and he at once took refuge in France.

Louis Philippe assigned him a residence in the city of Bourges, where he was joined by his family, and where for some years he maintained a mimic court, in which was observed all the elaborate etiquette of the Spanish monarchy. At length, sick of hope deferred, he in 1845 formally relinquished his claim to the Spanish crown in favour of his eldest son Don Carlos Louis Maria Fernando, Count de Montemolin. The abdication of Don Carlos was strongly opposed by his wife, the Princess Maria Theresa (daughter of John IV. of Portugal), and by his leading supporters, including General Cabrera. In Spain it probably strengthened the hands of the Queen; and the subsequent rising in favour of the Count de Montemolin was easily suppressed. Don Carlos was permitted in 1847 to remove to Trieste, where he remained in strict retirement till his death, March 10th, 1855.

CARTHAMIN. [Chemistry, *S.* 1.]

CASEARIA, one of the five genera of plants constituting the natural order *Samydaceæ*. Several of the species are used medicinally. The leaves of *C. ulmifolia* are astringent, and in the Brazils are applied to recent wounds. A decoction of the leaves of *C. lingua*, called by the Brazilians Cha de Frade and Lingua de Fin, is used in fevers and inflammatory disorders. *C. astringens* is used as an external application on account of its astringent properties. *C. Anavinga*, an Indian species, is bitter. The leaves of *C. esculenta* are eaten, but the root is bitter and purgative.

CASEIN. [Chemistry, *S.* 1.]

CASTAÑOS, FRANCISCO XAVIER, the most eminent Spanish general in the Peninsular War, was born at Madrid, according to the best Spanish authorities, about 1756. His father, who was a military officer, procured him a captain's commission at the age of twelve, and he remained in the service till he was ninety-six, being then probably the oldest soldier on record. In his early years he was sent with General O'Reilly to the court of Frederick the Great to study the Prussian tactics, and he passed through various grades in the Spanish army without achieving any high reputation till the invasion of Spain by Napoleon I., when he was fortunate enough to strike the first blow of the long series of victories against the French, which terminated in the downfall of their power. On the 22nd of July 1808, eighteen thousand French, commanded by General Dupont, laid down their arms and surrendered to the Spanish army, under Castaños, at Baylen. It is stated by Lord Holland, in his 'Reminiscences,' that when the French general delivered his sword to Castaños, he said, "You may well, General, be proud of this day; it is remarkable that I have never lost a pitched battle till now; I, who have been in more than twenty, and gained them all!" "It is the more remarkable," was the Spaniard's quiet reply, "because I never was in one before in my life." The chief merit of the victory has, however, been ascribed by many to the second in command, Aloys Reding, a Swiss patriot, who, after vainly endeavouring to defend his native country against Napoleon, had entered the service of Spain. The effect of this great battle was to drive Joseph Bonaparte from Madrid, and on the 23rd of August Castaños made his triumphal entry into the capital, where, on the next day, Ferdinand was proclaimed. Later in the same year, in November, Castaños was defeated by the French at Tudela, and he held but a subordinate position to the Duke of Wellington and Marshal Beresford during the remainder of the war, in which he took a share in the battles of Albuera, Salamanca, and Vitoria, particularly the last. In 1815, on the return of Napoleon, he was in command of an army of 80,000 Spaniards, which had already partly advanced into France when the news of the battle of Waterloo arrived. In the year before, however, he had received some disgusts from the government, which excited the indignation of the Duke of Wellington, his companion-in-arms; and in the years which followed he did not hold a prominent position, though he possessed much of the esteem of both parties. Towards the close of his life, however, his popularity revived, partly perhaps on account of the phenomenon of his great age, and the Duke of Baylen was looked on as the representative of Spanish chivalry. "In spite of his ninety years of age," says Mellado in 1846, "General Castaños, though much bent, still constantly shows himself in the public streets, moving about on foot, and in the enjoyment of astonishing health. For some time he has been an almost daily visitor at the royal palace, and has the reputation of being full of sharp and weighty sayings; many of his reputed repartees to King

Ferdinand, who was very fond of him, circulating amongst the lower classes." Among other posts of dignity, he held that of one of the guardians of the present Queen of Spain. He died at Madrid, on the 24th of September, 1852, and his remains were honoured with a public funeral.

CASTEL VETRANO, a town in the province of Trapani, in Sicily, is situated near the left bank of the Delia, 30 miles E. from the town of Trapani, about five miles from the nearest point of the south coast of the island, and has a population of about 13,000. The town is famous in works in coral and alabaster. It is built on a hill, and is an old-looking place, with an old castle, several churches, convents, and palaces. The country round Castel Vetrano is fertile in wine and rich pastures. A few miles from Castel Vetrano, to the south-eastward, are the ruins of the ancient *Selinus*. This ancient site is covered with broken columns, capitals, and other architectural fragments. The columns are all Doric, and of large dimensions; they are called 'Giants' Pillars' by the peasantry. A few columns are still standing. Some finely sculptured metopes were discovered at the base of the façade of the central temple in 1822. There are ruins of six temples in all.

CASTELLAMMARE, the chief town of a subdivision of the province of Napoli, in the kingdom of the Two Sicilies, is situated near the head of the Bay of Naples, on the lower slopes of the Monte d'Auro (an offshoot of the limestone ridge of Monte Sant'Angelo), 18 miles by railway S.E. from Naples, and has a population of 18,000. It is connected by a branch railroad with the Naples-Nocera line, the first railway opened in Italy. The town stands on or near the site of the ancient *Stabiæ*, which was ruined by Sylla in the Social War, and afterwards covered by ashes from Mount Vesuvius in the eruption of A.D. 79. During this eruption Pliny the elder lost his life at Stabiæ. The hill above Castellammare is call d Monte Qui-si-sana from its proverbial salubrity; it is covered with villas and casini; among the latter is the royal casino of Qui-si-sana, founded by Charles II. of Anjou, and now the property of the Russian prince Lieven. Behind the hill rises the imposing mass of Monte Sant'Angelo, which with its triple crest runs through the Sorrentine peninsula, and forms a conspicuous object between the bays of Salerno and Naples. The town derives its name (signifying 'castle by the sea') from its castle, which was erected by the emperor Frederick II., surrounded by walls and towers by Charles I. of Anjou in the 13th century, and subsequently strengthened by Alfonso I. of Aragon. The town was sacked by the army of Pius II. in 1461, and again in 1654 by the Duke of Guise. The harbour has a depth of three to four fathoms water; it is surrounded by spacious quays and protected by a mole. In connection with the harbour are a bagnio for galley slaves, and a royal arsenal and dockyard, where the ships of the Neapolitan navy are built. These establishments contribute materially to the prosperity of the town. Castellammare has been celebrated since the time of Galen for its mineral springs, which are very efficacious in gouty and rheumatic affections. There are twelve of these,—four chalybeate, four saline, and four sulphureous,—and they all rise at the base of the Monte d'Auro, within a short distance from one another. They are all of moderate temperature, seldom exceeding 65° Fahr. Great numbers of visitors frequent Castellammare and its delightful neighbourhood during the summer and autumn; the temperature is 8 or 10 degrees lower than that of Naples. The town, which gives title to a bishop, and has a handsome cathedral, is well built, partly on the lower slopes of Monte d'Auro, but chiefly along a sheltered beach commanding a view of the whole bay of Naples. Some wheat is exported; the chief imports are coal, timber, and machinery. Among the industrial products are maccaroni, silk and cotton goods, and sail-cloth. The fisheries along the coast employ a good many hands. Some excavations made among the ruins of Stabiæ in 1745 brought to light a few fragments of sculpture, some papyri, and paintings, which are now in the Museum of Naples.

There is another *Castellammare*, or *Castellamare*, in the province of Trapani in Sicily. It is situated on the southern shore of the Gulf of Castellamare, 22 miles E. from the town of Trapani, 27 miles W.S.W. from Palermo, and has about 6000 inhabitants. The town, which is ill-built and dirty, is named from its old decaying castle. It carries on a considerable trade by sea, and has large granaries; the exports are corn, wine, fruit, cotton, manna, shumac, &c. The remains of the ancient Segesta are near Castellamare: they consist of a Doric temple in tolerable preservation, the ruins of a theatre, and a part of the city walls. Castellamare is said to occupy the site of the port of Segesta. [TRAPANI.] The town was half destroyed by a waterspout in December, 1851.

CASTLE ACRE. [NORFOLK.]

CASTLE BLAYNEY. [MONAGHAN.]

CASTLE CARY. [SOMERSETSHIRE.]

CASTLE RISING. [NORFOLK.]

CASTRÉN, MATTHIAS ALEXANDER, one of the heroes and martyrs of modern philology, was born on the 2nd of December 1813 in the province of Uleoborg in Finland, not far from the boundary between Finland and Lapland, a little north of the town of Torneo, the place to which travellers usually resort to witness the phenomenon of the midnight sun. He received his early education at Torneo, and afterwards went to Helsingfors to pursue his studies at the university, which had been removed there by the Russian government after the conflagration of Abo. One effect of the transfer of Finland from Sweden to Russia had been to lessen the importance of the Swedish language, which had up to that period occupied much the same position in Finland which the English does in Wales, but which then ceased to be the language of the government, though it continued to be that of the educated classes. A lively interest was awakened in the Finnish, the old language of the country, which is still spoken by the peasantry, and which some recent philologists have not hesitated to pronounce one of the finest languages in Europe. Of the students at Helsingfors who followed up this study none were more enthusiastic than Castrén. He made a resolution to devote his life to the language and literature of his native country. Nor was this an idle vaunt. He commenced a course of inquiries into the mythology of ancient Finland, and finding that to complete his views it was desirable to ascertain with more exactness than had hitherto been thought requisite the mythology of the Laplanders, he looked about him for the means of making a journey into Lapland, and studying the language and religion of the Laps. In 1838 an opportunity presented itself, and he set out with three companions on a tour, which before its completion took him to Uitzoki and the great lake of Enaré. The travellers had to carry their charges of clothing and all their stores on their backs, and their journey both out and home was an almost uninterrupted series of labours, hardships, and privations. Castrén could learn less of the Lapland mythology than he had expected, for although the conversion of many of the tribes from heathenism had only taken place in the 18th century, the Christian Laps were so devout that they often spent twenty-four hours in succession in religious exercises, and many of them knew the whole of the New Testament by heart; the ancient mythology being regarded with proportionate abhorrence. On his return he learned that the Imperial Academy of Sciences at St. Petersburg contemplated sending an expedition to Siberia to prosecute researches in ethnology, and he put himself in communication with his fellow-countryman and fellow-philologist Sjögrén to undertake the task. For the time he was disappointed; but the Literary Society of Finland raised a scanty subscription to send him on a mission to Russian Carelia, to collect ballads, legends, and traditions illustrative of his favourite Finnish mythology, and he was remarkably successful. Soon after his return in 1841, he published, at Helsingfors, a translation into Swedish, in the metre of the original, of the great Finnish poem 'Kalevala,' the discovery of which by Dr. Lönnrot, who first noted part of it down from the lips of the peasantry, has made an epoch in the history of Finnish literature. It was this translation that first brought the poem into general notice; and, certainly, since Macpherson's 'Ossian,' no discovery of the kind, real or supposed, has produced an equal sensation. 'Hiawatha,' the recent poem of Professor Longfellow, though purporting to be an embodiment of the traditions of the North American Indians, is borrowed from the 'Kalevala' in its general style, in its peculiar metre, and even in some of its more prominent passages. Soon after its publication Castrén set out on his third philological journey, which appears to have been made in its outset at the expense of Dr. Lönnrot, and afterwards at that of the Russian Academy of Sciences. It took him first to his old quarters at Enaré, then to Kola, the capital of Russian Lapland, and finally to the Samoyeds on the coast of the White Sea. Here, with only fifteen rubles to keep him from starvation, he struck up an acquaintance with some of the savage Samoyeds, or cannibals, one of whom for an occasional glass of brandy undertook to teach him the Samoyed language; and in the hut of this man he passed nearly the whole of a summer, engaged in the study. Towards the end of his travels, which lasted for four years, from 1845 to 1849, he crossed the Tundras, or deserts of European Russia, between the White Sea and the Ural, where not even the rein-deer can front the wintry blast and live. Philology has its martyrs as well as religion. Castrén returned with his constitution ruined.

While on his travels he had written most interesting and animated letters, descriptive of his adventures and discoveries, which were printed in the 'Suomi,' an excellent periodical in the Swedish language published at Helsingfors. Many communications from him on learned subjects, chiefly written in German, appeared at the same time in the 'Bulletin of the Academy of Sciences' at St. Petersburg. On his return his name was universally known as that of a philologist of the first rank, but it was not till March 1851, on the occasion of a visit of the Grand Duke Alexander, the present Emperor of Russia, to the University of Helsingfors, that be was raised from the position of a 'privat-docent,' or private tutor, to that of professor of the Finnish and old Scandinavian languages. One of his duties was to deliver a course of lectures on Finnish mythology, which he immediately commenced composing, but before they could be finished he was no more. He died at Helsingfors on the 7th of May, 1852, from the effects of his Samoyed journey.

The translation of the 'Kalevala,' and some of Castrén's other works, have been already mentioned. His lectures, 'Vorlesungen über Finnische Mythologie,' were published in German at St. Petersburg in 1853 under the editorship of Schiefner. A German version of his travels by Helms was published at Leipzig in 1853, and analysed at some length in the 'Quarterly Review.' His other works were mostly of a philological character:—'Elementa Grammatices Tcheremissæ,' Kuopio, 1845, 8vo; 'Elementa Grammatices Syrjænæ,' Helsingfors, 1844, 8vo; 'De Affixis Personalibus Linguarum Altaicarum,' Helsingfors, 1850, 4to. There is also an Ostiak Grammar in German, forming a portion of a work called 'Nordische Reisen und Forschungen,' which was commenced at St. Petersburg in 1849. It need hardly be added that all these works are of the highest value to those who take an interest in what is called the Ugrian family of languages, comprising the Finnish, the Hungarian, the Syryanian, and other dialects scattered over the surface of European Russia, to investigate which was the object of Castrén's devoted exertions. It is much to be regretted for the sake of learning, as well as on other accounts, that he was snatched away before he had time to communicate to the world the results of his dauntless and ingenious labours.

CATALYSIS. [Chemistry, *S.* 1.]

CATAMARCA, one of the upper provinces of the Argentine Confederation, South America, is bounded N. and N.E. by the province of Tucuman, E. by Santiago, S. by Cordova, and S.W. by La Rioja, and comprehends the little visited country between the mountain ranges of the Sierra of Aconquija and Ambato on the east, and the Andes on the west. The inhabitants do not exceed 30,000. The country consists of a principal valley, Catamarca, from which the province derives its name, and in which most of the inhabitants are settled; and of some other valleys, running between mountain ranges south-east and north-west, and terminating at their southern extremity on the borders of the Gran Salina, being thus separated from the other inhabited countries by high mountains and deserts. The rivers which water these valleys are lost in the Gran Salina. The climate is sultry, especially when the south winds blow, which come over the desert. Maize and wheat are raised to a considerable extent, but cannot be exported over the mountains. The province sends only cotton and red pepper (dried capsicums) to the adjacent countries, the latter chiefly to Buenos Ayres, where it is extensively used. The present capital is *Catamarca*, or *San Fernando del Valle de Catamarca*, in 27° 28′ S. lat., whose population is stated to be 4000. The first capital, called London, which was founded at the time when Philip II. of Spain married Queen Mary of England, was destroyed by the Indians.

CATHA, a genus of plants belonging to the natural order *Celastraceæ*. *C. edulis* is the Kat or Khât of the Arabs. "It would appear," says Dr. Lindley, "to be of a stimulating character. According to Forskähl the Arabs eat the green leaves with greediness, believing them to have the power of causing extreme watchfulness, so that a man may stand sentry all night long without drowsiness. They also regard it as an antidote to the plague, and assert that a person wearing a twig of it in his bosom may go among the infected with impunity; they even believe that the plague cannot appear in places where the tree is cultivated." ('Vegetable Kingdom,' p. 587.) At the same time Forskähl adds, "The taste of the leaves does not seem to indicate such virtues."

CATHARINE'S, ST. [Canada, *S.* 2.]

CATHCART, LIEUTENANT-GENERAL THE HON. SIR GEORGE, K.C.B., was born in London, on the 12th of May 1784, the third son of William Shaw, the first Earl Cathcart. He was educated at Eton, and at the University of Edinburgh; and in 1810 he began his military life by joining the 2nd Life Guards. In 1812, by which time he had been promoted to a lieutenancy, he accompanied as aide-de-camp his father, who was sent as plenipotentiary to Russia. When they arrived the French were in possession of Moscow, and when the Emperor Alexander took the field in person in 1813, Lieutenant Cathcart joined the imperial army. He was with the grand army throughout the campaigns of 1813 and 1814, witnessed the battles of Lutzen and Bautzen, those of Dresden and Leipzig, of Brienne, Bar-sur-Aube, Arcis-sur-Aube, and the taking of Paris. Of these campaigns, and more particularly of the strategy of Napoleon I. as displayed in the battles, he published a volume of Commentaries in 1850, from the facts noted at the time, accompanied with diagrams showing the position of the armies, with their movements. It is a valuable work; additional interest being given to it by an introduction explaining the different military systems of the Allied Powers, as well as of the French, and displaying the effects of national character under the different circumstances of attack and defence. In 1814 he again accompanied his father, who was one of the three plenipotentiaries sent to Vienna. On the return of Napoleon from Elba he was appointed aide-de-camp to the Duke of Wellington, and was present at Quatre Bras and Waterloo. He was continued in the appointment when the Duke became master-general of the Ordnance, and accompanied him on his mission to Aix-la-Chapelle, Verona, and Berlin. In 1828 he had arrived at the rank of Lieutenant-Colonel, and served for about eight years in Nova Scotia, Bermuda, and Jamaica. In 1834 he retired on half-pay; but in 1837 was recalled into active service on account of the outbreak in Canada, where he proved himself an active and efficient officer. After serving there for more than six years he returned home, and again retired on half-pay in 1844. In 1846 he was made Deputy-Lieutenant of the Tower, an office which he held till 1852, when he accepted the governorship of the Cape of Good Hope, with the command of the forces, and brought the Kaffir insurrection to a successful termination. On his return to England he was immediately sent as General of Division to the Crimea, where much was expected from a man so thoroughly acquainted with the practice and science of his profession. He however had short time to display his capabilities. In the battle of Inkermann, on the 5th of November 1854, where he displayed the most heroic bravery, but in which the attack he made on the left was met by a force so superior that it failed in the desired effect, he fell, together with the other leading chiefs. He was buried on the spot—Cathcart's Hill—with eleven other officers who had fallen.

CATLINITE, a form of argillaceous mineral called Pipestone by the North American Indians. It comes from the Coteau des Prairies, and is a red claystone or compacted clay. A similar material is now accumulating on the north shore of Lake Superior, at Nepigon Bay. Another variety is used by the Indians of the north-west coast of America. (Dana, *Mineralogy*.)

CAT-MINT. [Nepeta, *S.* 1.]

CAT'S-EYE, a form of Chalcedony, of a greenish-gray colour, having a peculiar opalescence, or glaring internal reflections, like the eye of a cat: the effect is owing to filaments of asbestos. It comes from Ceylon and Malabar, and possesses considerable value as a gem. (Dana, *Mineralogy*.)

CAT'S-TAIL GRASS, the common name of *Phleum pratense*, an agricultural plant, also called Timothy Grass. [Phleum.]

CAUCHY, AUGUSTIN LOUIS, mathematician, was born at Paris, Aug. 21, 1789. His father, Louis François Cauchy, was a poet, and became archiviste of the Chamber of Peers. The son was carefully and religiously educated. In 1804, while at the Écoles Centrales, he was crowned by the Institute as the pupil who had carried off most prizes, among which was the first in Latin poetry. In the following year he entered the École Polytechnique as second scholar, and in 1806, when only in his seventeenth year, his solution of a difficult problem was printed in the 'Correspondance' of the school.

From the École Polytechnique, where he rose to the first place, M. Cauchy entered that of the Ponts et Chaussées, maintaining the same position. He was afterwards appointed engineer of the works for the port of Cherbourg; and from this date commences his long series of mathematical researches in questions previously unsolved. Among the first was his demonstration of Euclid's celebrated theorem on the polyedra. In 1813 he published his 'Méthode pour déterminer à priori le Nombre des Racines réelles négatives d'une Extraction d'un degré quelconque,' which was followed by papers on the properties of integrals, taking up questions started by Clairaut. In 1815 he received the grand mathematical and physical prize of the Institute for his paper 'Sur la Théorie des Ondes,' which became the basis of a theory of light.

In 1816 Cauchy was elected a member of the Academy of Sciences, and was appointed professor of mechanics in the École Polytechnique, and in the same year he published his demonstration of Fermat's theorem of the polygonal numbers. His lectures had a most salutary influence on the educational results of the school, and the progress of his pupils was materially aided by the works which he successively published: 'Cours d'Analyse,' 1821; 'Leçons sur le Calcul Différentiel,' 1826; 'Leçons sur les Applications du Calcul Infinitesimal à la Géometrie,' 2 vols. 4to, 1826-28. At the same time be continued his valuable series of papers for the Academy, among which are 'Sur les Intégrales définies entre les Limites Imaginaires,' 1825; 'Sur l'Application du Calcul des Residus à la Solution des Problèmes de Physique Mathématique,' 1827; 'Sur la Résolution d'Équations Numériques, et sur la Théorie de l'Elimination,' 1829; 'Sur la Théorie des Nombres,' and others. The last was presented in May 1830. The revolution which followed deprived M. Cauchy of his public employment, as his loyalty to the Bourbon dynasty prevented his taking the oath of allegiance to the government of Louis Philippe. Under these circumstances he accepted the offers of the King of Sardinia, who invited him to deliver a course of physico-mathematical lectures at the university of Turin. In 1832 the Royal Society of London elected Cauchy one of their fifty foreign members. In the following year he received an invitation from Charles X. to undertake the scientific education of the Duc de Bordeaux, who then resided at Prague; and be cheerfully devoted himself to the task. While thus engaged he resumed in 1835 the publication of his 'Exercises de Mathématiques,' which had been for some years interrupted. In 1836 he published his 'Mémoire sur la Dispersion de la Lumière.' In 1838, having terminated his work of instruction, he returned to Paris, and took part in a scheme for training a superior class of professors in the interests of legitimacy. He was chosen a member of the Bureau des Longitudes in 1839, but the minister refused to sanction the choice, remembering the refusal to take the oath of allegiance.

Cauchy's diligence appears to have increased with his years. The number and nature of his communications to the Academy may best be judged of by reference to the 'Comptes Rendus;' at one time they became so multiplied that their publication overstrained the Academy's funds. Concurrently he wrote papers which appeared in other scientific periodicals, chiefly in Liouville's 'Journal de Mathématiques,' among which his 'Note sur le Développement des Fonctions en Séries ordonées suivant les Puissances ascendantes des Variables,' published in 1846, is especially remarkable.

In 1848 a professorship of mathematical astronomy having been created at the Faculty of Sciences of Paris, M. Cauchy was appointed to the chair; but, as had happened eighteen years before, his refusal to take the oath required in 1852 again lost him his public employments. He still continued his studies; adding every month to the number of his works. He treated of the higher branches of algebra, the theory of numbers, the infinitesimal calculus, mechanics, astronomy, and physics, exploring indeed every branch of mathematical analysis. Of him it has been said that he "threw back the limits of the integral calculus; and if showing a preference for abstract questions, he on the other hand rendered important service to the elementary portions of science, by simplifying the theory of asymptotes, introducing the use of limits in all parts of geometry, and by giving an elegant demonstration of the fundamental theorem of the theory of equations."

M. Cauchy was a member of several scientific societies. Besides the works above mentioned, he published at Turin his 'Resumés Analytiques,' 4to. In 1836 appeared 'Sur la Théorie de la Lumière,' 8vo; 'Sur la Mécanique Celeste,' &c., 8vo, in 1831—and a large number of others in the 'Mémoires' of the Academy, in the 'Annales de Mathématiques,' and other scientific journals. He showed too, that he inherited his father's poetical ability and lively imagination, and relieved at times his severer studies by the composition of French and Latin poetry. In 1834 one of his poems 'Charles V. en Espagne' was published, which has much merit, and exhibits the monarchical predilections and religious opinions which actuated the whole life of the author. He died May 23, 1857.

CAVAIGNAC, GENERAL LOUIS EUGENE, son of Jean-Baptiste Cavaignac, member of the Convention and of the council of the Five Hundred, and brother of Godefroy Cavaignac, repeatedly prosecuted by Louis Philippe, was born at Paris on the 15th of December, 1802. In 1820, at the age of eighteen, he entered the École Polytechnique. In the years 1828-29 he served in the second regiment of Engineers as captain, and took an active part in the campaigns of the Morea. Like most of the sons of the noted republicans of the Great Revolution, he adopted early in life the principles of his father; he was consequently one of the first to adhere to the revolution of July, in 1830. But the free expression of his opinions having given offence to his superiors, he was sent in 1832 to join the army in Africa. Even there he could not control or conceal his republican opinions; but the brilliant courage he displayed, and the services he rendered, drew upon him the notice and the esteem of his commanding officers. He was employed in the expeditions of Medeyah, Bouffard, and Chirchell; and in the several battles and skirmishes of Ouara, Col de Moozaïa, &c., he gave proofs of that aptitude for war which bespoke the future general. But it was especially in the expedition against Tlemsen that he proved his capacity, and evinced his valour.

After the capture of Tlemsen, in January 1836, Marshal Clausel formed a battalion of volunteers to garrison the citadel of that town; and gave the command of the place to Captain Cavaignac. In this isolated position he maintained himself with great honour. Although frequently attacked by the Arabs, and blockaded by Abd-el-Kader, he held out, teaching his troops, both by his example and intrepidity, to endure the severest privations without a murmur. It was not however till May 1837 that he received further promotion. Shortly after the taking of Constantine, Cavaignac was transferred to the Zouaves; after which he had a battalion in the infantry of the line. In 1839 be published a work of considerable value, entitled 'De la Régence d'Alger.'

Although his health and constitution were at all times delicate, Cavaignac sustained with unfaltering resignation the trials and fatigues of a camp life; being remarked as constantly the first to meet the enemy, and the last to retire to his tent. At the same time his qualifications for providing resources and administering them when found, were of a high order. Having returned to the corps of Zouaves as lieutenant-colonel on the 21st of June 1840, he was created colonel the following year; but a short time before the battle of Isly, he joined the 32nd of the line. It was in the capacity of commander of the vanguard, in this memorable action, that he so ably supported General Bugeaud against the army of Marocco. For his behaviour in this battle he was made maréchal de camp on the 16th of September 1844. After suppressing several revolts among the tribes on the western frontier in 1845, he invaded Marocco in February 1846, at the head of 6000 men, driving before him the redoubtable Emir Abd-el-Kader.

In 1847 he succeeded Lamoricière in the government of Oran, and on the 24th of February 1848, he received his appointment as governor-general of Algeria, by a decree from the Provisional Government. Two months after this, Lamartine, having foreseen the impending dangers by which France was threatened, invited Cavaignac to the capital. His great ability, and his decision in quelling the insurrection of June, established his character both as a citizen and as a soldier. It was by far the most serious revolt which had occurred since 1789. Cavaignac met the threatened danger with promptitude. A force of 75,000 regulars and nearly 200,000 National Guards was collected in and near the metropolis. Several powerful barricades were approached, attacked, and carried in the regular order of battle, Cavaignac himself, accompanied by Lamartine, leading the attack of the one erected in the Faubourg du Temple. On the second day of the insurrection, Paris was declared in a state of siege, and General Cavaignac was appointed Dictator, all the civil and military powers being committed to his charge. After four days' hard fighting, the contest came to an end by the defeat of the anarchists. The loss on both sides was appalling: two generals were killed, four others mortally and five badly wounded. In all, some 8000 persons were killed and wounded, and 14,000 made prisoners. No sooner had he quelled this great revolt than the general laid down his authority. The National Assembly appointed him President of the Council, after which he became one of the candidates for the new office of President of the Republic. In this contest he failed, but was supported by 1,448,302 votes. On the 2nd of December 1851, he was arrested, but released after a short detention; and he was afterwards allowed to reside undisturbed in France, although he had not given his adhesion to the government of the Emperor. He died October 1, 1857.

CEDRELA. [CEDRELACEÆ, *S.* 1.]

CEDRIRET. [CHEMISTRY, *S.* 1.]

CELAKOWSKY, FRANTISEK LADISLAW, a Bohemian poet and philologist, was born at Strakonice, a small town about 60 miles W. from Prague, on the 7th of March 1799. When studying at the university of Prague, his enthusiasm for the long-neglected language of Bohemia was first aroused by the society of his friends and fellow-students Kamaryt, Chmelensky, and Vinaricky, all afterwards authors of some note. The first effect of it was that he made a grand auto-da-fè of all he had hitherto written, because it was in the German language. He then commenced an ardent study of the Slavonic languages, and made himself master of them all, as well as of Italian, French, and English, and at this time he made a list of four hundred English words "manifestly of Slavonic origin," says his biographer Maly, which would be of some interest, but does not appear to have been printed. His first publication was a volume of 'Poems,' which was soon followed by a Bohemian translation of Herder's 'Blätter der Vorzeit,' or 'Leaves of Antiquity.' We are told by Maly that the time of its appearance, about 1822, was "the period of transition from the old classic to the modern style" in Bohemian literature, and that the translation was "the earliest classical specimen of modern Bohemian prose." A more important production was a collection of Slavonic national songs, 'Slowanské národnj pjsni,' in three volumes (Prague, 1822-27), a publication somewhat resembling the 'Minstrelsy of the Scottish Border.' In 1828 Celakowsky published a translation of the 'Lady of the Lake,' into a new kind of poetical prose, somewhat of the Ossianic kind, but this attempt proved a total failure, and the only result of which the writer could be proud was that he received an autograph letter of thanks from Sir Walter Scott, to whom he had presented a copy. He was more successful in his next translation, the 'Ohlas pisni Ruskych,' a collection of Russian national songs, so beautifully rendered into the kindred Bohemian that they at once took a very high place in the literature of that country, and still retain it. Russian was at that time the favourite language of Celakowsky, and the Russian nation was high in his esteem, so much so that he lost the friendship of several of his Bohemian acquaintances on the outbreak of the Polish insurrection in 1831, from taking the part of the Russians against the Poles. He had then been for some time the editor of the leading Bohemian newspaper at Prague, a post to which he had been recommended by his patron, Count Chotck, and he was also professor of the Bohemian language at the university. When the Polish insurrection was suppressed however, he disapproved of the severity of the measures adopted by the Emperor Nicolas, and in an article of his paper compared the proceedings of the Czar to the tyranny of the Tartar khans of the Golden Horde over conquered Russia, in the times of its humiliation under the Mussulmans. The article happened to pass the censorship, but did not elude the vigilance of the Russian embassy at Vienna; a complaint was made to the Austrian government, and the unfortunate writer was at once dismissed from his editorship and his professorship—or in other words was ruined. In a paroxysm of bitterness Celakowsky composed a volume of epigrams against his persecutors, but as might be expected, the permission to print them was refused. He obtained the place of librarian to the Princess Kinsky, and published some poems of a milder character, of which the 'Hundred-Leaved Rose' ('Ruze Stolista') is spoken of as the finest. His fame was at this time widely extended. Dr. Bowring, now Sir John, dedicated to him in 1832 his volume of 'Cheskian Anthology,' in some stanzas in which he spoke of the kindness Celakowsky had shown him on his visit to Bohemia, and the material assistance he had afforded him in the preparation of the volume. The present King of Prussia was soon after his accession induced, by a deputation of Poles, to found professorships of Slavonic literature at two of his universities, Berlin and Breslau, and Celakowsky was offered the choice of either. He selected Breslau, and removed there in 1842, to enjoy again a competence, but in what appeared to him exile, in a country which had ceased to be Slavonian. He was always eager to greet any Slavonians who came to Breslau, and the time of vacation always found him at Prague. At length the events of 1848, so disastrous to Bohemia, when the general meeting of Slavonic deputies at the capital led to its bombardment by Windischgratz, brought about Celakowsky's return to his native country. In the following year a Professorship of Slavonic Philology was instituted at Prague as a concession to the national party, and it was offered to Celakowsky, whose offences were probably considered as sufficiently expiated by his seven years' expatriation. He returned, but his friends perceived that he was not to remain long among them. Always of a somewhat moody character, he was now wild and eccentric; some domestic calamities, particularly the loss of his wife, who left him burdened with a large family of children, had shaken his mind. He died on the 5th of August 1852.

Some of Celakowsky's works have been already mentioned. The most important of his other publications, his 'Mudroslovi národu slovanského v prislovich' ('The Philosophy of the Slavonic nation in proverbs'), a valuable collection of that nature, attracted much attention on its appearance after his return to Prague, and to increase which he left large manuscript additions, which are likely to see the light under the editorship of a friend. He had also been for years engaged in collections for a supplement to the valuable Bohemian dictionary of Jungmann, but on an extended plan, embracing a comparison with the other Slavonic dialects, as in the great Polish dictionary of Linde. This work is also destined for publication, and, it is anticipated, will prove a contribution to Slavonic literature of the very highest value.

CELA'NO, the ancient *Fucinus*, a lake in the Abruzzo in Italy. It is remarkable as being almost exactly in the centre of the Italian peninsula and the only lake of any considerable extent in the Central Apennines. The lake is nearly oval in shape, about 20 miles round, 2176 feet above the level of the sea, and situated in a basin without visible outlet, and screened on all sides by mountains. To the north rises Monte Velino with its double peak to the height of 8180 feet. To the east and west are limestone ridges, steep and rocky, and of much inferior elevation. On the north-west a moderate acclivity separates the lake from the valley of the Salto, an affluent of the Tiber. The lake, it appears, was traversed in ancient times by a river, called Pitonius, which must be the Giovenco, the only perennial stream of any magnitude that now enters the lake; and its surplus waters were carried off by subterranean channels, the opening of one of which is still visible, and called La Pedogna, a name clearly derived from Pitonius. The outlets, however, being insufficient, the lake frequently overflowed the low grounds along its banks. To obviate the evil, Julius Cæsar designed to cut a tunnel from the lake into the valley of the Liris; his plan, however, was not carried into effect till the reign of Claudius, who celebrated the opening of the tunnel with great magnificence. In the middle ages the tunnel became obstructed by the falling in of stones and earth, and many attempts have been made since the year 1240 to render it efficient in preventing inundations of the lake, but without success. Between 1745 and 1830 the encroachments of the lake had swallowed up 10,000 acres of the best land in the Abruzzo. Important repairs, however, were made at the expense of the King of the Two Sicilies, under the direction of Signor de Rivera (who examined the tunnel in detail, and described it in 1825), and the ancient tunnel was so far rendered available as to carry off a constant, though not a large, stream of water into the Liris, or Garigliano. The area covered by the lake, according to a late official survey, is 36,315 acres. A company was formed at Naples in September 1852 to effect the complete drainage of the lake.

Considered as a remnant of antiquity, the tunnel of

Claudius is an exceedingly interesting object. At the opening of it, near the lake, the tunnel is about 30 feet high and 28 feet broad; but it contracts considerably as it advances through the mountain. Its whole length is three miles. It is in part cut through the solid limestone of Monte Salviano, and in part through a chalky earth that has little tenacity. Wherever the latter substance occurs, the tunnel is supported by masonry of admirable workmanship. To admit light and air the Romans sunk shafts from above. The entrance to this tunnel is about a mile and a half to the south of the town of Avezzano, on the north-west shore of the lake. [ABRUZZO.]

CELBRIDGE. [KILDARE.]

CELLS. The ultimate structure of animal and vegetable bodies consists of minute vesicles, which are called Cells. In both animal and vegetable structures these organs are not generally visible to the naked eye, as they vary from the 1-500th to the 1-10000th part of an inch in diameter. In all cases they consist of an enveloping membrane or cell-wall, which incloses in a space more or less enlarged certain constituents, called cell-contents. The nature of the substances which enter into the composition of the cell-walls and constitute the cell-contents, differs in the animal and vegetable kingdoms, but there are certain properties which all cells possess in common. Sometimes these properties are called vital, to distinguish them from the properties possessed by inorganic or mineral bodies, which are called physical. It will, however, be seen that, independent of the formative power by which particles of gelatine, cellulose, &c., arrange themselves in the form of cells, and again these cells arrange themselves into the forms of organs and beings of a specific form, there are few of the functions performed by cells that may not be referred to the action of physical forces. One of the first and most necessary conditions of the cell is, that it shall allow of the passage, through the membrane of which its walls are composed, of those substances by means of which it grows, and which it acts upon for the production of the peculiar secretions which characterise either specific beings or parts of their organisation. This function, which is called Absorption, seems referrible to the physical relations which exist between liquids and gases and the membrane of which the cell-wall is composed. [ABSORPTION.]

The liquid or gaseous contents which are thus introduced into the interior of cells undergo a variety of changes, according to the position, age, or other circumstances of the cell. Sometimes the fluid that is absorbed appears to be transmitted in compound structures from cell to cell without undergoing any great amount of change. In other cases, the most decided chemical changes take place in the elements introduced. The cells of some parts of vegetable structures are an instance of the latter, in which carbonic acid and ammonia are absorbed with water, and converted, either during their passage through the cell-wall, or whilst in the interior of the cell, into cellulose, starch, sugar, protein, and other constituents of the cell. In other parts of plants the cells convey solutions of sugar and other substances without producing on them any change.

The constituents absorbed into the interior of the cell are the materials from which the cell-wall and all its contents are derived. The process by which the cell appropriates to itself these matters is called Assimilation. This function is supposed to be carried on by an independent force or power residing in the cell, or congeries of cells, which form an organ or a body, and has been called the 'assimilative force or property,' 'organising force,' 'plastic force.' It is necessary however in this process to separate between the changes by which one substance is converted into another, and which is probably the result of ordinary chemical force under other circumstances, and the power or force by which these substances are made to assume definite forms in cells and organs. The latter is a special force in the case of each cell, plant, or animal, and to which alone, of the changes involved in the function of assimilation, the term vital can be properly applied.

The result of the appropriation of the new matter absorbed from without in all cells is their enlargement or growth. This takes place in two ways: either the new matter is taken up into the interior of the substance of the cell-wall, which is always the case where the cell becomes augmented in size, or it is deposited in the form of layers in the interior of the cell. According as the first mode of growth is regular or irregular will be the form of the cell. The vegetable and animal kingdoms present almost all conceivable forms of cells, from the spherical and hexagonal cells observed in the lower forms of plants, and the less organised tissues of animals, as cartilage, up to the elongated vessels of the plant, and the irregular cells of bone or areolar tissue in animals. The animal kingdom presents by far the greatest variety in this respect, and so great are the changes that some of the animal cells undergo, that the terms Metamorphoses or Transformations have been applied to these changes. As examples of these cells we may quote—the horny scales of the epidermis, of the hair and the nails, and the laminated pavement, epithelium—in which the cells are flattened, polygonal, or fusiform, and the cell-wall is fused into one mass with the cell-contents; the contractile fibre-cells of the smooth muscles; the tubules of the lens; the prisms of the enamel; the various forms of bone-cells; and the transversely striated cells of muscular fibre.

All cells originate or are produced in the same way. Either they are developed free in vegetable or animal fluids, or they are produced in the interior of preceding cells. In all cases they originate in connection with a substance called protein, which exists in cells, either in the form of a small dark spot called a nucleus, or cytoblast, in the interior of which is a nucleolus, or of an expansion on the interior of the cell, when it is called the primordial utricle. Free cell-development has been observed to take place in plants, in saccharine and other liquids about to undergo the fermentation process, and amongst animals in the chyle, blood, and lymph. The exact mode of the development of cells under these circumstances has not been accurately observed, and the particles or granules of proteinaceous matter from which they are supposed to originate have not yet been proved to have had their origin independent of other cells. The most common form of cell-development is that in which the cell grows around or from the nucleus or primordial utricle. In the animal kingdom the development of the cell more frequently takes place around the nucleus, whilst in the vegetable kingdom its origin is more frequent from the folding in or contraction of the primordial utricle upon itself, by which means two cells originate in one.

Besides the development of cells around the nucleus and round the investing membrane, or primordial utricle, within the walls of the cell, a multiplication of cells frequently takes place by division of the whole cell. This takes place in many of the lower forms of animals and plants [PROTOZOA, *S.* 2], and also in the red blood-corpuscles of the embryos of birds and mammalia, and in the colourless blood-corpuscles of the tadpole. It is probable that further observation will extend our knowledge of this mode of cell-multiplication.

One of the highest problems for the physiology of the present day to solve is, the efficient causes of the phenomena of cell-development. The following propositions have been laid down by Kölliker as an attempt to follow up Schwann's idea of the analogy between chemical changes in inorganic bodies and those which occur in cells:—

1. The nucleus of the cell arises in the first place as a precipitate in an organisable fluid, and afterwards becomes consolidated in such a manner that a special investment and contents with a nucleolus appear. Its development may in this case be compared to that of inorganic precipitates, yet the constantly globular figure and size of the nuclei which are just formed, indicate some essential though not yet recognised condition peculiar to them.

2. In the development of cells by division the cell-nucleus plays exactly the same part which was previously ascribed to the nucleolus, and the occurrence of the formation of cells in this manner demonstrates that chemical conditions are not necessarily concerned therein.

3. In cell-development around portions of contents, and in the cleavage process, the nuclei also operate as simple centres of attraction upon a certain mass of blastema, and then follows the formation of a membrane upon the surface of this mass, which is most simply understood as a condensation of the blastema.

4. In the cell-development directly around the nucleus the investment with blastema is wanting, and the nucleus develops the membrane immediately around itself.

From what has been previously said, it will be seen that the cells are the active seat of the functions of both animals and plants, and the most conspicuous results of organisation take place in consequence of their agency. They not only constitute the mass of the body, but by their agency alone all the special secretions and products of individual plants and animals are formed. The food is conveyed into the body by cells, the blood of animals is charged with cells, and the functions of locomotion and sensation are carried on by the agency of cells. Nor are these last functions peculiar to the animal kingdom. Contractility and sensibility seem to be the property of the substance (protein) of which the nucleus and primordial utricle are composed. To this substance Mr. Huxley proposes to give the name Endoplast, and thus concludes a lecture on the identity of structure of plants and animals :—

"In both plants and animals then there is one histological element, the Endoplast, which does nothing but grow and vegetatively repeat itself; the other element, the periplastic substance (the cell membrane) being the subject of all the chemical and morphological metamorphoses, in consequence of which specific tissues arise. The differences between the two kingdoms are, mainly, 1, that in the plant the Endoplast grows, and, as the primordial utricle, attains a large comparative size; while in the animal the Endoplast remains small, the principal bulk of its tissues being formed by the periplastic substance; and, 2, in the nature of the chemical changes which take place in the periplastic substance in each case. This distinction however does not always hold good, the Ascidians furnishing examples of animals whose periplastic substance contains cellulose.

"The plant then is an animal confined in a wooden case; and nature, like Sycorax, holds thousands of 'delicate Ariels' imprisoned within every oak. She is jealous of letting us know this; and among the higher and more conspicuous forms of plants reveals it only by such obscure manifestations as the shrinking of the Sensitive Plant, the sudden clasp of the *Dionæa*, or, still more slightly, by the phenomena of the *Cyclosis*. But among the immense variety of creatures which belong to the invisible world she allows more liberty to her Dryads; and the *Protococci*, the *Volvox*, and indeed all the *Algæ*, are during one period of their existence as active as animals of a like grade in the scale. True, they are doomed eventually to shut themselves up within their wooden cages and remain quiescent; but in this respect they are no worse off than the Polype, or the oyster even."

For further information on the subject of Cells, see the articles HISTOLOGY, *S.* 2; CILIA, *S.* 1; TISSUES, ORGANIC, *S.* 1.

CENSUS OF 1851. The Census of Great Britain in 1851 differed in several respects from any previous Census. In some points the range of its inquiries was more minute and precise; in many others wider and more comprehensive. The character of the previous inquiries and the extent to which they reached have been sufficiently indicated in former volumes of the 'Penny Cyclopædia;' here, therefore, before giving some of the principal results of the Census, it will be enough to state, in the words of the very elaborate Report of the Registrar-General, prefixed to the volumes of Population Tables, printed by order of Parliament, what the Census of 1851 sought to accomplish :—

"At the present Census it was resolved to exhibit not merely the statistics, as before, of parishes, and, more completely, of parliamentary and municipal boroughs, but also of such other large towns in England and Scotland as appeared sufficiently important for separate mention, and of all the ecclesiastical districts and new ecclesiastical parishes which, under the provisions of various Acts of Parliament have, during the last forty years, been created in England and Wales. In addition also to the inquiry concerning the occupation, age, and birthplace, of the population, it was determined to ascertain the various relationships (such as husband, wife, son, daughter)—the civil condition (as married, unmarried, widower, or widow)—and the number of persons blind, or deaf and dumb. Further, under the impression that the fifth section of the Act would authorise such an inquiry, the design was formed of collecting statistics as to the accommodation afforded by the various churches and other places of public religious worship throughout the country, and the number of persons generally frequenting them; and also as to the existing educational establishments, and the actual number of scholars under instruction. It was, however, subsequently considered doubtful whether, upon a rigid construction, the Census Act rendered it compulsory upon parties to afford information upon these particulars; and the inquiry was therefore pursued as a purely voluntary investigation. It was not deemed necessary to procure, as at former Censuses, any abstract of the parish registers for the ten preceding years; the general system of registration of births, deaths, and marriages, which had been for that period in full operation, affording more complete and trustworthy information as to changes in the aspect of the population referable to the operation of these events."

For obtaining these objects, the local machinery introduced in England and Wales by the Poor Law and Registration Acts was employed, the general direction of the Census, under the Secretary of State, being given to the Registrar-General. The 624 Registration Districts, into which England and Wales was divided by the Registration Act, each having a superintendent-registrar, are subdivided into 2190 Subdistricts, each having a local registrar of births and deaths. These subdistricts were, for the purposes of the Census, and under the supervision of the registrars and superintendent-registrars, again divided into 30,610 Enumeration Districts, each such district being assigned to one enumerator, who was required to complete his enumeration in *one day*. In Scotland, where no such local machinery existed, the Census was taken through the agency of the sheriffs of counties and chief officers of boroughs; the working of the Act being devolved chiefly on the sheriffs-substitute, "who appointed a fit person, generally the parochial schoolmaster, in each parish to divide it into convenient enumeration districts, and superintend the proceedings of the Census therein." The number of enumeration districts formed throughout Scotland, in 1851, was 7878; in the Islands of the British Seas, 257 enumeration districts were similarly formed. Of the mode of taking the Census, it will suffice to say, that blank-forms were left at every house and public institution, with minute directions, in order that they might be correctly filled up with the requisite information concerning every person who abode in the house or apartment on the night of March 30, 1851. These forms were collected by the enumerators on the 31st of March; each enumerator being directed to satisfy himself, as far as possible, of the accuracy of the entries, and where inaccurate to correct them. The vast importance of the method adopted, as a security for the accuracy and precision of the returns, will be best understood by a comparison with the method adopted in taking the Census of the United States in 1850. At that date the territory of the United States comprised an area of 3,300,000 square miles. To number the inhabitants occupying that vast space the entire staff of superior and subordinate officers employed numbered only 3276 persons, less than one-tenth of the number employed for enumerating the population of England and Wales, a territory of 58,320 square miles, or less than a fifty-sixth of the area of the United States. It is at once evident that the American enumeration could not be made on one day, and accordingly we find that though the schedules were directed to be filled up with 'reference to' a particular day, the officer did not call at the house, the inmates of which were to be numbered, till some days, weeks, or even months after the time specified; when—the careless way in which people are accustomed to treat such things being taken into account—it is scarcely possible that errors can in very numerous instances be avoided, even as regards the mere number of residents, while in respect of age and other more minute matters, the probability of error is of course largely increased. As far as provision could be made by the strength and careful appointment of the official staff, and the strictness with which their duties were defined, the arrangements for the British Census of 1851 were in all respects admirable, and probably the returns were as accurate as under existing circumstances are attainable. It may serve to show the amount of labour which devolved on this army of enumerators (including Scotland, nearly 39,000 in number), to state that the blank-forms for England and Scotland, issued from the Census Office, amounted in all to nearly 7,000,000, the weight of them being nearly 40 tons: the "weight of the schedules, blank enumeration books, and other forms, despatched from the central office, exceeded 52 tons." The schedules, after being duly filled in, were subjected to revision by the registrars and superintendent-registrars before transmission to the Census Office, there to undergo final revision and generalization. The enumeration of the persons on board vessels, either in harbour or at sea, was accomplished by the officers of the Customs, the Admiralty, and the Registrar of British Seamen; the enumeration of the army by the officers of the various branches, under the direction of the Commander-in-Chief. In these, as in other matters, the returns were much more minute and extensive than in any previous Census; while several collateral returns were at the same time obtained, such as of the latest population of the several colonies, the number of British subjects in various foreign states, the number and rank of half-pay officers of the army, navy, and marines, of Chelsea and Greenwich pensioners, of officers employed in the civil service of the Crown, &c.

We proceed now to the *results* of the enumeration of the population. The number of people in Great Britain, including the islands in the British seas, on March 31, 1851, was 20,959,477; and the men in the army, navy, and East India Company's service, abroad, on the passage out, or round the coasts, belonging to Great Britain, on the same day, was 162,490. The total population of Great Britain may therefore be set down at 21,121,967. Of these 16,921,888 were in England, 1,005,721 in Wales, 2,888,742 in Scotland, 143,126 in the Isle of Man, Jersey, Guernsey, Alderney, and other small islands in the British seas; and 162,490 were at sea or serving abroad in the army.

The *proportion of males to females* has been preserved with remarkable regularity during the half century. In 1851 the male population of Great Britain was 10,386,048, the female 10,735,919; being an excess of 349,871 females; the excess of females at home was 512,361. The proportion in 1851 was 103,369 females to every 100,000 males; in 1801 it was 103,353 females to 100,000 males. At both periods there were somewhat less than 30 males to 31 females. In 1851 there were 20 males at home to 21 females. The excess of births, however, is in the opposite direction. During the 13 years (1839-51) in which accurate registers of births have been kept, there have been born 3,634,235 males and 3,465,629 females, or about 105 males to every 100 females (104,865 to 100,000). The disparity in the sexes at home is greatest in Scotland—110 females to 100 males; in England and Wales it is only 104 females to 100 males. To what degree the change in the proportions and the subsequent disparity of the numbers in the two sexes is due to emigration, or to a difference in degree of the dangers and diseases to which they are respectively exposed, this is not the place to consider.

The *increase of population* in the last half century nearly represents a new nation equal to that which existed in Great Britain at its commencement, and that notwithstanding the vast numbers who have "annually left the United Kingdom, settled and multiplied in millions in the United States, in the colonies of North America, of Australia, and of South Africa." The aggregate increase in the fifty years is 93·470 per cent., or at the rate of 1·329 per cent. annually. "The annual increase, however, has varied in each decennial period; it increased from 1·274 per cent. on the population in 1801-11, to 1·489 (nearly 1½) in 1811-21, when it was at the *maximum;* the annual rate of increase in 1821-31 was 1·408; in 1831-41 it fell to 1·279; and in 1841-51 to 1·186 per cent. annually. The population therefore is increasing, but the rate of increase has declined since 1811-21, when there was little emigration, and the mortality in England was lower than it has ever been before or since, down to the two last decennaries; when the public health has suffered from epidemics of influenza, cholera, and other diseases; while emigration from the United Kingdom has proceeded at an accelerated rate from 274,300 in 1821-31, to 718,000 in 1831-41, and 1,693,000 in 1841-51." During the same period the proportion of land to each person has decreased in Great Britain from 5·4 acres in 1801, to 2·7 acres in 1851; from 4 acres to 2 acres in England and Wales.

If the rate in which the population has increased since 1801 continued to prevail uniformly, the population would double itself in Great Britain every 52½ years; in England and Wales every 51 years.

The number of *families* in Great Britain in 1801 was 2,260,802; in 1851 it was 4,312,388; being an increase of 2,051,586. The families in England and Wales in 1801 were 1,896,723; in 1851 they were 3,712,290. In Scotland they were 364,079 in 1801, and 600,098 in 1851. The average number of families to a house in Great Britain in 1801 was 1·209; and of persons in a family, 4·645; in 1851 there were 1·182 families to a house, and 4·825 persons in a family. In Scotland in 1851 the average of persons in a family was 4·814, or nearly that of the whole island; but the average of families in a house was somewhat higher—1·621. In Glasgow the number of families to a house is 5·4; of persons to a house, 27·5; in Edinburgh the corresponding numbers are 4·2 and 20·6; in Aberdeen, 3 and 12·3; in Dundee, 3·2 and 15·7; in Perth, 2·8 and 12. In London, on the other hand, the numbers are only about the average of Scotland—1·74 and 7·7; but in some districts they are as high as 10, 11, and even 12 persons to a house. This excess in the northern cities was caused by a real difference in the habits of the people. "The towns and cities of the two northern English counties and of Scotland are built in the continental style; and the families of the middle classes, as well as the poor, live in large flats, which constitute separate tenements." The term house, in many parts of Scotland, has been usually applied to these several flats or floors; and in every census from 1801 to 1841 'flats' in Glasgow and some other Scottish towns were returned as separate houses. In 1851 this was corrected, and the enumerators were instructed that flats and sets of chambers must not be returned as houses. The returns from Scotland, as from England, are now, therefore, made on a tolerably uniform principle, and are fairly available for comparison. The variations in the several English counties and in different districts with respect to the proportion of families to houses, is considerable; but it would require far more space than we can spare to enter upon it. As a rule, in England and Wales, a house is inhabited by one family, the excess in the proportion being mainly caused by the large number of public institutions, hotels, lodging-houses, &c. The following is an analysis of the families in connexion with the houses which they occupy in 14 subdistricts of England, containing 35,876 inhabited houses, in which were 48,985 families (1,608 of the houses having the families absent), comprising 242,164 persons, or, on an average, nearly 7 persons to a house—5 to a family. Of these houses, 26,309 contained one family; 4,789, two families; 1,523, three; 748, four; 425, five; 224, six; 118, seven; 62, eight; 32, nine; and 38, ten families and upwards. This analysis is in the Report carried out with great minuteness into a variety of particulars, but which it is impossible for us here to follow.

The *number of houses* in Great Britain in 1851 was—inhabited, 3,670,192; uninhabited, 166,735; building, 29,194. In 1801 there were 1,882,476 inhabited, and 67,320 uninhabited; the number building was not returned. The following tables show (1) the number of principal public institutions,—of their inmates 35,516 were officers and servants; and (2) the number of persons sleeping in barges, barns, tents, and vessels.

Institutions.	No.	Persons.	Males.	Females.
Barracks	174	53,933	44,833	9,100
Workhouses	746	131,582	65,786	65,796
Prisons	257	30,959	24,593	6,366
Lunatic Asylums	149	21,004	9,753	11,251
Hospitals for the Sick	118	11,647	5,893	5,754
Asylums and other Charitable Institutions	573	46,731	27,183	19,548
Total	2,017	295,856	178,041	117,815

	Persons.	Males.	Females.
Persons in Barges	12,924	10,395	2,529
,, Barns	9,972	7,251	2,721
,, Open Air in Tents	8,277	4,614	3,663
,, Vessels in the Ports, engaged in Inland Navigation	8,575	7,730	845
,, Sea-going Vessels in the Ports	43,173	41,165	2,008
Total	82,921	71,155	11,766

"The enumeration of the houseless population, unsettled in families, is, however, necessarily imperfect; and the actual number must exceed the 18,249 returned, namely 9,972 in barns, and 8,277 in the open air. It is mentioned in one instance that a tribe of gipseys struck their tents and passed into another parish in order to escape enumeration. In 1841 the nnmber of the honseless class was 22,303 : owing to the more advanced period of the year (June 7) at which the Census was taken, many Irish people and labourers were then engaged in the hay harvest."

From honses and families we ascend to *towns and corporations*. No attempt was made to classify the smaller aggregates of honses by defining villages, hamlets, &c.; but 17,150 places which have defined boundaries are separately retnrned in the Population Tables, and each of these is assumed to be a *village*, or an aggregation of families round a chnrch or chapel: on an average these villages lie at a distance of about $2\frac{1}{2}$ miles apart, so that the inhabitants of the conntry around them, distributed over an area of 5 miles, lie at the average limit of $1\frac{1}{4}$ mile from the centre, or at the mean distance of six-sevenths of a mile.

"Great Britain has *eight hundred and fifteen* towns of various magnitndes, either market towns, connty towns, or cities, *five hundred and eighty* in England and Wales; *two hundred and twenty-five* in Scotland, and *ten* in the Channel Islands. To 21 of the preceding 'villages' there is on an average a town, which stands in the midst of 110 sqnare miles of country, equivalent to a square of $10\frac{1}{2}$ miles to the side, a circle having a radius of nearly 6 miles; so that the population of the country around is, on an average, about 4 miles from the centre.

"The population amonnted to 10,556,288 in the 815 towns, which stand on 3,164 miles of area. An average town of 12,953 inhabitants stands on an area of nearly 4 square miles; equivalent to a sqnare of 2 miles to the side, a circle $1\frac{1}{10}$th mile to a radins, and the population is less than three-quarters of a mile from the centre.

"The popnlation in the rest of Great Britain was 10,403,189; consequently if, for the sake of distinction, the detached houses, the villages, and small towns without markets, are called—conntry; at the present time the *town* and *country* popnlations of Great Britain differ so little in numbers, that they may be considered equal, for by the abstracts 10,556,288 people live in the towns, and 10,403,189 in the conntry. In the towns there were 5·2 *persons to an acre*, in the conntry 5·3 *acres to a person*. The density in the country was 120 persons—in the towns 3,337 persons—to a square mile. . . .

"The 815 towns are grouped aronnd 87 connty towns—52 in England, 32 in Scotland, and 3 chief towns, equivalent to county towns, in the Islands of the British Seas. Each of the central connty towns was surrounded on an average by eight or nine other towns, extending over an average area of 1,067 square miles, equivalent to a sqnare of 33 miles to the side; a circle of 18 miles radius: and without allowing for the extreme distance of the Islands in the British Seas, they were 35 miles apart. The popnlation of the connty towns of Great Britain, and the chief towns of the Channel Islands amounted to abont 626,547 in 1801, and to 1,391,538 in 1851; in England and Wales the popnlation of the county towns was about 473,239 in 1801, and 1,076,670 in 1851."

This equality of proportion between the town and conntry population of Great Britain is one of the 'great facts,' brought into prominent notice by the Census of 1851. The great relative increase of the popnlation collected in the principal towns is another of the more important facts which point to a change in the habits and condition of the people. Thus, in the 61 principal towns in England and Wales, which in 1801 contained 2,163,698 inhabitants, the popnlation had risen in 1851 to 6,254,251; in other words, in 1801, about 24 per cent. of the entire population resided in those 61 towns, while in 1851 very nearly 35 per cent. of the population resided in the same towns. In the seven principal towns in Scotland there resided in 1801, 271,486 ont of the entire population of 1,608,420, or 16·8 per cent.; in 1851, 779,698 ont of the entire population of 2,888,742, or 26·9 per cent.: or there occurred a relative increase in the 68 largest towns in Great Britain of npwards of 10 per cent., as compared with the increase of the entire popnlation: that is, whereas then *two* of every *ten* persons in Great Britain resided in 68 of the principal towns, now *three* out of every *ten* persons reside in them. The increase of the population of London and the other great towns was 4,609,525, or 189 per cent. in the half-centnry; that of the smaller towns and the country was 5,770,996, or 71 per cent. The actual increase in some of the great towns was very remarkable. In London the population increased from 958,863 to 2,362,236, being an increase of 1,403,373, or 146 per cent.; Manchester (with Salford) from 94,786 to 401,326; Liverpool from 82,295 to 375,955, its opposite neighbour Birkenhead rising in the same time from 110 to 24,285; Birmingham from 70,670 to 232,841; Preston from 12.174 to 69,584; Bradford from 13,264 to 103,778; Plymouth from 16,040 to 52,221; Sonthampton from 7,913 to 35,305; MerthyrTydfil from 10,127 to 63,080; Glasgow from 77,058 to 329,007; and other mannfacturing, mining, and sea-port towns at a proportional rate. The increase in the population of the watering-places, or towns chiefly devoted to pleasure, meanwhile being at least commensurate with that of the towns devoted to bnsiness: thns Brighton increased from 7,440 in 1801 to 69,673 in 1851; and Cheltenham from 3,076 to 35,051.

Dividing the towns into classes, it appears that "the greater part (3,022,776) of the increase (5,363,650) in the six classes of towns was in London and in the manufacturing towns; the (1) sea-ports, the (2) towns which are in mining districts, or are engaged in hardware manufactures, and (3) the county towns, severally contribnted more than three-quarters of a million to the increase; the increase of the people living in watering-places was 200,164. In the latter class the rate of increase was the greatest; it was 2·561 per cent. annually. The annual rate of increase was 2·380 in the manufactnring towns, 2·336 in the mining and hardware towns, 2·191 in the sea-ports, 1·820 in London, and 1·609 in the connty towns. The annual rate of increase in Great Britain during the same half-centnry was 1·377. The towns have increased most rapidly in which straw-plait, cotton, pottery, and iron are manufactnred."

The *density* and *proximity* of the population are elucidated in the Report and the Summary Tables in varions ways, and at considerable length: here, however, the matter must be treated briefly. The density of population, or, as a recent French authority (Baron de Prony in the 'Annuaire') has proposed to term it, the "specific population," after the analogy of "specific gravity," varies in the 624 districts of England and Wales, from 185,751 persons on a square mile in the East London district, to 18 on a square mile in that of Bellingham, Northnmberland. The greatest density of population ont of London is in the Liverpool district, which is 74,446, and the next Birmingham, which is 41,853 on a square mile. Manchester has 11,577, which is less than Leeds, which has 30,886; Bristol, which has 22,858; Plymouth, which has 20,441; Nottingham, which has 19,994; East Stonehouse, which has 19,913; Brighton, which has 18,088; Hnll, which has 17,750; Salisbury, which has 11,907; Greenwich, which has 11,849; and Exeter, which has 11,670. The smaller density of Manchester than such towns as Salisbury and Exeter is acconnted for, in a great measure, by the large spaces covered by the nnmerous great factories and warehonses; yet the result is scarcely what would be generally expected, especially as both Exeter and Salisbury are cathedral towns, having considerable open spaces within the city bonndaries. But the evidence of over-crowding in these two cities appears mnch stronger when they are compared with some of the other most popnlons manufacturing towns: Sheffield, for instance, which is among the densest, has 6,263, or little more than half as many on the square mile as Salisbury; Bradford, which has 2,887, or less than one-fonrth; and Blackbnrn, which has 1,333, or only one eighth. As respects proximity of population, regarding it upon the same hypothesis of equal distribntion, we find that the people of England were, in 1801, on an average 153 yards asunder, while in 1851 they were only 108 yards asunder; the mean distance apart of the honses in 1801 being 362 yards, and 252 yards in 1851. Or, as it may be otherwise expressed, on the same area the population has donbled; the proximity has increased—the separation has diminished—in the ratio of 3 to 2. In the London division the mean proximity has increased from 21 yards in 1801 to 14 yards in 1851.

The *Islands of the British Seas* are noticed more fully in this than any previous Census. Five hnndred islands and rocks have been numbered; but inhabitants were only found on the morning of March 31st, 1851, on 175 islands, or gronps of islands. Some of the others are, however, occasionally dwelt on by shepherds during summer. Passing over Ireland, which contained 6,553,178 inhabitants, we find that four of the larger islands have each npwards of 50,000 inhabitants:—Anglesey 57,318, Jersey 57,020, Isle of Man 52,344, Isle of Wight 50,324. Fonr others have each above

20,000:—Guernsey 29,757, Lewis 22,918, Skye 21,528, and Shetland 20,936. Two more nnmber npwards of 10,000:—Orkney 16,668, and Islay 12,334. Twenty nnmber between 1,000 and 10,000 inhabitants; fifteen between 500 and 1,000; thirty-seven between 100 and 500; fifteen betweeu 50 and 100; forty-five between 10 and 50; seven number 10 inhabitants on each; and twenty-five under 10, two of them having only one inhabitaut on each, Little Papa, one of the Shetlands, a womau, and Inchcolm, in Fifeshire, a man. Some of the more remote and smaller islands were now numbered for the first time, and mnch cnrious iuformation has been collected. St. Kilda, one of the Hebrides, 70 miles from the maiuland, is one of these. The population, now for the first time officially enumerated, consisted of 48 males and 62 females, all of whom were born on the island, except one female, aged 35, who was imported from Sutherlandshire. The excess of females is chiefly among children under 20, of whom there are 22 males and 30 females; and persons above 60, of whom 6 are females and 1 only is a male. The men are all farmers and bird-catchers, each "farmer" occupying abont three acres of land. Eight females are described as "weaveress in wool." The great majority of children die of what is called the "eight days' illness;" several were born during the previous twelve months, but only two were living. There are a manse and a church on the island; but no resident clergyman or medical man.

The nnmber of *boroughs* in England and Wales having municipal organisation according to the Municipal Reform Act, was 196, with a population of 4,345,269; of these boronghs 18 have had charters of incorporation granted siuce the passing of that Act. There are 89 unreformed boroughs. Of the reformed horoughs it is found that one-half of the population (2,220,542) is contained in 17 boroughs, each of which contains more than 60,000 iuhabitants. It appears also that 102 horoughs, or more than half of the total number, coutain less than 9,000 inhabitants iu each; in the aggregate, 472,551 inhabitants. Eighty-seven boroughs have from 2,000 to 7,000 inhabitants; twenty-seven, from 20,000 to 40,000; eight, from 40,000 to 60,000; seven, from 60,000 to 80,000; two, from 80,000 to 100,000; and three have 200,000 and upwards.

The 83 royal and municipal burghs of Scotland contained 752,777 iuhabitants; ouly three burghs coutained more than 60,000 iuhabitants; one, more than 40,000; three, from 20,000 to 40 000; fifteen, from 7,000 to 20,000; thirty-three, from 2,000 to 7,000; aud twenty-eight under 2,000 inhabitants.

Several of the most popnlons and important places in England and Wales are still without a municipal organisation. Among these are the metropolitan parliamentary boroughs of the Tower Hamlets, populatiou 539,111; Finsbury, 323,772; Marylebone, 370,957; Greenwich, 105,784; Lambeth, 251,345; and Westminster, 241,611; and the towns of Brighton, popnlation, 69,673; Bnrnley, 20,828; Bury, 31.262; Chatham, 28,424; Cheltenham, 35,051; Dudley, 37,962; Huddersfield, 30,880; Merthyr Tydfil, 63,080; Rochdale, 29,195; Stroud, 36,535; and Stoke-upon-Treut, 84,027. In Scotland there are no towns containiug a popnlation of 10,000 which are not mnnicipal burghs.

Additioual abstracts, of a very valuable character, have been published subsequeutly to the General Report relating "to the ages, occupatiou, civil condition, and birth-places of the popnlation; the numbers of the hlind, and of the deaf and dumb; and the extent of the accommodation throughout the country for the pnrposes of ednc ation and religion;" but this is not the place to go into qnestions of so wide a nature. In another article will be found a notice of the OCCUPATIONS OF THE PEOPLE [*S.* 2] as exhibited in the Census returns.

With respect to *Ireland*, the circumstance brought out with most startling prominence was the remarkable decrease in the popnlation since the previous Census. Up to that of 1841, each decennial Censns of the half-century had shown a steady if not rapid increase of the population. That of 1851 showed that during the past ten years the gain of the previons twenty had been more than nudoue. Iu 1821 the total population of Ireland was 6,801,827; in 1851 it was only 6,551,970. And the returns further showed that this decrease was general as compared with 1841; and even as compared with 1821, the only exceptions were some two or three places in Ulster, in each of which, from causes easily understood, there had been a continnous increase of inhabitants during the half ceutury. The large falling off of the population between 1841 and 1851 was mainly owing to the disastrons famine which afflicted Ireland in 1845–47, in consequeuce of the failure of the potato crop: partly, however, it was due to emigration, which, in its turn, had beeu greatly stimulated hy the failure of the potato, and the consequeut agricultoral distress. The total emigration from Ireland during the ten years between 1841 and 1851 is estimated to have amounted to 1,289,133, "varying with cousiderable regularity according to the variations iu the state of the labouring classes." For the sake of presentiug in one view the increase and decrease of the population of Ireland, we appeud a table of the number of inhabitants iu the four provinces at each decennial Censns from 1821 to 1851.

Population.

Provinces.	Area in Acres.	1821	1831	1841	1851
Leinster . .	4,876,211	1,757,492	1,909,713	1,973,731	1,672,591
Munster . .	6,064,579	1,935,612	2,227,152	2,396,161	1,857,412
Ulster . .	5,475,438	1,998,494	2,286,622	2,386,373	2,011,756
Connaught .	4,392,043	1,110,229	1,343,914	1,418,859	1,010,211
Total of Ireland . .	20,808,271	6,801,827	7,767,401	8,175,124	6,551,970

The decrease of population was as might be expected most marked in the rural districts. In several of the large towns the Ceusus of 1851 showed an actnal increase of population, while scarce any showed a falling off, a circumstance arisiug no doubt from the famishiug poor having crowded into them in the hope of ohtaining employment or of finding relief. Dublin city, which in 1821 contained 185,881 inhabitants, had 232,726 in 1841, and 258,361 in 1851. Cork, though it showed a decline of nearly 15,000 between 1821 and 1851, showed an increase of above a thousand from 1841. Belfast had more than doubled in population between 1821 and 1851, and between 1841 and 1851 had increased from 75,308 to 100,300. Galway town, which between 1831 and 1841 had falleu in popnlation from 33,120 to 17,275 had increased in 1851 to 23,695.

The two following tables will show in the readiest manner the general resnlts of the ennmeration of 1851.

Area, Houses, and Population, on March 31st, 1851.

	1851.						
	Area in Acres.	HOUSES.			POPULATION.		
		Inhabited.	Uninhabited.	Building.	Persons.	Males.	Females.

In the article GREAT BRITAIN of the 'Penny Cyclopædia' a table is given of the population of the counties of England, Wales, and Scotland, with the areas in square miles, according to the Census of 1831, and nnder the head IRELAND a similar table is given for that island. In the former Supplement, under the head CENSUS, tables are given of the population of the counties of Great Britain and Ireland, according to the Census of 1841. We now give tables of the population of Great Britain and Ireland, with the areas in acres, according to the Census of 1851, followed by a list of towns in Great Britain and Ireland, arranged under their respective counties, with the population of each in 1851.

In the following list, the towns generally contain a population of 2000 and upwards, but several are also inserted which have a smaller population. The Parliamentary Boroughs are placed first; then follows the list of the towns, including the parliamentary boroughs, which are in many instances also Municipal Boroughs, having a population different from that of the Parliamentary Boroughs. The Burghs and Contributory Burghs of Scotland are arranged under their respective counties, but a list of the Parliamentary Districts of Burghs is given at the end of the list for Scotland.

The abbreviation *P.B.* signifies Parliamentary Borough; *C.P.B.*, Contributory Parliamentary Borough; *M.B.*, Municipal Borough, and includes the Scotch Royal Burghs. Sometimes P. and T. are inserted in the figure-column, and signify Parish and Township, where the returns of the census do not state the population of the town itself.

CENTROPUS (Illiger), a genus of birds belonging to the order *Scansores*. The species are natives of India and Africa. They have a long pointed thumb-nail, the same as the larks. Their plumage is rigid and spinous. They build their nests in the holes of trees, and lay white eggs. They feed chiefly on grasshoppers, and dwell amongst reeds and other herbage, and do not often take to wing. Their flesh is not pleasant eating.

CERADIA, a genus of plants belonging to the Corymbiferous division of the natural order *Compositæ*. *C. furcata* is a half-succulent plant, inhabiting the most sterile regions of south-western Africa. It yields in some abundance a brittle resin-like substance, which gives out a fragrant odour when burnt, and has been called African Bdellium; it is however a very different thing from the true Bdellium. [Bdellium.]

CE'REUS, a genus of plants belonging to the natural order *Cactaceæ*. It is characterised by its sepals being very numerous, imbricate, adnate to the base of the ovarium, united into an elongated tube, outer ones shorter and like a calyx, middle ones longer and coloured, innermost ones petaloid; the style multifid at the apex; the berry areolate, tubercular, or scaly from the remains of the sepals. The species are fleshy grotesque shrubs, with a woody axis and soft interior. They possess angles which are vertical and covered with bundles of spines. The flowers are large, arising from the angles of the spines. They are called Torch-Thistles.

C. senilis, the Old Man Torch-Thistle, is an erect plant, having a stem with 20-25 vertical ribs, covered with fascicles of bristles, each fascicle containing from 15-20 radiating hair-formed curled bristles. Its long gray bristles give it the appearance of the head of an old gray-haired man. It is a native of Mexico.

C. flagelliformis, the Creeping Cereus, has prostrate stems with about 10 angles. It is very common in our gardens, and its trailing stems require the support of trellis-work. It bears an abundance of beautiful red and pink flowers. It is a native of South America, though now naturalised in Asia and Africa.

C. grandiflorus, the Night-Flowering Cereus, has rooting stems, with 5 or 6 angles and fascicles of bristles, with 5-8 in each fascicle. It is a native of the West India Islands, and is found in many parts of the mainland of South America. This plant when cultivated produces very large beautiful sweet-scented flowers. They are however of short duration, remaining open not more than six hours. They generally begin to open between seven and eight o'clock in the evening, and are fully expanded by eleven or twelve, and before the next morning they are quite faded.

C. speciosissimus is an erect plant, 3-4 angled, the angles toothed, the prickles subulate, straight, rising from a white tomentum. It is a native of Mexico, but is very commonly cultivated in our gardens, on account of its large flowers, which are of a beautiful scarlet, the inner petals having a violaceous colour. Nearly 100 species of this beautiful genus of plants have been described, and a fine collection of them exists in the Royal Gardens at Kew. They are of easy culture, and require the same general treatment as the order to which they belong. [Cactus.]

CERNE ABBAS. [Dorsetshire.]

CERNUA, a genus of Fishes belonging to the section *Acanthopterygii* and the family *Percidæ*. It includes the Ruffe or Pope, a British fish, which has also been named *Acerina vulgaris* and *Perca cernua*. The generic character of *Acerina*, as given by Yarrell in his 'British Fishes,' is as follows:—"Dorsal fin single, elongated, the rays of the first portion spinous, the others flexible; branchiostegous rays seven; teeth very small, uniform, numerous; head without scales; suborbital bone and pre-operculum indented; operculum ending in a single point."

In *Acerina vulgaris*, the Ruffe or Pope, the prevailing colour of the upper part of the body and head is a light olive-brown, passing into a yellowish-brown on the sides, and becoming almost silvery-white on the belly. The lateral line prominent and strongly marked. Small brown spots are disseminated over the back, dorsal fin, and tail, assuming on the latter, from their arrangement, the appearance of bars; pectoral, ventral, and anal fins, pale-brown. This fish is an inhabitant of fresh waters, and closely allied to the perch. It was first described by Dr. Caius, who called it *Aspredo*, being a translation of our word Ruffe (rough), which is applied to this fish on account of the harsh feel of its denticulated scales. It is common in all the rivers of England, especially the Thames, the Isis, and Cam, and is found in the colder parts of the European continent. It is like the perch in its habits. (Yarrell, *British Fishes*.)

CERTHILAUDA. [Alaudinæ, *S.* 2.]

CERVANTE'SIA, a name given by Ruiz and Pavon to a genus of plants, in honour of their immortal countryman Cervantes. One of the species, *C. tomentosa*, is a native of Peru, and yields seeds which are eaten in the same manner as almonds in Europe, or the Quandary Nut (*Fusanus acuminatus*), another Santalaceous plant, in Australia.

CESSIO BONORUM. The proceedings of the trustee in a *Cessio* have been subjected to the control of the Court, and its Accountant in Bankruptcy, in the same way as those in Bankruptcy. When a bankrupt's assets do not exceed 100*l.*, he is entitled only to the advantages of the judgment in a *Cessio* (19 & 20 Vict. c. 79).

CHALCEDONY. [Agate.]

CHALCIS, the ancient name of the town of Egripos. [Eubœa.]

CHALK FORMATION. [Cretaceous Group.]

CHALMERS, THE REV. DR. THOMAS, was born at Anstruther, in Fifeshire, on the 17th of March 1780. He was the sixth child of a family of fourteen, born to Mr. John Chalmers, a dyer, shipowner, and general merchant in Anstruther, by his wife Elizabeth Hall. Educated first at the parish school of Anstruther, and next at the University of St. Andrews, he very early displayed powers of no common order—less however in the formal business of the classes, than in his general intercourse with his fellow-students. Having chosen the clerical profession, and gone through the usual theological studies at St. Andrews, he obtained, when yet not past his nineteenth year, a preacher's or probationer's 'licence' in the Scottish Church. His first sermon, however, was preached in England, in the Scotch church in Wigan, on the 25th of August 1799, during a visit to an elder brother. The winter of that year and also that of the next were spent by him in Edinburgh, where he occupied himself in teaching, and also in attending the classes of Dugald Stewart, Robison, Playfair, and Hope, then in the height of their fame. It was at this time that his passion for mathematics and natural science, as well as his tendency to original speculation on moral and social subjects, first conspicuously revealed themselves. After a period of desultory occupation, first as assistant to the clergyman of Cavers in Roxburghshire, and then as assistant to the mathematical professor at St. Andrews, he was nominated to the living of Kilmany, in his native county of Fifeshire; into which parish he was inducted on the 12th of May 1803. He was then twenty-three years of age, and he continued in the position of parish clergyman of Kilmany till July 1815. These twelve years formed a very eventful period in his mental history. On adopting the clerical profession he had brought into it no very decided views in doctrinal theology. He was attached to what was called the 'Moderate,' as distinct from what was called the 'Evangelical' party of the Scottish Church. He was of opinion too, that by devoting a day or two each week to the preparation of his sermons and to official clerical acts, a clergyman could amply discharge all his proper duties, so as to have the rest of his time at his disposal for whatever other occupations interested him. He carried this view into practice. During the first year of his incumbency he varied his professional work at Kilmany by courses of lectures on mathematics and chemistry at St. Andrews. His preference at this time for professorial over clerical work, and for natural science over theology was indicated by his being candidate in 1804 for the chair of Natural Philosophy at St. Andrews. With even less chance of success he offered himself in the following year as a candidate for the mathematical chair in Edinburgh, vacant by the transference of Mr. Playfair to the Natural Philosophy chair on Robison's death. Mr. Leslie, afterwards Sir John Leslie, obtained the post, and it was with reference to an argument in Leslie's favour urged at the time by Playfair, to the effect that "the vigorous prosecution of mathematical or natural science was incompatible with clerical duties and habits" that Mr. Chalmers made his first literary appearance. In reply to Playfair he published an anonymous pamphlet, vehemently defending the clergy against what he regarded as a "cruel and illiberal insinuation"—a pamphlet, the main tenor of which, if not its specific statements, he lived to disown. His next publication was in 1807, when, his thoughts on political economy receiving a stimulus from the agitation caused by Napoleon's decrees against British commerce, he issued a pamphlet, entitled 'Inquiry into the Extent and Stability of National Resources.' This publication had success sufficient to inspire him for a time with the idea of coming to London to increase his literary connections. Circumstances preventing him from realising this idea, he continued at Kilmany, with a growing reputation for various attainments, as well as for extraordinary energy, accompanied with some eccentricity, of character and manner. In 1809 he made his first speech in the General Assembly of the Scottish Church—the scene of so many of his oratorical triumphs in after life. In the same year he became a contributor to the 'Edinburgh Encyclopædia,' under the editorship of Dr. Brewster, now Sir David; and it was partly to his studies while preparing an article on 'Christianity' for that work, and partly to the solemnising effects of a severe illness which, during the winter of 1809–10 brought him to the very brink of the grave, that he attributed the great moral and spiritual change of his life. Then, for the first time, as he thought, he saw Christianity in its true light; and then for the first time also were his views of the duties of the clerical office, as he thought, sufficiently deepened and enlarged. Externally the change exhibited itself in this, that whereas hitherto he had belonged to the 'Moderate' party in the Scotch Church then in the majority, he now ranked with the 'Evangelical' party, which formed but a minority. But the fruits of the change were more immediately visible in his own altered manner of performing his clerical duties. Not giving up his studies in natural science and in political economy, but carrying them on with the same zeal as before; contributing also to the 'Christian Instructor,' the 'Eclectic Review,' and other periodicals—it was now observed that in all that Mr. Chalmers did the influence of a deep sense of religion, and a conviction of the paramount claims of Christian faith on the thoughts of man, were discernible. Always eloquent in the pulpit, his eloquence now burst forth in strains of such passion and fervour as had never been heard from him before; and from far and near people went to hear the wonderful minister of Kilmany. Bible and missionary societies, for which he had formerly cared but little, now occupied much of his attention; and, instead of confining his ministerial studies to his weekly sermons from the pulpit, he began a regular organisation of his parish with a view to make himself familiar with the interests of every individual in it, and to provide for all its spiritual as well as intellectual and economic wants. In the midst of these new occupations, which he prosecuted with his constitutional enthusiasm, he married, in 1812, Miss Grace Pratt, the daughter of a retired captain in the army. In 1813 his article on 'Christianity' appeared in the 'Edinburgh Encyclopædia;' and in the same year it was published, with additions, in a separate volume as a treatise on 'The Evidences of Christianity.' The following two years were spent in assiduous parochial work, in theological studies, and in the composition of occasional works on various topics, including one on the reconciliation of scripture and geology.

The name of Mr. Chalmers was pretty well known over the south of Scotland as that of a man of powerful mind and extraordinary eloquence when, in 1815, or in the thirty-sixth year of his age, he was called from his quiet country parish to assume the pastoral care of Tron parish in the city of Glasgow. He remained in Glasgow in all eight years. In 1816 the degree of D.D. was conferred on him by the University of Glasgow. From 1815 to 1819 he was minister of Tron parish. From 1819 to 1823 he was minister of the newly-constituted parish of St. John's. These eight years were the period of his highest celebrity as a pulpit-orator. In this capacity, all Glasgow, and soon all Scotland rang with his fame. One of the most enthusiastic descriptions in Mr. Lockhart's account of Scottish celebrities at that time, published under the title of 'Peter's Letters to his Kinsfolk,' is that given of Chalmers in his Glasgow pulpit. A picture so elaborate and glowing from such a pen of a man whose professed position was simply that of a Presbyterian clergyman of a Glasgow parish, proves that already he was no longer thought of only in that capacity, but as a man of truly great genius. "I know not what it is," said Jeffrey, in 1816, "but there is something altogether remarkable about that man. It reminds me more of what one reads of as the effect of the eloquence of Demosthenes than anything I ever heard." The same impression was afterwards produced on men of all kinds in England, as well as in Scotland—on Hazlitt, Canning, Wilberforce, Hall, and Foster. Part of the secret was that Chalmers was not one of those orators whose power evanesces in the moment of their actual utterance, but a man of massive, large, and substantial thought, whose every speech was the enunciation and illustration of some principle or generalisation, and whose language was full of extraordinary felicities, memorable turns of phrase, and gleams of poetic conception. Perhaps the first exhibition of his oratory in which this union in him of high intellectual attainments and general literary genius with the specific qualities of the orator, was conspicuously brought out, was on the occasion of the delivery, in 1816, of a series of week-day lectures on Astronomy in its connection with Religion. The excitement caused by these 'Astronomical Discourses' was unprecedented; and their popularity, when published in the same year, rivalled that of the contemporary 'Waverley Novels.' But his regular pulpit sermons were no less extraordinary as displays of mental and oratorical power; and on his occasional visits to Edinburgh, London, and other places, his fame as an orator preceded him, and drew crowds to hear him. At Edinburgh his oratory was exhibited not only in the pulpit, but also in debate in the General Assembly, or annual ecclesiastical parliament of Scotland. Here as a leader of the 'Evangelical' party, then gradually attaining numbers and influence, he took a polemical part in some of the Scotch ecclesiastical questions of the time, and always with the effect of a man at once great in wisdom and resistless in speech. His speeches, like his sermons, were generally read; and very rarely indeed did he speak extempore. With all his extraordinary popularity as an orator, however, no man better appreciated than he did the exact value of such popularity—"a popularity," which, in his own characteristic language, "rifles home of its sweets, and by elevating a man above his fellows, places him in a region of desolation, where he stands a conspicuous mark for the shafts of malice, envy, and detraction; a popularity which, with its head among storms, and its feet on the treacherous quicksands, has nothing to lull the agonies of its tottering existence but the hosannahs of a drivelling generation." Far more important in his own eyes than these pulpit services which brought him such hosannahs, were his practical schemes for showing the social efficacy of Christianity. It was Dr. Chalmers's fixed and lifelong belief that in religion alone was there a full remedy for the evils of society, and that all schemes of social amelioration would be futile which did not aim at working Christianity through the hearts of the people down into their habits and households. Subordinate to this belief was his attachment to the parochial system of social organisation—that system which divides a community into small manageable masses, marked out by local boundaries, and each having a sufficient ecclesiastical and educational apparatus within itself. Disliking with his whole heart the English Poor-Law system, he was of opinion that, if the parochial system were properly worked, pauperism could be provided for without a poor-law at all, by the judicious direction, under clerical and lay superintendence, of private benevolence. In order practically to illustrate these views, he undertook a vast experiment, first with Tron parish, and then with that of St. John's. The population of this latter parish (in which Edward Irving was for some time Dr. Chalmers's assistant) was upwards of 10,000, including perhaps the poorest part of the operative population in Glasgow; but such was his zeal, such his practical sagacity, and such his power of influencing persons fit to be his agents, that in a short time the parish was organised both for economical and educational purposes in a manner unknown before, schools being set up in every part of it, and the poorest lanes visited periodically each by its own special teacher and inspector. The results of his experiment, with his speculations in connection with it, were published by him (1819-1823) in a series of quarterly tracts, on the 'Christian and Civic Economy of Large Towns;' which, with two volumes of 'Sermons,' published respectively in 1818 and 1820, two articles on 'Pauperism' contributed to the 'Edinburgh Review' in 1817, and a sermon in the same year on the death of the Princess Charlotte, formed along with the 'Astronomical Discourses' already mentioned, his chief literary exertions during his residence in Glasgow.

In the midst of the bustle and fatigue of his life in Glasgow, increased ten-fold by the hospitality which his celebrity obliged him to exercise, Dr. Chalmers had never ceased to sigh for the academic quiet of a professor's chair in one of the Scottish universities; and in January 1823, much to the surprise of the public, he resigned his charge, and accepted the chair of Moral Philosophy then vacant in his native University of St. Andrews. The new post was one of much less emolument, and of far less publicity than that which he had resigned; but even had his tastes not disposed him to accept it, he had paramount reasons in the state of his health, which was giving way under the wear and excitement of city-life. Forty-three years old when he accepted the chair, he retained it till his forty-ninth year, or from 1823 to 1828. The winters of these five years were spent by him in the preparation and delivery of his class-lectures, and in the genial society of many of his old friends; but he carried with him to St. Andrews those notions and schemes of Christian philanthropy which he had matured in Glasgow, and the little Fifeshire town felt during these five years the vivifying influence of his spirit and enthusiasm. Occasionally he preached in

St. Andrews and in the neighbourhood round; annually in May he visited Edinburgh to take part in the business of the General Assembly, where his eloquence as before was felt as a conquering force on the 'Evangelical' side in all the great ecclesiastical controversies of the time; and excursions in Scotland and Ireland, and journeys as far as London, varied his summer. It was proposed at one time to elect him to the Moral Philosophy chair in the newly-established University of London; but this proposal, which might have altered the whole tenor of his future career, was not carried out. The literary results of his five years' sojourn at St. Andrews were courses of 'Lectures on Moral Philosophy,' and on 'Political Economy,' prepared for his class and reserved for publication; a third volume of his 'Christian and Civic Economy of Large Towns,' published in 1826; and a treatise on 'Ecclesiastical and Literary Endowments,' published in 1827.

Dr. Chalmers's next appointment was to the chair of Divinity in the University of Edinburgh. The duties of this office he assumed in 1828, and he discharged them during fifteen years—*i. e.* from 1828 to 1843, or from his forty-ninth to his sixty-third year. His activity during these fifteen extraordinary years of his life (not taking account of his occasional sermons) was made up of three distinct kinds of work—his duties as theological professor; his continued exercises in literature, speculation, and schemes of Christian philanthropy; and his controversial energy in connection with the serious ecclesiastical struggle which during that time convulsed Scotland. 1. *His Labours as Theological Professor.*—In this important capacity, which involved the theological instruction and training of between one and two hundred young men annually for the Scottish Church, Dr. Chalmers exerted a vast influence, less as a man learned in theological lore, than as a man of noble purpose and burning enthusiasm, with whom no young man could come in contact without love and veneration, and who was in the habit not only of communicating massive thoughts of his own on almost all subjects, but also of stirring up thought in others. His class-room was truly a centre of life and intellectual influence; and those who went forth from it carried with them perforce much of his spirit and many of his views. 2. *His independent labours in literature, speculation, and Christian philanthropy.* Of these it is impossible to take full account; suffice it to say that in 1831 he published his treatise on 'Political Economy,' and in 1833 his Bridgewater treatise 'On the Adaptation of External Nature to the Moral and Intellectual Constitution of Man;' that in 1838 he delivered in London, and afterwards published, a series of 'Lectures in Defence of Church Establishments;' that in the following year he made a tour through Scotland to advocate the cause of church extension; that in 1841 he published a volume on 'The Sufficiency of the Parochial System without a Poor-Rate for the right Management of the Poor;' that during the same period he delivered, during the summer vacations various lectures to popular audiences on topics of natural science; and that he gave much of his time to the superintending of an attempt to carry out his notions of proper parochial management in one of the poorest districts of Edinburgh. Some of the labours here mentioned received public recognition, in the form of honours conferred upon him. Thus in 1830, he was appointed one of the king's chaplains for Scotland; in 1834 he was elected a Fellow of the Royal Society of Edinburgh, and a corresponding member of the French Institute; and in 1835 he received the distinction of Doctor of Laws from the University of Oxford. 3. *His connection with the Scotch Church Controversy.*—The 'Evangelical' party with which, since 1810, Dr. Chalmers had been so permanently connected, had gradually increased in the church, so as at last to attain the majority; and in 1832 Dr. Chalmers was elected to the moderatorship, or presidency, of the General Assembly of that year. In 1834 the Assembly, under the auspices of the ruling party, and with his advice and sanction, passed the famous 'Veto Act,' the design of which was to modify the action of the system of patronage of livings in the Church of Scotland, by enabling the Church Courts to reject any nominee of a patron on the ground of his being displeasing to the majority of the congregation or parishioners over whom he was appointed. Several nominees having in immediately subsequent years been rejected in accordance with this act, appeals were made to the Civil Courts of Scotland and to the House of Lords, and the result was that the Veto Act was declared to be contrary to the law of the land, and that not only were nominees rejected by it pronounced to be entitled to all the emoluments of the livings, but it was pronounced illegal in the church to appoint any other clergymen to the spiritual cure of the parishes in question. Thus arose a controversy which agitated Scotland throughout its whole extent for ten years; and in which the original question of the 'Non-Intrusion' of clergymen upon unwilling congregations was merged in the question of the proper relations between Church and State. Of this controversy Dr. Chalmers was, on one side, the chief champion; and for several years he was incessantly occupied in defending his view of the questions in dispute in speeches and through the press, both against the 'Moderate' party in the church itself, who had from the first opposed the Veto Act, and also against the civil courts and the government. More than once it seemed as if the legislature was on the point of devising some means of healing the breach which had been made, and restoring quiet to Scotland; but at last, these hopes being over, the struggle was ended at the meeting of the General Assembly on the 18th of May 1843, by the so-called 'Disruption'—*i. e.* by the voluntary secession of upwards of 400 clergymen, followed by a large portion of the people of Scotland from the Established Church, and the institution of a new ecclesiastical body called 'The Free Church.' At the head of this secession was Dr. Chalmers, who was nominated moderator of the first General Assembly of the new church.

The last four years of Dr. Chalmers's life were spent by him as Principal and Professor of Divinity in the New College founded by the adherents of the Free Church for the theological education of its ministers (his chair in Edinburgh University having been necessarily vacated by him on his secession from the establishment). During these years, too, he exerted himself prodigiously in arranging the organisation of the new church, and in raising funds for its support; and probably at no period of his life was the statesman-like character of his intellect, his power of dealing with new social emergencies, and of leading men, more conspicuously shown. He had seen the foundations of the new church laid very much to his mind, and was preparing to resign the farther work of completing its organisation into the hands of his many able and younger colleagues, and to devote the rest of his days to his labours as a theological professor, to Christian and philosophical literature in connection more immediately with the 'North British Review,' then started under his superintendence, and to a new experiment of Christian philanthropy which he had begun in one of the most wretched quarters of the old town of Edinburgh, when death removed him. He had just returned from a visit to England in apparently excellent health and spirits, to take part in the proceedings of the General Assembly of the Free Church, when on the morning of the 31st of May, 1847, he was found dead in his bed at his house at Morningside, near Edinburgh. His death was felt throughout Scotland like a national shock; and all ranks and parties joined in doing honour to his memory as one of the greatest men that Scotland had produced. He left a widow who did not survive long, and six daughters, one of them married to the Rev. Dr. Hanna, under whose superintendence a new issue of the collected works of Dr. Chalmers has been put forth in twenty-five volumes, and who has also written his life in four volumes, and edited much of his correspondence.

Dr. Chalmers was a man of powerful frame, not tall, but massively built; his head was very large. It was remarkable in a man so celebrated over Britain as an orator, that he always spoke not only in a broad Scottish, but also in a broad provincial Scottish accent, mispronouncing almost every word. Personally he was a man of most simple, bland, and sociable manners, with a great fund of anecdote and broad humour. His works, notwithstanding the force of intellect that they show (and his speculations in social and political economy, in particular, are valued by many of the best thinkers of the day who have no sympathy with his theological or ecclesiastical opinions), but faintly convey an idea of what the man was while he lived, and of what he still is in the memory and imagination of the Scottish people.

CHAMÆLAUCIACEÆ, Fringe Myrtles, a small natural order of Polypetalous Exogenous Plants. They are characterised by having a 1-celled ovary, ascending ovules, dotted leaves, and the embryo fused into a solid mass. They are small bushes with evergreen leaves, and in external appearance have a close resemblance to heaths. All their parts abound in glandular oily cavities. They are mostly regarded as belonging to *Myrtaceæ*, and there is no doubt of their affinity to that order. Their peculiar aspect, abortive stamens, simple ovary, and pappose calyx sufficiently distinguish them. They have the fragrance of *Myrtaceæ*. Fifteen genera and fifty species are included in this order, all natives of Australia. Their position, according to Lindley, is between *Asteraceæ* and *Combretaceæ*, near to *Myrtaceæ*. (Lindley, *Vegetable Kingdom*.)

CHANCERY, COURT OF. There are now three Vice-Chancellors (5 Vict. c. 5; 15 Vict. c. 4), before whom and the Master of the Rolls all suits in this Court are originally heard. An appellate tribunal has also been constituted by the stat. 14 & 15 Vict. c. 83, which consists of two Lords Justices; who may either themselves, or conjointly with the Lord Chancellor, exercise all the appellate jurisdiction of the Chancellor, the Chancellor still constituting in himself a Court of appeal. The Masters in Chancery, with whom the whole delay which has always been the standing reproach of this Court was thought to rest, have been abolished, their functions being now performed by the Master of the Rolls and Vice-Chancellors, assisted by their chief clerks, in their own chambers (15 & 16 Vict. c. 80). The procedure of this court generally and its jurisdiction in many respects have been subjected to great changes of late years, as to which see EQUITY, BANKRUPTCY, USES, TRUSTS, CHARITIES, LUNACY, JOINT-STOCK COMPANIES, all in *S.* 2.

CHAODINEÆ, Chaotic Plants, a family invented by Bory, for the purpose of placing a number of the lower forms of plants or organic beings of uncertain character, which could not be placed amongst other well-defined groups of *Cryptogamia*. To this family were at one time assigned forms of *Diatomaceæ*, *Desmideæ*, *Nostoc*, and others.

CHAR, or CHARR, one of the British species of the genus *Salmo*, of the Salmon Tribe (*Salmo salvelinus*).

CHARD. [SOMERSETSHIRE.]

CHARITIES. [USES, *S.* 2; TRUSTS, *S.* 2.] By the Charitable Trusts Act 1853, a body of commissioners has been created for England and Wales, with power to inquire into all charities, their nature, objects, and administrations, and the condition of the property belonging to them; to require the production of accounts and documents from the Trustees of Charities, and to cause inspectors to visit and report on their management. No proceeding with reference to any charity can be taken by any relative, without the sanction of this board, which is called 'The Charity Commissioners for England and Wales.' The Attorney-General alone may proceed by ex officio information. The board may direct in what court proceedings for the administration of any charity are to be taken; but where the income is under 30*l.*, the County Court of the district, or the Court of Bankruptcy of the district in which the charity is situated has jurisdiction. In other cases the Court of Chancery must be resorted to. The statute does not extend to Scotland or Ireland, to the Universities, or the City of London. A report of the proceedings of the Board must be annually laid before Parliament.

CHASSÉ, DAVID HENRY, BARON, the resolute defender of Antwerp, was born at Thiel, in Gueldre, March 18, 1765. In 1775, he entered the Dutch army as a cadet, but he left that service after the revolution in Holland in 1787, and attached himself to the French army, in which he continued for many years. He became a lieutenant-colonel in 1793. In the fierce war with Prussia in 1806, he greatly distinguished himself under the Dutch general Dumorceau, and was made general of brigade. He afterwards took part in the Peninsular War, and displayed so much intrepidity that the soldiers nicknamed him 'General Bayonet,' from his constant use of that weapon. In 1811 Napoleon created him a baron of the empire. He was frequently wounded, and during the campaigns of 1813 and 1814 he had several horses killed under him. He fought likewise at Waterloo. Soon after the peace he was made governor of Antwerp, and his admirable defence of the citadel in 1832, with a garrison of 6,000 troops, against an army of 75,000 French soldiers commanded by Marshal Gérard, attracted general attention throughout Europe, and made the brave old soldier very popular. He died on the 2nd of May 1849. (*Biogr. des Contemporaines*; Campo, *Life of Chassé*.)

CHATEAUBRIAND, FRANÇOIS RENÉ, VISCOUNT DE, the most celebrated French writer of the Napoleon era, was born at St. Malo on September 4th, 1768, being the youngest of ten children. He was at first intended for the church, but after a careful education for that calling, he entered the army as sub-lieutenant in 1786. After various adventures he appears to have visited Paris shortly before the Revolution, and to have witnessed the capture of the Bastile in 1789. His erratic disposition took him to America in 1791, to look for the North-West Passage. He spent several months in the States, had an interview with Washington, visited the falls of Niagara, and roamed through those virgin forests and wild scenes of primitive life which he has described so vividly in 'Réné' and 'Atala.'

On his return home he joined the army of Condé for a short time in 1792, and the next year he began a life of great misery as an emigrant in London, amidst a group of exiled nobles, equally wretched. The picture of his sufferings and privations at this time, as he relates them in his 'Memoirs,' is almost incredible. Nevertheless he continued in England nearly eight years, maintaining himself by translating for the booksellers, and giving lessons in French and Latin. In 1797 he published in London his 'Essay on Revolutions,' a work full of scepticism: but the death of his mother in 1798 gave a new turn to his thoughts, and restored his faith.

In the spring of 1800 he went to Paris, and his excellent friend, M. Fontanes, whose influence was already strong, had been appointed one of the editors of the 'Mercure,' in the columns of which 'Atala' appeared for the first time. This romance was followed by the 'Génie du Christianisme' in 1802, which made a deep impression on the public mind. The First Consul was so pleased with this work that he took the author into favour, and strove to bend him to his service by two successive employments. Unfortunately the execution of the Duke d'Enghien, on the 21st of March 1804, furnished the inflexible Breton with too just an excuse, and he resigned his appointment the same day. Fontanes, Madame Bacciochi, and even Josephine herself, could scarcely prevent the consequences of this rash act from falling upon the Viscount.

The reign of Napoleon, which lasted ten years (1804-14) was not favourable to literature, and during this period Chateaubriand produced nothing of note, save the 'Martyres' in 1807, and the 'Itinéraire à Jérusalem' in 1811: the latter was the account of his own visit to the Holy Land in the autumn of 1806. The fall of the empire in 1814 released his pen, and he produced his famous pamphlet, 'De Bonaparte et des Bourbons,' the influence of which in disposing the public mind to welcome the returned family was so powerful, that "it was equal," said Louis XVIII., "to an army of 100,000 men." The Viscount was now received with great favour at the Tuileries, but he refused office as a colleague with Fouché; and other circumstances delayed his entrance into public life until 1822, when he was sent as ambassador to the British court, and most honourably greeted by all classes of people. The next year he was appointed Minister of Foreign Affairs, which office he held during the war in Spain conducted by the Duke of Angoulême. In 1824 the minister Villèle dismissed him rather abruptly. Then, and for the next three years, Chateaubriand led the opposition against the government with merciless rancour both in pamphlets and newspapers, never desisting till it crumbled beneath his blows. In 1828 M. de Martignac gave him the embassy to Rome; but no sooner had the Polignac ministry been formed (August 8) than he resigned.

In 1830, after the fall of the monarchy, which he had assisted to destroy, this inexplicable man, whom the people claimed as their leader, and followed with acclamations, deliberately resigned his titles, his offices, his very means of subsistence, to rally to that cause which had no other supporter. A singular change came over his spirit; he sank into despondency, and a gloom, which deepened every year, almost extinguished his noble mind. This *ennui* was so contagious that his most faithful friends shrank from it. This sad state of mind is very visible in the last of his works, which appeared about the time of his death—'Les Mémoires d'Outre Tombe'—the reading of which is most painful. He died July 4, 1848. His character has been well summed up by a recent French writer:—"It was almost invariably the fate of M. de Chateaubriand to lead a party whose ruling principle was not his; so that at the very time he was crushing his adversaries, he had no influence over his friends."

(*Mémoires d'Outre Tombe*; *Biographie Universelle*; *Dict. de la Conversation*.)

CHATHAM. [CANADA, *S.* 2.]

CHEMISTRY. Although the original articles on Chemistry in the 'Penny Cyclopædia' were written up to the time they were produced, the progress of this science was so rapid that a large addition was made to them in the first supplementary volume in that work, under the head of Chemistry. In this second supplement an addition of the like kind was found necessary, and the same plan has been pursued of adding the additional matter in an alphabetical form.

In the original articles in the 'Penny Cyclopædia' it was not thought necessary to represent the various compounds by means of symbols. The study of the science is however so much facilitated by the use of symbols, and the progress of organic chemistry so comparatively unintelligible without them, that we here subjoin a list of symbols most commonly used by the chemists of this country and the continent. To each of the symbols there is also added the equivalent or atomic number, an explanation of which will be found in the 'Penny Cyclopædia' article Atomic Theory.

Name of Element.	Symbol.	Equivalent.
Aluminum	Al.	13·69
Antimony, or Stibium	Sb.	129·03
Arsenic	As.	75·00
Barium	Ba.	68·64
Bismuth	Bi.	70·95
Boron	B.	10·90
Bromine	Br.	78·26
Cadmium	Cd.	55·74
Calcium	Ca.	20·00
Carbon	C.	6·00
Cerium	Ce.	46·00
Chlorine	Cl.	35·50
Chromium	Cr.	28·15
Cobalt	Co.	29·52
Copper	Cu.	31·66

Zinc	Zn.	32·52
Zirconium	Zr.	33·62

In the following articles the number of atoms of each element in a compound body is added. In order to ascertain the relative weight of any element in a compound, the number of atoms of each must be multiplied by its equivalent weight, and thus the quantity of each element in a given weight of a compound may be ascertained. Most of the references refer to other names, given in the present article; where they refer to previous articles in the Penny Cyclopædia, P. C. is added.

Absinthine, is an active or bitter principle found in *Artemisia Absinthium*. It belongs to the class of non-azotised vegetable secretions. It is neutral in its relations to acids and forms a semicrystalline mass which is insoluble in alcohol. It is intensely bitter to the taste. The same principle is also probably present in the other species of *Artemisia*, which have to a certain extent the bitter taste of *A. Absinthium.*

Acetonitryle, $C^4 H^3 N$, is one of the compounds obtained from methyle. It is procured by distilling the double sulphate of potash and methyle with cyanide or ferrocyanide of potassium. It is a colourless volatile liquid, has a slightly alliaceous odour, and is somewhat stupifying in its effects. It is very combustible, and when heated with potash it yields ammonia and acetate of potash. Its elements may also be arranged in the form of a cyanide of methyle $C^2 H^3 + C^2 N$, and this compound is usually placed by chemists in the series of methyle compounds. [Chemistry, P. C., *S.* 1.]

Acetyle, $C^4 H^3$. The first effect of the oxidation of ether or alcohol is to produce a compound radical which is acetyle. It is however unknown in a separate form, but is easily obtained in the form of a hydrated protoxide which is called Aldehyde, $C^4 H^3 O + H O$ (Chemistry, P. C., *S.* 1.), or in the form of the hydrated peroxide, which is acetic acid $C^4 H^3 O^3 + H O$. [Acetic Acid, P. C.]

Hyduret of Acetyle. Acetyle may be regarded as the base of other compounds than those of aldehyde and acetic acid; thus olefiant gas or ethylene, $C^4 H^4$, may be expressed as $C^4 H^3 + H$, or a hyduret of acetyle. [Hydrogen, P. C.]

Oxychloride of Acetyle. When ether and dry chlorine are acted on by the sun's rays several compounds are formed, and amongst others this substance. Its composition is $C^4 H^3 + O + Cl^2$. It has in fact the same composition as acetic acid, but two equivalents of the oxygen of that compound are supplanted by two of chlorine.

Perchloride of Acetyle,, $C^4 H^3 + Cl^3$. This compound is also formed by the action of chlorine on ether, and has the same composition as acetic acid, the whole of the oxygen being supplanted by chlorine.

Acids, Organic. The acids met with amongst organised bodies differ in their elementary constitution from the inorganic acids, but are generally formed on the same plan. They are mostly composed of the three elements, Carbon, Hydrogen, and Oxygen, to which Nitrogen is not unfrequently added. The proportions in which these elements unite render the atomic numbers of the organic acids much higher than those of the inorganic acids, in which the distinguishing element, as in the case of Sulphuric Acid and Nitric Acid, unite in but one single proportion with several proportions of oxygen. The organic acids are easily decomposed by heat, whilst the inorganic acids resist this agency much more. Thus, oxalic acid and citric acid are easily decomposed by heat, but sulphuric and nitric acids resist its action.

There are two theories of the nature of organic acids, by which they are made to harmonise with the constitution of inorganic acids. In the first place, like sulphuric and nitric acids, they are regarded as oxygen acids. In this case, a compound radical is assumed which combines with the oxygen, and forms the acid which, to constitute the ordinary liquid acid, must unite with water. Thus, to take sulphuric acid. One part of sulphur combines with three of oxygen to form the dry acid, which must unite with water to form the liquid acid. Thus $S O^3 + H O$ represents the common hydrated sulphuric acid, or oil of vitriol. We may take acetic acid as an example of the organic acid. The compound radical which represents the sulphur of the sulphuric acid is acetyle ($C^4 H^3$). This combines with three parts of oxygen and forms the dry acetic acid. But in order to have the liquid acid there must be an equivalent of water. The two may be thus compared:—

Sulphuric acid, $S O^3 + H O$.

Acetic acid $(C^4 H^3) O^3 + H O$.

This analogy between the organic and inorganic acids may be pursued very consistently through the whole series. There are, however, many cases in which this theory cannot be proved to be true, in which, in fact, the water cannot be withdrawn and replaced with the facility which the above theory requires.

This has led to a second theory, which is becoming more generally adopted at the present day. It applies equally, however, to the inorganic as to the organic acids. It is very obvious that the compound $SO^3 + HO$ may be arranged as $SO^4 + H$, and that such a change may be effected in the expression of any of the acids. In this view of the composition of the acids, the hydrogen, not the water, is the removeable element; and it would appear from experimental researches, more especially on the organic acids, that such a theory is more compatible with the real condition of the acids than the first. This constitution is as easily applied to the organic acids as the other. Thus, instead of the above formulary, we have the following:—

Sulphuric acid, $SO^4 + H$.
Acetic acid $(C^4 H^3) O^4 + H$.

It has been objected to this theory that it assumes the existence of compound radicals which have not been demonstrated to exist, but many which were formerly only hypothetical have now been separated, and no argument against the theory can be successfully urged on this ground.

The advantage of this theory is, that the formation of salts is easily explained, on the supposition that the metal replaces the hydrogen of the acid. Thus, in the first system, sulphate of soda was formulated as $SO^3 + Na O$, and no account was taken of the water lost by the sulphuric acid. But under the new theory the oxygen of the metal needs not to be taken into the account, as it already exists with the sulphuric acid, and the change from sulphuric acid to sulphate of soda is seen as follows:—

Sulphuric acid, $SO^4 + H$.
Sulphate of soda, $SO^4 + Na$.

The sodium simply takes the place of the hydrogen.

In the constitution of the polybasic acids this theory is more strongly confirmed. Thus phosphoric acid was supposed to assume three forms, according as it united with one, two, or three atoms of water, and these were called monohydrated, bihydrated, and terhydrated acids. But Professor Graham showed that it would be better to regard these acids as combined with one, two, and three atoms of hydrogen, and proved that the phosphoric acid in its three forms united with metals by their taking the place of the hydrogen of the acid.

That the old formulæ for the organic acids may be easily reduced to the new is seen in the following examples:—

	OLD.	NEW.
Tartaric acid . .	$C^8 H^4 O^{10} + 2H O$	$C^8 H^4 O^{12} + H^2$
Malic acid . . .	$C^8 H^4 O^3 + 2H O$	$C^8 H^4 O^{10} + H^2$
Citric acid. . .	$C^{12} H^5 O^{11} + 3H O$	$C^{12} H^5 O^{14} + H^3$
Meconic acid. . .	$C^{14} H O^{11} + 3H O$	$C^{14} H O^{14} + H^3$
Saccharic acid . .	$C^{12} H^5 O^{11} + 5H O$	$C^{12} H^5 O^{16} + H^5$

In such acids there is always some hydrogen in the radical, of which it is a constituent, and some combined with the radical, which may be replaced by the metals. Amongst the organic acids, there are some facts which seem to show that this replaceable hydrogen exists. "Thus, meconic acid, which is tribasic, forms like tribasic phosphoric acid three series of salts, in which one, two, or three equivalents of the hydrogen are replaced by the metal. But while the meconic acid, as well as the tribasic phosphoric acid, readily forms with oxide of the silver, the salt in which all the hydrogen is replaced by silver; it cannot form, or forms with difficulty, a similar salt with potash, with which it forms very easily salts with one and two equivalents of metal, and two or one equivalents of hydrogen." (Gregory). This fact is difficult to be accounted for on the old theory, whilst it meets with an easy solution on the new. The oxide of silver easily parts with its oxygen, and there is no difficulty with it in substituting three atoms of silver for three atoms of hydrogen, but the potash does not part with its oxygen easily, and therefore will not form the compound with three equivalents of potassium.

Acroleine, $C^6 H^4 O^2$. A substance obtained by Redtenbacher by the distillation of glycerine with phosphoric acid. The operation must be carried on in vessels charged with carbonic acid gas, as acroleine is so rapidly oxidised in atmospheric air, that it cannot be obtained where it is present. It is a very pungent and suffocating substance, attacking the eyes and nose of the operator if care is not taken. It is composed of carbon, hydrogen, and oxygen, and may be regarded as the hydrated oxide of a radical called *acryle*. This substance resembles acetyle, and represents in acroleine the position of acetyle in aldehyde. Thus, $C^6 H^3 O + H O$ is the atomic constitution of acroleine. But this substance becomes oxidised in the atmosphere, and is then converted into *acrylic acid*, $(C^6 H^3) O^3 + H O$, a substance perfectly analogous to acetic acid. Acroleine is often formed as the result of the distillation of oils and fats. Thus, castor oil yields acroleine, and some other peculiar products on distillation. Glycerine may in fact be regarded as an hydrated oxide of acryle with three additional equivalents of water, as follows:—

Glycerine, $C^6 H^7 O^5$.
Hydrated oxide of acryle, $C^6 H^3 O + 4H O$.

Acryle. [Acroleine.]

Acrylic Acid. [Acroleine.]

Adipic Acid, $C^6 H^4 O^3 H O$. When oleic acid is acted on by nitric acid, several new acids are formed, and amongst them adipic acid. It occurs in round radiated masses, fusible and volatile.

Alanine, $C^6 N H^7 O^4$. When aldehyd-ammonia [Chemistry—Aldehyde, *S.* 1,] is acted on by hydrocyanic acid, and an excess of hydrochloric acid, a crystalline body, soluble in water, is formed, to which Strecker has given the name alanine. It is homologous with *glycocoll* and *leucine*, and isomeric with *lactamide*, *urethane* and *sarcosine*. When acted on by hyponitrous acid, it is converted into lactic acid, as follows:—

$$\underbrace{C^6 N H^7 O^4}_{\text{alanine.}} + N O^3 = H O + N^2 + \underbrace{C^6 H^6 O^6}_{\text{lactic acid.}}.$$

Nitrogen is given off during the decomposition.

Aldehyd-ammonia. [Aldehyde, *S.* 1.]

Allantoine. [Allotoin—Chemistry, *S.* 1.]

Alituric Acid, $C^5 N^2 H^3 O^4$. This acid was discovered by Schlieper, and is formed by the action of boiling hydrochloric acid on alloxantine. It is soluble in 15 to 20 parts of hot water, and on cooling it is deposited as a crystalline powder. When heated with potash it gives out ammonia.

Allophanic Acid, $C^4 N^2 H^3 O^5 + H O$. This acid is unknown in the hydrated or separate state. It forms crystallisable salts with baryta, potash, and soda. It is produced by the action of hydrated cyanic acid on alcohol. The water of the alcohol unites with the cyanic acid and forms the new compound which unites with the oxide of ethyle and forms an allophanate of the oxide of ethyle.

$$\text{Thus, } 2\underbrace{(C^2 N O + H O)}_{\text{cyanic acid.}} + \underbrace{C^4 H^6 O + H O}_{\text{alcohol.}}$$
$$= \underbrace{C^4 H^5 O}_{\text{oxide of ethyle.}} + \underbrace{C^4 N^2 H^3 O^6}_{\text{allophanic acid.}}.$$

Allyle, $C^6 H^5$, a compound radical, regarded as the base of oil of mustard. This oil is composed of carbon, hydrogen, nitrogen, and sulphur, which may be arranged as follows, $C^6 H^5 + C^2 N S^2$. The last part of this compound is sulphocyanogen, so that oil of mustard is a sulphocyanide of allyle. Oil of garlic (*Allium sativum*) has been demonstrated by Wertheim to be a sulphuret of allyle, $C^6 H^5 + S$. The oil of assafœtida is composed apparently of several oils, and Dr. Douglas Maclagan has pointed out that one of these is sulphuret of allyle. Wertheim has shown that allyle is capable of entering into numerous combinations, in the form of the sulphuret, forming double salts with the sulphurets of palladium, platinum, silver, and other salts.

Althionic Acid is produced when oil of vitriol in great excess is heated with alcohol. It has the same composition as sulpho-vinic acid, but its compounds differ in crystalline form. It is highly probable that the althionates are compounds of the sulphovinates and isethionates.

Aluminium, the metallic base of the earth Alumina, which is composed of oxygen and the metal aluminium. Its equivalent or atomic weight is 13·7, and its specific gravity 2·6. The metal is procured by decomposing the chloride of aluminium by means of potassium or sodium. The theory of the decomposition is that the chlorine unites with the potassium or sodium, and leaves the aluminium free. The metal is procured by washing away the chloride. Till very recently aluminium, although well known, had been procured only in very small quantities, and was regarded rather as a chemical curiosity than a substance of any value. It differed however from the other earthy and alkaline metals by its not being readily acted on by the oxygen of the atmosphere or water. In 1856, however, it was announced that M. St. Clair Deville, chemist to the Emperor of the French, had succeeded in obtaining this metal in very considerable quantities, and so readily as to lead to the supposition that it might be employed in the arts. The method employed by M. Deville is precisely the same as that pursued by earlier experimenters. This metal, on account of its lightness, and not being acted on by oxygen, would undoubtedly be valuable for a great variety of purposes, provided it could be obtained at a low price. Its cost however has been very considerable on account of the price of the metals by which it is obtained. Sodium is preferred by M. Deville in preference to potassium, but this metal has first to be obtained by costly processes. These last have been greatly diminished, so that sodium has been recently sold for 10*s.* a pound. This still renders the price of aluminium a barrier to the general use of that metal. Nevertheless it has been extensively manufactnred in Paris into spoons, tea-pots, coffee-pots, and other articles of use. In order to obtain aluminium, the chloride is introduced into iron tubes and heated with the sodium.

The chloride of aluminium, from which the metal is prepared, is not a natural compound, but has to be made from the earth alumina. It is prepared by mixing this earth, freshly precipitated with some form of carbon or carbonaceous substance, as charcoal, sugar, tar, &c., and the whole is made into a paste with oil. This is then dried and calcined in a crucible, and placed in a tube and exposed to the action of dried chlorine gas, when the chloride of aluminium is sublimed and collected by condensation. It has a straw colour, is solid and crystalline at ordinary temperatures, and combines readily with water, from which it is not separated by any means.

AMAPHENASE, another name for *Aniline.* [ANILINE.]

AMARINE, $C^{42} H^{18} N^{2}$, is one of the bases obtained from oil of bitter almonds. It is formed from hydrobenzamide ($C^{42} H^{18} N^{2}$), with which it is isomeric, by boiling the latter with potash. Amarine forms fine white needles; it is insoluble in water, but soluble in hot alcohol. It has the properties of a powerful organic base.

AMARYTHRINE, $C^{34} H^{24} O^{20}$, is one of the products found in the colouring matter of lichens.

AMASATINE, $C^{16} H^{5} N$, one of the numerous bodies formed by the decomposition of indigo.

AMBREINE is a fat, analogous to cholesterine, found in ambergris. When treated with nitric acid it yields *ambreic acid.*

AMYLE, $C^{10} H^{11}$. A compound radical, discovered by Frankland. It is procured hy the action of zinc on iodide of amyle. It is an oily liquid, boiling at a temperature of 311° Fahr., and is homologous with methyle, ethyle, &c. It combines with oxygen and the other compound radicals, and forms a series of highly interesting compounds resembling those of ethyle and methyle.

Oxide of Amyle = Amylic Ether, $C^{10} H^{11} O$, is obtained from the chloride of amyle hy acting on it with an alcoholic solution of potash. It boils at a temperature of 233° Fahr. This oxide is, like those of ethyle and methyle, capable of combining with almost all acids, and acting as a metallic base.

Hydrated Oxide of Amyle = Amylic Alcohol = Fusel Oil, $C^{10} H^{11} O + HO$. This substance is a true alcohol, the representative of the hydrated oxide of ethyle or common alcohol ($C^{4} H^{5} O + HO$). It is formed along with common alcohol during the fermentation of potato starch, and the starch of common grains. The process of its formation nnder these circumstances is not well understood, although it undoubtedly depends on the peculiar condition of the sugar during fermentation. It is on account of its being obtained from the decomposition of starch (*Amylum*) that it has obtained its name. This fermentation in which it is produced is called the amylic. It is the occurrence of this fermentation in grain used for obtaining distilled spirits that gives them a part of their noxious qualities, and it is the object of the distiller to prevent the development of fusel oil. It is a colonrless somewhat oily liquid, almost insoluble in water, and boiling at a temperature of 270°. It has a powerful odonr, which is very nnpleasant, and produces when inhaled a sense of suffocation. Its taste is nauseous, acid, and unpleasant. When heated in contact with potash hydrogen is given off, and valeric acid is formed, which unites with the potash. When heated with dry phosphoric acid it yields the carbo-hydrogen $C^{10} H^{10}$, which is isomeric with olefiant gas, and which is known by the name of *Amylene* or *Valerene.* This substance has lately obtained some repute, as it has heen administered in common with chloroform and ether as an anæsthetic (ANÆSTHETICS—MATERIA MEDICA, *S.* 2). The compounds of the oxide of amyle are very similar to those of the oxide of ethyle, but of course are not so volatile. These other compounds of amyle are very numerous, but as their composition is easily understood hy their formulæ, we need not describe them more particularly:—

Sulphanylic acid . . .	$C^{10} H^{11} O + S O^{3}$.
Carbamate of oxide of amyle .	$C^{12} N H^{13} O^{4}$.
Amylamine	$C^{10} H^{13} N$.
Amylo-urea	$C^{12} N H^{14} O^{2}$.
Diamylamine	$C^{20} H^{23} N$.
Triamylamine	$C^{30} H^{33} N$.
Tetramylium	$C^{40} H^{44} N$.
Triethylamylium . . .	$C^{22} H^{26} N$.
Diethylamylamine . . .	$C^{18} H^{21} N$.
Methylodiethylamylinm . .	$C^{20} H^{24} N$.
Methylethylamylamine . .	$C^{16} H^{19} N$.

AMYLAMINE. [AMYLE.]

AMYLENE. [AMYLE.]

AMYLO-UREA. [AMYLE.]

ANCHUSINE, the red colouring matter which gives to *Anchusa tinctoria*, the alkanet, its dyeing properties. It is resinous in its character, and neutral in its properties, and gives out violet vaponrs when heated.

ANEMONINE, $C^{8} H^{2} O^{2}$, a volatile crystallisable solid, obtained from various species of *Anemone.* It unites with bases yielding *anemonic acid.*

ANGELICINE, a non-azotised vegetable substance found in Angelica root (*Angelica Archangelica.*)

ANILIC ACID = *Indigotic acid = Nitro-salicylic acid,* $C^{14} H^{4} N O^{9} + H O$. This acid is one of the nnmerous substances formed by the decomposition of indigo. It is procured by ths long continned action of weak nitric acid on that substance. It is also formed in the preparation of Isatine (CHEMISTRY—ISATINE, *S.* 1.) It is identical with nitro-salicylic acid, which is formed by the action of nitric acid on salicine. It is a solid, fusihle, and volatile substance, forming fine yellowish white prisms, which shrink in drying. It combines with bases forming anilates. The anilate of the oxide of methyle may be obtained by the action of nitric acid on the oil of gaultheria, which is a salicylate of the oxide of methyle.

ANILINE = *Kyanole = Crystalline = Amaphenase, Phenylamene, Phenamine, Phcnamide, Benzidam.*

Hofmann has recently demonstrated that the base obtained by Unverdorben, under the name of *crystalline,* from the products of the distillation of animal matter or coal tar, is identical with aniline. The same distingnished chemist has added largely to our knowledge of this substance. He has shown that *Isatine,* which is oxidised blue indigo when treated with potash, yields aniline, and that chlorisatine and bromisatine when treated in the same way, yield products of the type of aniline, in which hydrogen is replaced by chlorine, bromine, or both. Aniline assumes a deep violet colonr when brought into contact with chloride of lime. It is remarkable for its power of entering into combination with other substances. Hofmann has obtained it from other substances besides isatine. When anthranilic acid is treated with powdered glass, it is resolved into carbonic acid and aniline.

Salicylamide and *Nitrotoluole* both yield this substance when exposed to heat with the bases lime, or baryta. The first yields little, hut the last compound is entirely resolved into aniline and carbonic acid. The following is a list of substances which are formed hy the simple substitntion of other elements for atoms of hydrogen in the aniline base:—

Aniline	$C^{12} H^{7} N$.
Chloraniline	$C^{12} H^{6} Cl N$.
Dichloraniline . . .	$C^{12} H^{5} Cl^{2} N$.
Trichloraniline . . .	$C^{12} H^{4} Cl^{3} N$.
Bromaniline	$C^{12} H^{6} Br N$.
Dibromaniline	$C^{12} H^{5} Br^{2} N$.
Tribromaniline . . .	$C^{12} H^{4} Br^{3} N$.
Chlorodihromaniline . .	$C^{12} H^{4} Cl Br^{2} N$.
Nitraniline	$C^{12} H^{5} N O^{4} N$.
Nitrodibromaniline . .	$C^{12} H^{4} Br^{2} NO^{4} N$.

Chemically, these componnds are of the highest interest. In the case of aniline, hromaniline, and chloraniline, chlorine and bromine are substituted for hydrogen, and this was one of the first instances known of the substitution of other elements for hydrogen in a basic compound, although many instances have since occurred. It will also be seen from these componnds that aniline has a close resemblance to ammonia. This is seen also in the fact, that just as ammonia forms the componnds carhamide and oxamide, so aniline will yield under the same circumstances *carbanilide* and *oxanilide.* It also forms acid anilides, as carhanilic acid, analogous to carbamic acid. Hofmann has also made the discovery that just as cyanate of ammonia passes into nrea, and the cyanate of methylamine into *methylo-urea,* so cyanate of aniline passes spontaneously into *anilo-urea.* For a full account of the chemistry of this highly interesting compound, the reader should consult the papers of Dr. Hofmann.

ANILOCYANIC ACID, C^2 N O C^{12} H^5 O, a compound of aniline and cyanic acid.

ANILOMELLONE, C^{18} H^4 N^4, a compound of aniline and mellone, obtained by the heating of melaniline.

ANISOINE, a substance obtained by acting on the oil of anise by strong acids, or the chlorides of tin or antimony. It is analogous to benzoine.

ANISOLE = *Phenomethole* = *Carbolate of oxide of Methyle,* C^{14} H^8 O^2. This is one of the many compounds of the oxide of methyle (C^2 H^3 O). It is obtained by heating *anisic acid,* which is itself obtained by oxidising the stearoptene of oil of anise with nitric acid. *Anisyle* is the radical of anisic acid, which is thus composed, C^{16} H^8 O^6.

ANISYLE. [ANISOLE.]

ARICINE, C^{20} H^{12} N O^3 ? An alkaloid found in a cinchona bark from Arica in Peru. It is similar in its properties to Cinchonine.

ASARONE, C^{20} H^{13} O^3, is a volatile principle, obtained from the *Asarum Europeum.* It has a remarkable tendency to crystallise in beautifully definite forms. It however readily assumes an amorphous condition, from which it is again easily restored to its crystalline condition. The facility which this circumstance affords for the study of crystallisation in general, has been taken advantage of by Schmidt, who has published a paper on the microscopic appearances of this substance during its crystallising condition in the 'Annalen der Chemie und Pharmacie,' for February, 1845.

ATHAMANTINE, C^{24} H^{15} O^7, is a crystalline, fatty body, obtained from the root of *Athamanta oreoselinum.* It contains valerianic acid, united to a base called *Oreoselone.* Athamantine combines with hydrochloric acid, and the compound, when boiled, deposits crystals of oreoselone combined with water (C^{14} H^6 O^4), a compound that is isomeric with benzoic acid.

ATROPINE, C^{34} H^{23} NO^6. This substance is an alkaloid, and is found in the *Atropa Belladonna.* It crystallises in white silky prisms, which are sparingly soluble in water and ether, but more so in alcohol. It is very bitter, acrid, and poisonous, and, like the extract and juice of the plant, dilates the pupil of the eye when taken or applied to the eye externally. It is fusible and volatile, and forms salts with the acids, which are bitter and poisonous. This alkaloid, like many others, is much the most certain form in which the belladonna can be applied for medical uses.

AZEDIRINE, an alkaloid found in *Melia Azedirachta.* It forms a crystallisable salt with sulphuric acid, and is said to be a powerful febrifuge.

AZOBENZOYLE, C^{42} H^{15} N^2, a compound obtained by Laurent from the oil of bitter almonds. Its base is benzoyle combined with nitrogen.

AZOLEIC ACID, one of the acids formed by the action of nitric acid on oleic acid.

BALENIC ACID, C^{38} H^{37} O^3 HO. A fatty acid melting at 164°.

BASSIC ACID, C^{36} H^{35} O^3 HO. This acid combines like the other fatty acids with oxide of glyceryle, or lipyle, and in this state is present in the butter of *Bassia latifolia,* one of the butter trees of Africa, and in the fat of *Cocculus Indicus.* It is a crystalline fatty acid, melting at 159° Fahr. It forms soaps with the alkalies. With chlorine it forms chlorobassic acid.

BEEBEERINE, C^{38} H^{21} O^6, is an alkaloid, and the active principle of the bark of the Beebeeru tree of Guiana. The bark of this tree has been found an excellent substitute for cinchona, and the beebeerine itself has been employed as a substitute for quinine. Planta obtained it in the form of a snow-white uncrystallisible powder. Its salts are not crystallisable, and they all act as febrifuges.

BENZAMIDE, C^{14} N H^7 O^2. This is a compound of benzoyle [CHEMISTRY—BENZULE, *S.* 1.] and amide. It is formed when dry ammonia acts on chloride of benzoyle, also when hippuric acid is boiled with peroxide of lead. It forms fine soft needles or pearly scales, very fusible and volatile. It yields ammonia when boiled with the alkalies, and a benzoate is formed.

BENZILE = *Benzoyle* = *Benzule.* [CHEMISTRY—BENZULE, *S.* 1.]

BENZIMIDE, C^{28} N H^{11} O^4. This is one of the numerous compounds described by Laurent as the result of the study of hyduret of benzule, the oil of bitter almonds. It is found in the oil in a crude state. It is crystallisable, and is decomposed by acids into benzoic acid and ammonia.

BENZOENE, a name synonymous with *Toluole.* [TOLUOLE.]

BENZOGLYCOLIC ACID, C^{18} H^7 O^7 + HO. This acid is formed when hippuric acid is exposed to the action of hyponitrous acid. It is crystalline, soluble in alcohol and ether, less soluble in cold water. When heated with acids it is decomposed, yielding benzoic acid and glycolic acid.

BENZOINE, C^{28} H^{12} O^4, a product belonging to the benzoyle series. It is procured by acting on crude oil of bitter almonds containing hydrocyanic acid with an alcoholic solution of potash or sulphuret, or cyanide of potassium. It occurs in the form of small crystals, insoluble in water, and soluble in alcohol. It dissolves in sulphuric acid with a violet colour. When passed through a red-hot tube it is converted into hyduret of benzoyle (C^{14} H^6 O^2).

BENZOINAM, C^{56} N^2 H^{24} O^2. When a mixture of ammonia, alcohol, and benzoin is left closed for some months, several new products are formed, amongst which is *Benzoinam.* It occurs in the form of small white needle-shaped crystals. It dissolves in acids, and is precipitated by alkalies.

BENZOINAMIDE = HYDROBENZOINAMIDE, is formed by exposing a mixture of benzoine and ammonia. It is a white, tasteless powder, and volatilises without decomposition.

BENZOLONE, C^{11} H^4 O. When *Hydrobenzamide* (C^{42} H^{18} N^2) is heated with potash till it becomes blackish brown, this compound is formed. The mass when washed with water yields benzolone in the form of small crystals. It gives a bright red colour when acted on by sulphuric acid.

BOLOARTINE, C^{40} H^{32} + 3HO, is the name of one of four resinous compounds found in the peat of Denmark on the remains of pine trees. It is a fusible compound, but not crystalline.

BROMAL, C^4 Br^3 O + HO. This compound is analogous to chloral (C^4 Cl^3 O + HO), and is formed by the action of bromine on alcohol. It is resolved into formic acid, and perbromide of formyle by the action of caustic alkalies.

BROMANILINE. [ANILINE.]

BRONAPHTASE, C^{20} (H^7 B^2), is one of the numerous compounds obtained from naphthaline. It is formed by the direct action of bromine on naphthaline, care being taken not to add the bromine in excess, which would produce *bronaphtese.* Bronaphtase is a colourless oil, decomposed by chlorine and bromine.

BRONAPHTESE, C^{20} (H^5 Cl^3), is formed by the action of bromine on naphthaline, or on *bronaphtase.* It is a crystallisable solid, and forms several compounds with bromine.

BRONAPHTISE, C^{20} (H^5 Br^3), is obtained by heating the bromide of *bronaphtese.*

BRONAPHTOSE, C^{20} (H^4 Br^3), a compound with the above formula, has been obtained in two forms, both crystallisable.

BUTYLE = *Valyle,* C^8 H^9. This compound was discovered by Kolbe, as the result of the decomposition of valerianic or valeric acid (C^{10} H^{10} O^4) by the action of the galvanic current. It is a transparent, colourless liquid, insoluble in water, and soluble in alcohol and ether. It has an agreeable smell, and a slightly acid briny taste. It is combustible, and burns with a bright but smoky flame. By the action of oxygen it is converted into butyric and nitropropylic acid. Kolbe has obtained a substance, which he calls *butylene,* and which is homologous with olefiant gas and with propylene. It has the formula C^8 H^8. It is found in oil gas.

Butylamine, C^8 H^{11} N, has been discovered by Anderson in Dippel's animal oil in company with ethylamine, methylamine, propylamine, and other bases. It is a volatile, oily, and powerfully basic substance.

Butyryle, C^8 H^7, belongs also to the butyle series with C^8. It has not yet been obtained separate, but its hydrated oxide *butyral* or *butyraldehyde,* is known.

Hydrated Ozyde of Butyryle, C^8 H^7 O + H O, was originally obtained by Guckelberger, amongst the products of the oxidation of fibrine, &c., by sulphuric acid and peroxide of manganese, or bichromate of potash.

Butyric acid, C^8 H^7 O^3 + H O. This acid is the hydrated teroxide of butyryle, and perfectly homologous with other acids with a compound radical, as acetic acid. It exists in butter in small quantities, and is combined in them with oxide of glyceryle. It is to this acid that the flavour of butter is mainly due. It can be obtained by fermentation from sugar or starch. The acid may be obtained from butyrate of lime by the action of sulphuric acid. It is an oily liquid substance, having a rancid smell. The rancidity of butter is due to this acid escaping, from its combination with the oxide of glyceryle. The butyrate of lime can be obtained in any quantity by fermenting sugar with cheese and adding chalk. Carbonic acid and hydrogen gases are set free.

Butyro-nitryle = *Cyanide of Propyle*, $C^8 H^7 N$. It is a question whether this compound is a true cyanide, or a nitryle. It is formed among the products of the oxidation of albuminous compounds.

Butyramide, $C^8 H^7 O^2 N H^2$. This substance is produced by heating the butyrate of the oxide of ethyle with ammonia in closed tubes.

Butyrone, $C^7 H^7 O$. This substance is homologous with acetone and propione. It is less volatile than propione. It is procured by heating the butyrate of baryta.

Butyrate of the Oxide of Ethyle, or *Butyric Ether*, $C^4 H^5 O + C^8 H^7 O^3$. This is a very fragrant and delicious ether, and is the principal element of the flavour found in the pine-apple, the melon, and some other fruits. It is this substance which is developed during the fermentation of the sugar from which rum is procured, and which appears to have got for this form of ardent spirits the name of pine-apple rum. This ether dissolved in alcohol, is sold in the shops under the name of essence of pine-apple, and is used for flavouring confectionary, &c. It is developed in rum more fully after long keeping. It is also found in some wines, and with acetic ether is one of the principal sources of their flavour.

BUTYRAL. [BUTYLE.]

BUTYRAMIDE. [BUTYLE.]

BUTYRIC ACID. [BUTYLE.]

BUTYRONE. [BUTYLE.]

BUTYRONITRYLE. [BUTYLE.]

BUTYRYLE. [BUTYLE.]

CAMPHOGEN, $C^{20} H^4$. This substance is obtained when common camphor ($C^{10} H^8 O$) is distilled with dry phosphoric acid. It is found also in the oil of cumin. It forms with sulphuric acid a compound, called sulphocamphic or hyposulphocamphic acid, $C^{20} H^{15} S^2 O^5 + H O$.

CAMPHORIC ACID, $C^{10} H^7 O^3 + H O$. This acid is formed by the action of nitric acid on camphor. It occurs in the form of crystalline scales, which fuse at a temperature of 158°, and are very soluble in alcohol and ether, but sparingly soluble in cold water. When distilled these scales are resolved into anhydrous camphoric acid and water. This acid combines with the oxide of ethyle, and forms two compounds:

1. *Camphoric ether*, an oily liquid, with a bitter taste and a nauseous smell.
2. *Camphovinic acid*, which has the power of forming soluble salts.

Anhydrous camphoric acid, $C^{10} H^7 O^3$, forms a different series of salts from those constituted by the hydrated acid. It is a solid crystalline and volatile body, and yields an acid amide called *camphoric acid*.

Sulphocamphoric acid is formed by the action of sulphuric acid on anhydrous camphoric acid with the disengagement of carbonic oxide.

CAMPHOVINIC ACID. [CAMPHORIC ACID.]

CAMPHRONE, $C^{30} H^{21} O$. This substance is formed when camphor is passed over red-hot lime.

CAOUTCHINE, $C^{10} O^8$. When caoutchouc (Indian rubber) is exposed to the action of heat, it first melts and then distils, and yields several oils which, like caoutchouc itself, are compounds of carbon and hydrogen. One of these is caoutchine, which combines with chlorine, forming an oil $C^5 H^5 + Cl$.

CAPRAL (CAPROIC ACID), CAPRAMIDE, is produced by the action of ammonia on the caprate of the oxide of ethyle. It occurs in the form of shining scales, which are fusible below 212° Fahr., soluble in alcohol, and insoluble in water.

CAPRIC ACID, $C^{20} H^{19} O^3 + H O$. This acid is formed with many others from butter and goat's fat. It is also produced by the oxidation of the oil of rue. It has also been found in the oil of grain. It is a solid, fatty body, melting at a temperature of 80°, and giving out a rancid odour similar to human perspiration. Like the other acids of the series to which it belongs, it unites with oxide of ethyle, an exceedingly fragrant compound, having a smell closely resembling pine-apples.

The base of this acid, *capryle* ($C^{20} H^{19}$), unites with oxygen to form the oxide of capryle, which again unites with water, forming the *hydrated oxide of capryle*, a substance homologous with the alcohols of the other compound radicals. Its composition is $C^{20} H^{19} + O + H O$. It constitutes the chief part of the oil of rue. When nitric acid is added to it and heated, it is converted into capric and pelargonic acids.

CAPRONE. [CAPROIC ACID.]

CAPROIC ACID, $C^{12} H^{12} O^4$. This is the hydrated teroxide of *caproyle*, and is almost the only compound yet known of that radical. It is found in goat's fat and goat's butter, also in cow's butter and cocoa-nut oil. It can be best obtained from the *cyanide of amyle* or *capronitryle* by boiling it with an alcoholic solution of potash. Caproate of potash is obtained, which, on being distilled with sulphuric acid, yields caproic acid, which is an oily liquid, with a strong smell of perspiration. When united with the oxides of methyle or ethyle it produces fragrant ethers, having the smell of melons, pine-apples, and other delicious fruits.

Caprone, $C^{11} H^{11} O$, is formed from caproic acid, by heating the caproate of baryta. It is accompanied by *capraldehyde* or *capral*, $C^{12} H^{12} O^2$.

CAPRONITRYLE. [CAPROIC ACID.]

CAPROTYLE, $C^{12} H^{13}$. This substance is obtained when œnanthylic acid is decomposed by galvanism. It is a base similar to ethyle, and probably capable of similar combinations.

CAPRYLIC ACID, $C^{16} H^{15} O^3 H O$. This acid is the hydrated teroxide of *caprilyle*. It is found combined with oxide of lipyle in butter. It is one of the compounds which gives flavour to this substance. It is an oily acid liquid smelling rancid, and having an odour of sweat. It boils at a high temperature. Its salts have a soapy character. When caprylate of baryta is heated it yields *caprylone*, $C^{15} H^{15} O$.

CAPRYLONE. [CAPRYLIC ACID.]

CAPSICINE is an alkaloid found in the capsules of *Capsicum annuum* and other species of *Capsicum*, which are used in the manufacture of cayenne pepper. It has a burning taste, and may be crystallised. It is insoluble in water and ether, soluble in alcohol. It forms crystallisable salts with sulphuric, nitric, and acetic acids.

CARAMEL is a name given to cane-sugar when it has been exposed to a temperature of 420°. The sugar loses three equivalents of water, and becomes converted into a brown tasteless mass.

CARAPINE, an alkaloid found in the *Carapus guianensis*. It forms crystallisable salts with hydrochloric and acetic acids.

CARBAMIDE, $C O N H^2$. This substance is produced by the action of chloro-carbonic acid gas on ammonia. Sal ammoniac is also formed at the same time. Under the influence of the mineral acids carbamide yields ammonia and carbonic acid.

CARBANALIDE, $C^2 O C^{12} H^6 N$. This substance is urea ($C^2 O^2 H^4 N^2$), in which two atoms of hydrogen are replaced by *phenyle* ($C^{12} H^5$). There is also a *carbanilic acid* ($C^{14} N H^6 O^4 + H O$).

CARBOLIC ACID = *Hydrated Oxide of Phenyle*, $C^{12} H^5 O + H O$, is one of the products of coal tar, and is found amongst those portions which boil between the temperature of 300° and 400°. It is procured by taking this peculiar product with twice its weight of potash ley. On the addition of an acid to this mixture hydrated carbolic acid may be obtained in the form of a heavy oil. When pure it is a heavy transparent oil, refracting light very strongly, neutral to test paper, and having a specific gravity of 1·062 to 1·065. It has the taste and odour of creosote, which it is very much like. They are probably identical, or have the same base. According to Laurent carbolic acid is the hydrated oxide of pheuyle. [PHENYLE.]

CAROTINE, the colouring matter of the common carrot, *Daucus Carota*.

CATECHINE = TANNINGENIC ACID, $C^{15} O^6 H^6$, is that portion of catechu which is insoluble in cold water. It is soluble in hot water, and crystallises in the form of a white silky powder. When heated with caustic potash it yields a black acid called *japonic acid*. Carbonate of potash produces with it *rubinic acid* ($C^{18} H^6 O^4$), which has a red colour.

CATHARTINE, the active principle of the various species of *Cassia*, which are used under the name of Senna.

CEDRIRET, one of the products of the distillation of coal tar discovered by Reichenbach. It is a volatile solid, and is obtained from creosote by the action of potash and acetic acid. It crystallises in a solution of sulphate of iron, forming orange red crystals, which dissolve with a blue colour in sulphuric acid. The colour of oil of tar seems to be owing to this substance.

CERASINE is that part of the gum of the cherry-tree which is insoluble in cold water. It is probably some transitionary form between starch and gum.

CEREBRIO ACID is a substance said to exist in the fatty matter of the brain. It is accompanied by another acid, the *oleo-phosphoric acid*, which is snpposed to be united to a componnd radical *cerebroleine*, in the manner of the fatty acids. These substances are of a very donbtfnl nature, and the chemistry of the nervons system is at present in a very imperfect state.

CERRBROLEINE. [CEREBRIC ACID.]

CERENE, $C^{54} H^{54}$, is a solid wax-like body. It has been obtained as a compound of sulphnric acid with cerotine, $C^{54} H^{55} O + H O + S O^3$.

CEROSINE, $C^{48} H^{50} O^2$, is a waxy snbstance fonnd on the surface of the sugar-cane. It is not saponifiable.

CEROTIC ACID, $C^{54} H^{53} O + H O$. This componnd was discovered by Brodie as an ingredient of bee's-wax in a free state. It may be procnred by dissolving wax in hot alcohol, and dissolving the residue deposited on cooling till its melting point rises to 162°. It is then purified by ether till its melting point is 171°, which is that of the acid. This substance was formerly called *cerine.* It has, however, acid properties, and combines readily with bases. It combines with oxide of ceryle, forming the cerotate of that substance, $C^{54} H^{55} O + C^{54} H^{53} O^3$, which is called *cerotine.* When heated with potash, it produces cerotate of potash and the *hydrated oxide of ceryle*, or *ceric alcohol.*

CERYLE, $C^{54} H^{55}$, the base of cerotic acid. [CEROTIC ACID.]

CETINE. [CETYLE.]

CETYLE, $C^{32} H^{33}$, a compound radical of the series C^{32}. It forms the following componnds :—

Cetylic Alcohol = Ethal, $C^{32} H^{33} O H O$. When spermaceti or cetine are treated with an alkali, a cetylate of the alkali is formed, and the *hydrated oxide of cetyle* is left. Although a true alcohol, it is not liqnid, but a fat, melting at a temperatnre of 118°. The crystalline part of spermaceti is called *cetine*, and is a cetylate of the oxide of cetyle.

Oxide of Cetyle, $C^{32} H^{33} O$, is procured by the action of sodium on cetylic alcohol, when hydrogen escapes, and the remainder being heated with iodide of cetyle, yields iodide of sodium and oxide of cetyle.

Sulphocetylic Acid, $2 S O, H O, C^{32} H^{33} O$, is perfectly homologous with snlphovinic acid: chloride, bromide, and iodide of cetyle are also known.

Cetylic Acid = Ethalic Acid, $C^{32} H^{31} O^3 + H O$, is obtained from spermaceti by saponification, and adding some stronger acid to the compound. Its salts with the alkalies form soaps. It melts at the temperature of 131°.

Tricetylamine, $C^{96} H^{99} N$, is formed when dry ammonia acts on iodide of cetyle.

Palmitic Acid is isomeric with cetylic acid, bnt melts at a temperatnre of 140°. It is the chief solid acid of palm oil.

CHELERYTHRINE, an alkaloid found in company with *Chelidonine* in the celandine (*Chelidonium majus*). It forms a gray powder, which excites violent sneezing. It forms red salts with the acids, which are narcotic and poisonous. *Chelidonine* is a bitter substance, insoluble in water, and forming crystallisable salts.

CHIOCOCCINE, an alkaloid very similar to *Violine.* The first is found in the snowberry (*Chiococca racemosa*), and the second in the violet (*Viola odorata*). Their action on the hnman system is precisely similar to that of *Emetine* obtained from ipecacuanha. On this account it has been snpposed that they are emetine disguised with foreign matters.

CHLONAPHTASE, $C^{20} H^7 Cl$. This is the first of a series of componnds formed from Naphtbaline, and described by Laurent. Naphthaline is composed of $C^{20} H^8$. Laurent has shown that various elements will supplant the hydrogen, and that not only in one, but in several proportions. He has therefore proposed to give names to these compounds, according to the quantity of the element supplanting the hydrogen. Thns, it will be seen that in Chlonaphtase one atom of chlorine supplants one of hydrogen. According to the number of atoms supplanted, Laurent employs the vowels a, e, i, o, n, in the last syllable of the name. Thus, Chlonaphtase has one atom of chlorine, but *Chlonaphtese* ($C^{20} H^6 Cl^2$) has two atoms, *Chlonaphtise* ($C^{20} H^5 Cl^3$) has three atoms, *Chlonaphtose* ($C^{20} H^4 Cl^4$) has fonr atoms, *Chlonaphtuse* ($C^{20} H^3 Cl^5$) has five atoms. When the vowels are exhausted, Laurent adds a syllable, so that the componnd $C^{20} H^2 Cl^6$ is *Chlonaphtalose*, the compound $C^{20} H^1 Cl^7$, is *Chlonaphtalise.* The same plan is pnrsued with bromine. But in all these cases the hydrogen may be replaced by atoms of both chlorine and bromine. In the same way the vowels are made to do duty for these compounds, as follows: chlonaphtose, $C^{20} H^4 Cl^4$; chloribronaphtose, $C^{20} H^4 Cl^3 Br$; chlorabronaphtose, $C^{20} H^4 Cl Br^3$; chlorebronaphtise, $C^{20} H^5 Cl^2 Br$; chlorebronaphtose, $C^{20} H^4 Cl^2 Br^2$; chloribronaphtuse, $C^{20} H^3 Cl^3 Br^2$. All these compounds are capable of acting as bases and combining with elements. Thus we have *chloride of chlonaphtose* and *chloride of chlonaphtese*, &c., *bromide of chlorabronaphtese*, &c.

CHLOROFORM. [FORMYLE.]

CHOLACROLE, $C^8 N^2 H^5 O^{13}$, one of the products of the action of nitric acid on *choloidic acid.*

CHOLALIC ACID, $C^{48} H^{40} O^1$, one of two prodncts formed by boiling cholic acid with potash. The other substance is *glycocine.* The cholalic acid occurs in very fine and regular crystals. Its salts form soaps. It is easily convertible by acids into choloidic acid.

CHOLEIC ACID, $C^{52} N S^2 H^{45} O^{14}$, is an acid fonnd in combination with soda in human bile. When boiled with potash it yields cholalic acid, and a substance called *taurine*, $C^4 N S^2 H^7 O^6$, in which it will be seen are contained all the snlphur and nitrogen of the acid.

CHOLIC ACID, $C^{52} N H^{46} O^{12}$, was first discovered in the bile by Gmelin. It is prepared by allowing a solution of dry bile in alcohol to be mixed with ether, when it deposits cholate of soda. If this is decomposed by snlphuric acid, gronps of radiated crystals are deposited, which are cholic acid. It is decomposed when heated with mineral acids and potash.

CHOLOIDIC ACID, $C^{48} H^{39} O^9$, is procnred from the decomposition of cholic acid when boiled with acids. It is cholalic acid with one eqnivalent less water. Choloidic acid is uncrystallisable, and its salts are amorphons. This substance was formerly called resin of bile. When choloidic acid is boiled with hydrochloric acid, it becomes converted into a nentral substance, *Dyslysine*, $C^{48} H^{36} O^6$, by the loss of three equivalents of water.

CHROMOCYANOGEN, $6(C^2 N) + Cr^2$, is a compound of chrominm and cyanogen. It combines with potassinm, forming a yellow crystallisable salt.

CHRYSENE, $C^3 H$, is one of the nnmerous compounds formed in coal tar. It is a yellow crystalline solid, melting at a temperature of 455°.

CHRYSOPHANIC ACID, $C^{10} H^8 O^3$, is fonnd in the *Parmelia varietina.* It occurs in the form of golden yellow crystals, and with solutions of potash and ammonia, in alcohol, yields a beantiful red colour.

CINNAMYLE, $C^{18} H^8 O^2$, the hypothetical radical of essence of cinnamon.

Hyduret of Cinnamyle, $C^{18} H^8 O^2 + H$, is the purified essence or oil of cinnamon. It is a fragrant oil, and forms with nitric acid a crystalline compound, $C^{18} H^9 O^2 + N O^5$, which, when mixed with water, is resolved into its original constituents, hyduret of cinnamyle and nitric acid. When it is exposed to the air it absorbs oxygen, and becomes converted into *cinnamic acid*, $C^{18} H^8 O^3 + H O$. This acid is also easily obtained by dissolving oil of Balsam of Peru in a solution of potash in alcohol, evaporating to dryness, dissolving in hot water, and adding to the cinnamate of potash then formed, hydrochloric acid. *Nitric* acid converts it into hyduret of benzoyle. When added to cold nitric acid it is converted into *nitro-cinnamic acid.* The salts of this acid detonate when heated. When oil of cinnamon is ponred upon fusing snlphnric acid, *sulpho-cinnamic acid* is formed.

Cinnameine, $C^{36} H^{14} O^4$, is found in Balsam of Peru. It contains cinnamic acid united to an ether.

Cinnamile, $C^{16} H^8$, is formed when cinnamic acid is distilled with baryta.

CITRACONIC ACID, $C^6 H^2 O^3$, is formed from *Itaconic acid*, $C^6 H^2 O^3 H O$, which is again formed from *Aconitic acid*, $C^4 H O^3$. The last acid is found in the *Aconitum Napellus*, and *Equisetum fluviatile.*

CNICINE $C^{28} H^{18} O^{10}$, an active principle fonnd in the group *Cynarocephalæ* of the compositons order of plants. It is neutral and bitter.

COLCHICINE, the active principle of the meadow saffron (*Colchicum autumnale.*) It was at one time regarded as identical with veratrine. It is soluble in water, alcohol, and ether. It forms salts with the acids, which are bitter, acrid, and poisonous. In small doses it causes purging.

Compound Radical, a term applied to those combinations of the elements which act towards oxygen, hydrogen, and acids, as simple elements. Examples of such compound bodies will be found under the heads, *amyle, butyle, cetyle, cinnamyle*, &c.

Collodion. [Gun Cotton.]

Creatine, $C^8 H^9 N^3 O^4$. This body, originally discovered by Chevreul, occurs in transparent very brilliant crystals. It has a bitter strongly pungent taste, and irritates the pharynx. It dissolves in 74 parts of cold water, and in boiling water in such quantity that on cooling the solution becomes consolidated into a mass of glistering needles. It dissolves sparingly in alcohol, and not at all in ether. It forms no definite salts with acids. According to Liebig it is best obtained from finely chopped flesh that has been well kneaded with water, and the fluid removed by pressure. The coagulable matters are then removed by boiling, and the phosphates by caustic baryta. The fluid left is then evaporated till the creatine is deposited in the form of needles. Creatine can also be obtained from the urine. It appears to be produced in the flesh of animals as the result of a process of retrogressive change in the elements of the tissues in which it is found. It is in fact a product of excretion.

Creatinine, $C^8 H^9 N^3 O^2$, was discovered by Liebig. It is obtained from creatine by the action of hydrochloric acid. It is found also in the muscles and the urine, with creatine, whilst these bodies are in their normal condition. But in putrid flesh and urine no creatine is found. Hence creatinine may be regarded as the result of the decomposition of creatine.

Cumidine, $C^{18} H^{13} N$, is obtained from the oil of cumin. It is a crystalline base, resembling *aniline;* and like that base it combines with chlorine, bromine, &c. *Cumole*, $C^{18} H^{12}$, is found in the oil of cumin and in the oil of coal-tar. *Cymidine*, $C^{20} H^{15} N$, and *cymole*, $C^{20} H^{14}$, are found in company with the above compounds in the same oil.

Cyameline, $C^2 O^2 + N H$. This substance is formed by the decomposition of cyanic acid when left to itself. It is an opaque white solid body, which has no acid properties. It dissolves in liquor potassæ with disengagement of ammonia, and the solution yields cyanurate of potash.

Dadyle, $C^{20} H^{16}$, is obtained by heating oil of turpentine with lime. It is a pure oil.

Diamylamine. [Amyle.]

Dibromaniline. [Aniline.]

Dichloraniline. [Aniline.]

Diethylamine. [Aniline.]

Dyslysine. [Choloidic Acid.]

Elaidic Acid, a fatty acid, obtained by the action of nitric acid on oleic acid.

Elaldehyde. When aldehyde is kept for some time in sealed tubes, it is converted into two polymeric bodies, *metaldehyde*, a hard crystalline inodorous solid, and *elaldehyde*, which is a liquid.

Erythric Acid = *Orcinolecanoric acid*, $C^{34} H^{19} O^{15}$. One of the acids found in the *Parmelia roccella* and *Roccella tinctoria*, lichens which yield the commercial substance archil. This acid is the most important of all the principles found in lichens. It yields ether when boiled with alcohol. Besides erythric acid, *lecanoric, alpha orcellic, beta orcellic*, and *evernic acids* have been found in lichens. They yield red dyes with ammonia, and are employed extensively in the dyeing of cotton and woollen cloth. These acids have been investigated by Schunck and Stenhouse, and the latter recommends that these acids, which are the valuable substances in dyeing, and which are not possessed by lichens in larger quantities than 2 to 12 per cent., should be separated on the spot where they grow, and thus spare the expense of the carriage of the useless parts. These acids are extracted by the following process:—"The lichens cut in small pieces are moistened with water, and after standing half-an-hour slaked lime is added, and the mixture allowed to stand for a time. It is then placed in a vessel with a double bottom, the upper being perforated and the liquid displaced by cautious addition of water, as long as that which drops gives a deep purple red colour with bleaching liquor, a character belonging to all the acids which yield archil. The solution is then supersaturated with hydrochloric acid, and a gelatinous precipitate falls, which is washed and dried. The acids are extracted from it by weak alcohol without boiling, which would form ether compounds." (Gregory.) Besides the acids there are three other compounds found in the lichens used for dyeing.—*Orcine, Picroerythrine*, and *Erythromannite*.

Orcine, $C^{16} N H^9 O^7$, occurs in the form of large transparent crystals. It has a sweetish taste, and is very soluble in water. When mixed with ammonia and exposed to the air, it assumes gradually a deep red colour, and when mixed with the fixed alkalies it has a rich violet colour.

Picroerythrine = Erythrin—bitter = Amarythrine, $C^{34} H^{23} O^{20}$, is formed when erythric acid, or the lichens containing it, are boiled in water.

Erythromannite, $C^{11} H^{14} O^{11}$, is formed when picroerythrine is boiled with baryta. It is dissolved by water and alcohol. It forms large colourless crystals, which have a sweet taste.

Ethal. [Cetyle.]

Ethalic Acid. [Cetyle.]

Ether, Butyric. [Butyle.]

Ether, Camphoric. [Camphoric Acid.]

Ether, Amylic. [Amyle.]

Ethylamine. [Ethyle.]

Ethyle, $C^4 H^5$. One of the earliest known of the compound radicals, and the base of the well-known substances ether and alcohol. It was for a long time unknown except in combination. Frankland, however, at last succeeded in separating it by the action of zinc in closed tubes upon the iodide of ethyle. The following equation expresses this result: $C^4 H^5 I + Zn = Zn I + C^4 H^5$. Part of the ethyle, however, is converted into zincethyle, $C^4 H^5 + Zn$, and another part into methyle and eloyle. In the latter case $C^4 H^5$ becomes $C^2 H^3 + C^2 H^2$. Ethyle is a colourless gas, having a faint smell like ether, and burning with a bright flame. It has a specific gravity of 2·00394, and is condensed into a liquid with $2\frac{1}{2}$ atmospheres. It is perfectly analogous to methyle ($C^2 H^3$), and according to the law which regulates these compounds, its density is higher whilst its volatility is less.

Oxide of Ethyle = Ether = Sulphuric Ether, $C^4 H^5 + O$. This ether is occasionally found in nature combined with acetic, butyric, and other ethers, which are found giving flavours to such fruits as melons, pine-apples, &c. This compound is obtained from alcohol by acting on it with sulphuric acid. [Æther.] Ether is now known to be perfectly analogous to the metallic oxides, its compound base ethyle taking the part of the metal. Thus, as $K O + \overline{A}$ represents acetate of potash, and $K O \overline{Bz}$ represents benzoate of potash, so $C^4 H^5 + O + \overline{A}$, and $C^4 H^5 + O + \overline{Bz}$ represent acetate and benzoate of ethyle.

Hydrated Oxide of Ethyle = Alcohol, $C^4 H^5 + O + H O = C^4 H^6 O^2$. This substance is formed when ether and water meet in their nascent state, as when some of the acid salts of ethyle are decomposed by heat. It is however produced during the fermentation of glucose or grape sugar, which is composed of $C^{12} H^{12} O^{12}$. During fermentation this compound loses 4 atoms of carbonic acid and leaves behind 2 atoms of the hydrated oxide of alcohol. Thus,

	C	H	O
Glucose	12	12	12
2 atoms of alcohol	8	12	4
4 atoms of carbonic acid . .	4	0	8

[Alcohol, P. C.]

Chloride of Ethyle, $C^4 H^5 Cl$, is formed by saturating alcohol with hydrochloric acid, and distilling the mixture in a vapour-bath, when the chloride of ethyle passes over.

Bromide, Iodide, and Sulphide of Ethyle, are analogous compounds, consisting of one atom of ethyle and one of the other element.

Hydrosulphuret of Sulphuret of Ethyle = Mercaptan, $C^4 H^6 S^2$, or $C^4 H^5 S + H S$, is formed when the double sulphate of lime and oxide of ethyle is distilled with its own bulk of a solution of potash saturated with sulphuretted hydrogen, and converted into $K S + H S$. It has a powerful and penetrating odour, smelling like the essence of onions concentrated. It adheres to the hands and clothes most pertinaciously, and is a most offensive subject to operate upon.

Zeise has described a persulphuret of ethyle, $C^4 H^5 + S^3$.

Seleniuret of Ethyle is formed when sulphuret of ethyle and potash is distilled with seleniuret of potassium. It is a volatile liquid, having an offensive alliaceous odour.

Cyanide of Ethyle, $C^4 H^5 + Cy = C^6 H^5 N$, is procured by heating cyanide or ferrocyanide of potassium with the double sulphate of potash and ethyle. It is a very offensive compound, smelling like putrid fish. It produces stupefaction when inhaled.

Oxide of Ethyle unites with sulphuric and phosphoric acids, forming sulphates and phosphates. *Nitrate of the oxide of Ethyle*, $C^4 H^5 + O + N O^5$, is the *Nitric Ether* of chemists, but the *Sweet Spirit of Nitre*, or *Spiritus Ætheris Nitriosi* of the London Pharmacopœia, is an impure hyponitrite of the oxide of ethyle, $C^4 H^5 + O + N O^3$, dissolved in alcohol.

Carbonate of Oxide of Ethyle = Carbonic Ether, $C^4 H^5 + O + C O^2$, is an aromatic liquid, boiling at a temperature of 260°. It unites with carbonate of potash, forming a double carbonate of ethyle and potash, $C^4 H^5 + O + C O^2 + K O + C O^2$.

Carbamate of Oxide of Ethyle = Carbamic Ether = Urethane, $C^6 H^7 N O^4$, is formed by the action of ammonia or *Chlorocarbonic Ether*, $C^6 H^5 Cl O^4$, with sal-ammoniac. It is distilled over, and crystallises on cooling. *Lactamide*, *Sarcosine*, and *Alanine*, are substances having the same composition, but assuming very different forms. The following is a list of other compounds formed from ethyle, or having this substance as their base. This list not only indicates the relations of ethyle, but of several other compound radicals which may be substituted for it.

Oxalate of Oxide of Ethyle = Oxalic Ether, $C^4 H^5 + O + C^2 O^3$.

Acid Oxalate of Ethyle = Oxalovinic Acid, $C^4 H^5 + O + C^2 O^3 + C^2 O^3 + H O$.

Oxamate of Oxide of Ethyle, $C^4 H^5 + O + C^4 N H^2 O^5$.

Benzoate of Oxide of Ethyle = Benzoic Ether, $C^4 H^5 + O + C^4 H^5 O^3 + H O$.

Hippurate of Oxide of Ethyle = Hippuric Ether, $C^4 H^5 + O + C^{18} N H^8 O^5$.

Salicylate of Oxide of Ethyle, $C^4 H^5 + O + C^{14} H^5 O^5$.

Cyanate of Oxide of Ethyle = Cyanic Ether, $C^4 H^5 O + C^2 N O^2$.

Ethylo-urea, $C^6 N^2 H^8 O^2$.

Ethylamine, $C^4 H^7 N$.

Diethylamine, $C^8 H^{11} N$.

Triethylamine, $C^{12} H^{15} N$.

Tetrethylium, $C^4 H^6 N$.

Methylotriethylium, $C^{14} H^{18} N$.

When ethyle in the form of its oxide ether, or the hydrated oxide, alcohol, is exposed to the air, they become converted into aldehyde, acetic acid, formic acid, oxalic acid, and finally carbonic acid and water. In this way the radicals *acetyle*, $C^4 H^3$ and *formyle*, $C^2 H$, are produced. [ACETYLE; FORMYLE.]

EUGENINE, a product obtained from the oil of cloves, having the same composition as Eugenic acid, $C^{20} H^{12} O^4$.

Eupion, one of the products of the destructive distillation of wood, discovered by Reichenbach, in company with creosote.

EXCRETIN, a substance discovered by Dr. Marcet in the excretions from the human bowels.

FICHTELITE, a fusible volatile crystalline substance, found in the submerged pine-trees of the Fichtel-gebirge. It is probably derived from the essence of turpentine, and has a composition $C^{20} H^{16}$.

FORMIC ACID. [FORMYLE.]

FORMYLE, $C^2 H$, is a compound radical unknown in its separate condition. When hydrated oxide of methyle is distilled with sulphuric acid, water, and peroxide of manganese, a liquid is produced which contains a formiate of the oxide of methyle, and a liquid called methylal, $C^6 H^8 O^4$. The latter is regarded as a hydrated oxide of formyle, and it is found that this hypothetical base is capable of entering into combinations in the same way as ethyle, acetyle or methyle.

Formic Acid, $C^2 H O^3$, is a teroxide of formyle. It originally obtained its name from having been found present in the red ant, (*Formica rufa*). Hence also the name of the base formyle. This acid may be procured from pyroxilic spirit, $C^2 H^3 O + H O$, by the loss of two equivalents of hydrogen, and the addition of two of oxygen, $C^2 H O^3 + H O$. It may also be procured by mixing starch or sugar with peroxide of manganese, water, and sulphuric acid, and distilling. It is found also under a great variety of circumstances. It unites with lead, forming a formiate of lead, and from this formiate of soda may be procured by the addition of carbonate of soda. It unites freely with most of the metals, and the salts when heated in closed vessels give off carbonic acid and carbonic oxide, leaving the pure metal. It unites also with ammonia, the salt containing the elements of hydrocyanic acid and water.

Chloroform = Terchloride of Formyle, $C^2 H Cl^3$. Chlorine combines with formyle and forms a very interesting series of compounds, none of more importance than that with three atoms of chlorine, a substance which has been extensively employed as one of the least injurious of the various anæsthetic agents which have been recently employed in medicine. It is a liquid, having a specific gravity of 1·50, and is transparent, colourless, and volatile. It is best obtained by distilling pure alcohol with water and bleaching powder (chlorinated lime). It is then well washed with water and redistilled, and washed with sulphuric acid to remove the water and other adulterations. [ANÆSTHETICS—MATERIA MEDICA, *S.* 2.]

FUMARAMIDE, $C^4 H O^2 + N H^2$. When the *fumarate* of oxide of ethyle, which is a heavy oily liquid, is acted on by *aqua ammoniæ*, it forms a white insoluble powder, which is *fumaramide*, and possesses all the characters of a compound amide.

FUSEL OIL. The oils which contaminate potato and grain spirit are called by the Germans under the common name *fuseloel*, and the same term translated is applied by English chemists to these oils. Potato spirit is accompanied by the hydrated oxide of amyle, or oil of potato spirit [AMYLE], whilst grain spirit is accompanied by an oily matter consisting of margaric, capric, and œnanthic acids, which probably, with the spirit form their corresponding ethers. Dr. Gregory suggests that this is probably the composition of the oil of grain, the *Oleum siticum* of Professor Mulder.

GEINE, a name given to *humus* in common with *ulmine*, *humic acid*, *ulmic acid*, *humine* and *geic acid*. This substance is obtained from common mould, which when boiled with alkalies, and the solution filtered and treated with acids, yields a brown deposit, which has the above names. Mulder states that the substance contains two and a half to seven per cent. of nitrogen. These substances appear to be vegetable matters in a state of decay.

GEIC ACID. [GEINE.]

GENTIANINE, a non-azotised vegetable compound, obtained in the form of yellow needles from the *Gentiana lutea*.

GLAUCINE, an alkaloid found in the leaves and stem of *Glaucium luteum*. It forms salts with the acids, and has a bitter acrid taste. It occurs in the form of pearly scales. *Glaucopicrine*, found in the same plant, differs from the above compound. The composition of both is doubtful.

GLYCERYLE, $C^6 H^7$, is the hypothetical radical of the substance called Glycerine, which is the hydrated oxide of Glyceryle, $C^6 H^7 O^5 + H O$. [GLYCERIN—CHEMISTRY, *S.* 1.] By the action of heat Glycerine is decomposed, and a volatile principle is produced, which is called *Acroleine*. [ACROLEINE.] Glycerine is the substance that combines with the fatty acids, forming the various oils and fats. Berzelius, however, has suggested that this compound is not present in some fats, but that a body having the composition $C^3 H^2 O$ occurs, and which he calls *oxide of lipyle*. Two atoms of this substance with three of water is equal to one atom of the hydrated oxide of glyceryle; thus, $C^6 H^7 O^5 = 2 (C^3 H^2 O) + 3 H O$.

GLYCOCINE = *Glycocoll* = *Sugar of Gelatine*, $C^4 N H^5 O^4$, is a compound found amongst the products of boiling gelatine with potash or acids. It may also be prepared by beating hippuric acid with hydrochloric acid, when benzoic acid, water, and glycocoll are produced. It forms transparent crystals, which are soluble in water and sweet to the taste. It combines with acids and bases. Its easy formation from the animal compound gelatine, has led to the supposition that it may play an important part in the animal body.

GUAIACYLE, $C^{14} H^7 O^4$, the theoretical base of the resin called guaiacum. If this resin is distilled, an oily liquid is obtained, which is regarded as a hyduret of guaiacyle, $C^{14} H^7 O^4 + H$.

GUANINE, $C^{10} N^5 H^5 O^2$, a compound discovered by Unger in guano. It resembles urea in its properties, forming crystallisable salts with hydrochloric, sulphuric, and nitric acids. It is a white powder, and insoluble in water. Its salts are all neutral or acid, none basic.

GUARANINE, $C^{16} H^{10} O^4 N^4$, a substance identical with theine and caffeine, and found in the *Guarana officinalis*.

GUN-COTTON, a substance discovered by Professor Schönbein. It is made by immersing one part of cotton wool in ten parts of an acid composed of equal parts of sulphuric and nitric acids. After immersion for about two minutes, the wool is withdrawn and the liquid is pressed out, and it is rapidly washed with water till all remains of the acid are gone. One hundred parts of cotton thus treated yield one hundred and sixty-nine parts, of which one hundred and two are nitric acid, water has disappeared, and the rest is cellulose. According to Porret and Teschemacher, gun-cotton consists of $C^{12} H^{8} O^{8} + 4N O^{5}$. Gun-cotton bas not superseded the use of gunpowder, as in fire-arms its explosive force is found inferior, but in the blasting of rocks it possesses some advantages over gunpowder. Gnn-cotton is solnble in ether, and a compound is formed, to which the name of *collodion* has been given. This substance has been fonnd of the greatest use in many of the arts, especially photography. On being exposed to the air the ether evaporates, leaving a thin transparent film behind. This is applied to wounded surfaces instead of gold-beater's skin. It may be made into delicate bags into which hydrogen may be introduced for balloons. In photography the collodion is mixed witb the iodides to be acted on by light, and, being spread on glass, pictures, from which any number of impressions may be taken, are produced.

Harmaline, $C^{27} H^{14} N^{2} O^{2}$, and *Harmine*, $C^{27} H^{12} N^{2} O^{2}$, are alkaloids occurring in the seeds of *Peganum Harmala.* They are united with phosphoric acid. Harmaline forms yellow salts with the acids, and is transformed into a red matter by oxidising agents. The *harmala red* of commerce is the powder of the seeds. It is used in dyeing red, rose-colour, and pink. It is used in large quantities in Russia. Harmaline yields a nnmber of substitution products, sucb as *nitroharmaline, cyanoharmaline*, &c.

Hatchetine, a fossil resin found in the lignite of Wales. It is colourless, fnsible, and volatile.

Helicine, $C^{26} H^{16} O^{14}$, a compound formed when *salicine* is acted on by dilnted nitric acid. It contains the elements of sugar and hydnret of salicyle. It crystallises in the form of small white needles. When heated to 347° it forms a resinous insoluble substance.

Hellenine, $C^{16} H^{10} O^{2}$, is a concrete volatile principle allied to the essential oils. It is a solid crystalline body, and is obtained from the *Inula Helenium.* With nitric acid it yields *nitro-hellenine*, &c.

Hippuric Acid, $C^{18} N H^{8} O^{5}$, is found in large quantities in the urine of the cow and the horse, aud other herbivorous animals. It has also been detected in hnman urine. It is procured by evaporating the urine of the horse or cow to a small bnlk, and acidulating with hydrochloric acid. The mixture deposits hrown crystals of hippuric acid, whicb may be made white by boiling with lime, and dissolving tbe hippurate of lime, and again adding hydrochloric acid, when the pure hippnric acid is thrown down. It forms large semi-transparent fonr-sided prisms, which are sparingly soluble in cold water, and very soluble in hot water and in alcohol. Under heat it melts and gives off benzoic acid, benzoate of ammonia, and a fragrant oily snbstance. It forms salts which are soluble and crystallisable.

Humic Acid. [Geine.]

Humine. [Geine.]

Hyperuric Acid, $C^{10} N^{4} H^{8} O^{9}$, discovered by Unger, and formed by acting on guanine with hydrocbloric acid and chlorate of potash. It differs in composition from nric acid by 1 eqnivalent of water and 2 of oxygen, hence its name. It is colourless, and crystallises in short rhombic prisms, and when heated, is resolved into hydrated cyanic acid, water, and carbon.

Idrialine, $C^{3} H$, a carbohydrogen found in the mines of Idria. It colours sulphuric acid intensely blue. It is probably identical with *succisterene*, a snbstance obtained from amber, and which has the same property of colonring oil of vitriol intensely blue.

Inosite, $C^{12} H^{12} O^{12} + 4H O$, is a pecnliar species of sngar, discovered by Scherer in the jnices obtained from the flesh of animals. It crystallises in large crystals, which have a sweet taste, but which do not enter into a state of fermentation. It yields, however, both lactic and bntyric acids wben exposed to the action of caseine. It differs from glucose in its not giving the nsnal reaction with the salts of copper and potash, and in possessing two atoms more water in its composition. It has not yet heen found ready formed in the animal system.

Iridiocyanogen, $C^{2} N + Ir$, is a hypothetical compound radical. It forms with hydrogen Iridiocyanic acid, and with potassinm an Iridiocyanide of potassium. It occurs in the form of colonrless crystals, and gives a deep indigo blue with the salts of peroxide of iron. This is one of the many compounds of a metal with cyanogen, like ferrocyanogen, and which have all the power of combining with other metals possessed by that body. Thus there are cobaltocyanogen, chromocyanogen, platinocyanogen, &c.

Isatinic acid, $C^{16} H^{6} N O^{6} + H O$, is formed by the action of a strong solntion of potash on isatine, $C^{16} H^{5} N O^{4}$. The compound formed is isatinate of potasb, from wbich the isatinic acid may be separated. It is, however, at once resolved into isatine and water, but if isatinate of lead be treated with sulphuretted hydrogen in vacno, a wbite flocculent powder is obtained, which becomes red on being dissolved by boiling water, and the solntion on cooling deposits isatine. Isatinic acid nnites with the metals, the latter representing in the varions compounds the hydrogen of the water.

Isatyde, $C^{16} H^{6} N O^{4}$, is a prodnct of isatine, when this substance is acted on by sulphide of ammonium. It is a gray crystalline powder, and represents isatine with one equivalent of hydrogen. This equivalent of hydrogen may be supplanted by chlorine and snlphur, and thus *chlorisatyde* and *sulphasatyde* are produced.

Jamaicine is formed witb *Surinamine* in the *Geoffræa inermis* and *G. Surinamensis.* They are crystallisable alkaloids, capable of forming with the acids salts, which are precipitated with tanrine and corrosive sublimate.

Kakonyle. [Caconyl—Chemistry, *S.* 1.]

Kinic or Quinic Acid, $C^{7} H^{4} O^{4} + 2 H O$, is obtained from cinchona bark, in the mannfacture of sulphate of quinine. It occurs in the bark united with the quinine, and when lime is added to a solution of bark, a kinate of lime is formed. The kinic acid is procnred from this compound by the action of oxalic acid. It forms salts with the metals highly interesting to the chemist.

When kinic acid, or kinate of lime is distilled with sulphuric acid, a new compound called *kinone* is obtained. It occurs in crystals of a fine golden yellow colour, whicb are soluble in water, having a pungent smell when in the state of vaponr. When kinone is acted on by rednci‌ng agents, it takes up 2 and 4 equivalents of hydrogen, forming *green* and *white hydrokinone.* The first forms green crystals of exceeding beauty, the latter are white. Wöhler has obtained several componnds of kinone, of which the following tabular statement gives the names as far as they are yet known :—

Kinone	$C^{25} H^{8} O^{8}$
Green hydrokinone . . .	$C^{25} H^{10} O^{8}$
White bydrokiuone . . .	$C^{25} H^{12} O^{8}$
Chlorohydrokinone . . .	$C^{25} H^{10} Cl^{2} O^{8}$
Chlorokinone	$C^{25} H^{6} Cl^{2} O^{8}$
Brown sulphohydrokinone . .	$C^{25} H^{11} S^{4} O^{7}$
Yellow sulphohydrokinone . .	$C^{25} H^{12} S^{3} O^{7}$
Brown Chlorosulphokinone . .	$C^{26} H^{8} S^{4} Cl O^{8}$
Orange do.	$C^{25} H^{6} S^{4} Cl O^{8}$

Kreatine. [Creatine.]

Kreatinine. [Creatine.]

Kynole. [Aniline.]

Lactamine, $C^{6} N H^{7} O^{4}$, is obtained by the action of lactic acid on ammonia. It is interestiug as being identical in composition with three other bodies, alaniue, sarcosine, aud urethane (carbamate of the oxide of ethyle). They have all of them, however, very distinct properties. This substance differs from the others in yieldiug lactic acid and ammonia when acted on hy acids and bases; hence its name.

Lactucine is the active principle of tbe *Lactuca virosa*, or wild lettuce. It is obtained from the juice of this plant, which is called Lactncaricum. It is a bitter, crystalline, resinoid snbstance, possessing anodyne properties.

Lampic Acid. Another name for *Aldehydic acid.* [Aldehydic Acid—Chemistry, *S.* 1.]

Lauric, or Laurostearic Acid, $C^{24} H^{23} O^{3} H O$, a crystalline fatty acid, obtained from the fat of the berries of *Laurus nobilis.* It forms soaps with the alkalies.

Lecanoric Acid, $C^{18} H^{4} O^{9}$, is found in several lichens, especially *Lecanora tartarea*, and *Gyrophora pustulata.* It occurs in the form of miuute white crystals, wbich are insoluble in water, hnt solnble in ether and alcohol. When heated with alkalies, it yields a carbonate of the alkali, and a sweet substance called orcine. Thus :

$$\underbrace{C^{18} H^{8} O^{8}}_{\text{lecanoric acid.}} \quad 2 C O^{2} + \underbrace{C^{16} H^{8} O^{4}}_{\text{orcine.}}$$

The same change takes place when lecanoric acid is boiled in water. By the action of air and ammonia, this acid is gradually converted into a deep blue or pnrple colonr (Erythric Acid). This acid combines with bases, and with the compound radicals. *Lecanorate of oxide of ethyle* is the *Pseudoerythrine* of Heeren, and the *Erythrine* of Kaue. It is produced by boiling tbe licbens with alcohol. It was discovered by Schunck, to whom chemistry is greatly indebted for a knowledge of the compounds contained in the lichens.

Leiocome is the name given to a substance possessing the properties of gum, and which is produced by simply exposing starch to a temperature of 300°. It has a brownish yellow colour, and acts in the same manner as gum, and is externally used instead of this substance in calico printing.

Leucic Acid, $C^{12} H^{12} O^{6}$, an organic acid belonging to the leucine series.

Leucine, $C^{12} N H^{13} O^{4}$, is a substance identical in composition with glycocine and alanine. It has the same relation to valerianic acid that they have to formic and acetic acids. It forms crystalline scales, which are volatile, and when heated with potash they yield valerianic acid, carbonic acid, and hydrogen. This substance has been detected in the liver of the calf as a natural product. It is also found among the products of the putrefaction of fibrine and albumen.

Leucoline = *Quinoline*, $C^{18} H^{8}$, is one of the compounds found in the least volatile portions of the basic oil of coal-tar. It is also formed when quinine, cinchonine, strychnine, or thialdine are heated in contact with potash. It is a liquid with a disagreeable smell, and boiling at the temperature of 460°. It neutralises acids, and forms with them salts.

Leucoharmine. [Harmaline.]

Lichenine, $C^{12} O^{10} H^{10}$, is a variety of starch found in the *Lichen islandicus*, or Iceland moss. It is colourless and tasteless, swelling up into a jelly-like mass in cold water, and dissolving in hot. Its solution is not coloured blue by iodine, but the jelly is. It is converted into sugar by diluted and boiling sulphuric acid.

Limonine, $C^{42} H^{26} O^{13}$, is a bitter crystalline substance found in the seeds of lemons and oranges. It closely resembles *Cnicine*, the bitter principle of the *Cynarocephalæ*. It contains 2 atoms less water.

Lipyle. [Glyceryle.]

Lophine, $C^{46} H^{16} N^{2}$, is one of the bases derived from the oil of bitter almonds. It is formed when hydrobenzamide ($C^{42} H^{18} N^{2}$) is distilled. Ammonia is given off, and lophine is left undissolved. It is soluble in alcohol with acids, and precipitated again by ammonia. It occurs in the form of fine silky crystals, and acts towards acids in the manner of a base. By the action of nitric acid it yields a yellow crystalline compound called *trinitrolophyle*.

Luteoline is a non-azotised colouring principle found in the woad (*Isatis tinctoria*). It is volatile and crystallisable.

Malamide, and Malamidic Acid, are synonyms of *Asparagine* and *Aspartic acid*. [Asparagin—Chemistry, *S.* 1.]

Melampyrine is a crystallised non-azotised substance obtained from the cow-wheat, *Melampyrum nemorosum*. It is a tasteless neutral principle.

Melassic Acid, $C^{24} H^{12} O^{16}$, is formed from cane sugar by the action of heat and alkalies. It has a very dark colour, and when thrown down by hydrochloric acid appears as a black flocculent deposit.

Melissic Acid, $C^{60} H^{59} O^{3} + HO$, is one of the substances yielded by wax. According to Brodie, when the *hydrated oxide* of *melissyle* or *melissine* is heated with lime and potash, it yields hydrogen gas and melissate of the base. When the acid is separated, it presents itself as a crystalline waxy substance, melting at 192°.

Mellone. [Mellone—Chemistry, *S.* 1.]

Melissyle, $C^{60} H^{61}$, a negative radical found in myricine, a substance which forms about four-fifths of bees'-wax. It consists of the hydrated oxide of melissyle combined with palmitic acid. The palmitic acid is easily separated from the hydrated oxide of melissyle by saponification. The latter is a true alcohol, and, like common alcohol, yields a carbo-hydrogen resembling olefiant gas. Its composition is $C^{60} H^{62} O^{2}$. It is identical with *melissene* or *melissic alcohol*. This compound is very interesting, as it has been shown by Brodie to possess the same relations, and to form a series of compounds homologous with those of ethyle and methyle, the lowest of the series of carbohydrogen radicals.

Menispermine, $C^{18} H^{12} NO^{2}$, is a white fusible crystallisable alkaloid, forming salts with the acids found in the seeds of the *Menispermum Cocculus*, known as *Cocculus Indicus*.

Menyanthine is a non-azotised uncrystallisable neutral principle found in the common buck bean, *Menyanthes trifoliata*.

Mesitylole, $C^{18} H^{12}$, is obtained from the distillation of acetone with fuming sulphuric acid. Thus, 3 equivalents of acetone $= 3(C^{6} H^{6} O^{2})$, yield 6H O and mesitylole. The atoms of hydrogen may be substituted by chlorine, bromine, and nitrous acid.

Mesaconic Acid, $C^{8} H^{2} O^{2} + H O$, is an acid described by Gottlieb and obtained from the action of nitric acid on citraconic acid. It forms minute crystals, sparingly soluble in water.

Methionic Acid, $S^{2} C^{2} H^{3} O^{7}$, this acid with *Ethionic*, isethionic, and althionic acid is formed by the action of sulphuric acid on ether and alcohol.

Methylo-urea. [Aniline.]

Methylodiethylamylium. [Amyle.]

Methylethylamylamine. [Amyle.]

Mimotannic Acid. The tannic acid produced from catechu possesses some properties different from that of the tannic acid from oak bark, and Berzelius proposed calling the one mimotannic acid, from *Mimosa*, and the other quercitannic acid, from *Quercus*, the name of the oak.

Myricine. [Melissic Acid.]

Myriospermine. Balsam of Peru, according to Richter, contains two oils, *myroxyline*, which is insoluble in alcohol and *myriospermine*, which is soluble in that liquid. The latter substance when treated with an alcoholic solution of potash, yields an acid resembling cinnamic acid, which is called *myriospermic acid*.

Myristic Acid, $C^{28} H^{27} O^{3} + H O$, is a crystalline fatty acid found in the seeds of *Myristica moschata*, the common nutmeg. Combined with the oxide of lipyle, it forms the fat of the nutmeg, with the oxide of ethyle a myristate which is an oily liquid.

Naphthaline, $C^{10} H^{4}$, or $C^{20} H^{8}$, is found in all kinds of tar, but especially in coal tar. It is easily obtained by redistilling this latter substance, when it occurs in a semi-solid state. It may be then purified by sublimation and crystallised from hot alcohol. It is colourless and volatile, forming large tabular transparent crystals, with a peculiar smell and an acrid taste. It is volatilised like camphor by exposure to the air, and boils at a temperature of 414°. It forms with bromine and chlorine a large number of compounds by substitution, and is acted on in the same way by sulphuric and nitric acids. These compounds have been studied with great diligence and singular accuracy by Laurent, who has founded on them his great *law of substitutions*, which has been one of the most remarkable aids to the development of modern organic chemistry. [Chlonaphtase.]

The compounds of chlorine and bromine with naphthaline are very numerous, and have many of them been carefully described by Laurent. The whole of the possible compounds of these two elements with naphthaline amounts to the large number of 1040. In the same manner sulphuric and nitric acids are found to act on naphthaline, and to give a long series of compounds highly interesting to the chemist, but which have not yet been fully studied. The following are a few examples of these compounds:—

Hyposulphonaphthalic acid .	$C^{20} H^{8} S^{2} O^{5} + H O$.
Hyposulphonaphthic acid . .	$C^{11} H^{5} S^{2} O^{6}$.
Sulphonaphthiline . .	$C^{20} H^{8} S O^{2}$.
Sulphonaphthilide . . .	$C^{24} H^{10} S O^{2}$.
Nitronaphthaline . . .	$C^{20} H^{7} N O^{4}$.
Thionaphthamic Acid . .	$C^{20} N S^{2} H^{8} O^{5} + H O$.
Nitronaphthese . . .	$C^{20} H^{6} N O^{4}$.
Nitronaphtale	$C^{19} H^{5} N^{8} O^{11}$.

Odorine. [Picoline.]

Œnanthic Acid, $C^{14} H^{13} O^{2} + H O$, is found in wines in combination with oxide of ethyle, forming an ether, which is one of the elements of the odour of wines. It is also found in the spirit of fermented grain. In order to obtain the acid, the ether is decomposed by caustic potash, and the œnanthate of potash thus formed is distilled with dilute sulphuric acid. The acid thus obtained is a semi-liquid substance, insoluble in water, but soluble in alcohol and ether. The œnanthate of oxide of ethyle, *œnanthic ether*, is a colourless liquid, having the well-known smell of wine, and producing a stupifying effect. This ether has been shown by Mulder to be only one of many ethers which give the peculiar odours or *bouquet* to wines. (Mulder's 'Chemistry of Wine.')

Œnanthyle, $C^{14} H^{13}$, is known by some of its compounds. *Hydrated Oxide of Œnanthyle—Œnanthole—Œnanthal*, $C^{14} H^{13} O + H O$, is the aldehyde of œnanthylic acid, and is obtained from castor oil. *Œnanthylic Acid*, $C^{14} H^{13} O^{3} + HO$, is an oily acid, and yields fatty salts. The œnanthylates of the oxides of ethyle and methyle are fragrant compounds.

Oleo-phosphoric Acid. [Cerebric Acid.]

Opiammon, $C^{40} H^{19} N O^{16}$, is obtained from the opianate of ammonia by the loss of one equivalent of ammonia and four of water. It is a pale yellow powder, which, when boiled with water, yields opianic acid and opianate of ammonia.

Opianic Acid, $C^{20} H^{10} O^{10}$, is formed from the decomposition of *Narcotine*, one of the compounds contained in opium. This acid forms soluble and crystallisable salts, with the oxides of the metals and oxide of ethyle. The latter is *opianic ether*.

Opianine, $C^{66} N H^{36} O^{23}$, is a crystalline compound found in company with narcotine and other compounds in opium.

Opianyle, $C^{20} H^{10} O^{8}$, is formed by the action of nitric acid on narcotine. It crystallises in fine needles, which are soluble in ether and alcohol, and become of a deep purple when brought in contact with sulphuric acid.

Orcine. [Erythric Acid.]

Oreoselone. [Athamantine.]

Oxamic Acid, $C^{4} O^{5} N H^{3}$, is one of the products of the action of heat on oxalate of ammonia. This acid forms soluble and crystallisable salts, with lime, baryta, ammonia, and oxide of silver.

Palmitic Acid. [Cetyle.]

Papaverine, $C^{40} N H^{3} O^{8}$, a crystalline base discovered by Merck in opium.

Paramide, $C^{8} H N O^{4}$, is formed when mellitate of ammonia is heated in a retort to about 320°. It is accompanied by another body called *Euchronic Acid.* Paramide is a solid yellow substance, which when long boiled with water is changed into a bimellitate of ammonia.

Paranaphthaline = *Anthracene*, $C^{30} H^{12}$, is a substance polymeric with naphthaline, and also found in coal tar. It melts at 356° and distils at 392°, crystallising in foliated plates. It forms with nitric acid a series of compounds, in which oxygen is substituted for hydrogen. These compounds are again capable of uniting with hyponitrous acid. As with the compounds of naphthaline we are indebted for all that is known of these to the researches of Laurent.

Parellic Acid, $C^{21} H^{8} O^{10}$, one of the substances produced in the various dyeing lichens of commerce. It is found in company with lecanoric acid.

Parietine = *Rhabarbine* = *Parietinic Acid* = *Chrysophanic Acid*, $C^{10} H^{8} O^{3}$. This substance, which was first found in rhubarb and has the above names, is also found in the *Parmelia parietina.* [Chrysophanic Acid.]

Pelargonic Acid, $C^{18} H^{17} O^{3} + H O$, is found in the oil of *Pelargonium roseum.* It is an acid oily liquid, with a rancid smell. It becomes solid at low temperatures, and its salts form soap. It forms a *Pelargonate of the oxide of Ethyle*, $C^{4} H^{5} O + C^{18} H^{17} O$, which is an oily liquid of a very peculiar smell. It is stated by Frankland that whiskey owes its peculiar flavour to the presence of this compound. It is manufactured for the purpose of giving new whiskey the flavour of old. It is probable this acid is formed from sugar, as all oily acids are found to be.

Phenyle, $C^{12} H^{5}$, the hypothetical base of carbolic acid, which according to Laurent is an *Hydrated oxide of Phenyle*, $C^{12} H^{5} O + H O$. Laurent has succeeded in obtaining with this radical phenyle a series of compounds resembling those of indigo, salicyle, and other bodies.

Phillyrine is a non-azotised compound, crystallising in silver scales and of a bitter taste, obtained from various species of *Phillyrea.*

Phloretine. [Phloridzin.]

Phloridzeine. [Phloridzin.]

Phloridzin, $C^{42} H^{29} O^{24}$, is a substance closely resembling salicine. It is obtained from the roots of the apple, pear, plum, &c., and is extracted in the same way as salicine. It crystallises in the form of small scales, which are soluble in hot water and in alcohol. It is very bitter and powerfully febrifuge. When boiled with dilute sulphuric acid, it yields a resinous substance called *phloretine*, $C^{30} H^{15} O^{10}$, and grape sugar. If phloridzin moist be exposed to atmospheric air and ammonia it forms a deep red substance, soluble in ammonia, and which is precipitated from the solution by acids. It has the same elements as phloridzin, with eight equivalents of oxygen and two of ammonia. This is *phloridzeine.*

Pthalamide, $C^{16} H^{6} N O^{5}$, is formed from pthalic acid by ammonia.

Pthalic acid, $C^{16} H^{4} O^{6} + 2H O$, is formed by the action of nitric acid on chloride of naphthaline.

Picoline, $C^{12} H^{7} N$, is a volatile oily base, isomeric with aniline, and found in coal tar. It has very powerful basic properties, and is probably the same substance as the *odorine* described by Unverdorben.

Picric Acid = *Carbazotic Acid* = *Nitropicric Acid* = *Nitrophenisic Acid*, $C^{12} \left\{ \begin{matrix} H^{2} \\ 3\ N\ O^{4} \end{matrix} \right\} O + H O$, is formed by the action of nitric acid on anilic acid, indigo, salicine, salicyle, salicylic acid, hydrate of phenyle, common silk, and other substances. However obtained it assumes a crystalline form, and is of a pale yellow or white. It has a very bitter taste, and is said to be used for adulterating bitter beer. It is fusible and volatile, readily uniting with bases; its salts crystallise and explode when heated.

Picrotoxine, a bitter principle obtained from the seeds of *Menispermum Cocculus* (*Cocculus Indicus*). It forms white prisms on crystallising, and appears to be a vegetable base containing nitrogen.

Picryle = *Picrine*, $C^{42} H^{15} N O^{4}$, is yielded by the distillation of the product obtained by acting on oil of bitter almonds with sulphuret of ammonium. By the action of nitric acid it is converted into *trinitropicryle* $C^{42} \left\{ \begin{matrix} H^{12} \\ 3 NO^{4} \end{matrix} \right\} NO^{4}$ which is a yellow crystalline powder.

Pine Apple flavour. [Butyle.]

Poaphyroxine, a crystalline compound found in Bengal opium.

Propione, $C^{5} H^{5} O$, is a compound homologous with acetone. It is formed when propylate of baryta is exposed to heat. When oxidised it yields propylic acid. It is a volatile oily fragrant liquid. It was formerly called metacetone.

Propyle, $C^{6} H^{7}$, a compound hypothetical radical. Some of its compounds are known, but not its ether or its alcohol. *Propylic acid*, $C^{6} H^{5} O^{3} + H O$, is however well known, and has this radical for its base. This acid is next above acetic acid in the series of volatile acids. It is procured by heating the cyanide of ethyle with a solution of potash in alcohol. Propylate of potash is thus obtained, which must be distilled with sulphuric acid, when propylic acid passes over. It is an oily acid, and its salts have something of a fatty character.

Rhabarbine. [Parietine.]

Rhodeoretine, $C^{42} H^{35} O^{20}$, an acid found in jalap. It has the property of striking a fine red colour with sulphuric acid. When combined with bases, it takes up an equivalent of water, and is then called *hydrorhodeoretine.* When acted on by hydrochloric acid, it is resolved into glucose and an oily substance called *rhodeoretinole.* In this respect rhodeoretine resembles salicine and phloridzine.

Rubiane, $C^{72} H^{40} O^{40}$, a yellow crystalline acid found in madder (*Rubia tinctorium*).

Rubinic Acid, a red acid obtained from catechine, or tanningenic acid. [Catechine.]

Rue, Oil of. [Capric Acid.]

Saliaretine. [Chemistry—Salicin, *S.* 1.]

Sanguinarine, an alkaloid found in *Sanguinaria canadensis.* It is a gray powder, which produces powerful sneezing. Its salts are of a red colour.

Saponine, an active principle found in the *Saponaria officinalis.* Although this plant is apparently inactive, this principle is a powerful sternutatory, and has a sweet and acrid taste. It is soluble in water, and when agitated it froths like soap. *Saponaria* was formerly used as a detergent.

Sarcocollin, $C^{22} H^{19} O^{10}$, a gum found in the Sarcocolla of commerce, which is the dried juice of the *Penæa mucronata.* It has a sweet and bitter taste, and is soluble in both water and alcohol.

Sebacic Acid, $C^{10} H^{8} O^{3} + H O$, is obtained by distilling oleic acid or oleine, and boiling the product with water, when the solution on cooling deposits crystals of sebacic acid. This acid is soluble in alcohol and ether, and forms salts with the metals and compound radicals. The sebate of the oxide of ethyle has a fragrant smell like melons.

Selenaldine, a compound formed by the action of seleniuretted hydrogen on aldehydammonia.

Seneguine, an acrid non-azotised principle, obtained from the *Polygala Senega.* It acts as a sternutatory.

Sinapoline, $C^{14} H^{12} N^{2} O^{2}$, a base obtained from oil of mustard by the action of the moist hydrated oxide of lead.

Sinnamine, $C^{8} H^{6} N^{2}$, a base obtained by acting on *Thiosinnamine*, $C^{8} H^{8} N^{2} S^{2}$, by any oxide of lead or mercury, when the latter loses all its sulphur, and a portion of its hydrogen, and sinnamine is left. It forms definite compounds with chlorides of mercury and platinum.

Spaniolitmine, $C^{18} H^7 O^{16}$, one of the three solids which, according to Kane, exist in litmus, in addition to *Erythroleine*, which is a red fluid. The other solids are *Azolitmine* and *Erythrolitmine*.

Stilbene, $C^{28} H^{12}$, one of the products of the decomposition of the compounds of benzoyle. It is formed from the hyduret of *Sulphobenzoyle*, $C^{14} H^5 S^2 O$, which, when strongly heated, gives off sulphuretted hydrogen, and at last distils over, in pearly scales, stilbene. It forms a compound with chlorine when this gas is passed through melted stilbene. Bromine also combines with stilbene, forming bromide of stilbene, with the addition of nitric acid, *nitrostilbase*, *nitrostilbese*, and *nitrostilbic acid*.

Styracine, $C^{36} H^{10} O^4$, is a substance procured from liquid storax, by distillation with carbonate of soda. At the same time it yields cinnamate of soda and *styrole*, $C^{16} H^8$. It is probable from this fact that styrole and cinnamole are the same substance. Styracine may be regarded as a compound of cinnamic acid, $C^{18} H^7 O^5$, with the oxide of a compound radical, $C^{18} H^9$, which is called *styryle*. If styracine be heated with a solution of potash, a cinnamate of potash is left, and a *hydrated oxide of styryle* distils over. This substance exists in two forms, as a solid and as a liquid, and has been described under the name of *styrone*.

Suberyle, $C^8 H^6 O$, the hypothetical radical of suberic acid, which would thus have this formula, $C^8 H^6 O^3 + H O$.

Suainamine. [Jamaicine.]

Synaptase = *Emulsin*. The white part of both sweet and bitter almonds is principally composed of a peculiar matter very soluble in water, which has been called *synaptase* by M. Robiquet. It appears to be identical with a substance described by Liebig and Wöhler, and called by them emulsin. Robiquet prepared synaptase by submitting sweet almonds, from which all the oil had been expressed, to maceration for two hours, and then subjecting them to pressure gradually increased. The filtered liquid holds vegetable albumen in solution which may be thrown down by acetic acid, also gum which may be precipitated with acetate of lead. The liquid now contains acetate of lead, acetic acid, sugar and synaptase. The lead may be thrown down by sulphuretted hydrogen, and the synaptase by alcohol. The synaptase should be washed with alcohol, and dried in ovens over sulphuric acid. The dry synaptase is a yellowish white opaque horny mass, which is very soluble in cold water. Iodine produces in the solution a rose colour. The synaptase soon decomposes in solution, deposits a white precipitate, and acquires a mouldy odour. It coagulates at 140°, like albumen. It contains azote and produces ammonia. The following is the result of two analyses of this substance by Dr. R. D. Thomson, and Mr. Richardson.

Carbon . . .	49·025	48·555
Hydrogen . . .	7·788	7·677
Oxygen	24·277	25·026
Nitrogen . . .	18·910	18·742
	100·000	100·000

The action of synaptase on the amygdalin of the almond is very singular, and throws light on the way in which the oil of bitter almonds is formed in some of the seeds of the almond-tree. "On mixing a solution of 10 parts of amygdalin in 100 parts of water, a particular decomposition immediately takes place; the mixture becomes opalescent without losing its transparency; acquires the odour of bitter almonds, and gives on distillation hydrocyanic acid and hyduret of benzoyle with the vapour of water. The residue is rendered turbid by coagulated synaptase, and on continuing the evaporation, a very sweet liquid is obtained, which contains crystallisable sugar. After destroying the sugar by fermentation, a fixed acid remains in the residue. The quantity of sugar obtained is more considerable than what the elements of the amygdalin could produce; it would appear, therefore, that the elements of the synaptase contribute to its formation. The decomposition is not complete unless the amygdalin and synaptase are dissolved in a proper quantity of water; if it is insufficient to dissolve the hyduret of benzoyle liberated, a corresponding quantity of amygdalin remains undecomposed. (Traité, p. 276.) The constituents of the bitter almond are the fixed oil, which is separated by expression, and the synaptase and amygdalin, the two last in such a condition that they cannot re-act upon each other. When the almond cake is treated with boiling alcohol, the amygdalin is dissolved out, and the synaptase coagulated. When the cake is moistened with water, the odours of hydrocyanic acid, and of the essence, are immediately perceived, but the cake must be diffused through a certain quantity of water, in order that the mutual action of the synaptase and amygdalin may be complete, and that the whole of the last may disappear. In preparing the distilled water of bitter almonds of pharmacy, M. Liebig recommends that a mixture of 1 part of the cake and 20 parts of lukewarm water be made, and left to itself for twenty-four hours before submitting it to distillation. One atom of amygdalin contains the elements of (Liebig):—

1 equiv. of hydrocyanic acid . .	$C^2\ H\ N$
2 equiv. of hydruret of benzoyl .	$C^{28} H^{12} O^4$
½ equiv. of sugar	$C^8\ H^5\ O^5$
2 equiv. of formic acid . . .	$C^4\ H^2\ O^6$
7 equiv. of water	$H^7\ O^7$
1 equivalent of amygdalin . .	$C^{40} H^{27} N\ O^{22}$

One hundred parts of amygdalin are said to yield 47 parts of the crude essence of bitter almonds, and these 47 parts to contain 5·9 parts of free hydrocyanic acid. The last acid is not indicated by nitrate of silver added to a solution of the crude essence in water, owing to the presence of the oil; to obtain a precipitate of cyanide of silver, ammonia-nitrate of silver must be used, and the ammonia saturated with nitric acid, after the lapse of some time." (Graham's 'Chemistry.')

Syringine, a non-azotised bitter principle, found in the common lilac (*Syringa vulgaris*).

Tanacetine, a non-azotised vegetable principle, obtained from the *Tanacetum vulgare*, the common tansy.

Tanghine, a non-azotised bitter principle, obtained from the *Tanghinia venenifera*, a poisonous tree in Madagascar.

Tartralic Acid, $C^{16} H^8 O^6 + 2 H O$, and *Tartrelic Acid*, $C^{16} H^8 O^{20} + 2 H O$, two acids obtained from tartaric acid. By long contact with water their salts are converted into tartrates and tartaric acid.

Teropiammon, $C^{60} N H^{29} O^{26}$, a compound described by Anderson. It is obtained from narcotine by the action of nitric acid of moderate strength. It forms small white crystals, which are sparingly soluble, and which present a crimson red colour when heated with sulphuric acid.

Thiosinnamine, $C^8 H^8 N^2 S^2$. When ammonia is added to the pure oil of mustard, $C^8 H^5 N S^2$, this substance is formed. It is crystalline, acts as a powerful base, and yields a variety of interesting compounds. [Sinnamine.]

Toluole = *Tolene*, $C^{14} H^8$. This substance, which, according to Deville, is a radical base, is contained in the Balsam of Tolu. It is homologous with benzole. When it is acted on by nitric acid, the hydrogen is replaced by nitrous acid, and two new compounds, *Nitrotoluole* and *Dinitrotoluole*, crystalline, are formed. The first is a liquid, and the second is a solid. Other compounds have been produced by Deville. *Toluylic acid*, $C^{16} H^8 O^4$, corresponds with benzoic acid.

Uramile. [Uryle.]

Uryle, $C^8 N^2 O^4$, is the hypothetical base of the various compounds obtained from uric or lithic acid. This base is also known by the name of *Cyanoxalic acid*, as it contains the elements of 2 equivalents of oxalyle, and 2 of cyanogen.

The following table will show the relation of this substance to the various compounds derived from uric acid:—

Uric acid	$C^{10} N^4 H^4 O^6$
Alloxantine	$C^8 N^2 H^6 O^{10}$
Alloxan	$C^8 N^2 H^4 O^{10}$
Dialuric acid	$C^8 N^2 H^4 O^8$
Hydurilic acid . . .	$2 (C^{12} N^3 H^6 O^{11})$
Nitrohydurilic acid . .	$C^8 N^3 H^2 O^{14}$
Uramile	$C^8 N^3 H^6 O^6$
Thionuric acid . . .	$C^8 N^3 H^7 O^{14} S^2$

Valeryle, $C^{10} H^9$, a compound radical not known in its separate state. Its hydrated protoxide *valeral* or *valeraldehyde*, is said to be one of the products of the oxidation of albuminous matter. It is a volatile liquid, yielding valerianic acid when exposed to oxidising agents. It unites with ammonia, forming a crystalline compound with ammonia.

Valerianic acid, $C^{10} H^9 + O^3 + H O$, is found in nature, in the oil of valerian, obtained from the *Valeriana officinalis*. It has also been found in train-oil and sperm-oil combined with the oxide of lipyle. It also occurs in various fats and oils from the animal kingdom, and in the seeds of the guelder rose (*Viburnum Opulus*).

Valerate of the oxide of Ethyle is a fragrant ether, and is found in plants, giving a peculiar scent to those which possess it. It combines with various other bases. The compounds of valeryle, as far as they are known, are homologous with those of methyle, ethyle, formyle, and acetyle.

XYLOIDINE, $C^{12}\left\{\begin{matrix} H^{8} \\ 2NO^{4} \end{matrix}\right\}O^{10}$. When potato starch is rubbed up with strong nitric acid, the starch is dissolved, and a viscid liquid is produced from which water precipitates the compound called xyloidine. It resembes in some of its properties gum tragacanth, but it contains so large a quantity of nitric acid that it is explosive.

The following works may be consulted on the subject of the present state of Organic Chemistry:—Gregory's *Handbook of Organic Chemistry;* Fowne's *Elements of Chemistry*, edited by Jones and Hfomann; Lechmann's *Physiological Chemistry*, translated by Day for the Cavendish Society; Gmelin's *Handbook of Chemistry*, translated by Watts for the Cavendish Society; Bowman's *Medical Chemistry;* Turner's *Elements of Chemistry*, edited by Liebig; and Graham's *Elements of Chemistry*.

CHERT, a variety of quartz being a kind of granular Chalcedony. It is a transition from the smoother forms of Quartz to Hornstone. [AGATE.]

CHESHUNT. [HERTFORDSHIRE.]

CHIGWELL. [ESSEX.]

CHILDREN, JOHN GEORGE, was born on the 18th of May, 1777, at Ferox Hall, Tonbridge. From the Grammar school of that town he went to Eton, and afterwards, in 1794, entered Queen's College, Cambridge, as fellow-commoner. He studied with a view to the church, but the early death of his wife led him to travel in the south of Europe and in the United States, from whence he returned to devote himself to scientific pursuits.

While studying mineralogy, chemistry, and galvanism, he made the acquaintance of Davy, Wollaston, and other leading men of science. In 1807 he was elected a Fellow of the Royal Society. In the following year he contributed a paper to the 'Philosophical Transactions,' on 'Some experiments performed with a view to ascertain the most advantageous method of constructing a voltaic apparatus, for the purposes of chemical research,' in which he determined the effect of unusually large battery plates. With twenty pairs of plates each four feet long and two feet wide, he confirmed Davy's observation, "that intensity increases with the the number [of plates], and the quantity of electricity with the extent of the surface."

This was followed in 1815 by a paper, published also in the 'Philosophical Transactions,' 'An account of some experiments with a large voltaic battery,' in which a further series of singularly interesting results was described, among them the conversion of iron into steel by union with diamond, under the sole action of the battery.

Between the dates of these papers Mr. Children travelled in Spain, and visited the quicksilver mines of Almaden, then but little known in England. In 1816 he was appointed one of the librarians in the department of Antiquities (afterwards of Natural History) of the British Museum. In 1819 he published a translation of Thénard's 'Essay on Chemical Analysis,' and in 1822 of Berzelius's 'Treatise on the Use of the Blowpipe,' with additional experiments and notes. He discovered a method for extracting silver from its ore without amalgamation, and derived considerable profit by selling the right to use it to several South American mining companies in 1824. He helped in establishing the 'Zoological Journal,' which appeared in 1825, and was one of the first editors. In 1826 he was elected secretary of the Royal Society, and resigning the following year on account of ill health, was re-elected in 1830, and retained the office for seven years. In 1839, on the death of his third wife, Mr. Children resigned his post at the British Museum. He died on the first day of 1852.

CHINA. In the previous Supplement, under the head CHINA, an account is given of the last war between Great Britain and China, from its commencement in 1840 to its termination in September, 1843, as well as of the events which preceded the war, and the treaties by which it was followed. In 1856 a dispute occurred between the British and Chinese authorities at Canton. A small vessel, not British, but with a British register, and bearing the British flag, was boarded by the Chinese, and twelve of the crew were seized. This led to a demand for apology, required by the British plenipotentiary, but refused by Yeh, the Chinese commissioner or governor of Canton. Hostile proceedings followed. The forts in the Canton river were attacked and taken, and a large number of war-junks burned. Lord Elgin was sent out as Her Majesty's commissioner, with a fleet and troops, for the purpose of entering into negotiations with the Emperor of China. Meantime the great mutiny had broken out in Hindustan, most of the troops sent from England were required to assist in quelling it, and the quarrel with the Chinese remained unsettled. As however the dispute was confined to Canton and the authorities there, especially the commissioner, Yeh, the British authorities, in conjunction with the French, resolved to attack the fortifications of Canton. This operation was successfully performed in the morning of the 28th of December, 1857, when the principal forts were carried by escalade, and the whole of the defences of the city were taken possession of. The assault was conducted by Major-General Van Straubenzee, commander-in-chief of the British troops in China, with about 4000 men, assisted by Rear-Admiral Sir Michael Seymour, commander of the British naval forces, and by Rear-Admiral Sir Rigault de Genouilly, commander of the French naval forces, with about 1500 men. The British and French forces continue to hold possession of Canton. Commissioner Yeh was captured on the 5th of January, 1858, and also the Tartar general.

CHINCHAS, a group of three islands in the Bay of Pisco, on the coast of Peru, lies between 13° and 14° S. lat., 76° and 77° W. long. They are naturally bare rocks, without a sign of vegetation of any sort, but they have obtained great celebrity for the vast quantities of guano with which they are covered. The islands lie nearly north and south, and are separated by channels from one mile to two miles broad. In their general formation they are all alike. On the eastern side they present a perpendicular wall of rock, from the edge of which the guano slopes towards the centre of each island, where a pinnacle of rock rises above the surface; from this point there is a gentle slope to the western shore, the guano continuing to within a few feet of the water. Each of the islands is about two miles round; and each presents the appearance of a flattened cone, the rocky inequalities of the original surface having been filled up and covered with the guano, the cuttings of which vary in depth from a hundred feet to a few inches. Round the base of the islands little rocky peninsulas jut out, in which the washing of the sea has formed many caverns, the resort of sea-lions. Whales also are frequently seen gamboling about the islands. The middle island has been moderately worked, but the greatest quantity of guano has been taken from the north island: the south island is still untouched. The quantity of guano on the three islands has been estimated at 250 millions of tons. Guano is also found on the Battista Islands, and upon San Gallen Island, which lie immediately south of the Chinchas, but only in small quantities. It is also found on the Lobos Islands, off the north-west coast of Peru, and at various points along the coast of South America; but what is obtained from the Chincha Islands is prized above all other deposits on account of its extreme dryness. [GUANO, *S.* 2.]

CHIOCOCCA (from χιὼν κόκκος), a genus of plants belonging to the natural order *Cinchonaceæ*. Calyx with an oval tube, and an acutely 5-toothed permanent limb. Corolla funnel-shaped, with an obconical tube or throat, and five acute lobes. Stamens with the filaments hardly adnate to the bottom of the corolla, downy, and shorter than the anthers, which are inclosed and linear. Style rather clavate at the apex, entire or slightly 2-lobed. Berry somewhat didymous, compressed, crowned by the teeth of the calyx, containg two chartaceous 1-seeded pyrenæ. Seeds pendulous. Embryo with a long superior radicle. Albumen cartilaginous. Shrubs generally with a somewhat climbing habit. Leaves opposite, ovate or oblong acute, glabrous. Stipules broad at the base, permanent, more or less apiculated. Racemes axillary, opposite, simple or panicled. Flowers pedicellate, of a yellowish-white colour. Roots emetic and alexiteric.

C. racemosa, Racemose Snow-Berry, has oval leaves acuminated at both ends, smooth; stipules broad at the base, and apiculated by a long point at the apex; filaments of stamens downy. It is a native of the West Indian Islands and Carthagena, on hills. It is a very variable shrub. The corollas at first are white and scentless, but at length become yellowish and sweet-scented. The berries are snow-white, hence the English name. The root has an acid bitter taste, and has long been used as a strong resolutive or attenuant.

C. densiflora, Dense-Flowered Snow-Berry, has ovate rather coriaceous leaves, many-flowered racemes, the corolla much longer than the calyx, the filaments densely-bearded. It is a native of Brazil, in woods at Almeida and Serradas, on the mountains of Bahia, and at the port of St. Catherine.

C. anguifuga, Anguifuge Snow-Berry, has ovate acuminated leaves; stipules very broad, short, each ending in a short point; racemes panicled; corolla not quite three times longer than the calycine teeth. It is a native of Brazil in woods, French Guyana, Trinidad, Peru, Cuba, and on the Spanish Main.

C. odorata, Sweet-Scented Snow-Berry, has broad oval leaves, rather coriaceous, very blunt, acute at the base, and running down the short petioles; peduncles axillary, solitary; 3-4-flowered corolla, with a bearded throat. It is a native of Elizabeth Island, one of the Society Islands.

C. barbata, Bearded Flowered Snow-Berry, has oval leaves, acute at the base, and tapering into short tepioles, acuminated and obtuse at the apex; pedoncles axillary, solitary; 1-3-flowered; corolla with a bearded throat; 5-cleft. It is a native of the Society and Friendly Islands.

C. Javana, Java Snow-Berry, is a parasitical shrub, with oblong lanceolate leaves, acnminated at both ends, glabrous, velvety, and shining above; corymbs terminal, trichotomons. This is a native of Java, on the mountains, upon trees.

All the species of *Chiococca* grow best in a mixtnre of loam, peat, and sand, and strike freely in sand nnder a hand-glass.

CHIPPING NORTON. [OXFORDSHIRE.]

CHUMLEIGH. [DEVONSHIRE.]

CHURCH BUILDING COMMISSIONERS were first appointed by the statute 58 Geo. III. c. 45 (which however was amended by npwards of thirty snbseqnent Acts), for building new chnrches in popnloos districts, and for dividing existing parishes, and assigning new ecclesiastical districts and determining their endowment and patronage, their recommendations being notified and carried into effect by orders in council. In this way, not only have new districts been carved ont of existing parishes, and themselves considered as original parishes, but churches and chapels have in some cases been constituted the parish church, and the original parish church has become a district chnrch or chapel of ease. The ministers of these districts are nsually denominated *incumbents*, not being *parsons* and *vicars*, properly so-called. The Church Building Commission, although by the original Act limited to ten years, was from time to time extended; and the powers of the commissioners have been recently transferred to the Ecclesiastical Commissioners.

CINCHOVATINA. [CHEMISTRY, *S.* 1.]

CINNAMODENDRON, a genus of plants referred to Von Martius's doubtful order *Canellaceæ*. This genns has been separated from *Canella*, which is well represented by *C. alba*, a common West Indian aromatic shrub, with evergreen coriaceous obovate alternate stalked leaves, no stipules, and corymbs of purple flowers. *C. alba* is often called Wild Cinnamon in the West Indies, on acconnt of its warm aromatic fragrant properties. There is bnt one other species of *Canella*. *Cinnamodendron* has hut one species, *C. axillare*. It is a Brazilian tree with aromatic properties. Its bark is used as a tonic and stimulant. It is administered in low fevers and relaxed sore throat.

CLARE. [SUFFOLK.]

CLARK, WILLIAM TIERNEY, a civil engineer, was born at Sion House, Somersetshire, August 23, 1783. He was apprenticed when very young to a millwright in Bristol, and followed the trade for several years in that city and at Colebrookdale. In 1808 he removed to London, and entered the service of the late Mr. Rennie as draughtsman; and held the employment till 1811, when he was appointed engineer of the West Middlesex Waterworks. The establishment was at that time on a very small scale—an engine of twenty-horse power supplying the neighbouring hamlets from an insufficient reservoir, yielding no profit to the company, But nnder Mr. Clark's advice the works were enlarged, and he spared no exertion to render them complete and effectual, nntil at last there were three pumping-engines of the aggregate power of 245 horses, and reservoirs capacions enough to contain from 35 to 40 million gallons, and prodocing ao annnal rental of nearly 70,000*l.* This post he retained for the rest of his life.

In 1819 Mr. Clark undertook to complete the Thames and Medway Canal, a work which had been stopped for want of capital, and nnder his direction it was finished some years afterwards; and the great tnnnel through the Frindsbory hills remains as a solid proof of his ability. His next work was the snspension bridge over the Thames at Hammersmith, which was commenced in 1824 and finished in 1827. It is chiefly remarkable for the small deflecion of the chains between the chord-line or points of suspension. The suspension-bridge at Marlow was also designed by Mr. Clark, and he was employed by the late Duke of Norfolk to build one over the Arun.

Mr. Clark was however best known by the suspension-bridge which he constructed across the Danube at Pesth. It was begun in 1839 and finished in 1849, at a cost of 622,000*l.* At times the bnrsting of dams and the pressnre from accnmulated ice in the winter threatened a total stoppage of the works, bnt all obstacles were overcome by the energy and perseverance of Mr. Clark, and the bridge remains an admirable monument of his genius and skill.

Mr. Clark was elected a Fellow of the Royal Society io 1837; he was a Fellow also of the Astronomical Society, aod a member of the Institution of Civil Engineers. He died September 22, 1852.

CLARKSON, THOMAS, was born March, 26, 1760, at Wisbeach, Cambridgeshire, where his father, who was a clergyman, was master of the free grammar school. He was at first educated nnder his father, and after that was sent to St. Panl's School, London, and thence to St. John's College, Cambridge, where he gained the first prize for a Latin dissertation proposed for the middle bachelors. In the following year, 1785, the Vice-Chancellor of the University announced as the snbject of a Latin dissertation for the senior bachelors, 'Anne liceat invitos in servitutem dare?' ('Is it right to make slaves of others against their will?'). The prize was awarded to Clarkson for his essay, which was read with great applause in the Senate Honse, in June, 1786. He had used much industry in collecting materials for this dissertation, and had become greatly excited by what he had read of the miseries to which the slaves were subjected in the carrying on of the trade. He resolved to use all his efforts to get it soppressed, and in order to do so relinquished his chances of advancement in the chnrch, for which he had been intended, and in which he had taken deacon's orders. He translated his essay into English, and its publication bronght him into connection with a small body of Quakers who had for several years formed an association for the snppression of the slave-trade, and he was afterwards introduced to Mr. Wilberforce, and other persons of influence. William Penn in 1668 had denounced the trade as cruel, impolitic, and unchristian; in 1727, at a general yearly meeting of the Quakers in London, it was declared "that the importing of negroes is cruel and unjust, and is severely censured by the meeting;" and in 1760 a similar meeting passed a resolntion to exclnde from their society all who "participated in any way in that guilty traffic." While Mr. Wilberforce, seconded by a party which gradually increased, repeatedly brought the question before the House of Commons, Mr. Clarkson was labouring without the walls of parliament, was collecting evidence, writing letters and pamphlets, and attending meetings at Liverpool and Bristol, then the chief centres of the trade, and at Plymouth, Bridgewater, and other places. He even went to Paris, and remained there six months in the greatest heat of the French revolution, furnishing Mirabeau with materials for speeches against the trade, which were delivered before the French Convention, but without producing the desired effect. In England, however, after more than twenty years of incessant exertion, the cause was won: a law for the entire abolition of the trade in slaves was passed March 25, 1807, Mr. Wilberforce having first brought the subject before parliament in 1787.

Bnt the exertions of Clarkson and his supporters, who had now become numerous, did not terminate with the suppression of the trade in slaves. The struggle was afterwards continued during another twenty years for the total abolition of slavery in the British West India Islands. In 1833 their efforts were again crowned with success, by the passing of the Emancipation Act, which liberated nearly a million of slaves, and awarded twenty millions of ponnds sterling as compensation to their late owners. Declining health hsd prevented Clarkson from appearing in pnblic during the latter years of the movement. Cataract had formed in both his eyes, and for a short time he was qnite blind. He nnderwent an operation whicb completely restored his sight, and in 1840 he made his last pnblic appearance at a meeting of the Anti-Slavery Convention at Exeter Hall, over which the Duke of Sussex presided. His talents and nntiring energy were unanimonsly acknowledged, and he was enthnsiastically greeted as the patriarch of the cause. He died at his residence, Playford Hall, Sussex, September 26, 1846, at the age of eighty-six.

Besides several pamphlets and other small works, all bearing more or less directly on the one great object to which he had devoted his life, Mr. Clarkson pnblished, in 1806, 'A Portraitnre of Quakerism,' 3 vols. 8vo; in 1808, 'The History of the Abolition of the Slave Trade,' 2 vols. 8vo; in 1813, 'Memoirs of the Public and Private Life of William Penn,' 2 vols. 8vo; and in 1836, 'Researches, Antedilnvian, Patriarchal, and Historical,' 8vo.

(Thomas Taylor, *Biographical Sketch of Thomas Clarkson; Gentleman's Magazine.*)

CLARY. [SALVIA.]

CLAY, HENRY, was born in Hanover county, Virginia, April 12, 1777. He was the seventh son of a clergyman, who died when Henry was very young, leaving his widow and family but scantily provided for. Having received a common school edncation, Henry obtained a sitnation as copying clerk in the chancery court of Richmond. Here he probably received a certain amount of initiation in legal proceedings, so that, altbongh he was nineteen years of age when he formally commenced the stndy of the law, he was when only twenty admitted to practise at the bar. The tide of migration was then setting strongly westward, and the yonng advocate thought that the fertile valleys of the west offered for him also a promising field of labour. He accordingly removed to Lexington in Kentucky, and there, in October 1799, he fairly commenced his legal career. As an advocate he quickly achieved a marked snccess. Young Clay, it was soon seen, not only possessed great natural ability and donbled its value by constant diligence, but had the more marketable talent of knowing how to manage a jury. Yet though he found himself on the road to fortune, bis ambition was directed rather towards political than professional snccess. The convention for framing a constitution for the state of Kentncky soon afforded him the opportnnity be desired of taking a prominent part in political movements. His advocacy of a provision for the gradual abolition of slavery entailed on him some temporary nnpopularity, but this was removed by his opposition to measures wbich were regarded as an encroachment on the part of the central government, and he was at the next election (1803) returned to the state legislature.

His political career was now fairly begun, and for nearly fifty years his life may be said to have been devoted to the service of his country. His first election to Congress was in 1806, bnt it was only for the remaining portion of a term; and in 1807 he was again elected to the General Assembly of Kentucky, of which he was chosen speaker; an office he held till he was in 1809 elected for an unexpired term of two years to the senate of the United States. In 1811 he was sent as a representative to Congress, and on the meeting of the Honse of Representatives he received the very remarkable honour of being elected speaker, though he was now for the first time a member of the house. But his speeches in the senate, and his conduct as speaker of the Kentncky Assembly, had established his reputation; and so well satisfied were the members with their choice, that he was five times re-elected speaker. During this period he took a prominent part in the great questions of the day, bnt especially distinguished himself by his earnest denunciations of the English claims to right of search and other maritime prerogatives; and as he was one of the prime instigators to the war with England, so during its continuance he remained one of its strongest advocates. He was in 1814 appointed, avowedly in conseqnence of the leading part he had taken in the discussions on tbe war, one of the commissioners to negociate the treaty of peace. On his return to America he was at once re-elected to Congress.

He now directed his energies to home legislation; but when the question of Sonth American independence was mooted, Clay eagerly nrged its immediate recognition: he was already promulgating his favonrite idea of the eradication of every species of European anthority from the American continent. While engaged in a decided conrse of opposition to the general policy of President Monroe, there were two great measures which specially occupied his mind. One was the establishment of a national system of internal improvements, which the president opposed as nnconstitntional, but which Clay successfully vindicated from that objection; the other was a retnrn to a modified protective system. Both of these measnres were carried, and the successfnl issue of his exertions placed Clay in the estimation of a large portion of his countrymen in the very first rank of American statesmen. He was now looked to by many as the probable successor to the presidential chair, and it was well nnderstood that he himself coveted that elevated post. That be might be in a better position to bear the increased expenditure its acceptance would necessarily entail, he resigned in 1819 his seat in Congress, and retnrned to the active pnrsuit of his profession, in which he promptly regained a highly lncrative practice. But when the conventions began to consider the claims of the candidates for the presidency, it was apparent that Clay wonld not be chosen; his name was therefore withdrawn, and he returned in 1823 to tbe House of Representatives, by whom he was immediately restored to his place as speaker. Three candidates went to the vote for the presidency, but as neither could obtain the absolute majority required by law, the election lay ultimately in Congress, and there Clay exerted all his influence in favour of Adams, who was cbosen; and he in return appointed Clay secretary of state. This office he held until 1827, and during his occnpancy of it discharged its duties with marked diligence and vigour.

On the election of General Jackson in 1829, Clay retired for awhile into private life, bnt in 1831 he was elected to the United States senate. In 1833 Clay was sgain an unsuccessful candidate for the presidency. He had now to renew the struggle for his protective tariff. The entire snbject was re-opened, and the country was agitated from end to end. South and north were almost in open conflict. At length Clay brought forward his 'Compromise Bill:' it was accepted by both parties, and modified protection to national interests became the established law of the United States. His snbsequent tonr through the middle and eastern states was a continued triumph. Passed over at the presidential election of 1836, at that of 1839 his claims were again put forward; bnt though his party was now in the ascendancy, at their convention he wss set aside by them for General Harrison, who was accordingly elected. Clay remained a member of the senate till 1842, when, finding that his strength was insufficient to sustain him in his arduous course of self-imposed labour, and vexed at President Tyler snccessively vetoing measures which he had succeeded in persuading Congress to adopt, he took a formal leave of the scene of his prolonged labonrs and trinmphs in a speech which produced a powerful impression on the senate and on the conntry. It was generally felt that the veteran statesman had scarcely been treated by his countrymen as his long and on the whole nnqnestionably popular course of pnblic service deserved. It was acknowledged by his party that in their presidential conventions the honourable claims of this really great man had been set aside, and the coveted honour bestowed on obscure mediocrity. 'Jnstice to Clay' was adoped as a rallying cry, snd in the election of 1844 he was put in nomination and supported by the full strength of his party. But tbis time the majority was on the other side, and Polk was elected. Clay remained in retirement till 1849, when he was again returned to the senate. To him was due the famous slavery 'Compromise Act' of 1850, which for a brief space quieted the bitter strife which the question of slavery had enkindled in the nnion. But it only for the moment allayed the storm; and Clay lived long enougb to perceive that as a permanent measure his project was a failnre. He had laboured beyond his strength in endeavouring to reconcile the irreconcilable, and now he longed only for rest. But his was not to be a rest on earth. He resigned his office as senator, but before the day named for his resignation to take effect, he had cessed to live. He died June 29, 1852, aged 75. Henry Clay was nndoubtedly a man of powerfnl intellect, bnt he will hardly retain the rank which his contemporaries too readily assigned him. He was wanting in comprehensiveness. His views were at best too strictly national, and, as in the case of the protective tariff, and in his general foreign policy, he too readily took for granted that what seemed to give an advantage to his countrymen was really for their benefit in the large view of things.

CLINKSTONE, a grayish blue rock, consisting principally of Felspar. It passes gradually into gray basalt, but is distinguished from that rock by its lower specific gravity. When struck with a hammer it rings like iron. It is frequent in volcanic districts. It is also called *Phonolite.*

CLINTON, HENRY FYNES, was born January 14, 1781, at Gamston in Nottinghamshire. He was the eldest son of the Rev. Charles Fynes Clinton, D.D., prebendary of Westminster, and incumbent of St. Margaret's, Westminster, and was descended in direct line from Henry, second earl of Lincoln. The family name was Fynes till his father obtained a royal licence, April 26, 1821, to resume the ancient family name of Clinton.

Mr. Clinton was educated at Southwell School, Nottinghamshire, where he remained from 1789 till 1796, and was well grounded in the classic languages. In September 1796 he was removed to Westminster School, where he remained till Easter 1799, not on the foundation. In April 1799 he went to Oxford, where he was entered a commoner of Christ Church, and remained till 1806. He graduated B.A. in 1803, and M.A. in 1805.

At the general election of 1806 he was returned M.P. for Aldborough, through the interest of the Duke of Newcastle, and continued to be one of the representatives of that borough till the dissolution of 1826, after which he was succeeded in his seat by his next brother. He was diligent in his parliamentary attendance, but was not a speaker. In his politics he was a conservative. After the death of Mr. Planta, in December 1827, he was a candidate for the office of principal librarian of the British Museum; but the claims of Sir Henry Ellis from long service and experience determined the choice of the Marquis of Lansdowne, then Home Secretary, in his favour. Mr. Clinton inherited an ample fortune from a distant relative. He died at his residence, Welwyn, Hertfordshire, October 24, 1852.

Mr. Clinton married June 22, 1809, but his wife died February 2, 1810. He married January 6, 1812, a daughter of Dr. Majendie, bishop of Bangor, who survived him, together with eight daughters. His only son, Charles Francis Clinton, graduated B.A. of Christ Church, Oxford, in 1836, served in Spain in the Christino army, was decorated with the Cross of San Fernando by Espartero, was appointed in 1843 British arbitrator under the treaty with Portugal for the abolition of slavery, and died at Loando, on the west coast of Africa, in 1844.

Mr. Clinton was a classical scholar of the highest class. He read carefully all the best works of the Greek and Roman writers with a diligence perhaps unexampled, at least in modern times. He himself states, that while at Oxford, during less than seven years, he read 5223 pages of the Greek poets and prose-writers; but that afterwards, between 1810 and 1820, he read about 40,000 pages: the reading at Oxford amounting to 746 pages annually, while the reading during 1810-20 amounts to 4000 pages annually, which is at any rate more than five times greater.

Mr. Clinton's two great works, the 'Fasti Hellenici' and 'Fasti Romani,' have a European reputation, and are literary works of which every classical scholar of Great Britain may well be proud. The 'Fasti Hellenici' (the 'Civil and Literary Chronology of Greece'), 3 vols. 4to, Oxford, was commenced in 1810, and was published in four separate volumes in 1824, 1827, 1830, and 1834; but the work is now divided into 3 vols., which are sold separately—vol. i. extending from the earliest accounts to the 55th Olympiad, vol. ii. from the 55th to the 124th Olympiad, and vol. iii. from the 124th Olympiad to the death of Augustus. Besides the chronological tables, of which these volumes for the most part consist, they are interspersed with dissertations on the early inhabitants of Greece, the Messenian wars, scripture chronology, the writings of Homer, the population of ancient Greece, and other interesting subjects. The 'Fasti Romani' (the 'Civil and Literary Chronology of Rome and Constantinople, from the Death of Augustus to the Death of Heraclius'), 2 vols. 4to, Oxford, were published in 1845 and 1850. In 1851 Mr. Clinton published 'An Epitome of the Civil and Literary Chronology of Greece, from the Earliest Accounts to the Death of Augustus,' 8vo, Oxford; and in 1853 appeared 'An Epitome of the Civil and Literary Chronology of Rome and Constantinople, from the Death of Augustus to the Death of Heraclius,' 8vo, Oxford: two abridgments which are very useful to those students who cannot afford to purchase the larger and more expensive works.

(*Literary Remains of H. F. Clinton, edited by C. J. F. Clinton,* 1854; *Gentleman's Magazine.*)

CLONES. [MONAGHAN.]

CLOWES, WILLIAM, printer, was born at Chichester, January 1, 1779; died January 26, 1847. The father of Mr. Clowes was educated at Oxford, and kept a large school at Chichester; but he died when the subject of this notice was an infant, leaving his widow to support two children with straitened means. She was enabled, by keeping a small school, to give her son a business education; and he was apprenticed to Mr. Seagrave, a printer at Chichester. He came to London in 1802, and worked as a compositor with Mr. Teape, of Tower Hill. In 1803 he commenced business on his own account in Villiers-street, Strand, on a capital of 350*l.* He purchased one press, engaged one assistant; and, after working as a compositor through the day, would often, for two or three consecutive nights, toil at press, to have his stock of type free for the next day's demand. It was this energy of character that raised Mr. Clowes to his subsequent eminence. Fortune favoured his exertions. He married when he was at the age of twenty-four, a cousin of Mr. Winchester, a stationer, who had much government business; and by him he was recommended for important official work. His punctual industry and obliging and kindly disposition brought friends around him; and in a few years the humble beginner with one press had a considerable printing office in Northumberland Court, Strand. This office was burnt down; but a larger rose in its place. In 1823 he commenced steam-printing. He had two or three machines in a dark cellar; and, the process being novel, his office had many visitors of literary reputation. Mr. Clowes was always a signal example for the honest ardour of manufacturing enterprise to lead the way under new circumstances. He saw that newspapers were printed by steam; and he estimated the possibility that books might be demanded in sufficiently large numbers to make the new invention of more universal application than was at first considered probable. An action brought by the Duke of Northumberland, whose palace was close to Mr. Clowes's printing-office, to abate the steam-press as a nuisance, was successfully defended; but the printer removed his noise and his dirt, under the award of arbitrators; and the decision was a fortunate one for him. In 1826 he became the occupier of the spacious and well-known premises in Duke-street. Stamford-street. In the course of years the humble establishment of the young Sussex compositor grew into 24 steam-presses and 28 hand-presses, giving employ to 600 persons in the largest, most complete, and well-organised printing manufactory that had ever existed in the world. The creation of literature that should at once reconcile the apparently dissimilar qualities of goodness and cheapness, through a demand for books before unprecedented, gave a considerable impulse to the energies of Mr. Clowes. 'The Penny Magazine' and 'The Penny Cyclopædia' issued with undeviating regularity for fourteen years from his printing-office. Mr. Clowes was not a common man. His powers of arrangement were most acute; he was at once bold and prudent. He was one of those few men who would not recognise the word 'impossible' as one to be lightly employed. He who in 1803 had a few hundred weight of type to be worked from day to day like a banker's gold, would not hesitate, in the height of his prosperous career, to have tons of type locked up for months in some ponderous blue-book. To print an Official Report of a hundred folio pages in a day or night, or of a thousand pages in a week, was no uncommon occurrence. Mr. Clowes's name will not be associated with the honours of the great classical printers; his was another ambition. He lived in an age when knowledge was to become the inheritance of the many; and he furnished the means of carrying out this literary revolution in a more efficient manner than any of his professional competitors. His name will be permanently associated with the intellectual development of our time. (*National Cyclopædia.*)

CLUNCH, a name given to the lower and harder beds of the Cretaceous Rocks. They are occasionally used for building purposes, and have been especially employed for internal work in cathedrals and other large public buildings. This material stands well if not exposed to accidents from mechanical violence. (Ansted, *Elementary Geology.*)

CLUSIACEÆ. [GUTTIFERÆ.]

CLUTHALITE. [MINERALOGY, S. 1.]

COAL, an opaque combustible mineral substance of a black or brown colour, and in all cases giving indications of having been derived from a vegetable source. Such is a definition that would probably inclnde all those substances which are used in domestic economy and the arts for the purposes of combnstion, and popnlarly called Coal. At the same time it should be stated that the term has at present no special scientific application that is universally admitted, and each investigator thinks himself at liberty to apply the term in accordance with his own views. As the knowledge of chemical principles and methods of investigation have advanced, substances which at one time were regarded as identical have been shown to have a very different chemical composition as well as microscopic structure. This has led in some instances to the discussion of the question, What is Coal?

For instance, in onr courts of law, one of the most recent cases—that of Gillespie v. Russel—was tried in Edinburgh in the year 1853. In this case, by an agreement for a lease entered into between the plaintiffs and defendants, the former agreed to grant to the latter a lease of "the whole coal, ironstone, iron-ore, limestone, and fire-clay, but not to comprehend copper or any other mineral whatsoever." It was alleged by the plaintiffs that, although the defendants had in the course of their operations come upon iron-ore and ironstone, coal, and fire-clay of workable value, they had neglected these, and had chiefly worked a certain mineral substance which the plaintiffs contended was not let to the defendants, not being one of the mineral substances specified in the agreement. This mineral was of much greater value, it was stated, than any which the defendants were permitted to work. Although nsed as a combustible material, it was alleged that this substance was not coal, and that its chemical, microscopical, and mineralogical characters were not those of coal. On the other hand, it was asserted by the defendants that the mineral in qnestion was coal; that they had been led to seek a lease of the Torbane-Hill estate from the fact that on the adjoining lands of Boghead this mineral existed, and was worked and sold as coal, being known in the markets by the name of the 'Boghead Gas Coal.' This mineral, they contended, was true coal, belonging to the variety known as Cannel or Parrot Coal. This trial was interesting on account of the large nnmber of chemists, mineralogists, geologists, and microscopists examined, who appeared in about equal numbers on either side; one set of them contending that the mineral was coal, whilst the others contended it was not. A large amount of interesting facts on the nature of coal and the substances with which it is found associated was laid before the jnry, who came to the conclusion that, whatever might be the result of scientific investigation in more rigorously defining the natnre of coal and limiting the nse of that term, both plaintiffs and defendants called this mineral coal when the lease was drawn up, and therefore gave a verdict in favour of the defendants.

The same qnestion which has thus been debated in Scotland has also come before the law courts of Germany and of the United States of America with the same differences of opinion; and we refer to these cases to show the difficulty of defining accurately this well-known substance. It may be regarded in the present state of onr knowledge as one of those instances in which the typical form is lost by irregular combination with other and different substances.

That Coal is and must be of vegetable origin seems to be agreed upon by all inquirers, but the question of how to determine that origin in particular cases is the difficulty. Again, it is well known that coal after it is deposited nndergoes certain chemical changes by which substances with a very different chemical character are produced, such as bitnmen, paraffine, &c. These, mixed with the coal itself and the earthy matters around, may form compound substances about whose natnre there may be considerable difference of opinion. This is not improbably the case with the Torbane-Hill mineral, and will account for the peculiarity of both its chemical and microscopical characters.

Coal presents itself ordinarily in a massive form, and is brittle or sectile. It has a hardness of 2·5, and a specific gravity of 1·2 to 1·75. It is opaque, and has a black or brown colour. Its chemical composition is distinguished by the presence of carbon; in addition, it also yields, on nltimate analysis, hydrogen, oxygen, and nitrogen. On burning it leaves an ash which consists of varying quantities of silica, alnmina, and oxide of iron. The carhon and hydrogen are often found chemically nnited to form bituminons compounds which are mixed with the coal. It is the presence of these componnds which causes coal to burn with a bright flame; at the same time they give off a bituminous odour. Those destitute of bituminous compounds bnrn with a pale blue flame, due to carbonic oxide, which is formed in these cases through the decomposition of the water present.

The following table, fonnded on Mr. Mushet's Analysis of Coal, is taken from Professor Ansted's 'Elementary Course of Geology, Mineralogy, and Physical Geography:'—

Analysis of various kinds of Coal.

Locality.	Description of Coal.	Specific Gravity.	Carbon.	Bitumen. Volatile Matter. Water.	Ash.
Newcastle-upon-Tyne	Bituminous	1·257	57·00	37·60	5·40

Bengal	Slaty	1·447	41·00	36·00	23·00
America, Ohio	Bituminous	—	55·55	41·85	2·60
America, Alleghany	Dry	—	78·85	9·47	11·73
America, Nova Scotia	Bituminous	1·321	58 80	28·20	12·95
America, Pennsylvania	Anthracite	—	92 60	2·25	2·25

The following analyses of the Torbane-Hill Mineral and Cannel Coal were presented by Dr. Fyfe at the trial in Edinburgh:—

	Carb.	Hyd.	Oxy.	Nit.	Sulp.	Ash.
Torbane-Hill Mineral	60·25	3·3	3·6	1·5	9·8	25·6
Capeldrae Cannel Coal	56· 7	6·8	8·8	1·9	0.25	25·4

The Torbane mineral is only remarkable amongst other coals for the large quantity of sulphur it contains.

A large series of coals, more especially Welsh, has been snbmitted to chemical examination by order of the government; and the following table is taken from the 'Report on the Coals suited to the Steam Navy,' by Sir Henry De la Beche and Dr. Lyon Playfair, in the second volume of the 'Memoirs of the Geological Survey of Great Britain:'—

Locality, or name of Coal.	Specific Gravity of Coal.	Carbon.	Hydrogen	Nitrogen.	Sulphur.	Oxygen.	Ash.

Coal differs considerably in its physical properties, and it has obtained various names in the markets. The mineralogist generally divides it into two varieties:—

First, Coal without Bitumen.

Second, Coal with Bitumen.

The first variety is known by the general name of *Anthracite*. It has however various local names. [ANTHRACITE.] It is sometimes very hard, and has a high lustre, and is often iridescent. Besides being used for fuel, it is often made into inkstands, small boxes, and other articles of use. This is more especially the case with the Anthracite of America. It is the most common form of coal in the Welsh beds.

The Bituminous varieties of Coal present greater differences of structure and appearance, and have a larger number of names. By the above analyses it will be seen that the quantity of Bitumen, or substances resembling it [BITUMEN], differ very much in different specimens of coal. It is generally softer and less lustrous than Anthracite, although occasionally specimens exhibit a very brilliant fracture. Its specific gravity is less than that of Anthracite, seldom exceeding 1·5, whilst the specific gravity of Anthracite ranges from 1·3 to 1·75. The kinds of this coal are known by various names.

The following are analyses of the different kinds of Coal as they occur in the Newcastle beds:—

	Splint Coal.	Caking Coal. No. 1.	Caking Coal. No. 2.	Cherry Coal.
Density	1·302	1·274	1·280	1·266
Carbon	74·961	83·588	67·8[illegible]9	84·691
Hydrogen	6·251	5·150	5·1[illegible]9	5·054
Nitrogen and Oxygen	4·873	8·743	5·139	8·476
Ash	13·912	2·591	1·393	1·576
Relative heat by the same weight of Coal . . .	110·310	114·980	122·560	116·630
Relative heat by the same volume of Coal . .	108·990	111·310	119·030	112·070

Pitching or *Caking Coal* is known by its velvet or grayish-black colour. When first thrown on a fire it breaks into small pieces, but on the continued application of heat the pieces again unite into a solid mass or cake. It burns readily with a yellow flame, but on account of its caking quality it is likely to clog the fire unless it is frequently stirred. The Newcastle beds mostly yield this form of coal.

Cherry Coal resembles in external appearance the pitch coal, and when exposed to heat it cracks and flies, but does not cake. It is very brittle, and on this account much loss is occasioned in mining it. It burns with a clear yellow flame. This kind of coal occurs in the Glasgow beds.

Splint Coal is a variety found in connection with the last, and is remarkable for its hardness; for which reason it is sometimes called Hard Coal. It is found at Glasgow.

Cannel Coal has little lustre, is very compact and smooth in its texture, and breaks with a large conchoidal fracture. It burns very readily, giving out a clear yellow flame without melting. In consequence it has been employed in the making of candles—hence its name. It is often employed for making inkstands, snuff-boxes, and other articles of use. At the Great Exhibition of 1851 several models of public buildings, monuments, &c., were exhibited, formed of Cannel Coal.

The above coals are those most commonly burned. Their goodness for heating is tested by the quantity of water they evaporate. The following are the results of some recent experiments:—

	lb.	oz.
Common Scotch Bituminous Coal . . .	5	14
Carr's West Hartley Main (Newcastle) .	7	5
Merthyr Bituminous Coal	8	0
Pure Welch Anthracite	10	8½

From which it will be seen that the heating power of anthracite nearly doubles that of some bituminous coals.

Brown Coal, Wood Coal, Lignite, are names given to less perfect varieties than the last. Specimens of these coals have a brownish-black colour, and burn with an empyreumatic odour.

On placing sections of Lignite under the microscope, the structure of the wood of the plant forming it can be readily detected. This is not the case with the other kinds of coal, where, although the woody fibre can be frequently made out, it has evidently undergone considerable change. Professor Quekett, on this ground, proposes to confine the term Coal to those mineral substances alone which are evidently made up of the woody tissue of plants. He maintained that the Torbane mineral was not coal, on the ground that it was not composed of the debris or remains of vegetable woody tissue. Although woody and vascular tissue can be seen in the Torbane mineral, Professor Quekett maintains that this has been accidentally introduced, and that no true vascular or spiral tissue is found in coal.

The term *Brown Coal* is frequently applied to coal more recently deposited than that of the great coal-beds of the world, and this quite independent of its structure or any peculiarity in combustion. *Lignite* is also a term applied to the semi-carbonised forms of wood which are frequently found in deposits later than those of the coal deposits. Most of these varieties of coal contain a large quantity of water, and the quantity of matter given off at a moderate heat by distillation is at least equal to that of the carbon contained.

"*Dysodil* is a yellow or grayish highly laminated substance, often found with lignite, and burning vividly, and spreading an odour of assafœtida." (Ansted.)

Jet is another variety of coal belonging to the bituminous series. It sometimes occurs in elongated reniform masses, and sometimes in the form of branches with woody structure. It is soft and brittle, with a conchoidal fracture. Its specific gravity is but little greater than that of water. It is opaque, of a velvet colour, and has a brilliant and resinous lustre. It is found in Saxony, and also in the Prussian amber-mines in detached fragments. It is sometimes washed up on the shores of Great Britain. The finer sorts are used in the manufacture of ornaments and trinkets of various kinds. The coarser sorts are burned as fuel. It gives out when burning a greenish flame and a strong bituminous smell, and leaves a yellowish ash. It contains about 37½ per cent. of volatile matter.

For an account of the origin of Coal, and the beds of Coal on the surface of the earth, see COAL FORMATION and COAL PLANTS.

COBOURG. [CANADA, *S.* 2.]

COCCIDÆ. [GALLINSECTA.]

COCKBURN, ADMIRAL, THE RIGHT HONOURABLE SIR GEORGE, G.C.B., who represented a branch of the same family as Lord Cockburn, was born in 1772, and entered the navy in 1781. Having served in the East India, Home, and Mediterranean stations, in 1795 he co-operated with the Austrian troops in Piedmont, and took part in the capture and blockade of Leghorn. He subsequently received the thanks of the House of Commons for his operations against Martinique, which resulted in that island being ceded as a British colony. In 1812 he was sent as commissioner for reconcilling Spain and her transatlantic colonies. He was conspicuous in the hostilities with America in 1813 and 1814. On the cessation of hostilities he was employed to convey Napoleon to St. Helena. Having sat in the unreformed parliament from 1818 to 1830 for Portsmouth, Weobly, and Plymouth, he was returned for Ripon in 1841. He was a Lord of the Admiralty from 1818 to 1828, and again, from 1841 to 1846, when he retired from public life. When far advanced in years he inherited his brother's baronetcy, and died in August 1853.

COCKBURN, HENRY THOMAS, LORD, a Lord of Session in Scotland, was the son of Archibald Cockburn, of Cockpen, one of the Barons of the Exchequer in Scotland, by a sister of the wife of the first Viscount Melville, and represented an ancient Scottish family which has produced many distinguished members. He was born in 1779, and called to the Scottish bar in 1800. His family connections belonged to the Tory school, but although the Scotch patronage of the crown for many years was dispensed by Lord Melville, Mr. Cockburn in early life adopted liberal opinions.

It was not until November 1830 that any high legal position fell to Mr. Cockburn, when he became solicitor-general for Scotland, upon the promotion of Jeffrey to the attorney-generalship. He had however long before this time risen to considerable eminence in his profession, and was particularly distinguished for the ability of his advocacy, and the influence which he exerted upon the minds of juries. Among other cases in which he was engaged may be particularly mentioned that of the Queensberry title, in which considerable property was at stake. He had also brought himself into notice by gratuitously defending the prisoners charged with treason at Stirling, Glasgow, and other Scotch towns, in the year 1818. As a strong proof of his success as an advocate, we may mention that he was engaged to defend Mrs. McDougall, who was put upon her trial at Edinburgh as the accomplice of Burke and Hare, and that he obtained her acquittal. During the earlier part of his legal career, the arguments of counsel were delivered partly in writing, and partly '*vivâ voce*' (as is the case now in the House of Lords). The drawing up of these arguments frequently involved points of the greatest nicety, and several drawn up by Mr. Cockburn attracted the observation of the bench, and even as a young man his papers on feudal law had met with general approval.

Such a man as Cockburn could not long remain without reaping a more permanent reward than the solicitor-generalship. Accordingly in 1834 he was promoted to the Scottish bench as one of the lords of session, to which three years later was added the further appointment of a lord commissioner of justiciary. Upon the bench Lord Cockburn was surpassed by few in his clear enunciation of law, and in his charges to juries. He was distinguished by a skilful detection of whatever was false in principle or in evidence, as well as by the breadth and grasp of his legal judgments, which were seldom reversed on appeal.

Besides the 'Life' of his friend Lord Jeffrey in 2 vols. (1852), Lord Cockburn published only one small pamphlet, which was entitled 'On the best way of spoiling the beauties of Edinburgh.' He was an early contributor however to the pages of the 'Edinburgh Review;' and it is said that an article from his pen in that review was mainly instrumental in causing a reform in the method by which Scotch juries had been previously chosen.

As a friend, neighbour, and citizen, no less than as a relative, Lord Cockburn was beloved. His death, which happened April 26, 1854, while he was on circuit at Ayr, was preceded by an illness of but a few days' duration. He left a large family by his widow, who is sister of the wives of the late Scotch judges, Lords Fullerton and Dundrennan.

COD-FISH. [MORRHUA.]

CODEIA. [CHEMISTRY, S. 1.]

CODRINGTON, SIR EDWARD, ADMIRAL, G.C.B., was born in 1770. He was a grandson of Sir Edward Codrington, first baronet, of Dodington, Gloucestershire. He entered the navy July 18, 1783, and served in several ships till he became lieutenant, May 28, 1793. He served as lieutenant on board the Queen Charlotte, 100 guns, Lord Howe's flag-ship, in the victory over the French fleet off Brest, June 1, 1794, and was appointed to bear to England the duplicate despatches. He was in consequence promoted to the rank of captain, and continued in active service till 1797. He was unemployed from this time till 1805, when he was appointed to the command of the Orion, 47, and was engaged in the battle of Trafalgar. For his services in this victory he was rewarded by a gold medal. He left the Orion in December, 1806, and in November, 1808, was appointed to the command of the Blake, 74, in which ship he sailed under Lord Gardner in the expedition to Walcheren, and was thanked for his services in forcing the Schelde, in August 1809. In 1810, 1811, and 1812, Captain Codrington was employed on the coasts of Spain, in the defence of Cadiz and Tarragona, and in co-operating with the Spanish patriots in Catalonia. In January 1813 he returned to England.

In 1814 Captain Codrington sailed to North America, and while there was promoted to the rank of rear-admiral, and was appointed captain of the fleet under Sir Alexander Cochrane. He took part in the attack on New Orleans. At the conclusion of the war with the United States he returned to England, and was created a knight commander of the Bath, January 2, 1815. He attained the rank of vice-admiral July 10, 1821.

Sir Edward Codrington was appointed, November 1, 1826, commander-in-chief of a squadron in the Mediterranean destined to observe the Turco-Egyptian fleet, and hoisted his flag on board the Asia, 84. He was joined by a French and a Russian squadron, and the battle of Navarino took place October 20, 1827; when the Turco-Egyptian fleet, consisting of 81 ships of war, was almost entirely destroyed. For this victory Sir Edward Codrington was advanced to the dignity of knight grand cross of the Bath; but as there was much doubt among politicians as to the propriety of destroying this fleet, and the Duke of Wellington admitted that it was an "untoward event," Sir Edward was recalled from the Mediterranean in April 1828. In 1832 he was elected M.P. for the borough of Devonport, and was re-elected in 1835, and again in 1837. He was of liberal politics, and very popular. In 1837 he attained the full rank of admiral, and on the 22d of November 1839, was appointed commander-in-chief at Portsmouth, when he resigned his seat as a member of parliament. He occupied his station at Portsmouth for the usual term of three years. He had a good-service pension of 300*l.* a year. He died in London, April 28, 1851.

CŒLÉBOGYNE, a genus of plants belonging to the natural order *Euphorbiaceæ*. This genus was named by Mr. J. Smith from a specimen grown in the Royal Gardens at Kew. It is remarkable for the fact that being diœcious, the pistiliferous flowers have ripened their fruit and produced seeds containing a perfect embryo without the presence of the staminiferous plants. This appears to be quite an exceptional case to the law of production of the embryo by the agency of the pollen cells coming in contact with the ovule. Further observation may detect some hitherto undiscovered means by which the pollen-cells of perhaps an allied plant may come in contact with the pistils of the *Cœlebogyne*. (*Linnæan Transactions.*)

COGGESHALL. [ESSEX.]

COLBY, THOMAS, Major-General in the army, and one of the Directors of the Ordnance Survey, was born at Rochester, 1st of September 1784. When his father, Captain Colby, of the Royal Marines, sailed with the fleet under Lord Howe, he was sent to Dr. Crockell's school at Northfleet, and from thence he entered the Royal Military Academy at Woolwich. He obtained his first commission as second lieutenant of engineers in 1801, being then but seventeen years of age. His diligence and success in scientific study were such that in January of the following year, at the special request of Captain Mudge, then superintendent of the ordnance survey, he was appointed one of the assistants in that great work. Entering at once on his duties, he justified the expectations formed of him, by the intelligence and conscientious activity which he brought to the work of surveying. He was on a tour of inspection in Cornwall, in 1803, when he lost his left hand by the bursting of an old pistol, and suffered at the same time such a fracture of the skull from a fragment of the barrel, that he felt the effects of the accident for the rest of his life whenever he attempted any long-continued mental exertion. Though the loss of his hand was a hindrance to the active discharge of his duties, Colonel Mudge was so well satisfied of his merits, that he kept the young lieutenant permanently attached to the survey.

In 1803 Lieutenant Colby was observing at Dunnose, one of the prominent points of the survey: in 1804 at Beaumaris; and in 1806 with the zenith sector at Burleigh Moor and Delamere Forest. The winter months he passed in the

'Drawing Room' at the Tower, computing and preparing the results for puhlication, and superintending the construction and eograving of the ordnance maps on a scale of one inch to the mile. So thoroughly was he identified with that great nationsl work, that the history of one becomes in great measnre the history of the other. In 1807 Colhy was promoted to the rauk of captain. The third volume of 'An Account of the Trigonometrical Sorvey of England' was pohlished in 1811, and his name appearing jointly with that of Colonel Modge on the title-page, showed how highly his services had been appreciated hy his chief. In 1813 it was determined to extend the meridian line into Scotland, a task which called oot in an especial manner the energies for which Captain Colby was remarkahle. Within the next three years he visited and observed at the principal stations heyond the Tweed, hesides attending to his official husiness at the Tower. The persevering lahour and activity required for a season of observation on the hills wonld appear incredihle to one unacqnainted with the nature of the work. Besides the mental exercise of keeping all the snhordinates to their dnty, so as to produce harmony in the resnlts, there was much personal fatigue to be endured in long walks over the country, together with storms and wearisome delays on the mountain tops. But with Captain Colhy duty was paramonnt, and he cared not for privation, so that the work was perfect. Major Dawson in his account of 'A Season on the Hills' gives a striking picture of the toils and hardships experienced: "It was no uncommon occnrrence," he remarks, "for the camp to he enveloped in clonds for several weeks together, without affording even a glimpse of the sun or of the clear sky doring the whole period. And then in a moment the clouds wonld hreak away or snhside into the valleys, leaving the tips of the monntains clear and hright above an ocean of mist, and the atmosphere calm and steady, so as to admit of the ohservations for which the party had waited days and weeks to be taken in a few hours." At times the tents wonld he hlown down hy storms—or the camps wonld he whitened hy a fall of hail or snow in Joly: or the captain taking two or three of the jnnior officers and a few men with him would start on a 'station-hnnt;' steering a conrse direct hy compass for the peaks that seemed most suitahle, regardless of the nature of the intervening conntry. In these explorations they walked from thirty to forty miles a day, wading streams, crossing bogs, scaling cliffs, and sliding down into rocky valleys, Captain Colhy ever the foremost; and when they came to a summit which his experience told him was suitahle for a station, he wonld help with his own hand in hnilding up the great pile of stones hy which it was to he distinguished and observed from distant points. Sometimes the resting-place at night would he a miserahle hovel where no other food was to be ohtained than the national porridge; at others the weary explorers rested nnder a dncal roof—and on the west coast during the hot months they were tormented and hlistered hy the hites of innomerahle midges. In one trip in 1819 the party walked 586 miles in twenty-two days. From this hrief summary, a notion may he formed of the severe labour of the snrvey, apart from the scientific dnty of ohserving with the instruments, which on all favourahle occasions was continned from sunrise to snnset.

Captain Colhy's activity and kindliness of disposition were not less apparent in camp than on the station-honts. He would assist in erecting houses to "shelter the soldiers; and occasionally join with the men in a game of qnoits, or in pntting the stone or crowhar, and was a warm promoter of their feast at the close of each trigonometrical season." He was quite indiffereot as to personal fame, hnt not so as to making known the merits of his officers, and he at times permitted them to pnhlish portions of the work in their own names rather as principals than assistants. His command over his temper was perfect; hut he disliked to be disturhed by curious visitors when hnsy with ohservations for which he had long waited the opportunity. Once, while encamped on Slieve Donard in Ireland, the snmmit of Sca Fell in Cnmberland became visihle at the distance of 111 miles, and after many trials the instrument was hrought to hear npon it. "Colby was on the point of snccessfully finishing his ohservation, which wonld have heen a geodesical trinmph, as inclnding the longest side of a triangle ever attempted, when an officer on entering the ohservatory accidentally struck his elhow, and threw the telescope off the ohject. A momentary ejacnlation of anger escaped his lips, hnt though he coold not again sncceed, and the ohject was therefore lost, he never afterwards alluded to the snhject."

He was one of the party that accompanied Biot on his trip to Shetland in 1817, when, in compliance with the wishes of the French government, one of their savants was permitted to ohserve on the line of the English arc. A coolness however arose between Biot and Colby, and while the latter, undeterred hy fog or storm, made his observations with the sector on the rock of Balta, the former carried on his pendulnm ohservations on the island of Uist; and Colhy afterwards assisted in connecting the French with the English triangulation hy the ohservations across the straits of Dover.

In 1820 Captain Colhy was elected a Fellow of the Royal Society; he took an active part in estahlishing the Astronomical Society; and General Mndge having died, he was appointed his successor as snperintendent of the Snrvey, and in the Board of Longitnde. In 1821 he was promoted to the rank of major, and in 1824 he undertook the snrvey of Ireland. In this work the nsual mode of proceeding was modified: the survey was made dependent on actual measurements with the chain, with a trigonometrical point fixed for every 400 acres; and the whole series of operations was so ahly comhined that one portion hecame a check on the other, and the ntmost accuracy was arrived at, althongh the nnmber of persons employed exceeded two thonsand, mostly from the native peasantry. A change was also made in the puhlication: the sheets were engraved on a scale of six inches to the mile, all the principal farms, fields, and inclosures being represented, so that the maps have ever since been regarded hy the government, land-proprietors, and snrveyors, as anthentic plans of all the estates in the conntry. Poor-law honndaries, townlands, land-improvements, engineering works, and the Irish census, have all heen based npon them. They are comprised in 1939 sheets.

In 1825 Major Colby hecame lieutenant-colonel, and in that year he obtained the Duke of Wellington's sanction for raising and training three companies of sappers and mioers to aid in the Irish survey, as the want of really efficient assistants was felt at first as a serious hindrance to the progress of the work. In the course of the operations Colhy measnred a hase-line of eight miles, on the south shore of Lough Foyle, with 'compensation-bars' which he had himself invented. He had carried on a series of experiments on the heating and cooling of metal rods, and he sncceeded io constructing a har of hrass and iron in comhination, the extremities of which remained always the same distance apart whatever might he the temperatnre. Snch is the exactitnde ohtained with this apparatus that it has since been used in measnring a base of eight miles at the Cape of Good Hope, in the remeasurement of the English bases, aod in those required for the great arc of the meridian in India.

In 1838 Colonel Colhy resnmed the triangnlation of Scotland, which had been snspended; and from this date op to his promotion to the grade of major-general in 1846, wheo hy the regulations of the service his connection with the snrvey ceased, he continned his usual active and energetic superintendence of the varions operations. He hronght the engraving of the English maps to an excellence never before achieved. The seconds of latitude and longitude were marked on the margins, and he co-operated with Sir Heory De la Beche in introducing the geological facts and features which have since become so importaut a part of the sorvey. He took the necessary measures for a series of tidal observations ronnd the coast of Ireland, for the pnrpose of establishing a true datnm level: "the most important series of tide-ohservations," says the astronomer-royal, "that has ever been made."

Throngh all his scientific career General Colhy never sacrificed duty to selfish considerations; and his rare administrative abilities, and sonnd jndgment comhined with high principle, enahled him to accomplish well all that be nndertook. He had resources ready for every emergency, and the hardy perseverance that triumphed over all obstacles. He died in Liverpool on the 9th of Octoher 1852, leaving a widow and seven children. He was a fellow of the chief scientific societies of London, Edinhurgh, and Duhlin; LL.D. of Aherdeen, and a knight of Denmark.

(*Professional Papers of the Royal Engineers; Proceedings of the Royal Society; Monthly Notices of the Astronomical Society.*)

COLERAINE, county of Londonderry, Ireland; partly in the parish of Killowen and harony of Coleraine, and partly in the parish of Coleraine and barony of the north-east liberties of Coleraine; a sea-port and post-town, a municipal and parliamentary borough, and the seat of a Poor-Law Union, is distant 145 miles N. from Dublin. The population in 1851 was 5920, exclusive of 342 inmates of the Union workhouse. Coleraine returns one member to the Imperial Parliament. The paving, lighting, &c., of the town are under the care of 21 town commissioners. Coleraine Poor-Law Union comprises 20 electoral divisions, with an area of 112,366 acres, and a population in 1851 of 43,021.

Coleraine is situated on both banks of the river Bann, at a distance of 4 miles from the sea. The principal part of the town is on the right bank, and consists of a central square called the Diamond, with several leading streets diverging from it. The bridge connecting this portion of the town with the suburb of Killowen or Waterside on the left bank of the river is a stone structure of three arches, 288 feet long and 32 feet in breadth, erected at a cost of 14,500*l.* There is a great thoroughfare by this road between the northern parts of the counties of Antrim and Londonderry. The parish churches of Killowen and Coleraine stand in the respective divisions on either side of the river. There are also two Roman Catholic chapels and six meeting-houses of various denominations of Dissenters, an Endowed school, a National Model school, and a savings bank. The old court-house and town-hall stands in the centre of the Diamond. There is a new market-place with a commodious market-house. The town is lighted with gas. Vessels of 200 tons burden can ascend the river to the quay; but the principal maritime trade of Coleraine is conducted from the harbour of Port Rush, 5 miles distant on the coast near the embouchure of the river. At Port Rush is a harbour formed by two piers of 800 feet and 650 feet in length, inclosing an area of 8 acres, with from 15 feet to 20 feet of water at the wharfs. The customs duties of the Coleraine district in 1856 amounted to 8050*l.*: the excise duties amounted to 40,644*l.* The number and tonnage of vessels belonging to the port in 1856 were ten vessels of 233 tons aggregate burden. The entrances and clearances at the port in the coasting and cross-channel trade in 1856 were:—Sailing vessels, inwards 120, tonnage 6080; outwards 44, tonnage 1365: steam vessels, inwards 121, tonnage 29,966; outwards 51, tonnage 11,365. In the foreign and colonial trade there entered 9 vessels of 1922 tons, and cleared 4 vessels of 1790 tons. The principal trade is the manufacture and bleaching of linens and the salmon-fishery. A fine description of linen manufactured here is known as 'Coleraines.' The annual sales of linens are estimated at 600,000*l.* The fisheries (of salmon and eel) are the property of the Irish Society, who farm them out at an annual rent of 1200*l.* Upwards of 300 persons are employed as water-bailiffs in the protection of the Bann and its tributaries. Fairs are held on May 12th, July 5th, and November 3rd; markets are held on Monday, Wednesday, Friday, and Saturday. There are tanneries, bleach-grounds, paper-mills, and soap and candle works. Quarter sessions of the peace for the county of Londonderry are held here in rotation; and petty sessions fortnightly. Coleraine in the Presbyterian Church arrangement is the seat of a Presbytery of the General Assembly, consisting of 16 congregations.

Coleraine is remarkable in early Irish history as the place in which Patrick found a Christian bishop already located on his first progress through the northern parts of Ireland. A castle was built here in 1213 by Thomas Mac Uchtred, a Scottish adventurer. One of De Courcy's followers, called De Sendall, also erected a castle very soon after the conquest. The present town stands on the site selected by the Irish Society in 1613. It was at first fortified by an earthen wall with bastions. The place held out against the rebels in 1641. In 1683 the whole customs of the port amounted to only 18*l.* 9*s.* 8½*d.* The neighbourhood is rich and well cultivated. A fall of the Bann over a ledge of rock of 12 feet high, at the Cutts, about a mile above the town, adds considerably to the picturesque interest of the environs.

COLERIDGE, HARTLEY, the eldest son of Samuel Taylor Coleridge, was born at Clevedon, near Bristol, September 19th, 1796. Two sonnets of his father are commemorative of his birth; and an exquisite poem of Wordsworth, 'To H. C. six years old,' describes the peculiarities of the child, "whose fancies from afar are brought." His infancy is also associated with two poems of his father, 'Frost at Midnight,' and 'The Nightingale.' In 1800 S. T. Coleridge went to reside in the Cumberland Lake district; and there Hartley was reared; having a brother, Derwent, four years younger than himself, and a sister, Sara, six years younger. He was taken to London in 1807; and the various sights which he saw "made an indelible impression on his mind, the effect being immediately apparent in the complexion of those extraordinary day-dreams in which he passed his visionary boyhood." In 1808 he was placed, as well as his brother Derwent, as day-scholars of the Rev. John Dawes, at Ambleside. As a school-boy his powers as a story-teller were unique; his imagination weaving an enormous romance, whose recital lasted night after night for a space of years. During their school-days, the boys had constant intercourse with Mr. Wordsworth and his family; and Hartley made the acquaintance of Professor Wilson, who was his friend through life. His friendships and connections formed the best part of his education, —"by the living voice of Coleridge, Southey, and Wordsworth, Lloyd, Wilson, and De Quincey." In 1814 Hartley left school; and in 1815 went to Oxford, as a scholar of Merton College. His extraordinary powers as a converser, and his numerous invitations to wine-parties, were injurious to him in two ways—he used great freedom of remark upon "all establishments," and he acquired habits over which he had little subsequent power of control. He passed his examination for his degree in 1818, and soon afterwards obtained a fellowship at Oriel, with high distinction. An unhappy issue followed this honourable and independent position. "At the close of his probationary year, he was judged to have forfeited his Oriel fellowship, on the ground, mainly, of intemperance." The infirmity was heavily visited. We have no record that any friend stepped in to rescue one, so otherwise blameless, so sensitive, so unfit for any worldly struggle, from the permanent consequences of this early error. His brother, who records this painful epoch of his life, with a manly and touching sincerity says, "As too often happens, the ruin of his fortunes served but to increase the weakness which had caused their overthrow." It is unnecessary for us to follow the biographer's explanation of some of the causes which led to this unhappy result—his morbid consciousness of his own singularity—his despondency at being unsuccessful in obtaining University prizes—his incapacity for the government of the pupils whom he received while at college —his impatience of control, and a belief that he was watched by those who looked with suspicion upon the most harmless manifestations of his peculiar temperament. His qualification for future active exertion was irretrievably destroyed.

After leaving Oxford, Hartley Coleridge remained in London two years, occasionally writing in the 'London Magazine,' in which some of his sonnets first appeared. Against his will he was established at Ambleside to receive pupils. The scheme failed; and after a vain struggle of four or five years, the attempt to do what he was unfit for was abandoned. From that time to his death, in 1849, he chiefly lived in the Lake district—idle, according to ordinary notions, but a diligent reader, a deep thinker, and a writer of exquisite verses, and of prose of even a rarer order of merit. From 1820 to 1831, he contributed to 'Blackwood's Magazine.' In 1832 and 1833 he resided with Mr. Bingley, a young printer and publisher at Leeds; for whom he produced a volume of 'Poems,' and those admirable biographies of the 'Worthies of Yorkshire and Lancashire,' which make us more than ever regret that one who wrote with such ease and vivacity, should have accomplished so little. In 1834 his father died, having, in a codicil to his will, expressed great solicitude to ensure for his son that "tranquillity indispensable to any continued and successful exertion of his literary talents," by providing for him, through the proper application of a bequest after the death of his mother, "the continued means of a home." Mrs. Coleridge died in 1845, and an annuity was then purchased on Hartley's life. Meanwhile, he lived with a humble family, first at Grasmere, and then at Rydal, watched over by the kind people with whom he was an inmate, and beloved by all the inhabitants of the district. His illustrious friend Wordsworth was his close neighbour; and the house of the poet was always open to the child-like man of whose wayward career he had been almost prophetic. In 1839 Hartley wrote a life of Massinger, prefixed to an edition of his works published by Mr. Moxon; and during the latter years of his life he wrote many short poems, which appear in the two volumes published by his brother, 'With a Memoir of his Life,' in 1851. Hartley Coleridge died in the cottage which he had long occupied on the bank of Rydal Water, on the 6th of January 1849; and was buried in Grasmere churchyard. His grave is by the side of that of Wordsworth.

COLERIDGE, SARA, the only daughter of Samuel Taylor

Coleridge, was born at Keswick in 1803. Until her marriage she resided in the house of Robert Southey, who married her mother's sister. To his influence and paternal kindness the formation of her mental character must be largely ascribed, though she possessed in a remarkable measure the intellectual characteristics of her father. Her opening womanhood was spent at Keswick in the diligent culture and exercise of her remarkable powers. She readily lent her assistance to Southey in lightening as far as she could his literary labours: she often accompanied Wordsworth in his mountain rambles. In 1822 she had completed her first literary work, 'An Account of the Abipones, an Equestrian People of Paraguay, from the Latin of Martin Dobrizhoffer,' a translation suggested by Southey, and the admirable execution of which he has commemorated in a stanza of his 'Tale of Paraguay.' In 1829 she married her cousin, Henry Nelson Coleridge. [COLERIDGE, HENRY NELSON, *S.* 1.]

She now gave herself to her domestic duties, and her next literary production was prepared as a Latin lesson-book for children, 'Pretty Lessons for Good Children,' and speedily passed through several editions. On the death of her father in 1834, her husband, who was the poet's literary executor, set himself to the task of preparing such of the poet's unpublished works as would serve best to exhibit him as a theologian, philosopher, poet, and critic, and Sara Coleridge most heartily devoted herself to assist in this pious duty. During her husband's life much of the collation and a considerable portion of the annotation fell to her share. After his death she did not hesitate to take upon herself the whole of the arduous labour. The 'Aids to Reflection,' 'Notes on Shakspeare and the Dramatists,' and 'Essays on his Own Times' were edited by her alone, and to some of them were affixed elaborate discourses on the most weighty matters in theology, morals, and philosophy, which were discussed in a clear and vigorous style, with a closeness of reasoning and an amount of erudition quite remarkable in one of her sex. But Sara Coleridge, like her father, had in no stinted measure the imaginative as well as the reasoning faculty. Her fairy tale, 'Phantasmion' wanted only the colouring of verse to have been generally allowed to rank among the more beautiful poems of the age; but in prose its often exquisite imagery and delicate shades of thought and feeling seemed to lack some clear and palpable intention; and it was regarded for the most part as vague, visionary, and obscure. Probably it will be on her commentaries upon her father's works—from which they are not likely to be by any future editor dissociated—that her fame will ultimately rest; but her rare acquirements and rarer gifts being thus expended on annotations, are now scarcely likely ever to meet with their due recognition. Sara Coleridge survived her husband ten years. She died May 3rd, 1852. At her death she was engaged in preparing a new edition of her father's poems, which was completed and published by her brother, 'Poems of S. T. Coleridge, edited by Derwent and Sara Coleridge,' 1852.

COLESHILL. [WARWICKSHIRE.]

COLLINS, WILLIAM, R.A., was born in Great Titchfield-street, London, September 18, 1787. His father, a native of Wicklow, was the author of various works which attracted some notice in their day; among others a poem on the slave trade, a novel entitled 'Memoirs of a Picture,' and a 'Life of George Morland.' The elder Collins was a picture-dealer as well as an author, though in neither calling had he had much pecuniary success. Morland was a friend of his, and when his son began to exhibit a fondness for art and some skill in drawing, he readily obtained Morland's consent that the youth might stand beside him and watch him paint. William made tolerable progress in his pictorial studies. He entered in 1807 as a student at the Royal Academy at the same time as Etty, and in after life the two R.A.'s were fond of comparing their early drawings and subsequent progress. His earliest appearance as an exhibitor on the walls of the Royal Academy was in 1807, when he contributed two small 'Views on Millbank,' and from that time, with the exception of two years when he was away in Italy, he did not miss an exhibition for the remaining nine-and-thirty years of his life. His father's death in 1812 threw upon the young painter serious responsibilities, but these only stimulated him to increased exertions. For some time he was forced to paint portraits as the readiest means of securing a moderate income, but his landscapes and rustic groups began to make their way, and he was soon enabled to follow the bent of his genius. Almost from the first he showed his fondness for painting groups of homely children engaged in some favourite diversion, or taking part in some juvenile trick; but it was not till the year following his election as associate of the academy, which took place in 1814, that he struck into that path—the representation of coast scenery—which perhaps most surely led him to fame and fortune. From that time—indeed, for some three or four years previous—Collins never wanted patrons; his course from first to last was one of moderate but unbroken success.

As a painter of rustic life, or rather, perhaps, we ought to say of country children and homely country scenery, Collins had hardly a rival. He watched the habits and noted every movement of the rough and unsophisticated urchins, and seldom failed to depict them in their most natural and unrestrained gaiety. Swinging on a gate, 'happy as a king;' gazing with unbounded admiration at the newly born puppy; enticing the 'stray kitten;' outwitted by the saucy robin just at the moment when making sure that the pinch of salt was about to fall on the bird's tail; exhibiting the fresh-found nest; buying the cherries—however the youngsters were represented the truth of the portraiture was at once apparent: and some quaint or novel incident was sure to be added, which marked more graphically than even the principal feature, the keenness of the painter's eye, and the skilfulness of his hand. In his coast scenes these characteristics were equally visible; and equally evident also was his happiness in his choice of a subject. In neither was there ever any attempt to surprise or excite. The painter knew exactly what was within the range of his powers. He saw his subject clearly; knew what he meant to accomplish, and seldom failed to accomplish it. Hence his pictures, apart altogether from their artistic skill, always appear to have a purpose. They show that there was something which really interested and pleased the painter, and as a consequence the spectator is himself also interested and pleased. But their technical qualities are of a very high order. Collins had an excellent eye for form, chiaroscuro, and colour. From the first he painted always with the greatest conscientiousness. He never slighted any part of his work, and always did his best; and hence his course exhibited continual progress. In his earlier pictures there may be traced something of feebleness arising from an excess of anxiety to render his work perfect. But, with increased command over his materials, he gradually acquired greater breadth and vigour; and though he always continued to finish his pictures with scrupulous care, he early recognised the truth of the axiom that mere correctness of detail is not finish. And then with his technical and manipulative skill there was shown a close study of nature. The receding or advancing wave, the moist or parched sand, the teeming clouds, every phase and every feature of earth, and sea, and sky, were faithfully observed and unobtrusively represented. No wonder that in a country like this, where every one who can turns to the scenery of nature with never-tiring zest, such faithful transcripts of her commoner aspects, animated too by life-like groups of those peasant children who, to city dwellers at least, always seem so genuine a part of the scenery, should have found abundant admirers and ready purchasers.

In 1836 Mr. Collins visited Italy, and remained there nearly two years; diligently availing himself of every opportunity of examining the works of the great masters, but at the same time filling his sketch-book with transcripts of the more striking features of the natural scenery and careful studies of the monks and peasants, and, above all, of the children, in that land of lazy enjoyment and perennial beauty. On his return in 1839, he sent to the academy as the fruits of his journey two views in Naples: one with groups of young lazzaroni playing the game of 'arravoglio;' the other with 'Poor Travellers at the door of a Capuchin Convent;' also a view at Subiaco. They manifested an increase of artistic knowledge and power, and were greatly admired. The next year he appeared in quite a new branch of art, that of historical painting. With increasing years Mr. Collins had been increasing in the depth and earnestness of his devotional feelings, and he not unnaturally felt a strong desire to represent in his own way the scenes on which his imagination loved to dwell. 'Our Saviour with the Doctors in the Temple" accordingly appeared on the Academy walls in 1840; 'The Two Disciples at Emmaus' in 1841. They of course attracted attention, and supplied a topic of conversaton in art circles, nor did they fail of purchasers; but it was felt to be a positive relief by the great body of the painter's admirers when, after a little coying with native scenery in one or two small pictures exhibited in 1842, he reappeared with all his old freshness and vigour in 1843 and succeeding years, with his 'Windy Days,' and 'Cromer Sands,' and 'Prawn Fishers,' and 'Cottage Doors,' and the like; and never did Collins enjoy more general popularity as a painter than in these last three or four years of his life.

Collins's journey to Italy not only led him to waste on uncongenial subjects several of the best years of his life, but during it he laid the foundation of the disease which shortened his days. It was not however till 1844 that disease of the heart declared itself in a decided form; but from that time he obtained only temporary relief from its distressing symptoms, though he laboured on at his calling with unabated industry, and almost to the last with little perceptible loss of power. He died on the 17th of February 1847, at his house, Devonport-street, Hyde Park Gardens.

Collins was elected R.A. in 1820; in 1840 he was appointed librarian to the Academy, but resigned it on finding that its duties required a greater devotion of time than he could afford to give to them. Collins was, as we have already noticed, fortunate in early finding friendly and liberal patrons. As early as 1818 one of his Norfolk coast scenes obtained a place in the Royal Collection, and George IV. subsequently commissioned a companion to it—'Prawn Fishers at Hastings.' Yet, though so much in request, the painter never obtained any of those extravagant sums for his works which we sometimes find popular painters demanding. The largest sum he ever received for a picture was 500 guineas, from Sir Robert Peel, for his large and admirable 'Frost Scene.' The paintings of Collins are to be met with in most of the great private collections in this country. In the National Gallery the foreigner would look in vain for a specimen of this, one of the most thoroughly national of English painters. Fortunately, the Vernon collection to a certain extent supplies the deficiency: there may be seen an excellent example of his delineations of rustic enjoyment in 'Happy as a King,' painted in 1836; one of his pleasant coast-scenes, in 'The Shrimpers—Evening,' painted in 1831; and his 'Fisherman's Widow,' painted in 1835. Mr. Collins married in 1822 the daughter of Mr. Geddes, A.R.A., and sister of Mrs. Carpenter, the well-known portrait-painter; and by her had two sons.

COLNE. [LANCASHIRE.]

COLOMBO. [COLUMBO.]

COLUBRINA, a genus of Plants belonging to the natural order *Rhamnaceæ*. It has a spreading 5-cleft calyx; petals 5, obovate-convolute; stigmas 3. Fruit capsular, dehiscent, tricoccous, girded at the base by the calyx. The seeds are furnished with a short stalk. The species are shrubs with alternate, quite entire, or crenulated leaves, netted with distant feather-nerves, smooth but usually pubescent or rusty villous. The flowers are in axillary short crowded cymes, or in fascicles with simple peduncles.

C. fermentum, Fermented Snake-Wood, is a native of Guinea; the bitter bark of which tree is said to bring on violent fermentation in the liquors into which it is thrown. There are several other species described, natives of South America, Africa, and the East Indies. None of them are of any known use, and are not worth cultivation except in general collections.

COLUMBITE. [COLUMBIUM.]

COLYTON. [DEVONSHIRE.]

COLZA. [BRASSICA.]

COMBE, DR. ANDREW, was born in Edinburgh, October 27, 1797, the fifteenth child and seventh son of a family, which numbered seventeen in all. His father was a respectable brewer in Edinburgh, and a man of superior mind and integrity; his mother also was a superior person. Educated in his boyhood and youth very much under the care of his elder brother George, the well-known phrenologist, he chose the medical profession; and, having studied at Edinburgh and Paris, and taken the degree of M.D., he began practice in Edinburgh in 1823. A pulmonary complaint under which he had laboured since 1819, and which obliged him to make frequent journeys into warmer climates, precluded him from such an active career as a physician as he might otherwise have been fitted for. In 1836 he was appointed Consulting Physician to the King of the Belgians. As early as 1818 he had, like his brother George, given his attention to phrenology and become a convert to it; and both during his practice as a physician and afterwards, he continued to advocate its doctrines through the 'Phrenological Journal.' He was also a distinguished writer on general scientific and medical subjects. The following is a list of his most important separate works:—'Observations on Mental Derangements,' 12mo, Edinburgh 1831; 'The Principles of Physiology applied to the preservation of health, and to the improvement of physical and mental Education,' 8vo, Edinburgh, 1834—a work which has been highly appreciated, and has gone through sixteen or seventeen editions; 'The Physiology of Digestion considered with relation to the Principles of Dietetics,' Edinburgh, 1836, also a most popular and useful work; 'A Treatise on the Physiological and Moral Management of Infancy,' 8vo, Edinburgh, 1840, eight editions of which have been sold. These works were written by Dr. Combe in the intervals during which he enjoyed comparative freedom from the malady which he knew was to carry him away. The last years of his life were spent by him as a confirmed invalid, either shut up in his room in Edinburgh, or seeking health by continued travelling and sea-voyages. In 1842 he was in Madeira. The mildness of his demeanour during his long illness, and the zeal with which he continued to forward every scheme of benevolence which accorded with his sense of what was right and expedient, obtained him the peculiar regard of all who knew him. His death, long expected, took place on the 9th of August 1847. An interesting and affectionate account of his 'Life and Correspondence' was published in 1850 by his brother George.

COMBE MARTIN. [DEVONSHIRE.]

COMPOUND RADICLE. [CHEMISTRY, *S.* 2.]

COMTE, AUGUSTE, a French philosopher, whose peculiar system of views has been put forth by himself, and is now generally referred to under the name of 'The Positive Philosophy,' was born within a year or two of the close of the last century. His family was strongly Catholic and royalist. Educated at one of the French lyceums, he gave very early proofs not only of a speculative turn of mind, but also of a dissatisfaction with the existing methods of knowledge and the existing forms of society, and a belief that he was destined to play the part of a Bacon in the 19th century, and initiate a new philosophical revolution. Mathematics and the physical sciences occupied much of his attention, but he had already extended his views to social questions, and become possessed with the doctrine that the time had come when all science and all philosophy must be treated from the social, as the supreme point of view. It was with views and aims of this kind fermenting in his mind, that, while yet a mere youth, he was involved within the powerful vortex of the Saint-Simonian school, which, immediately after the restoration of 1815, began to figure in Paris. The genius of Saint-Simon, then between his fiftieth and sixtieth year, drew around him, as by a kind of magnetic fascination, a number of ardent young men, whom he indoctrinated with his views, and almost all of whom—notwithstanding that few of them in mature years have adhered to the philosophy of their master—have been distinguished in one way or another in the subsequent history of France. Of these Comte was the youngest—the Benjamin, as he was called, of the Saint-Simonian school. Saint-Simon had high hopes of him; and when, about 1820, the school put forth, as one of their propagandist works, an exposition of the scientific basis of their system, it was on Comte that the preparation of the work devolved. The work entitled 'Système de Politique Positive' however only partially satisfied Saint-Simon, who said that while "it expounded the generalities of his system from the Aristotelian point of view," it overlooked "their religious and sentimental aspect." The truth is, Saint-Simon and Comte were beginning to part company. The discrepancy did not become decided till after the death of Saint-Simon in 1825, when Comte broke off from the little band of Saint-Simonians—including Enfantin, Bazard, Rodrigues, and Augustin Thierry—who remained faithful to the views of their master, and set about forming an organisation for their farther propagation. Comte subsequently spoke disparagingly of Saint-Simon, and represented his temporary connection with that enthusiast as rather an interruption to his own true intellectual development than a furtherance of it; but certainly there are such coincidences between M. Comte's subsequent works and the cardinal speculations promulgated by Saint-Simon when alive, that, unless we can suppose that the pupil prompted the master to a greater extent than usually happens in such cases, it is impossible to acquit M. Comte of a certain appearance of ingratitude in his allusions to this part of his education. In 1826 M. Comte was seized with what he calls 'a cerebral crisis,' which for the time was believed to be irrecoverable insanity. He did recover however, and lived to propound the philosophy with which his name is associated. Supporting himself by teaching mathematics—in which capacity he was professor at the École Polytechnique, till differences with his colleagues and the accession of Louis Napoleon to the empire deprived him of his office, and reduced him to a state of indigence in which his chief support consisted of voluntary contributions from his admirers in France and England—he published during the last seven and twenty years a series of works, all devoted to the elucidation of his 'Positive Philosophy,' and in which even those who have no sympathy with that system in its fundamental doctrines and its spirit, or even abhor it, recognise great power of intellect, and an extraordinary fertility of generalisation on all subjects.

First, published at intervals in six large volumes, between 1830 and 1842, came out his greatest work, entitled 'Cours de Philosophie Positive.' In this work, after propounding his main doctrine, which is, that the human mind has, by a natural law, passed through three successive stages in its thoughts upon all subjects; namely, the *theological* stage, in which phenomena are accounted for by the supposition of the agency of supernatural beings to produce them; the *metaphysical* stage, in which, while living supernatural beings are got rid of, certain abstract ideas, such as those involved in the words 'Nature,' 'Harmony,' and the like, take their place in men's thoughts as the productive causes of everything; and the *positive* stage, in which, shaking off both unseen spiritual agencies and abstractions, the mind grasps the notion of the universe in all its departments as proceeding according to certain laws or uniform sequences, to be ascertained by observation and induction;—he proceeds to apply this view to the entire system of human knowledge. All that man knows, or can know, he says, consists of certain sciences which may be arranged in a hierarchical order as follows, according to the increasing speciality and complexity of the facts with which they respectively deal:—1st, *Mathematics*, the most general and simple of all, which deals with the mere facts of number and magnitude; 2nd, *Astronomy*, which presupposes mathematics, but takes in as additional the facts of the celestial sphere, i. e. suns, planets, moons, comets, &c., as they are seen as mutually acting masses; 3rd, *General Physics*, which takes for granted mathematical and astronomical laws, but concerns itself also with the motions and other mechanical phenomena of bodies on our earth; 4th, *Chemistry*, which, in like manner, presupposes all the foregoing, but investigates farther the phenomena of the molecular changes and constitution of bodies; 5th, *Biology* (subdivided into Vegetable and Animal, and involving Psychology as a department of Animal Biology concerned more immediately with the phenomena of nerve and brain-function), undertaking the farther study of individual organised beings; and 6thly, *Sociology* or the *Social Science*, investigating, as the most complex phenomena of all, those of social or corporate life. Hitherto, according to M. Comte, only the first four of these sciences have been even partially emancipated from the theological and metaphysical spirit, and pursued positively; but the time had come, as he thought, for the extension of the true positive or scientific spirit to all, and consequently for the expulsion of theology and metaphysics from the universe. As the apostle of this great speculative change he first reviewed the various sciences up to the last and chief one, which, by a gross but convenient grammatical hybridism, he calls Sociology, giving in fact a series of treatises in which the generalities of mathematics, astronomy, general physics, chemistry, and biology, are lucidly expounded, and then reserves his strength, in the last three volumes, for Sociology. Here he reviews the history of the world, and protesting against the anarchy of all existing politics, attempts to lay down the basis of a true or positive politics, such as states will ultimately be governed by, when the positive millenuium shall have come. Apart from the main purpose, this portion of the work abounds with striking thoughts and propositions of wide application.

In 1843 M. Comte published a small mathematical work entitled 'Traité Elémentaire de Géométrie Analytique à deux et à trois dimensions,' followed not long afterwards by a popular treatise on astronomy, which has been highly admired; and in 1844 he published a 'Discours sur l'Esprit Positif,' enforcing popularly the ideas of his larger work. Within the next few years, however, a second vital 'crisis' of his life—not this time of the 'cerebral' kind, but of the sentimental—worked a certain change in his views. A virtuous affection, to which he makes frequent allusion in subsequent autobiographic passages in his prefaces, for a lady named Clotilde, whose death left him miserable, revealed to him, what Saint-Simon had long before hinted, the deficiency and meagreness of his philosophy on the sentimental and religious side. To make up this deficiency was the object of all his later activity. This he attempted to do, not by obliterating any part of his already-proclaimed philosophy, not by calling back either cashiered theology or cashiered metaphysics into the universe, but by supplementing *positivisme* with the necessary effusion from the heart. In fact, during the last eight years, M. Comte endeavoured to found a new religion, consistent with the fundamental doctrine of positivisme; to accomplish which, seeing that positivisme denies deity or invisible spirits of any kind apart from humanity, he makes humanity itself the object of the new worship. In 1848 he published a 'Discours sur l'Ensemble du Positivisme,' in which the notion of the new religion, as the necessary appendix to his philosophy, was promulgated, and in 1849 he published a singular book of a more precise nature, entitled 'Culte Systematique de l'Humanité: Calendrier Positiviste, ou Système général de Commemoration publique,' in which work he proposed a systematic worship by humanity of itself, as represented in its greatest men of all ages—twelve of whom he specified as worthy to preside over the twelve months of the year, while for each week he nominated subordinate men, and for each day minor celebrities still (it was singular to the reader to note how many Frenchmen there were among these gods and godkins); and also arranged some of the formalities of the worship. In 1852 appeared the 'Catéchisme Positiviste, ou Sommaire Exposition de la Religion Universelle en onze Entretiens Systematiques entre une Femme et un Prêtre de l'Humanité;' M. Comte himself giving in the meantime practical effect to his views by assuming the office and title of the chief priest of his own religion, preaching as such, and performing the marriage ceremony and funeral rites when called upon by his disciples to do so. His disciples in this sense however were never numerous, and while publishing his last work, entitled 'Système de Politique Positive, ou Traité de Sociologie, instituant la Religion de l'Humanité,' the first volume of which appeared in 1851 and the others have been issued since, he was not only in poor circumstances, but complained of the desertion of his pupils one after another, and expressed his sorrow that he saw no one all over the earth whom, before he died, he could ordain as his successor in the chair of the new philosophy and the pontificate of the new religion. M. Comte died Sept. 5, 1857.

Those who desire farther information respecting the life and views of this very extraordinary personage, will find it either in his own works above enumerated, or in two works published in this country presenting an abstract of his views —'Comte's Philosophy of the Sciences, being an Exposition of the Cours de Philosophie Positive,' by G. H. Lewes; and Miss Harriet Martineau's 'Positive Philosophy of Auguste Comte freely translated and condensed' (5 vols. 1853.) Comte's 'Philosophy of Mathematics,' extracted from his main work, has been translated in America by W. M. Gillespie; and his 'Popular Astronomy' also, if we mistake not, has found an English translator.

CONDAMINEA, a genus of Plants belonging to the natural order *Cinchonaceæ*. It has a campanulate calyx, 5-crenate or 5-toothed limb, deciduous; corolla funnel-shaped, with a somewhat curved tube, which is a little longer than the calyx, a dilated throat, and a 5-parted limb; stamens inserted above the middle of the tube or near the throat; anthers oblong, linear, bifid at the base, length of corolla; stigma 2-lobed. Capsule turbinate, truncate, opening in the middle of the cells. Seeds numerous, very small, wedge-shaped. The species are American shrubs, with 2-parted acuminate stipules and terminal many-flowered corymbs.

C. corymbosa is a native of the hills and ravines of the Peruvian Andes. It has ovate-oblong leaves, acuminate, cordate, sessile, plicated, coriaceous; corymbs large, brachiate, trichotomous; corolla purple externally, with the throat and filaments naked; teeth of the calyx broad, short, and blunt. The bark is febrifugal. The bark gatherers of Peru are said to use this plant for adulterating samples of *Cinchona*. Its bark is only slightly bitter, and may be easily recognised by its being white inside, rather bitter, and viscid.

C. tinctoria is a native of South America, and is used occasionally as a dye.

CONDER, JOSIAH, was born in London on the 17th of

September, 1789. He was the son of a bookseller, and very early displayed a taste for literature. His first attempts were given to the world in the 'Athenæum,' a monthly magazine then edited by Dr. Aikin; and in 1810, in connection with a few friends, a volume of poems was published under the title of 'The Associate Minstrel.' In 1814, being at the time a publisher and bookseller in St. Paul's Churchyard, he purchased the 'Eclectic Review,' of which he continued to be editor until 1837, though he retired from the bookselling business in 1819. Under his management the 'Eclectic Review' received the assistance of many eminent men among the non-conformists, such as Robert Hall, John Foster, Dr. Chalmers, Dr. Vaughan, and others. During this period, his industry was displayed by the production of other works also. In 1818 appeared two volumes 'On Protestant Nonconformity.' In 1824 'The Modern Traveller' was commenced: it extended to thirty-three volumes, nearly the whole of which were compiled by Mr. Conder, and all under his superintendence. In 1824 also appeared 'The Star in the East,' a poem; and in 1834 a 'Dictionary of Geography,' and a new translation of the 'Epistle to the Hebrews, with Notes.' In 1836 he edited 'The Congregational Hymn-Book,' issued under the sanction of the Congregational Union; and in 1837 he published 'The Choir and Oratory: Sacred Poems,' to which Mrs. Conder was a contributor. He was the author of many other works, but we have mentioned the principal.

Mr. Conder's reputation having become established among the Dissenters, he was requested in 1832 to undertake the editorship of 'The Patriot,' a newspaper recently established in the dissenting interest. From this time he took a more active part in the public proceedings of the Dissenters, attending their meetings, and affording them the assistance of his counsels. 'The Patriot,' under Mr. Conder's management, became the organ of what may be termed in politics the Whig section of the Dissenters, as opposed to the Radical section; while in ecclesiastical affairs it represented the Congregationalists and Baptists. For twenty-three years Mr. Conder fulfilled the duties of his office with exemplary care, industry, and liberality; producing also occasionally works of importance, such as 'Analytical and Comparative View of all Religions,' 'The Harmony of History with Prophecy,' &c., and several pamphlets on stirring topics of the day.

Mr. Conder married in 1815 Joan Elizabeth, the daughter of Mr. Thomas of Southgate, by whom he left four sons and a daughter. After a short illness, he died on Dec. 27, 1855.

CONFEDERATION, ARGENTINE. [Plata, La, States of.]

CONIA. [Chemistry, *S.* 1.]

CONICINA. [Chemistry, *S.* 1.]

CONSCIENCE, COURTS OF. All the Courts of Conscience, Courts of Requests, and other similar tribunals were abolished in 1846, by the statute 9 & 10 Vict. c. 95, on the creation of the new County Courts. [Courts, *S.* 2.]

CONOPS, a genus of Insects belonging to the order *Diptera* and the family *Conopidæ*. The family *Conopidæ* is thus characterised:—Proboscis distinct, last joints of antennæ forming a short style. Wings perfect. Cubital vein simple; brachial veins without spurious vein; axillary lobe rounded. Halteres uncovered.

The genus *Conops* has the following characters:—Body of middle size, rather slender, generally adorned with yellow or red bands. Head thick, vesiculose, the crown especially, with a transverse vesicular tubercle; front broad in both sexes. Eyes prominent, oblong; ocelli none. Proboscis long, porrect, stiff, clavate, horizontal, or somewhat raised into a curve, geniculate at the base, arched above, hollow beneath, obliquely notched at the tip, much shorter than the labium. Lingua slender, filiform, transparent. Palpi uniarticulate, short, very small, fringed at the tips with fine bristles. Labium obliquely porrect, cylindrical, twice the length of the lingua, narrower towards the tip, most slender in the male, bilobed, slightly hairy, and with three shallow transverse furrows at the tip. Antennæ about as long as the head, porrect, seated on a tubercle, approximate at the base, diverging thence; first joint short, cylindrical, pubescent, forming an angle with the second; second long, sub-clavate; third conical, shorter than the second; fourth very short; fifth and sixth larger, widened on one side; sixth and seventh like a little spine. Thorax almost quadrate, slightly convex above, with a scapula on each side; scutellum small, semicircular. Wings lanceolate, finely pubescent, incumbent, and parallel in repose, præbrachial vein united with the cubital towards the tip; præbrachial and discal areolets long, the latter closed near the posterior margin by a transverse vein; anal areolet long, distinct, complete. Abdomen arched, rather long, with six segments more or less slender towards the base, obclavate towards the tip, which is incurved. Legs rather stout; tibiæ very slightly curved, compressed and dilated at the tips, in some cases with a transverse suture; tarsi rather broad; ungues and onychia distinct.

Male.—Abdomen with a projecting conical process on the fourth segment beneath.

These flies frequent flowers; their larvæ are parasitic on those of the humble-bee. There are twenty species of this insect in the collection at the British Museum, of these not more than three are found in England, the rest having been caught in the south of France, North America, and Australia.

A single specimen of *C. strigata* was found near Killarney, in Ireland, in the year 1850. (Walker, *Insecta Britannica.*)

CONSTANTINA. [Constantina.]

CONYBEARE, VERY REV. WILLIAM DANIEL, Dean of Llandaff, was born at his father's rectory, St. Botolph's, Bishopsgate, London, June 7, 1787. He entered Christchurch College, Oxford, in January 1805, and took his degrees B.A. in 1808, and M.A. in 1811. Mr. Conybeare was one of the earliest promoters of the Geological Society, and the important services he rendered to geological science may be seen in his numerous papers printed in the Society's 'Transactions.' He was the discoverer of the Plesiosaurus, that strangest of all the antediluvian monsters, and for his descriptions of the animal Cuvier paid him the highest compliment that can be offered by one scientific philosopher to another. His papers on the coal-fields, giving a description of the physical geography of important districts, and establishing the relations of some of the most remarkable British rocks, and their order of superposition, have furnished data for practical purposes, and show how the absurd mistakes of mining speculators are to be avoided. As will be seen from the subjoined titles, his researches were extended to various branches of inquiry. His first paper presented to the Geological Society was 'On the Origin of a remarkable Class of Organic Impressions occurring in Nodules of Flint,' vol. ii., 1814; 'Descriptive Notes referring to the Outline of Sections presented by a Part of the Coasts of Antrim and Derry,' vol. iii., 1816, made in a tour conjointly with the Rev. Dr. Buckland, Dean of Westminster; 'Notice of the Discovery of a New Fossil Animal, forming a link between the Ichthyosaurus and Crocodile,' &c., vol. v., 1821. In vol. i., new series, 1824, further notices are given, and 'On the Discovery of an almost perfect Skeleton of the Plesiosaurus;' and the same volume contains 'Observations on the South-Western Coal District of England,' written conjointly with the Dean of Westminster; 'Extraordinary Landslip and great Convulsion of the Coast near Axmouth,' Jameson's 'Edin. Journal,' 1840; 'On the Phenomena of Geology which seem to bear most directly on Theoretical Speculations,' 'Phil. Mag.' vols. viii. and ix., second series; 'On the Structure and extent of the South-Welsh Coal Basin,' *ib.* vol. xi.; 'Outlines of the Geology of England and Wales; with an introductory Compendium of the General Principles of that Science,' &c., 8vo, London, 1822 (conjointly with W. Phillips). He also drew up the 'Report on the Progress, Actual State, and Ulterior Prospects of Geological Science,' published in the first volume of the 'Reports of the British Association.'

Mr. Conybeare was elected a fellow of the Royal Society in 1819. He was a fellow of the Geological Society, and corresponding member of the Institute of France. He became Dean of Llandaff in 1845, having previously been public preacher in his own university, and Bampton lecturer in 1839. He died after three hours' illness, on August 12th, 1857, at Itchen Stoke vicarage, while staying with his third son.

COOKIA, a genus of plants belonging to the natural order *Aurantiaceæ*. The species are small trees with imparipinnate leaves; leaflets alternate, unequal at the base, or oblique.

C. punctata is a native of China and the Moluccas; it has ovate lanceolate leaflets, acuminated, hardly unequal at the base. It is a middle-sized tree bearing eatable fruit about the size of a pigeon's egg, yellow on the outside, the pulp white, rather acrid, but sweet. This fruit is esteemed as an article of diet in China and the Indian Archipelago, and is known by the name of Wampee. There are two or three other species, natives of the East, all known as Wampee Trees.

COOKSTOWN. [Tyrone.]

COOPER, JAMES FENIMORE, was born at Burlington, New Jersey, United States, on the 15th of September, 1789. His father was of a Buckinghamshire family, which emigrated to America some twenty years before the birth of the future novelist. When James was about two years old his father removed to the banks of the picturesque Otsego Lake, Western New York, and there founded the village of Cooperstown; and somewhat later he was elected a judge of the state of New York. Having himself initiated his son in the rudimentary branches of learning, he transferred him to the care of the Rev. J. Ellison, an episcopal clergyman at Albany, by whom he was prepared for college. He remained at Yale college from 1802 to 1805, when, having taken his degree, he entered the navy as a midshipman. He served at sea for six years, and his conduct won the approbation of his superiors, and the esteem of his fellow-officers. It was here he acquired that familiarity with a maritime life, and knowledge of the scenes and phenomena of the ocean, which lend such a charm to his naval stories. On retiring from the service he in 1811 married Miss Delancy, a sister of Bishop Delancy of New York, and took up his abode in the family village of Cooperstown.

His next few years were spent in private life. It was not till 1821 that Mr. Cooper appeared as an author. His first work was a novel, 'Precaution,' which professed to be a story of English life. It met with no success, but the author, little daunted, speedily ventured before the public again, with 'The Spy—a tale of the Neutral Ground.' A thoroughly original and genuine American novel caught the American ear, much as 'Waverley' had caught the Scottish. Its success was immediate and unbounded. In England its vivid portraiture of American character and scenery gave it the additional charm of novelty, and Cooper at once took rank with the leading novelists of the day. The 'Pioneers' followed in 1823, and confirmed the reputation of its author. A year later appeared 'The Pilot—a Tale of the Sea.' These were the types of a long series of novels which during many years flowed from Cooper's prolific pen. He had in them brought before his readers the mighty forests and wide prairies,—the backwoods of America, with their original occupants the Red Indians and the Anglo-American hunters and settlers, who were rapidly supplanting them; and the sea with its daring American privateers; and again and again he was to reproduce these in more or less varied forms. The strength of his narrative, his power in delineating character, his command of the passions, keenness of observation, and descriptive skill were acknowledged without stint, and America was admitted to have produced a great original novelist.

Cooper, like Scott, thought the tide of success was to be taken at the full; and he published novel after novel with a rapidity rivalling that of the author of 'Waverley.' For a time his imagination and stores of knowledge appeared to sustain without diminution the heavy drain. He was never happier in depicting peculiarities of character, nor carried the reader along with more rapidity and interest, than in the 'Prairie' and the 'Last of the Mohicans,' which appeared after 'Lionel Lincoln' and one or two others, in 1826; in the 'Red Rover' and the 'Water Witch,' and the 'Wept of the Wish-ton Wish,' which followed in succeeding years. But in these and a few others he exhausted his genius, and novels like 'Ned Myers,' the 'Sea Lions,' 'Mercedes of Castille,' and 'The Headsman of Berne,' served only to call into clearer notice the weak points of their author; yet the 'Deerslayer' and one or two other of his later stories had so much of beauty and strength, that had there been no intervening failures, there would have been little reason to fancy that the hand of the great American novelist had lost its skill.

In 1826 Mr. Cooper visited Europe, where he remained for about ten years, his longest sojourns being made in London and Paris. The fruits of his European travel were the novels of 'The Headsman,' 'The Bravo,' 'Heidenmaur,' and 'Mercedes,' none of which were very successful; and 'Homeward Bound,' and 'Home as Found,' which, with the 'Introductory Letter to his Countrymen,' stirred up some strong feeling. Nor was he, as we have already intimated, happier in the novels he wrote on his return to America, although in several of them he recurred to his old American forests and sea haunts. But he wandered also often into the regions of home and foreign politics, not even keeping clear of controversy in his novels; and his very inaptitude for reasoning rendered him the more dogmatic in maintaining his own views and irascible under contradiction or dissent. Some of his home critics he prosecuted for libel; his foreign opponents he denounced with unbounded wrath. However, as time wore on his better spirit resumed its sway, and it was rewarded at home and abroad with a return of the old admiration and esteem; so that his death, which occurred at Cooperstown on the 14th of September, 1851, caused a general expression of sorrow throughout America, which was sincerely responded to in this country, where he had hardly fewer readers and admirers than in his own land.

Besides the novels mentioned above, Mr. Cooper wrote 'The Pathfinder,' 'The Monikins,' 'The Two Admirals,' 'Wyandotte,' 'Wing and Wing,' 'Afloat and Ashore,' 'Autobiography of a Pocket Handkerchief,' 'Satanstoe,' 'The Chainbearer,' 'The Crater,' 'Oak Openings,' 'Jack Tier,' 'The Sea Lions,' and we believe one or two others. He also wrote a 'History of the United States Navy,' which does not bear a very high reputation; 'Lives of Distinguished American Naval Officers,' 'Gleanings in Europe,' 'Sketches of Switzerland,' 'Notions of the Americans by a Travelling Bachelor,' and 'The Way of the Hour.' Most European languages have translations of some of Cooper's novels, and it is stated that one or two of the Oriental tongues possess a version of at least one of his stories. Most of the earlier novels and several of the later have been rendered into German; and in French there is a translation by Defauconpret in 23 vols. 8vo, Paris, 1838-45, and another in 6 vols. by Messrs. Laroche and de Montémont.

COOT (*Fulica atra*). [RALLIDÆ.]

COOTEHILL, county of Cavan, Ireland, a post-town and the seat of a Poor-Law Union, in the parish of Drumgoon and barony of Tullaghgarvey, is situated in 54° 5′ N. lat., 7° 3′ W. long., 73 miles N.N.W. from Dublin. The population in 1851 was 2105, besides 1101 in the Union workhouse and other public institutions. Cootehill Poor-Law Union comprises 19 electoral divisions, with an area of 105,848 acres, and a population in 1851 of 44,333.

Cootehill lies on the road from Kingscourt to Clones, and has four principal streets, which are wide and substantially built. It contains a neat church, besides chapels for Roman Catholics, Presbyterians, Methodists, Moravians, and Quakers. There is here a brisk trade in linens, and a large market for agricultural produce. The town stands at the western extremity of a series of lakes which are navigable for the greater part of the distance (7 miles) hence to Ballybay. The neighbourhood is well cultivated, and adorned with numerous demesnes and mansions. Quarter sessions for the county are held at Cootehill. There are here a bridewell, a dispensary, and a station of the constabulary force. A fair is held on the second Friday in each month.

COPLESTON, REV. EDWARD, D.D., was born February 2, 1776, at the rectory-house, Offwell, Devonshire. His father, the Rev. John Bradford Copleston, was the rector of that parish, and he educated at his own residence a limited number of pupils, among whom was his son Edward. In 1791 Edward Copleston was elected to a scholarship at Corpus Christi, Oxford; in 1793 he obtained the Chancellor's prize for a Latin poem; and in 1795 he was elected a Fellow of Oriel College. He obtained the Chancellor's prize for an English essay on 'Agriculture,' in 1796, and in 1797 was appointed college-tutor, though he had not then taken his degree of M.A. In 1802 he was elected Professor of Poetry to the university, in which office he succeeded Dr. Hurdis. He published in 1813 the substance of the lectures which he had delivered, under the title of 'Prælectiones Academicæ', a work which gained him a high reputation for pure and elegant Latin composition combined with extensive poetical information. Some severe attacks on the University of Oxford having been made in the 'Edinburgh Review,' Mr. Copleston published in 1810 'A Reply to the Calumnies of the Edinburgh Review against Oxford,' which was followed by another 'Reply' in the same year, and by a third in 1811. These replies were greatly esteemed by the university, and regarded as a triumphant defence. In 1814 Copleston was elected Provost of Oriel College, and soon afterwards the degree of D.D. was conferred upon him by diploma, the instrument setting forth that this distinction resulted from a grateful sense of the many public benefits which he had conferred upon the university. Dr. Copleston is chiefly remembered as a divine by his work on 'Predestination,' which consists, for the most part, of three sermons preached at St. Mary's church, Oxford, 'An Enquiry into the Doctrines of Necessity and Predestination, with Notes and an Appendix on the 17th Article of the Church of England,' 8vo, London, 1821. Between the years 1811 and 1822 he contributed many articles to the 'Quarterly Review.' In 1826 Dr. Copleston was appointed to the deanery of Chester, and in 1827 he succeeded Dr. Sumner in the bishopric of Llandaff and deanery of St. Paul's, London. He also held the honorary appointment of professor of ancient history to the Royal Academy of Arts, and was a fellow of the Society of Antiquaries. After he became a bishop his time was chiefly occupied in the performance of the duties of his diocese. Some of his sermons, charges, and speeches in the House of Lords, were published at the time when made. He resided mostly during the latter part of his life at Hardwick House, near Chepstow, where he died October 14, 1849. (*Memoirs of E. Copleston, Bishop of Landaff, with Selections from his Diary and Correspondence, &c.*, by William James Copleston, London, 1851, 8vo.)

COPROLITES (κόπρος and λίθος), the fossilised excrements of reptiles, fish, and other animals, found in various strata of the earth. Dr. Buckland in his 'Bridgewater Treatise' first drew attention to the probable nature of these substances, some of which had been previously known under the name of Bezoar Stones. These fossils were first detected in the Lias at Lyme Regis and in other localities, and their true nature inferred from the fact of their identity with similar masses found actually within the body of many species of *Ichthyosaurus*. The *Coprolites* are often found to contain scales of fishes, and occasionally teeth, and fragments of bone, belonging to species of fishes and reptiles which have been swallowed by the animal as food, and have passed undigested through its stomach. They often occur in a spirally twisted form, which is a characteristic of the excrements of some of the larger forms of recent fish, and have been accepted by comparative anatomists as indications of the nature of the intestinal tube in the extinct forms of Reptiles and Fishes.

Professor Liebig says in his 'Letters on Chemistry,' "In the autumn of 1842 Dr. Buckland pointed out to me a bed of Coprolites in the neighbourhood of Clifton, from half to one foot thick, inclosed in a limestone formation, extending as a brown stripe in the rocks for miles along the banks of the Severn. The limestone marl of Lyme Regis consists for the most part of one fourth part of fossil excrements and bones. The same are abundant in the Lias of Batheaston, and Broadway Hill, near Evesham. Dr. Buckland mentions beds several miles in extent, the substance of which consists in many places of a fourth part of Coprolites."

Coprolites, when chemically examined, are found to contain a large proportion of phosphate of lime. Liebig states that some he examined from Clifton contained above 18 per cent. of phosphate of lime, whilst other specimens have afforded a much larger per centage. The occurrence of phosphate of lime in these substances has led to their use as manures, and large quantities are annually collected in this country for that purpose. Before being used they are submitted to the action of sulphuric acid, by which the phosphate is converted into a super-phosphate of lime.

Not only have the beds of the Lias afforded deposits of phosphate of lime which have received the name of *Coprolites*, but they have also been found in the Greensand, in the Wealden Formation, and in the Red Crag. In the latter formation it may be altogether doubted as to whether the phosphate of lime there found in the form of dark-brown or blackish smooth nodules, can be appropriately called Coprolites. These nodules occur in beds or seams running through the Red Crag of Suffolk, where, in the neighbourhood of Ipswich and Woodbridge, and on the sea-coast of Felixstow and Bawdsey, it is worked to a considerable extent. In addition to these nodules, are found the fragments of the bones of various forms of *Cetaceæ*, all of which contain large quantities of phosphate of lime, and are collected under the name of Coprolites. It is still a question of interest as to how the nodules not having an organic basis have been formed. It has been supposed that all deposits of phosphate of lime are derived from the destruction of organised beings, but it is very evident that phosphate of lime must have existed in some form or another before the creation of either vegetable or animal beings. The increase also of the number of individuals of species of plants and animals demand that there should be some constant supply of this substance from the mineral kingdom. Whatever may be the result of further inquiry on this point, there can be little doubt of the impropriety of calling all deposits of phosphate of lime Coprolites. A better general name and which is not exposed to the objection of a false theory would be *Phosphatite*. [PHOSPHATITE, *S.* 2.]

COPYHOLD. The statute 4 & 5 Vict. c. 35, has been amended by the 6 & 7 Vict. c. 23; 7 & 8 Vict. c. 55; and 15 & 16 Vict. c. 51. The result of these statutes may be shortly stated thus. The lord may now be compelled by the tenant, or the tenant by the lord, to enfranchise the copyhold at the first surrender and admittance that takes place, and on terms, if the parties cannot agree, to be fixed by the Copyhold Commissioners.

COPYRIGHT. In order to take advantage of any disposition which may be manifested by foreign nations to recognise British copyrights, powers have been conferred on the Sovereign, by the stat. 7 & 8 Vict. c. 12, to grant, by Order in Council, privilege of copyright in this country to the authors of books, prints, and works of art, first published abroad. The exclusive right of representation may in like manner be granted to the authors of dramatic or musical compositions. Such Order in Council cannot, however, be made until due protection for British copyrights has been secured by the government of the country to the subjects of which the privilege of copyright in this country is conceded.

Under this Act, conventions for the mutual protection of copyrights have been entered into with the following eleven states:—Prussia, 1846 and 1855; Saxony, 1846; Brunswick, 1847; the Thuringian Union, 1847; Hanover, 1847; Oldenburg, 1847; France (and colonies), 1851; Anhalt-Dessau-Coethen, and Anhalt-Bernburg, 1853; Hamburg, 1853; Belgium, 1853; Spain, 1857; and their stipulations have been confirmed by the statute of 15 & 16 Vict. c. 12. Authorised translations of foreign books and dramatic pieces are by this statute protected for a term not exceeding five years from publication.

The Designs Act, 1850, enables designs to be provisionally registered for *one* year, and confers powers on the Board of Trade to extend the copyright for a term of three years. The same statute provides for the registration and protection against piracy of sculpture, models, copies, and casts. The copyright in engravings, prints, &c., is extended by the statute 15 & 16 Vict. c. 12, to prints taken by lithography, or other process of indefinite multiplication. ['Blackstone's Commentaries,' Mr. Kerr's ed., vol. ii. pp. 416-417).

CORACIAS. [ROLLER.]

CORALLINACEÆ, a family of Marine Plants belonging to the order *Algæ*. According to Harvey's definition it includes the *Corallinæ* and *Spongiteæ* of Kützing, and the *Corallinidæ* and *Nulliporidæ* of Dr. Johnston.

The forms referred to this family have been alternately regarded as animals and plants. When their structure was imperfectly understood they were regarded with many of the zoophytes (*Polypifera* and *Polyzoa*) and sponges as seaweeds. When the animal nature of these beings was established, it was again an inference that the Corallines belonged to the animal kingdom. Recent researches have however demonstrated the truly vegetable nature of this family both in their general structure and mode of reproduction. The following is Dr. Harvey's diagnosis in his 'Manual of the British Marine Algæ:'—Rigid, articulated, or crustaceous, mostly calcareous sea-weeds, purple when recent, fading on exposure to milk-white. Composed of closely-packed elongated cells or filaments, in which carbonate of lime is deposited in an organised form. Tetraspores tufted, contained in ovate or spherical conceptacles. Ceramidia furnished with a terminal pore.

The following general remarks on this family are taken from Dr. Harvey's work:—The root, where this organ is manifested, is an expanded crustaceous disc, often widely spreading. The frond almost always calcareous, effervescing strongly when thrown into acids, rarely destitute of lime, very variable in aspect and habit. The lowest forms of the order are simple incrustations, spreading like the crustaceous lichens over the surface of rocks, or the fronds of the larger *Algæ*. In the smaller of these the crust is a mere film, as thin as paper, generally circular, and extending by means of small additions to the circumference, so that the frond becomes marked as it advances with concentric circles. In the larger the crust is thick and stony, rising here and there into prominences and sinking into depressions. Still farther advance manifests itself by the crust assuming a branched habit: at first papillæ rise from the surface; these thicken, and widen, and lengthen, and at length throw out branches, till a shrubby frond, of stony hardness, but extremely brittle, is formed. All those changes in character take place within the limits of a single genus, *Melobesia*. Nearly related to this (and by many botanists considered identical) is *Mastophora*, a genus in which the frond is expanded into leafy lobes, usually fan-shaped, sessile, or stalked, but not adnate to rocks; of a flexible substance, containing a smaller portion of carbonate of lime than the former group. Some of these have the habit of *Padina*, but differ from that genus in being of a red colour. They are the most perfectly organised of the leafy or frondose Corallines (*Milleporeæ*). The articulated or true Corallines are filiform, either pinnated or dichotomous, the branches formed of strings of calcareous articulations, truncated at the upper extremity and rounded at the lower, each articulation connected with that above and below it by a flexible joint composed of cellular tissue, destitute of carbonate of lime. This joint in our British species is scarcely evident till after maceration; but in many exotic species (of *Amphiroa*) it is so long as to interrupt the continuity of the articulations, and is either marked or coated with wart-like calcareous tubercles.

The form of the articulations varies extremely, and often in the same species, or even in the same specimen, so that the determination of these plants is sometimes difficult. In many the articulations are cylindrical, in others oval and compressed, in some flat and irregularly shaped; but in the greater number they are heart-shaped or wedge-shaped, with the upper angles frequently prolonged with horns.

The fructification consists of hollow external or immersed conceptacles containing a tuft of oblong spores, divided at maturity by three horizontal fissures into four parts. They are therefore tetraspores, precisely similar to those of *Plocamium, Hypnea*, &c. The nature of the conceptacle varies even in the same species. Thus in *Corallina* it is normally formed by the metamorphosis of the terminal articulation of the branches, which swells at the sides and becomes pierced at the apex; but in *C. squamata* and even in *C. officinalis* other articulations frequently bear numerous small hemispherical conceptacles on their sides; and sometimes the whole surface is warted with such, and these irregular organs are equally furnished with tetraspores as the normal ones. These latter conceptacles, which are irregular in *Corallina*, are the normal fruit of *Amphiroa*, a genus chiefly from the Southern Ocean. In *Jania* the conceptacle is similar to that of *Corallina*, except that it generally bears a pair of ramuli (resembling the antennæ of an insect) from its upper angles.

The Corallines are found in all parts of the ocean, but are much more numerous in warm than in cold countries, and some of the species of the tropical and sub-tropical ocean are among the most beautiful of marine vegetables. Until recently the plants of this order were with other calcareous *Algæ* confounded with *Zoophytes*, or polypiferous corals. They are however undoubtedly of vegetable nature, and when the lime which they contain is removed by acid, the vegetable framework concealed beneath it is found to be of a similar structure to that of other Rhodosperms, to which group of *Algæ* they are further allied by their colour and the nature of their spores. The order consists of two, or if *Lythocystes* be rightly placed in it, of three sub-orders, as follows:—

Synopsis of the British Genera.

Sub-order 1. *Corallineæ*.—Frond filiform, articulated.

1. *Corallina*. — Frond pinnated. Ceramidia terminal, simple.

2. *Jania*.—Frond dichotomous. Ceramidia tipped with two horn-like ramuli.

Sub-order 2. *Nulliporeæ*.—Frond crustaceous or foliaceous, opaque, not articulated.

3. *Melobesia*.—Frond stony, forming either a crustaceous expansion, or a foliaceous or shrub-like body.

4. *Hildenbrandtia*.—Frond cartilaginous, not stony, forming a crustaceous expansion.

Sub-order 3. *Lythocysteæ*.—Frond plane, hyaline, composed of cells radiating from a centre. Fructification unknown.

5. *Lythocystis*.—A minute parasite.

Sub-order 1. *Corallineæ*.

1. *Corallina*. — Frond filiform, articulated, branched (mostly pinnate), coated with a calcareous deposit. Fructification turbinate or obovate, mostly terminal ceramidia, pierced at the apex by a minute spore, and containing a tuft of erect pyriform or club-shaped transversely parted tetraspores. Name from *Corallium*, Coral, which these plants resemble in having a stony substance.

C. officinalis is the most common example of this genus on British shores. It is decompound, pinnate, the lower articulations cylindrical, twice as long as broad, upper slightly obconical, round-edged, their angles blunt, ultimate ramuli cylindrical obtuse. It is found on rocks between the tide marks, extending from the limits of high to the extremity of low water mark. Perennial. Winter and spring. The root is a widely expanded red crust. The fronds from two to six inches high, tufted, much branched, bipinnated, but varying greatly in luxuriance according to the depth at which it grows.

C. elongata and *C. squamata* are both British species, and are mentioned in Dr. Johnston's work on the Corallines, and also by Dr. Harvey.

2. *Jania*. — Frond filiform, articulated, dichotomous, branched, coated with a calcareous deposit. Fructification urn-shaped. Ceramidia formed of the axillary articulation of the uppermost branches (mostly two-horned), pierced at the apex by a minute pore, and containing a tuft of erect pyriform transversely parted tetraspores. Named from *Janira*, one of the *Nereides*.

J. rubens is found on all parts of the British coast on the smaller *Algæ* between tide marks. The articulations of the principal branches and ramuli are cylindrical, about four times as long as broad. The fronds are from half an inch to two inches high, densely tufted, dichotomous, many times forked, fastigiate; branches either erect or spreading gradually, tapering upwards. Articulations cylindrical in all parts of the frond, without prominent angles; those near the base very short, the upper ones gradually longer. Ceramidia subterminal, urn-shaped, with long horns, formed of two to four articulations. Colour a pale red, with a purplish shade when quite fresh.

J. corniculata is also found on the southern shores of England and Ireland, and in Jersey.

Sub-order 2. *Nulliporeæ*.

3. *Melobesia*. — Frond attached or free, either flattened, orbicular, sinuated or irregularly lobed, or cylindrical and branched (never articulated), coated with a calcareous deposit; fructification conical, sessile. Ceramidia scattered over the surface of the frond, and containing a tuft of transversely-parted oblong tetraspores. The genus is named from one of the sea-nymphs of Hesiod.

M. polymorpha is found attached to rocks, thick, stony, incrusting, or rising into short clumsy branches, which are seldom much divided, and often merely rudimentary. Much is yet to be done in working out the species of this genus.

M. pustulata is the largest and most developed of the parasitic section of the genus. It is found on *Phyllophora rubens, Chondrus crispus*, &c. It is thick, of a dull purple or green colour, oblong or lobed, incrusting, smooth. Ceramidia numerous, large, rather prominent, and conical. Dr. Johnston refers his species to *Corallina officinalis*. This plant, he says, appears first in the guise of a circular calcareous patch of a purplish colour, and in this state is common on almost every object that grows between tide-marks. When developing on the leaves of *Zostera*, or in other unfavourable sites, these patches are usually pulverulent and ill-coloured, green or white, and never become large; but in suitable situations they continue enlarging in concentric circles, each marked with a pale zone, until they ultimately cover a space of several inches in diameter. The resemblance which in this condition the crust has to some crustaceous fungi, more especially to *Polyporus versicolor*, is remarkably exact; and neither is it less variable than the fungus in its growth, the variations depending on the nature of the site from which it grows. If this is smooth and even, the folliaceous coralline is entirely adnate and also even; but if the surface of the site is uneven or knobbed, the coralline assumes the same character. If it grows from the edge of a rock, or the frond of a narrow sea-weed, or from a branch of the perfect coralline, the basal laminæ spread beyond in overlapping imbrications of considerable neatness and beauty; they are semicircular, wavy, either smooth or studded with scattered granules, and these granules (ceramidia) may be either solid or perforated on the top. Such states of the coralline have been described as *Millepora lichenoides*, while its earlier states constitute Lamoroux's various species of *Melobesia*.

4. *Hildenbrandtia.*— The frond cartilagineo-membranaceous (not stony), crustaceous, suborbicular, adhering by its lower surface; composed of very slender closely-packed vertical filaments; conceptacles immersed in the frond, orbicular, depressed, pierced by a hole, and containing tetraspores and paraphyses at the base of the cavity.

H. rubra is found on smooth stones and pebbles between tide-marks and in deep water. It is very common, and forms a thin membranous crust, at first orbicular, and spreading concentrically, at last irregular in form, following the sinuosities of the body to which it may be attached. Viewed under the microscope, a small portion shows minute cells lying in a clear jelly. When in fruit, the surface is pitted with disc-like depressions, pierced by a hole which communicates with a chamber in which the spores lie. The colour is variable; now a bright, now a dull red.

Sub-order 3. (?) *Lithocysteæ.*

Lithocystis.—Plant calcareous; consisting of a single plane of cellules, which are disposed in radiating dichotomous series, forming an uppressed flabelliform frond. Named from a stone in the bladder, because the cells have stony coats.

5. *L. Allmanni* is parasitical on *Chrysymenia clavellosa* from an oyster-bed at Malahide, Dublin, by Professor Allmann. It forms minute dot-like patches of a whitish colour on the fronds of the *Chrysymenia.* Each dot consists of one or several fan-shaped fronds composed of quadrate cells disposed in dichotomous series. The plant is brittle, colourless, and effervesces in acid.

(Harvey, *British Algæ.*)

CORBRIDGE. [NORTHUMBERLAND.]

CORBULA, a genus of Marine *Mollusca,* belonging to the *Lamellibranchiata.* The shell is suborbicular or oval, tumid or depressed, very inequivalve, slightly inequilateral, rounded anteriorly, more or less truncated posteriorly; beak prominent; surface of the valves more or less furrowed or transversely striated, covered with an epidermis. Hinge composed of a recurved primary tooth in one or both valves, with corresponding socket and ligamental pit beside it. Ligament small, interior. Muscular impressions slightly marked, united by a pallial one with a very slight sinus. The animal is short, with very short united siphonal tubes. Orifices fimbriated. Mouth closed, except in front, where there is an opening for a bony narrow thick foot of considerable dimensions. Anal siphon with a conspicuous tubular membrane. Labial tentacles slender.

This genus was once abundant in the European seas, especially during the early part of the Tertiary epoch. Only a few species now exist. It has more species in the tropical seas of the present day.

C. nucleus is one of the most common species in the seas around the British Islands. Whilst very frequently found in the dredges, it is seldom washed on shore or found in shallow waters. It is about half an inch in length and about one-fourth less in breadth.

This genus belongs to De Blainville's family *Pyloidea,* which embraces *Solen, Panopea, Mya,* and other allied species. [PYLORIDEANS.]

CORBY. [LINCOLNSHIRE.]

CORCHORUS, a genus of Plants belonging to the natural order *Tiliaceæ.* The leaves of *C. olitorius* are used in Egypt as a pot-herb. Fishing-lines and nets, rice bags, and a coarse kind of linen called tat, are made in India of the fibres of *C. capsularis.*

CORDIA, a genus of Plants belonging to the natural order *Cordiaceæ.* It has a tubular calyx, 4-5 toothed. Corolla funnel-shaped or campanulate, with a flat 5-7-cleft limb, and a hairy or naked throat. Stamens 5, short, inserted in the throat of the corolla. Style protruding, bifid, with 4 stigmas. Ovary 3-4 celled. Drupe containing 1 stone with 1 or 3 cells, two of which are usually abortive.

C. latifolia is a native of Hindustan. It has numerous spreading and drooping branches; the young shoots angular and smooth. The general height of trees ten or twelve years old about 20 feet. Leaves alternate, petioled, round, cordate, and ovate, often slightly repand; 3-nerved; of a hard texture, smooth above, scabrous and pale underneath; from 3 to 7 or even 8 inches long, and rather less in breadth. Petioles nearly rounded and smooth. Panicles short, terminal, and lateral, roundish; the branches alternate, diverging, and one or more frequently dichotomous. Flowers numerous, small, white. Bracts minute, villous. Calyx villous, campanulate, leathery; mouth unequally toothed. Corolla short, campanulate. Segments 5, linear oblong; filaments as long as the segments of the corolla, and inserted immediately under their fissures. Anther incumbent. Ovary ovate, 4-celled, with one ovule in each attached to the upper end of the axis. Style short. Stigma 4-cleft; segments long, rugose, and recurved. Drupe oblate-spheroidal, about an inch or an inch and a quarter in diameter; smooth when ripe, straw-coloured, covered with a whitish bloom. Under the name Sebesten Plums, Sebestans, or Sepistans, two sorts of Indian fruit, have been employed as pectoral medicines, for which their mucilaginous qualities, combined with some astringency, have recommended them. They are believed to have been the *Persea* of Dioscorides. Linnæus has erroneously applied the name of Sebesten to an American species of this genus which is not known in medicine.

C. Myxa is a native of many parts of India, Persia, Arabia, and Egypt. The trunk is generally crooked, from 8 to 12 feet high, and as thick or thicker than a man's body. The bark gray, cracked in various directions. Branches numerous, spreading, and bent in every possible direction, forming a dense shady head. The flowers are numerous, white, small; a very large proportion of them are sterile, and they always want the style. The drupe is globular, smooth, the size of a cherry, sitting in the enlarged calyx; when ripe, yellow; the pulp is almost transparent, very tough, and viscid. The smell of the nut when cut is heavy and disagreeable; the taste of the kernels like that of filberts. It is the true Sebesten of the European Materia Medica. The fruits, according to Roxburgh, are not used in the Circars medicinally, but when ripe are eaten by the natives, and also most greedily by several sorts of birds, being of a sweetish taste. The wood is soft, and of little use except for fuel. It is reckoned one of the best kinds for kindling fire by friction, and is thought to have furnished the wood from which the Egyptians constructed their mummy cases. The wood is said by Dr. Royle to be accounted a mild tonic.

C. Gerasacanthus is a native of the West Indies in woods, and of Mexico, near Acapulco. It has ovate oblong leaves, acute, quite entire, glabrous; racemes terminal, aggregate; flowers verticillate, sessile; calyx 10-furrowed, 10-striped, downy; limb of corolla 5-cleft; throat villous; stamens the length of the corolla. This is esteemed one of the best timber-trees in Jamaica, of which it is a native. The wood is of a dark brown colour, and gently striped: it is tough and elastic, of a fine grain, and easily worked. It is called Spanish Elm or Prince Wood by the English, and Bois de Chypre by the French.

C. Rumphii has brown wood beautifully veined with black, and smelling of musk.

There are above 100 species of this genus.

CORDOVA, the most important next to Buenos Ayres of the provinces of the Argentine Confederation, South America, comprehends the Sierra de Cordova and the surrounding hilly country, with some adjacent plains. It is divided on the N.E., N., and N.W. by the Grand Salina from Santiago, Catamarca, and Rioja, and on the W. by a travesia, or desert country overgrown with stunted prickly trees from San Juan. A sterile and thinly inhabited country lies on the south-east between it and San Luis. On the south it extends to the Pampas of Buenos Ayres. The low sterile tract in which the rivers Segundo and Primero are lost, and the Laguna Salados de los Porongos is situated, separates it on the east from Santa Fé. It has a population variously estimated at from 65,000 to 90,000. Cordova is much more fertile than the countries which surround it. Numerous rivers descend from the Sierra de Cordova, but all are lost in the desert, except the Rio Tercero, which, during part of the year, finds its way to the Carcarañal, which falls into the Paraná near Santo Espiritu below Santa Fé. This river would be navigable for six or eight months in the year, but for two small rapids, which however might easily be removed. The valleys within the Cordova Mountains, and those which extend along their sides, have a fertile soil, and maize and fruits are raised there in abundance, but the plains, as well as the declivities of the mountains, are only fit for pasture. Cattle and sheep constitute the principal wealth of the republic. Hides in large numbers and wool are exported to Buenos Ayres. At present the produce of this province is all sent to Buenos Ayres, but when steam navigation is established on the Paraná, the commercial intercourse will probably be largely carried on through Santa Fé. The province is ruled by a governor, assisted by a junta occasionally convoked; but the authority of the governor is in effect almost unlimited.

Cordova, the capital, is situated in 31° 26′ S. lat.; it is built on the banks of the Rio Primero, in a narrow valley considerably depressed below the general surface of the country. This situation is in many respects disadvantageous, but it is thus sheltered from the north and south winds, which blowing alternately on the higher grounds produce sudden changes in the atmosphere which are injurious to health. The town contains about 15,000 inhabitants. The streets are regularly laid out, and the houses are built of brick, and better than in other towns in the interior; most of them have balconies. In the centre of the town is a spacious square, on one side of which is a neat town-hall, and on the other a fine cathedral. There are also ten other well-built churches of old date and chiefly Moorish in style; and one modern church erected in a very costly manner. The University erected by the Jesuits is on a scale of great magnitude, covering an area of four acres. In former times it was famous, being the principal college (the Colegio Maximo) of the order in this part of the world. It contained also a very important library, which on the expulsion of the Jesuits was sent to Buenos Ayres. The university is still maintained, but is now hardly better than a provincial college. There are two nunneries and two convents of Dominicans and Franciscans. A fine public promenade occupies a considerable space; it includes a square sheet of water of about four acres supplied by a running stream, which is surrounded by walks, well shaded by trees, and has in the centre a lantern-shaped temple. The Segundo which waters the town is in summer a shallow stream, but in winter becomes a deep and wide river; to preserve the town from the effects of its overflow a strong wall has been built, yet destructive floods still sometimes occur. Cordova was formerly the depôt of the European merchandise intended to be sent to Peru, but this branch of commerce no longer exists. There is a mint in the town. The only manufacture is that of leather. There are no foreigners in the town, and scarcely any in the province of Cordova. Religious toleration is unknown.

Alta Gracia, a neat town near the base of the Sierra de Cordova, contains nearly 3000 inhabitants.

CORNCRAKE (*Crex pratensis*). [RALLIDÆ.]

CORNEL-TREE. [CORNUS.]

CORNWALL. [CANADA, *S.* 2.]

COROPHIUM, a genus of Animals belonging to the class *Crustaceæ* and the family *Gammarinæ*. With the whole of the family it is remarkable for the length of its antennæ. It has no claws. One of the species, *Cancer grossipes* of Linnæus, *Gammarus longicornis* of Fabricius, *Oniscus volutator* of Pallas, is well known on the coast of La Rochelle for its habit of burrowing in the sand. They live principally upon the annelides which inhabit the sand, and are remarkable for assembling in great numbers around their prey, and destroying it although it may be twenty times as large as themselves. They also attack fishes, *mollusca*, and the dead bodies of other animals.

CORPORATIONS. There has been a great increase of late years of bodies having many of the characteristics and privileges of Corporations, to which the remarks under CORPORATION in 'Penny Cyclopædia,' v. viii. p. 46, do not apply.

In effect there are now three distinct species of Corporations—1. Those which may be described as existing at common law, having been generally created by Royal Charter. 2. Municipal Corporations. 3. Trading Corporations.

Under the first head may however be classed those Municipal Corporations to which the Municipal Corporations Reform Act does not apply, the universities and the colleges therein, and most of the old chartered bodies, such as the College of Physicians, the Companies of London and other cities, and many more of our ancient charitable institutions. These are governed by the provisions of their Charters and Bye-Laws, adherence thereto being enforced when necessary by the Queen's Bench or in Chancery.

The second class of the Municipal Corporations have been treated of under the head of BOROUGHS.

The third class, or Trading Corporations, comprises Railway and Canal Companies, and similar bodies, created by Act of Parliament, having commercial profit for their object. Thus Joint-Stock Companies for the purpose of banking or insurance are each regulated by different statutes, and must each be constituted according to the provisions of these Acts. Other trading companies may constitute themselves into Corporations by registration in a prescribed form, and on complying with certain requisites.

The distinctive ranks of these different kinds of Corporations are noted under the appropriate heads. [JOINT-STOCK COMPANIES, *S.* 2.]

CORREA, a genus of Plants belonging to the natural order *Rutaceæ*, of which one of the species, *C. alba*, is used by the settlers in Australia as a substitute for tea.

CORRIENTES, one of the Riverine provinces of the Argentine Confederation, South America, comprehends the northern portion of the peninsula formed by the rivers Paraná and Uruguay; the southern portion of the peninsula being occupied by the province of Entre Rios. The population is about 35,000.

The southern and eastern parts of the province are somewhat hilly, but the remaining and by far the greater part is low. About half the surface is covered with timber-trees, much of the wood being available for house and ship-building. Some thousand square miles are covered with palm-trees, which are used for a great number of purposes. In the northern part of the province is the Laguna Ybera, which is in fact a vast marsh overflowed during the periodical risings of the Paraná. It feeds all or nearly all the rivers which rise in the interior of the province and fall into the Paraná on the one side or the Uruguay on the other. The soil of Corrientes is generally sandy, but produces excellent crops. Cotton, tobacco, rice, sugar, indigo, and other tropical productions flourish, yet little attention is given to them, partly owing to the scantiness of the population and partly to the general dislike of the peasantry for agricultural occupations. Besides the articles mentioned above, maize and barley, arrow-root, melons, sweet potatoes, and various tropical fruits are raised. The sugar-cane is at present only grown in order to extract molasses for distilling; the sugar consumed in the province is imported from Brazil. All kinds of crops suffer at times from visitations of enormous swarms of ants and locusts, which entirely devastate the districts in which they appear. The chief employments of the inhabitants are the rearing of cattle and horses, there being a considerable extent of good pasture land; sheep however do not thrive very well. Large numbers of hides are exported. Mechanical pursuits are entirely neglected. The province is well adapted for commerce, there being on the Paraná four places which serve as good ports, and three on the Uruguay. The opening of these rivers will doubtless prove of great benefit to Corrientes, but the traffic can only be fairly developed when the rivers are navigated by steam-vessels. The inhabitants are for the most part a mixed race of Indians and Spanish, and of indolent habits. The language spoken, according to Mr. Woodbine Parish, is "more Guarini than Spanish." There are exceedingly few foreigners in either the capital or the country parts of the province. Most of the peasantry possess 40 or 50 mares, 30 or 40 cows, and from 100 to 200 sheep. The women are of more industrious habits than the men. They do a good deal of the agricultural labour, as ploughing, hoeing and attending to the crops, and reaping; make cheese for sale as well as home consumption; act as shepherds; and spin and weave both cotton and woollen cloths for summer and winter garments.

The government is almost entirely in the hands of a governor, who is elected by the Congress for a term of three years. The Congress consists of 15 deputies,—one from each of the 14 departments, except that of the capital, which returns two deputies. The revenue is derived chiefly from customs duties, and the church property which was seized by government during the civil wars. The army consists in time of peace of 1000 men, but during war all males between the ages of 14 and 60 are liable to serve. Indeed during the late war with Buenos Ayres a reserve corps was formed of 900 or 1000 women mounted on horseback, who are said to have proved of great service in some engagements with the army of Rosas. Corrientes took a leading part in the revolt of the other provinces against the supremacy of Buenos Ayres, and entered into the engagements with foreign powers which led to the downfall of Rosas. The main incitement to these measures on the part of Corrientes was the determination of Rosas to enforce the closing of the Paraná and Uruguay against all foreign vessels; and Corrientes made the opening of the navigation of these rivers a leading object in all negociations. The army of Rosas was defeated Feb. 3, 1851, by the army under General Urquiza, the governor of Corrientes. Rosas himself escaped to Buenos Ayres, and proceeded on board a British steam-vessel to England.

Corrientes, the capital, population about 5000, is situated in 27° 27′ S. lat., 58° 50′ W. long., below the confluence of the Rio Paraná with the Paraguay; and stands on a considerable elevation. It is rather a well-built town, but contains few buildings of any consequence. The situation of the town is admirably adapted for commercial purposes, affording on the one hand every facility for inland intercourse; and on the other for carrying on the export and import trade with Buenos Ayres and with foreign states by the navigation of the Paraná. *Santa Lucia*, also on the Paraná, 29° S. lat., 58° 55′ W. long., is the next important town in the province. It has some trade, but contains less than 3000 inhabitants.

The *Missiones*, which, according to the treaty between Brazil and Buenos Ayres, in 1828, was to constitute an independent republic, extend eastward from Corrientes, between the Paraná and Paraguay, to the confines of Brazil. This fertile tract, which was very populous under the sway of the Jesuits, is now filled with depopulated ruins. It contained only about a thousand inhabitants in 1825. Many of them perished in the following war and others emigrated, and it is now almost entirely depopulated.

CORROFIN. [CLARE.]

CORSHAM. [WILTSHIRE.]

CORWEN. [MERIONETHSHIRE.]

CORYPHODON, a genus of Fossil Animals belonging to the family of Tapirs. The remains of this genus have been found in this country; and although closely allied to the genus *Lophiodon* of Cuvier, Professor Owen regards its differences as of sufficient importance to constitute a new type. The specimen on which this genus was established is unique, and was dredged up from the bottom of the sea between St. Osyth and Harwich on the Essex coast, and now forms part of the collection of John Brown, Esq., of Hanway Green, near Colchester. This specimen is petrified, containing metallic salts, and having the appearance of fossils from the London Clay. There can be little doubt that it was originally imbedded in the Eocene Tertiary Formation of the Harwich coast. It consists of the right branch of the lower jaw, containing the last and part of the penultimate molar teeth of the lower jaw. Although this fragment resembles the same bone in the genus *Lophiodon*, yet a close examination of the crown of the last molar tooth exhibits a smaller antero-posterior diameter in proportion to its transverse diameter, as compared with the corresponding tooth in that genus. It also differs from the teeth of *Anthracotherium*, to which it has some resemblance. Professor Owen infers from this and other characters of these teeth that "the whole dental series of the extinct Eocene Pachyderms offered modifications of the Lophiodont type of dentition, which led towards that of the *Anthracotherium*, more especially of the smaller species from Garonne and Valery. From the closer resemblance which the fossil presents to the true Lophiodons, it must be regarded as a member of the same family of Tapiroid Pachyderms; indicating therein a distinct sub-genus, characterised by the want of parallelism of the two principal transverse ridges, and by the rudimental state of the posterior talon in the last molar tooth of the lower jaw. The name *Coryphodon*, which I have proposed for this sub-genus, is derived from κορυφή, a point, and ὀδοὺς, a tooth; and is significative of the development of the ridges into points. The broad ridged and pointed grinding surface of the tooth indicates its adaptation to comminute the coarser kinds of vegetable substances; and it is very probable that the habits and food of the Tapir, which is the nearest existing analogue of the *Coryphodon*, are not very dissimilar from those which characterised of old the present extinct species and the true Lophiodons."

Professor Owen gives the species the name of *Coryphodon Eocænus*. He also describes a tooth found in digging for a well at Camberwell, at a depth of 160 feet in the Plastic Clay. After describing this tooth, Mr. Owen says, "From its close resemblance in the essential characters of its form to the canines of the great extinct Tapiroid Pachyderms, and the apparent specific distinctions from any of the known species of *Lophiodon*, I strongly suspect it to have belonged to a *Coryphodon*."

(Owen, *British Fossil Mammals and Birds*.)

COSTA RICA, *Republic of*, the most southern state of Central America; occupies the western part of the table-land which divides the plains of Panama from those of Nicaragua. It lies between 8° and 11° N. lat., 82° 30′ and 86° W. long. On the S.E. it is bounded by the republic of New Granada, from which it is divided by a line extending from Point Burica (about 83°) north by east, to a point a little west of the lagoon of Chiriqui; on the N. it is bounded by the republic of Nicaragua, from which it is divided by the Rio San Juan from its mouth in the Caribbean Sea to the point where it issues from Lake Nicaragua, and west of that by the southern extremity of the lake itself, and thence westward by an imaginary line about 11° N. lat., to Salinas Bay on the Pacific Ocean. On the E., Costa Rica is bounded by the Caribbean Sea; on the W. by the Pacific Ocean. Its extreme length is about 260 miles, its average breadth about 80 miles. The area is 17,000 miles; the entire population 100,174.

Coast Line, Surface, &c.—Both the eastern and western coasts have a general north-western and south-eastern direction, but they differ considerably in character. Along the Caribbean Sea the coast is bordered by a narrow plain, is little indented by creeks or bays, and affords no large or secure harbour. Port Matina (10° 20′ N. lat.) at the mouth of the river of the same name, though small and far from safe, is the best harbour on this coast: it serves as the port of Cartago, and is occasionally visited by vessels from the West Indies. The western coast is much more broken. At its southern extremity is the wide open Golfo Dulce, the low shores of which are much indented by the numerous streams which fall into it. Farther north is Port Mantas, and beyond that is the bay formed by the Rio Estrella: neither of these appears to be used by shipping. More important is the Gulf of Nicoya, which is some distance northward. It has a wide open entrance turned to the south-south-west, but becomes narrower inland. It affords good shelter for shipping, is about 70 miles in length, and contains several islands. Punta de Arenas, on the eastern side of the gulf, is one of the best harbours on this part of the Pacific for vessels not drawing more than 10 feet of water. The Punta de Arenas is the port of San José, the present capital of Costa Rica. One other good harbour occurs on this coast, Punta Calebra, which is formed by the rocky headland called Punta Catalina.

The surface of Costa Rica comprises for the most part a table-land with an elevation of upwards of 2000 feet above the level of the sea. From the range of the Cabeçares Mountains in Veragus, east of the plain of Chiriqui, which connects the table-lands of Veragua and Costa Rica, there stretches a considerable number of mountain peaks, many of them of considerable height, and a large part of them volcanic. Some of them attain an elevation of 10,000 feet; the Volcano of Cartago is said to be 11,480 feet high. Towards the Caribbean Sea the descent is for the most part abrupt, but terminating from 20 to 30 miles from the sea, between which and the bases of the hills is a low, level, and marshy tract, covered with forests and subject to floods. Towards the Pacific the descent is more gradual; while the high land advances much nearer to the sea and descends to it in a series of terraces. A continuous range of volcanic hills extends from the north-western corner of the table-land of Costa Rica around the western side of the Lake of Nicaragua. The north-eastern extremity of the country subsides gradually into the plain of Nicaragua.

The only important river of Costa Rica is the San Juan, which is common to it and Nicaragua. It issues from the south-eastern extremity of the Lake of Nicaragua, and from that point to its outlet in the Caribbean Sea forms the boundary between the republics of Costa Rica and Nicaragua. It is a considerable stream and is navigable for some distance, but a large portion of its course is shallow or obstructed by sand-banks and rapids. From its commencement in Lake Nicaragua to its mouth, the distance, following the windings of the river, is 70 geographical miles. The width varies from 100 to 400 feet. The difference of level between the Lake of Nicaragua and the Caribbean Sea is 121 feet. It is by means of this river and the Lake of Nicaragua, with a canal from the lake to the Pacific Ocean, that it has been proposed to form the Nicaragua line of communication between the Atlantic and Pacific Oceans. At present the San Juan is only navigated by flat-bottomed barges.

The other rivers which enter the Caribbean Sea are very numerous, but all have very short courses, and none of them is navigable. The principal are the Matina, the Purissima, and the Tortuga. The great want of the state is a ready communication with the Atlantic, and this it is said might be met by forming a road about 66 miles long, from San José to the Sarapéqui, a feeder of the San Juan, and by improving

X 2

the navigation of those rivers, thus enabling the produce of the republic to be shipped at the port of San Juan de Nicaragua. The rivers which fall into the Pacific have all a short course. The Estrella, the Arena, and the Baranca are among the more important. Several small lakes occur on the table-land.

Climate, Soil, and Productions.—The climate of Costa Rica is on the whole more regular and healthy than in other parts of Central America. There are two seasons, a dry season, which commences in November and lasts until April, and a wet season which occupies the remainder of the year. The thermometer rarely rises above 85° or falls below 65°. In the rainy season thunderstorms of a very severe description are frequent.

The soil is of varied quality, but in many parts very fertile. On the more elevated districts there are few forests, but on the lower declivities, and especially along the eastern coast, they are very abundant. A good deal of timber, especially Brazil wood, mahogany, and cedar is exported.

Around the town of Cartago and on the western and north-western parts of the country, wheat is cultivated to some extent. Maize is grown much more extensively, and is exported somewhat largely to Chili and Peru. Coffee is however the staple: it is of fine quality, and meets with a ready sale. Tobacco is raised to some extent on the table-land both for home consumption and exportation. Sugar is an important article in the agriculture of Costa Rica; it is chiefly grown on the western side of the country, and exported from Punta de Arenas. Cacao, indigo, &c., are also grown. All the articles peculiar to intertropical regions are produced abundantly except cotton, the vine, and cochineal, which are destroyed by the heavy rains. Agriculture however, though it is upon its agricultural produce that Costa Rica is chiefly dependent, is in a very backward state, and the capabilities of the soil are very far from having been made fully available. The most common fruits are apples, pears, peaches, &c. Of vegetables the leguminous kinds, as peas, beans, lentils, &c., are the most common. There are some good pasture lands, and along the San Juan cattle forms an important part of the wealth of the country. Horses and mules are bred, but not in large numbers. Swine are raised in the low districts. Sheep are tolerably abundant on the table-land. Poultry are bred in great numbers.

Fish are very plentiful along the coasts and in the rivers. In the Gulf of Nicoya pearls and the pearl-shells are obtained; also a shell-fish which yields a purple dye.

Several metals are said to exist, but gold is the only one which is worked. The most important gold mines are those of Aquacte not far from the gulf of Nicoya and Real del Monte. Coal is reported to have been found, but it is not worked.

The manufactures are confined to the coarser articles of home consumption. They consist chiefly of coarse cotton goods, common hats, coarse earthenware, furniture, wooden utensils, &c. The commerce appears to be steadily increasing. The exports consist of coffee, of which about 15,000 cwts. are exported annually; hides, about 10,000 annually; with mahogany, cedar, Nicaragua wood, sarsaparilla, mother-of-pearl, and a small quantity of pearls. Grain, fruit, drugs, cattle, and poultry, and various miscellaneous articles likewise form a part of the exports. The total annual value is estimated at upwards of a million dollars. The imports amount in value to about three-fourths of the exports. The exports are chiefly made in British vessels. All the shipments are made from the Pacific ports, and mostly from Punta de Arenas. The exports are chiefly to the northern states of Central America, Chili, Peru, and the West Indies. The imports from Great Britain consist principally of cotton goods, woollens, hardware, and other dry goods. Crapes and other China goods are brought largely in American vessels, as well as coarse stuffs. Silks, brandies, and trinkets are brought from France; wines from Spain. A commercial treaty was made with England in 1850.

Divisions, Towns, &c.—Costa Rica is divided into six departments—San José, Cartago, Heredia, Alajuela, Guanacente, and Punta de Arenas. The only towns of any importance are the capital, San José; Cartago, the former capital; and Alajuela and Villa Vieja on the western coast.

San José, the capital of the republic, population about 16,000, stands on the elevated table-land, 9° 46′ N. lat., 84° W. long. Its site is said to be 4500 feet above the level of the sea. It is a modern city, having grown up since the declaration of independence; and though the seat of the government, legislature, and courts of justice, as well as of the bishop, it has no buildings of any beauty or importance. It is however a busy commercial town. It communicates by a cart-road 72 miles long with its port, *Punta de Arenas*, which is also a thriving place, being the principal port of Costa Rica.

Cartago stands at the base of the Volcano of Cartago, about 16 miles E. by S. from San José: population about 5000. It was once the capital of Costa Rica, and a place of some commercial as well as political consequence, but in both respects it has given way to San José. In 1841 it was almost entirely ruined by an earthquake, which destroyed seven out of its eight churches and nearly 3000 houses. It has never recovered from the calamity.

Alajuela, population, including the surrounding district, about 10,000, stands nearly midway between San José and Punta de Arenas, and is a place of some trade. A good deal of sugar is raised in the vicinity. *Villa Vieja*, about 7 miles W. from San José, is likewise a place of some trade. Curridabat, Assari, Paraiso, Heredia, Barba, and Esparza, are other towns of more or less consequence.

Government, &c.—The government is in the hands of a president elected for six years, and a legislative assembly consisting of 12 deputies elected for three years. The revenue, derived principally from a duty on tobacco and spirits, land sales, stamps, &c., amounts to about 120,000 dollars. The state has no debt either foreign or domestic, and it has happily enjoyed internal and external peace for several years. The chief court of justice is the Tribunal of San José, which is presided over by seven judges. The militia consists of 5000 men, of whom 200 are called upon at a time to form the army on duty.

The white inhabitants of the republic are relatively more numerous in Costa Rica, than in the other republics of Central America: the ladinos, or mulattoes, are also numerous. They are chiefly settled on the western side of the table-land. The eastern side of the country is occupied by the Indians, who number about 10,000. The Roman Catholic is the established religion, but other forms of worship are permitted. The church is presided over by the Bishop of San José.

During the Spanish occupation of this part of America, Costa Rica formed a part of the kingdom of Guatemala. After the declaration of independence by the Spanish American colonies, September 1821, it remained for a short time united to the Mexican kingdom of Iturbe; but when the new federal union of the United States of Central America was established in 1823 after the model of the United States of North America, it formed one of the united states. On the dissolution of this short-lived union, Costa Rica became an independent republic, and has so continued ever since.

COTARNINA. [CHEMISTRY, *S.* 1.]

COTTON, MANUFACTURE OF. London, Liverpool, and Glasgow, are the three great places of import for cotton into this country, especially Liverpool; and the amount of this import is truly marvellous. Liverpool and Manchester often take opposite views of the cotton trade; they stand to each other in the relation of seller and buyer in respect to this commodity; and their interests frequently lead in opposite directions; but no such difference can affect the real magnitude of the trade. When we consider that Lancashire now contains nearly two millions of souls, that the Glasgow district contains seven hundred thousand, that the manufacture is the chief source of industry in both these districts, and that Cheshire and Yorkshire, together with other counties, also contain their hundreds of thousands of cotton-workers—we can hardly fail to see how extremely important the regular supply of cotton must be to Great Britain.

In our previous article (vol. vii. p. 93) we have brought down the statistics of the supply of this important article to 1835. The vast increase of our manufactures has of course occasioned a demand for larger supplies of the raw material, for which the United States of America are still our chief source, and on the whole it is the best, the cheapest, and the most reliable. But the British manufacturer does not like depending for so material an object on one country only particularly for a crop which is so likely to be affected by seasons, and of which the cultivation, which is by slave labour, he apprehends may be some day suddenly interrupted

For many years he has been looking out for places where a future supply may be looked for. But our East India possessions, Brazil, and Egypt (which is made to inclnde Syria and a few other districts of the Mediterranean coasts of Asia) have long furnished a portion of his material, bnt by no means enough to satisfy his wants. The cultivation of cotton has been urged in Australia, the Cape of Good Hope, the West India Islands, and Guyana, among onr own settlements; and recently Dr. Livingstone has stated the probability of obtaining a large snpply from the interior of Africa with a likelihood at the same time of suppressing the slave-trade by occnpying the natives in nseful and profitable industry, instead of their barbarons and predatory wars. This, if ever realised, must evidently be a work of time. In our own settlements the price of labonr seems on the whole to be too high to admit of any considerable increase of the quantities we derive from thence; for though there has been a general increase, the supply is very irregular, and is not large. In the year 1856 the United States supplied 77 per cent., the British possessions 17, Brazil 2·1, Egypt 3·3, and other places 6 per cent. of the total quantities imported. A portion, varying from one-sixth to one-sixteenth, is re-exported in the raw state, for most of the European nations are competitors with ourselves in the cotton markets of the world. Hambnrg, Amsterdam, Rotterdam, Trieste, Antwerp, and France (chiefly at Havre) collectively take abont two-sevenths of the quantity imported into the United Kingdom. A part of this, as we have said, is sent from England, but on the other hand there is every year imported a quantity of cotton manufactures, such as East India piece goods, stockings, fringe, yarns, &c., to the value of about 1,500,000*l.*, which has not been included in the following statement of the import of raw material, and the declared value of exports from the year 1836 inclusive. We have given occasionally a statement of the sources whence the raw material is derived, as they show the enormous differences of the crops in different places, and sometimes that an insnfficient snpply from America has been in some measure made np by an increase from other places, and especially from our own possessions; bnt we have not thought it necessary to repeat it for every year.

	Imported.	lbs.	1836.	Exported.	£
1836.	Total . .	406,969,057		Manufactures .	18,511,652

	Egypt . .	2,864,698			
	Other places .	9,992,811			
		368,155,226			

Here was a large falling-off everywhere except in the British possessions, and in "other places," showing the efforts made to procure the raw material. Probably a portion was obtained from the continent. The exported mannfactnres, however, do not appear to have suffered. The following year shows a large increase from the British possessions:—

		lbs.			£
1840.	United States .	481,572,510	1840.	Manufactures .	17,567,310
	Brit. Possessions	77,133,730			7,101,308

		858,709,712			

The prices given for cotton vary greatly. Different countries, different years, different qualities in the same year, all lead to difference of price. Sea Island cotton always realises the best price, while Surat cotton is near the bottom of the list; 1848 was a cheap year, while 1850 was a dear year; the lowest Sea Island (in the beginning of Oct. 1850) was qnoted at 8*d.* per lb., while the highest reached 24*d.*, and Surats were 5*d.* to 7*d.* As the very dear cottons are sold only in small quantity, the average price for 1849 was probably about 6*d.* per lb., and for 1850 abont 8*d.* We give the prices varied at periods, ten years apart, with the latest prices of the so-called Orleans for America, and Pernambuco for Brazil:—

	New Orleans.	Brazil.	East Indies.
1815	24*d.* to 27*d.*	34*d.* to —*d.*	17*d.* to 20*d.*
1825	8*d.* „ 12*d.*	12*d.* „ 18*d.*	6*d.* „ 8*d.*
1835	9*d.* „ 14*d.*	13*d.* „ 15*d.*	7*d.* „ 9*d.*
1845	4*d.* „ 8*d.*	6*d.* „ 8*d.*	2*d.* „ 4*d.*
1855	5¼*d.* „ 6¼*d.*	6¼*d.* „ 6½*d.*	3¾*d.* „ 4¼*d.*
1856	7⅜*d.* „ 7⅞*d.*	7¼*d.* „ 7¾*d.*	5¼*d.* „ 5½*d.*
1857 Dec. 31	6¼*d.* „ 6½*d.*	6¾*d.* „ 7½*d.*	4*d.* „ 4½*d.*

In the year 1856, the qnantities exported were 2,035,491,291 yards of cotton cloth of the declared value of 28,527,789*l.*; 82,583,605 yards of lace and patent net, value 425,783*l.*; 5,442,359 lbs. of thread for sewing, value 586,383*l.*; 1,009,519 dozen pairs of stockings, value 308,656*l.*; and other descriptions of mannfactures to the value of 370,485*l.*, independent of the yarn. The following list gives the products with the places to which they were sent in the first eleven months in 1857:—

Cottons, Calicoes, Cambrics and Muslins, Fustians and Mixed Stuffs.

	1857. Yards.
Hanse Towns	48,751,442

Other countries	33,697,262
Total	164,757,459

The total declared values of the cotton exports for the first eleven months of 1857 are as follows:—Cottons, calicoes, &c., 26,876,622*l*. Cotton yarns, including stockings and cotton thread for sewing, 8,155,905*l*.

A more detailed notice of the sources of production is given in the following statement of the amount of cotton in stock at Liverpool on December 31, 1857: the quantity is stated in bales:—

Sea Island	10,960
Stained	630
Bowed	56,940
Orleans	120,820
Alabama and Mobile	109,390
Pernambuco, Aracati, &c.	19,700
Bahia and Maceio	7,380
Maranham	8,920
Surinam } Demerara }	—
Barbadoes	70
Laguayra	110
Carthagena	3,170
Peruvian	1,070
Common West India, &c.	—
Smyrna	—
Egypt	15,200
Surat	141,030
Madras	3,860
Bengal	150
Total	400,300

At the same period there were 41,290 bales, chiefly East Indian, in stock in London; and 10,920 in Glasgow, making a total of 452,510 bales.

The quantity of cotton used in the mills of this country does not always show the quantity of work done. The quantity thus consumed was enormously greater in 1848 than in 1847, and a little greater still in 1849; but the quantities of work done, and wages paid, did not increase in a similar ratio. The latter two elements depend in great measure on the weight of cotton used in making a particular size of cloth or yarn. In some states of the market, heavy goods pay the manufacturer better than those of lighter texture; and at such a time the consumption of cotton is increased, though neither the manufacturers' profits nor the workmen's wages may have reached a higher aggregate. In some cotton fabrics, the material is worth two-thirds of the whole value; in others it amounts only to one-fiftieth: these are extreme cases; and between them every kind of ratio is observable in some or other of the numerous varieties of manufacture. In the case of yarns, the material is worth three-fourths of the whole price in some specimens, and only one-twentieth in others. A given number of spindles, employed in making cotton twist of the thickness called No. 20, would use up 1340 lbs. of cotton, in the time which would elapse in producing No. 30 out of 840 lbs., No. 40 out of 525 lbs., and No. 60 out of 224 lbs.; in the high Nos. the relative value of the labour is higher, and consequently the relative value of the material lower, than in the low Nos. In some of the gigantic cotton mills 30,000 or 40,000 lbs. of cotton less will be used in some weeks than in others, although all the machinery and all the hands may be employed at both periods; the difference arising from fine light goods being made at one time, and coarse heavier goods at another. When the demand for printed muslins, and other light goods, is relatively brisker than that of "domestics," or coarser cotton goods, the consumption of cotton in England is found to lessen. An advance in the price of cotton is much more strongly felt in respect to coarse goods and yarns, than in fine; so much so, indeed, that the demand from many foreign markets almost ceases if the price fluctuates beyond its usual limits; whereas in light goods, wherein labour forms a large ratio of the selling price, a rise in the price of the raw material is not so sensibly felt. Whenever the supply is deficient and the price high, the manufacturer has an inducement to produce light goods instead of heavy; and for a like reason, when the demand is slack, there is less dead weight of such capital in a stock of light goods than of heavy goods of equal market value.

The arguments put forth to show that we ought not to continue to be so much dependent, as we now are, on the United States for our supply of cotton, are somewhat as follows:—That our yearly supply from other quarters has been gradually decreasing; that while our consumption is increasing, the supply available for consumption increases in a less ratio, so that it can only be kept up by encroaching on the reserve store; that the United States is the only country where the growth of cotton is materially on the increase, and this increase is not equal in rapidity to the increase of manufacturing or consuming power in Europe and the United States; that no stimulus of price can materially augment the increase of supply in the United States, since the planters always grow as much cotton as the negro population can pick; and that, consequently, if the cotton manufacture of this country is to increase, it can only do so by applying a great stimulus to the growth of cotton in other countries adapted to the culture.

Which these "other countries" are to be, is a question whereon much difference of opinion prevails. In the early stages of the cotton manufacture, the countries surrounding the Mediterranean furnished us with nearly our whole supply. In the 18th century the West Indies provided the chief cotton supply; but at present the Mediterranean and the West Indies combined furnish a very insignificant ratio. Brazil, Egypt, and India, have successively entered the market; Australia and South Africa have recently done the same; and the question arises, which of all these, or whether all combined, can furnish a supply which will materially lessen our dependence on the United States? The Lancashire authorities themselves are at issue on this matter; for while some point to the East Indies as the source of an exhaustless supply; others feel reliance only on our own colonies in the West Indies, Africa, and Australia.

Since 1835 there have been no inventions to alter materially the processes of manufacture in cotton, but the improvements in the machinery have greatly facilitated the production in most of the various branches both of weaving and printing.

COUNTY COURTS. The whole jurisdiction in civil causes of the old *schyremote*, or County Court ('Penny Cyclopædia,' v. viii. p. 113), has been transferred to the new County Courts, first established for the recovery of claims not exceeding 20*l*. in amount, in 1846, but whose jurisdiction has since been considerably extended by 9 & 10 Vict. c. 95; 12 & 13 Vict. c. 101; 13 & 14 Vict. c. 61; 15 & 16 Vict. c. 54; and 19 & 20 Vict. c. 30.

The new County Courts were intended, not only to bring justice to every man's door (like the ancient Saxon tribunals whose place they have taken), but also to supply the place of a great variety of inferior courts, established in different localities by as many different Acts of Parliament, obtained for that purpose. These tribunals which were called Courts of Requests, or Courts of Conscience, and were intended solely for the recovery of small debts, were consequently abolished when the new County Courts were established.

The County Court may entertain suits for the recovery of all debts, damages, and demands, legacies, and balances of partnership accounts, where the sum sued for does not exceed 50*l*. If the parties consent in writing, claims to any amount may be determined; but the Court has no jurisdiction (unless the parties consent in writing) in any action in which the *title* to real property or in which the *validity* of any bequest under a will or settlement, may come in question; nor in any action for a malicious prosecution, for libel or slander, or seduction.

The Crown may sue in this Court for duties and penalties not exceeding one hundred pounds, the judgment in such cases being final. An action again may be brought in it against a custom-house officer, in respect of any illegal seizure of vessels or goods, where the damages do not exceed fifty pounds; but in this case there is an appeal, as in an ordinary action (16 & 17 Vict. c. 107). Questions between the Crown and any party liable for Succession Duties (not exceeding fifty pounds) may also be determined in this Court; the decision of the judge in such cases also being final (16 & 17 Vict. c. 51).

The County Courts are essentially *local* courts, for to give jurisdiction the defendant must reside within the district of the court, at the time of the action being brought. By leave of the Court, however, an action may be brought where the cause thereof arose within the district of the Court, in cases in which the defendant or one of several defendants has dwelt or carried on business in such district within six months. The Court has also jurisdiction to give a landlord possession of premises of which the rent does not exceed 50*l.* annually, and no fine has been paid, where the tenant's term has determined, or he has received notice to quit, or where the rent is half a year in arrear.

Its jurisdiction in testamentary matters is explained elsewhere. [PROBATE, *S.* 2.] The County Court has an exclusive jurisdiction in determining the claims and disputes of the members and officers of Friendly Societies, Industrial and Provident Societies, and of Literary and Scientific Institutions (18 & 19 Vict. c. 63, s. 41; 15 & 16 Vict. c. 31, s. 8, the Literary and Scientific Institutions Act, 1854), and in the appointment of trustees to, and the regulation of, all charities within the district of the Court, of which the gross annual revenue does not exceed 30*l.* [CHARITIES, *S.* 2.]

A suit is begun by the entry of a plaint at the office of the Court, which sets out the names of the plaintiff and defendant, and the nature of the action. Thereupon a summons is issued, a copy of which is served on the defendant by one of the bailiffs of the Court, requiring the defendant to appear; which he must do at the Court to which he is summoned, or have judgment given against him. If defence is made, the matter in dispute is, on the trial, inquired into, and disposed of summarily by the judge; who is to decide all questions, as well of fact as of law, unless one or other of the parties has demanded a jury for the trial of matters of fact; for in actions for sums above 5*l.*, a jury of five may be obtained as of right; in this case the facts are to be tried by the jury.

In actions for more than 20*l.*, an appeal lies to either of the superior courts of law at Westminster, against the decision of the judge in matter of law, or in the reception or rejection of evidence. No appeal lies against his decision in matters of fact.

The Court, which is held once a month, is a court of record. On its judgment execution may be issued against the goods of the unsuccessful party. If he has nogoods, but has the means of paying, and refuses to do so, he may be punished, after inquiry into his circumstances, by imprisonment for a period not exceeding forty days; or the judgment (if for more than 20*l.*) may be removed into one of the superior courts, and enforced there by the ordinary process of execution.

To encourage suitors to resort to this Court, the plaintiff in the superior courts (in suits in which they have concurrent jurisdiction) does not in general obtain costs in actions of *contract* where he recovers less than 20*l.*, and in actions of *tort* where he recovers no more than 5*l.*, unless the judge who tries the cause certifies for costs, or it appears that there was sufficient reason for bringing the action in the superior court.

Previously to the establishment of the County Courts, the Courts of Bankruptcy had, by the statutes 5 & 6 Vict. c. 116, and 7 & 8 Vict. c. 96, called usually the 'Protection Acts,' jurisdiction to grant to any person who was *a trader* owing less than 300*l.* in all, or who was *not a trader* within the bankrupt laws, protection from all process. This jurisdiction was, by the statute 10 & 11 Vict. c. 102, vested in the County Court, and the Court for the Relief of Insolvent Debtors, in London. [PROTECTION ACTS, *S.* 2.] In the County Court, also, may now be tried all actions of replevin. [REPLEVIN, *S.* 2.] The judge has also power to grant a warrant for the arrest of an absconding debtor, and by statute 17 and 18 Vict. c. 104, to direct a vessel which has caused injury by collision or otherwise to another vessel to be detained until satisfaction is made for the injury, or security given to abide the event of legal proceedings.

The nature and jurisdiction of this Court have been described thus fully, in consequence not only of the recent erection of these tribunals, but of the extent and variety of the powers vested in them, and the important position they have taken in the estimation of the people. (Blackstone's 'Commentaries,' Mr. Kerr's edition, vol. viii., p. 38.)

COURTS.—The re-construction of local courts, anticipated in the article on this subject ('Penny Cyclopædia,' v. viii. p. 115), took place in 1846, in the re-organisation of the County Courts, with a simple and inexpensive procedure, and a professional judge in lieu of the Sheriff and suitors of the old *schyremote*. [COUNTY COURTS, *S.* 2.] The Court of the Marshalsea, or Palace Court, has also been abolished, and provision made for the surrender of the inferior local courts by corporations and the lords of manors and hundreds. Most of these indeed have long been as much in desuetude as the court of piepoudre. Many of the more important borough courts have however obtained a renewed vitality, by having the provisions of the Common Law Procedure Acts of 1852 and 1854 extended to them, by order in Council. This has, of course, produced some anomalies. An inhabitant of Liverpool, for instance, may find himself commanded to enter an appearance at Westminster by the Queen; obliged to obey a like order to appear at Lancaster by the Duchess of Lancaster; threatened with judgment and execution by the Mayor of Liverpool, if he fail to appear at the Court of Passage in that town; and finally summoned to answer a plaint in the County Court of Lancashire holden at Liverpool. As to the alterations which have been made in the jurisdiction of other courts, see BANKRUPTCY, *S.* 2; EQUITY, *S.* 2; PROBATE, *S.* 2; DIVORCE, *S.* 2.

COWPER, EDWARD, was born in 1790. Little or nothing has been published concerning the circumstances and events of the early life of this distinguished inventor and improver of machinery. It is known however that it was chiefly owing to some of his inventions in cylinder-printing that Mr. Applegath was induced to build the extensive printing-office in Duke-street, adjoining to Stamford-street, London, now occupied by Messrs. Clowes, and he was a partner with Mr. Applegath in that establishment. They were also connected in making machines for calico-printing, and in the construction of new machinery for printing the 'Times,' of which, in conjunction with Mr. Applegath, he published a description. In fact, some of the most important improvements in machine-printing were of his invention, such especially as the giving a diagonal action to the rollers on the self-acting inking-tables. In the Great Exhibition of 1851 he exhibited a model, made by T. B. Winter, a student in King's College, London, of the printing-machine now in general use; and by such machines the catalogues of the Great Exhibition were printed. He had for many years an engagement at the large blacking-factory of Messrs. Day and Martin, in printing their labels in such a manner as to defy imitation. He furnished some contributions to the 'Penny Cyclopædia,' one of which was an elaborate article on a 'Button.'

Mr. Cowper, during some of the later years of his life, was professor of mechanics and manufacturing arts at King's College, and it is as a lecturer that he was best known to the public. His process of imparting knowledge consisted not only in giving descriptions, and illustrating them by models, but in exhibiting the machines themselves, and showing them at work. His manner of lecturing was simple and popular, and he had always a full attendance. His knowledge of machinery, of mechanical construction, and the mechanic arts, embraced the most minute as well as the largest objects. He delivered lectures on the mechanical structure of the Crystal Palace of 1851. He was much respected for his urbanity, and for his readiness in making communications from his large stores of information to the humblest individuals as well as to persons of higher station. He died at his residence, Kensington, London, October 17, 1852.

COWSLIP. [PRIMULA, *S.* 1.]

CRAG, the uppermost of the distinctly Tertiary Strata of England—using this term in a sense which is perhaps gradually passing away, to be replaced by the larger meaning of Cainozoic. The Crag of Norfolk and Suffolk is partly a calcareous mass, rich in delicate corals; partly a subcalcareous sand, rich in shells; and partly a rudely aggregated deposit of sand, shells, pebbles, and bones. To these divisions, whose origin is due to different local conditions, and successive times, Mr. Charlesworth has assigned the titles of Coralline Crag, Red Crag, and Mammaliferous Crag. The position of these beds will be best seen from the following table of the classification of the Tertiary Rocks from Professor Ansted's 'Elementary Geology.'

Newer Tertiary, or Pliocene Series :—
1. Upper Gravel and Sand.
2. Till.
3. *Mammaliferous Crag.*
4. Fresh-Water Sand and Gravel.
5. *Red Crag.*

Middle Tertiary, or Miocene Series :—
6. *Coralline Crag.*

Lower Tertiary, or Eocene Series :—
7. Fluvio-Marine Beds, &c.

CRAIL. [FIFESHIRE.]

CRANBROOK. [KENT.]

CRASSULA, a genus of plants, the type of the natural order *Crassulaceæ*. It has a 5-parted calyx, much shorter than the corolla; sepals flattish; the petals 5, stellate, spreading, distinct; the stamens 5, filaments awl-shaped; scales 5, ovate, short; carpels 5, many-seeded. The species are very numerous. They are succulent herbs or shrubs, and are mostly natives of the Cape of Good Hope. Their leaves are opposite and entire, or nearly so. The flowers are mostly white, rarely rose-coloured. Upwards of fifty species have been described; and many of them, on account of their grotesque appearance, are cultivated in our gardens. They are greenhouse plants. One species, *C. tetragona*, is used at the Cape of Good Hope as a remedy in dysentery. Any medicinal properties they possess is probably owing to the presence of tannin.

CRAWFORD, THOMAS, an eminent American sculptor, was born at New York on the 22nd of March, 1813. At school he obtained some acquaintance with Greek and Latin literature, but, as is frequently the case with youths in his country, he seems to have heen allowed in early life to follow very much his own conrse. Like Chantrey, his earliest instructor in the use of the chisel was a carver in wood. Whilst with him however his strong desire for higher training began to develop itself. He formed a collection of casts of ancient and modern works of a high class, and he learnt to model in clay. At length he was placed as a pupil under Messrs. Frazee and Launitz, and entered as a student the academy of design in New York. Mr. Launitz urged him to proceed to Rome, and gave him a letter of introduction to Thorwaldsen. Accordingly he proceeded to Italy in 1834, and was received into the studio of Thorwaldsen, to whose friendship he was greatly indebted. Thrown by the death of his father on his own resources, he for some time supported himself by making busts. The first poetic work of his which attracted particular attention, was the statue of Orpheus, designed in 1839, bnt which he was compelled to leave unfinished hy an attack of brain-fever, the precursor of his premature fate. On his recovery he completed the Orpheus in marble, a commission having during his illness arrived for it from the Boston Athenæum. It excited general admiration and anticipation. He worked on diligently, gaining in executive skill and confidence, and rising steadily in reputation. Among the chief of his earlier works are his 'Herodias with the head of John the Baptist;' 'The Babes in the Wood;' 'Flora;' and 'The Dancers'—two life-size statues of children, which have had considerable popularity. Among the best of his later works are his bronze statue of Beethoven, now in the Athenæum at Boston, America; the eqnestrian statue of Washington, which stands in the square at Richmond, Virginia; and the more ambitious alto-rilievo of the 'Progress of Civilisation in America,' which he was commissioned by the federal government to execute for the pediment of the Capitol at Washington. Others of his works are his statues of 'The Genius of Mirth;' 'A Shepherdess;' 'David;' and 'Prayer;' his gronps of 'Adam and Eve,' of heroic size; 'A Family suffering under the plague of Fiery Serpents;' 'A Mother attempting to save herself and Child from the Delnge;' and his ideal busts of Sappho, Vesta, &c. He also made numerous designs for bassi-relievi illustrative of the Old and New Testaments; the poets of Greece, Italy, and England; events of American history, &c., as well as several models of leading American statesmen.

From first entering Rome, Crawford made that city his home. He had just completed a new and spacious studio, in order to work with more convenience at the numerous commissions which awaited completion, when he was stricken with a disease—tumour on the brain—which rendered him unable again to take up his chisel. He came to London for the benefit of medical advice, but failed to obtain relief, and died in London on the 8th of October, 1857. Crawford was a sculptor of a very high order of merit, not reaching to the first rank, but coming close to it. His works display originality and vigour rather than refinement; mental power rather than technical skill. Casts of some of his statues are in the Crystal Palace at Sydenham.

CREATINE. [CHEMISTRY, *S.* 2.]

CREATININE. [CHEMISTRY, *S.* 2.]

CRESCENTIACEÆ, a natural order of plants, formerly included in the *Solanaceæ*, allied to *Gesneraceæ* and *Bignoniaceæ*. The species are trees of small size, with alternate or clustered simple leaves without stipules. The flowers grow out of the old stems or branches; the calyx free, undivided, eventually splitting into irregular pieces; the corolla monopetalous, irregular, somewhat 2-lipped, with an imbricated æstivation. The stamens are four in number, growing on the corolla, didynamous, with the rudiment of a fifth between the posterior pair, which are the longest; anthers 2-lobed, bursting longitudinally; ovary free, surrounded by a yellow annular disc, 1-celled, composed of an anterior and posterior carpellary leaf, with 2 or 4 equidistant parietal placentæ, which sometimes meet and produce additional cells; ovules 0-0, horizontal; style 1; stigma of 2 plates. Fruit woody, not splitting, containing a multitude of large amygdaloid seeds buried in the pulp of the placentæ; skin leathery, loose; embryo straight, without albnmen, with plano-convex fleshly cotyledons, and a thick short radicle next the hilnm.

CREX. [RALLIDÆ.]

CREWE, Cheshire, a town in the parish of Coppenhall and hundred of Nantwich, is situated in 53° 5′ N. lat., 2° 25′ W. long., distant 24 miles S.E. by E. from Chester, 166 miles N.W. from London by road, and 157½ miles by the London and North-Western railway viâ Trent Valley. The population of the town of Crewe in 1851 was 4491. The living is a perpetual curacy in the archdeaconry and diocese of Chester.

The town of Crewe owes its erection entirely to the formation of the London and North-Western line of railway. The inhabitants consist chiefly of persons in the employment of the railway company, with their families. The houses and shops are well built; the streets are wide, and the footpaths are laid with asphalte. The town is lighted with gas, and well supplied with water, a powerful steam-pump supplying at once the engines in the extensive workshops of the company, the locomotive engines, and the honses in the town. The water intended to be used hy the inhabitants passes through two filtering processes before reaching the houses. Baths are also provided at a cheap rate. The town of Crewe has a council for the management of the affairs of the community; two-thirds of the council are elected by the workmen and inhabitants, and one-third by the directors of the railway company. A church has been erected by the compauy: the Wesleyan, Primitive, and New Connexion Methodists, Independents, Scotch Presbyterians, Baptists, and Roman Catholics have places of worship. Schools for boys, girls, and infants have been provided by the company, and a library and a mechanics' institution are snpported by subscription. Medical attendance and medicine are secured for the workmen and their families on payment of a small weekly rate, the highest charge (that for a married man with a family) being 2d. per week. A field in the neighbourhood is used for cricket-playing. The railway station at Crewe is very spacious. From this place branch off five lines of railway, affording ready means of communication with all parts of the country. The workshops and machinery of the North Western Railway Company at Crewe are on a very extensive scale. Railway carriages and locomotive engines are manufactured and repaired. The number of carriages of all kinds maintained at Crewe amounts to about 700, of which 100 at a time are usually under repair. Crewe Hall, the seat of Lord Crewe, is in Crewe township, about one mile from the railway station.

CRICH. [DERBYSHIRE.]

CRIEFF. [PERTHSHIRE.]

CRINAN CANAL, Argyleshire, a canal connecting the Lochgilp branch of Lochfyne with the Sound of Jura, and constructed for the purpose of enabling vessels of small burden to dispense with the rather dangerous passage round the

Mull of Cantyre. The project of forming this canal was first started about sixty years back, with the co-operation of the then Duke of Argyll. Sir John Rennie having surveyed the ground and reported favourably, an Act of Parliament was obtained, a company was formed in 1793, and the works were forthwith commenced. The canal was opened in 1801. The canal, although not more than 9 miles in length, has been of great service to the coasting trade of the west of Scotland and the Highlands; the original shareholders of the canal company, however, have never received any return for the outlay of their capital. The number of locks in the Crinan Canal is fifteen; the average breadth is 24 feet, and the depth of water 10 feet; if found necessary 12 feet depth of water could be maintained. Since 1818 the canal has been under the management of the Commissioners of the Caledonian Canal, with the navigation of which it is intimately connected; together, these canals form an important portion of the inland passage between Glasgow and Inverness. Vessels of 200 tons burden can pass through the Crinan Canal.

CROKER, RIGHT HONOURABLE JOHN WILSON, was the representative of a branch of an ancient family which was settled for many generations at Lineham, in South Devon. A member of this family emigrated to Ireland about the year 1600, and his sons distinguished themselves at the capture of Waterford in 1650. Various descendants of this branch received grants of land in the south of Ireland, which they increased from time to time by marriages with influential families. Mr. Croker, the father of the subject of our present memoir, was for many years surveyor-general of Ireland, and in that position became extremely popular. By his marriage with Hester, daughter of the Rev. R. Rathborne, he had an only son, John Wilson Croker, who was born in Galway, December 20, 1780.

After receiving his early education at a school in Cork, where he displayed great precocity and an inquisitive disposition, he was entered at Trinity College, Dublin, at the age of sixteen, under the late Dr. Lloyd. He soon began to show extraordinary readiness and ability by the part which he took in the 'Historical Debating Society,' since suppressed, but which then was in active operation, drawing out and developing the characters of young men, and preparing them for their appearance afterwards on the stage of public life. So highly did the society esteem the share taken in its proceedings by Mr. Croker, that it voted him its first gold medal. Intended by his parents for the study of the law, Mr. Croker had no sooner taken his B.A. degree in 1800, than he was entered as a student at Lincoln's Inn; but he continued to reside in Dublin, and to mix with the society of that capital. He was called to the Irish bar in 1802. He had leisure hours on his hands, and these he devoted to literature. His first production as an author, if we except a short paper of mere ephemeral interest, was a series of 'Familiar Epistles to J. F. Jones, Esq., on the Present State of the Irish Stage,' which was published in 1803, and was followed in 1805 by his 'Intercepted Letter from China;' both anonymous. Both were clever and caustic satires, excited much curiosity and attention, and ran speedily through several editions.

In 1807 he published a work of a graver kind on 'The State of Ireland, Past and Present,' in evident imitation of the treatise of Tacitus 'De Moribus Germanorum.' In this pamphlet he strongly advocated Catholic emancipation. At the close of the preceding year Mr. Croker was employed as counsel for Sir Josias Rowley, at the election for Downpatrick. Sir Josias withdrew just before the election, and Mr. Croker was nominated in his place, but was defeated by a small majority. In the following May however he was returned for the borough, and confirmed in his seat on petition.

He had not been long in parliament when an opportunity offered for the display of his oratorical powers. Early in 1809 the Duke of York was brought practically upon his trial before the country for corrupt administration at the Horse Guards, and the best and most successful speech made in defence of his Royal Highness against Colonel Wardle's motion of censure, was delivered by Mr. Croker on the 14th of March. This speech contained a minute dissection of the evidence brought forward against the duke, and was couched in vigorous and pointed language. It may be presumed that the grateful sense which his Royal Highness thenceforth entertained for this support hastened the advance of Mr. Croker to office. In the course of the same session the late Duke of Wellington, then Sir Arthur Wellesley, and chief secretary for Ireland, being obliged to repair to Dublin, entrusted to Mr. Croker the parliamentary business connected with that country; and he fulfilled that trust with so much ability and discretion, that shortly afterwards Mr. Perceval, when he formed his ministry in 1809, offered to Mr. Croker the post of Secretary to the Admiralty. For upwards of twenty years Mr. Croker continued to discharge the duties of this post with unremitted application, under three successive First Lords of that department, and under King William IV. when Lord High Admiral. During this time he sat in parliament for various boroughs; amongst others for Aldborough, Yarmouth, and Bodmin; and in 1827 he had the satisfaction of being returned for the University of Dublin, on the elevation of Lord Plunket to the chancellorship and peerage, with whom he had twice unsuccessfully contested the seat: but his views being in favour of Catholic emancipation, Mr. Croker was subsequently defeated. He took a very active part in the parliamentary committee appointed to consider the question of erecting New London Bridge; and his zeal for science and literature was shown in another way soon afterwards, by founding the Athenæum Club. He was amongst the earliest advocates for a state encouragement of the fine arts. His speech on the proposed purchase of the Elgin marbles was much in advance of the general tone of parliament on such subjects. When the Reform Bill was proposed, Mr. Croker opposed it at every stage by powerful speeches and a ready pen, as he considered it a revolutionary measure.

The passing of the Reform Bill compelled Mr. Croker to withdraw from parliamentary life. Even during the most active portion of his parliamentary career, his pen was seldom unemployed. His printed speeches and pamphlets on current political questions amount to a very considerable number, and his contributions to the 'Quarterly Review,' extending over more than a quarter of a century, would alone fill several volumes. His most extensive work is an edition of 'Boswell's Life of Johnson,' in 4 vols., 8vo, published in 1831, which was handled with considerable severity by Mr. Macaulay in the 'Edinburgh Review.' His poems of 'Ulm and Trafalgar,' and 'Talavera,' are the best known and most admired of his productions in verse. His 'Stories from the History of England' is a highly popular book for children. The following is a list of the most important works not mentioned above, which were either published or edited by Mr. Croker: 'A reply to the Letters of Malachi Malagrowther;' 'Military Events of the French Revolution of 1830;' 'Letters on the Naval War with America,' and 'Songs of Trafalgar.' He was also the author of several lyrical poems of merit, including some touching lines on the death of Mr. Canning, to whom he was very firmly attached. Mr. Croker also edited the 'Suffolk Papers,' 'Lady Hervey's Letters,' 'Lord Hervey's Memoirs of the Reign of George II.,' and 'Walpole's Letters to Lord Hertford.' He died August 10, 1857.

CROKER, THOMAS CROFTON, was born January 15, 1798, in the city of Cork, Ireland. He was the only son of Major Thomas Croker, of the 38th regiment of foot. At the age of fifteen he became an apprentice in a mercantile establishment in Cork. Between the years 1812 and 1818 he made excursions occasionally on foot in the south of Ireland; and it was during these rambles that he commenced making his collections of the legends and songs of the peasantry in Ireland. In the year 1818, Moore, in an advertisement to the 7th number of the 'Irish Melodies,' expressed his obligations to him for about forty Irish airs which he had sent, for many curious fragments of Irish poetry, and for several interesting local traditions. Crofton Croker had also acquired considerable skill in making pen-and-ink sketches, and some of them were exhibited at Cork in 1818.

Major Croker died in 1818, and his widow soon afterwards made application to Mr. John Wilson Croker, then secretary to the Admiralty, who was a friend of the family, but no relation; and through his interest in February, 1819, Thomas Crofton Croker become a clerk in the Admiralty, with a salary of 2*l.* a week. While in this situation he contributed to the introduction of lithography into the Admiralty as a substitute for transcribing several copies of the same document, and for confidential circulars; and he had for many years the superintendence of the private lithographic press of the Admiralty. He subsequently became a clerk of the first class, with a salary of 800*l.*; and he retired in 1850 with a pension of 580*l.*

Mr. Crofton Croker's first literary work was his 'Researches in the South of Ireland,' published in 1824, in 4to, and consisting for the most part of the notes made during his early excursions in 1812-1818, and during a subsequent tour in 1821. His next work was the 'Fairy Legends and Traditions of the South of Ireland,' London, 1825, 3 vols. sm. 8vo. In the first edition of this work he was assisted by Dr. Maginn, Mr. Pigott, and Mr. Keightley; but the materials supplied by his assistants, or at least most of them, were afterwards omitted. A second edition was illustrated with etchings, after sketches by Maclise, then, as Croker states, "a young Irish artist of considerable promise." The 'Fairy Legends' appeared in 1834 in one volume, forming a part of the 'Family Library.' This work, when first published in 1825, produced a long complimentary letter from Sir Walter Scott; and on the 20th of October 1826, he was introduced to Sir Walter at the residence of Mr. Lockhart in Pall Mall. His personal appearance is thus described in Scott's Diary:—"Little as a dwarf, keen-eyed as a hawk, and of easy prepossessing manners, something like Tom Moore."

In 1829 Mr. Crofton Croker published 'Legends of the Lakes, or Sayings and Doings at Killarney, collected chiefly from the manuscripts of R. Adolphus Lynch, Esq., H.P., King's German Legion,' London, 2 vols. cr. 8vo. This work was followed in 1832 by two small novels—'The Adventures of Barney Mahoney,' and 'My Village versus Our Village,' of which the first was very favourably received, but the second less so. In 1839 he edited, with very copious notes, 'The Popular Songs of Ireland,' 12mo. He was a contributor to some of the annuals which were in fashion about 1830-40, especially to 'The Amulet,' and 'Friendship's Offering;' and he edited for two or three years 'The Christmas-Box.' He wrote many small articles, some for magazines, and some which were printed privately. He was a constant contributor to the early volumes of 'Fraser's Magazine,' frequently to 'The Literary Gazette,' and occasionally to 'The New Monthly Magazine.' He had always a taste for antiquities, and he was early elected a Fellow of the Society of Antiquaries. He was chosen a member of the Royal Irish Academy in 1827. He took part in the foundation of the Camden Society in 1839, and of the Percy Society in 1840. He was a member of the council of both these societies, and he edited some of the works published by them. When the British Archæological Society was founded in 1843, he became one of the committee. He was also a member of the United Service Institution, of the Irish Archæological Society, of the Numismatic Society, of the Hakluyt Society, and he was perpetual president of the club of antiquarians called the Society of Noviomagians. He had collected an extremely interesting museum of Irish antiquities, which was sold by auction after his death. He died at his residence, Old Brompton, London, August 8, 1854.

CROMFORD. [DERBYSHIRE.]

CRONSTEDITE. [MINERALOGY, *S.* 1.]

CROSSE, ANDREW, a celebrated experimenter on electricity, was borne at Fyne Court, in the parish of Bromfield, on the Quantock Hills in Somersetshire, on June 17, 1784. His father was the proprietor of the estate, to which he succeeded in 1800. He was educated at the school of the Rev. M. Sayers, at Bristol, where he had for school-fellows W. J. Broderip, the Rev. John Eagles, and other equally celebrated men. In 1802 he matriculated at Brasenose College, Oxford, where he was very uncomfortable, the habits, especially that of drinking, being particularly unsuited to him. He returned home in June 1805, on account of the illness of his mother, who shortly afterwards died. Even when at school he had become greatly attached to the study of electricity, and on settling on his paternal estate he devoted still more of his attention to the subject. He provided himself with electrical apparatus, and pursued his experiments wholly independent of theories, and searching only for facts. In a cavern near his residence, called Holwell Cavern, he observed the sides and roof covered with arragonite crystallisations, and his observations led him to conclude that the crystallisations were the effects, at least to some extent, of electricity. This induced him to make the attempt to form artificial crystals by the same means, which he began in 1807. He took some of the water from the cave, filled a tumbler, and exposed it to the action of a voltaic battery, excited by water alone, letting the platinum wires of the battery fall on opposite sides of the tumbler from the opposite poles of the battery. After ten days of constant action he procured crystals of cabonate of lime, and subsequently by altering the arrangements he produced them in six days. He found however that darkness was essential to the certainty and rapidity of their production. He carried an insulated wire above the tops of the trees around his house to a length of a mile and a quarter, afterwards shortened to a distance of 1,800 feet. By this wire, which was brought into connection with his apparatus in a chamber, he was enabled to see continually the changes in the state of the atmosphere, and could use the fluid so collected for a variety of purposes. In 1816, at a meeting of country gentlemen, he prophesied "that, by means of electrical agency, we shall be able to communicate our thoughts instantaneously with the uttermost ends of the earth." But though he foresaw the powers of the medium, it does not appear that he took any means towards fulfilling his prophecy, or even made any experiments in that direction; he continued to confine himself to the endeavour to produce crystals of various kinds, in which he eminently succeeded, having ultimately obtained forty-one mineral crystals, or minerals uncrystallised, in the form in which they are produced by nature, including one, sub-sulphate of copper, an entirely new mineral neither found in nature nor formed by art previously. His belief was, that even diamonds might be formed in this way. Still he worked alone; he published none of his experiments to the world, and he propounded no theories. At length, in 1836, the British Association for the Advancement of Science held its meeting in Bristol, and Mr. Crosse attended it, intending to be an auditor only; but having mentioned his discoveries to some of the scientific gentlemen there, he was induced to explain them publicly, and though unprovided with apparatus, they were so struck with the importance of them, that he was publicly complimented by the president, the Marquis of Northampton, and by Dr. Buckland, Dr. Dalton, Professor Sedgwick, and others. A few months after this meeting, while pursuing his experiments for forming crystals from a highly caustic solution out of contact with atmospheric air, he was greatly surprised by the appearance of an insect. Black flint, burnt to redness and reduced to powder, was mixed with carbonate of potash and exposed to strong heat for fifteen minutes. The mixture was poured into a black-lead crucible in an air furnace. It was reduced to powder while warm, mixed with boiling-water, kept boiling for some minutes, and then hydrochloric acid was added to supersaturation. After being exposed to voltaic action for twenty-six days a perfect insect, of the Acari tribe, made its appearance, and in the course of a few weeks about a hundred more. The experiment was repeated in other chemical fluids with the like results, and Mr. Weeks, of Sandwich, afterwards produced them in ferrocyanuret of potassium. This discovery occasioned great excitement at the time. The possibility was denied, though Mr. Faraday stated in the same year that he had seen similar appearances in his own electrical experiments; and he was accused of impiety, as aiming at creation. He was much hurt by these attacks, for he was a truly pious man. He says he was inclined to believe that the insects were formed from ova in the water, but failed to detect any; and adds, "I have formed no visionary theory that I would travel out of my way to support." He attempted to give no explanation of what he admitted he could not comprehend, and in answer to a person who had written to him, calling him "a reviler of our holy religion," he replied that he was sorry if the faith of his neighbours depended on the claw of a mite. These insects, if removed from their birthplace, live and propagate, but uniformly die on the first recurrence of frost, and are entirely destroyed if they fall back into the fluid whence they arose. This was the most remarkable of his discoveries; but his labours were in some instances more useful. He invented a method, which was patented by others, for purifying sea-water by electricity, which water possessed peculiar antiseptic properties; this process was also capable of being used for the improvement of wines, by removing the predominance of bitartrate of potash; to the improvement of spirits by removing acidity; and to the stopping of the fermentation of cider. He also made experiments of the effects of electricity on vegetation. He found that positive electricity advanced the growth, as was shown by the cultivation of two vines by Mr. Boys of Margate; and that negative electricity favoured the growth of fungi, and produced something like the rot in the potato. But Andrew Crosse did not confine his labours to scientific matters. Though living chiefly on his estate in the country, he took an earnest part in all local affairs. He was an active magistrate, just, but benevolent; he advocated the instruction of the poor, and he gave lectures on various subjects to the neighbouring institutes; he left a quantity of poetry, considerably above mediocrity, which he could not be induced to publish in his lifetime, but which has been given to the world by his widow, in a memoir of him written with much good taste; and he died, after a short illness, July 6, 1855, leaving behind him the character of a pious good man, and an indefatigable searcher for truth.

CROTCH, WILLIAM, Doctor of Music, was born in 1775, in the city of Norwich. While yet a child, he exhibited faculties of musical perception and execution which were quite marvellous, and rival those of Mozart. An account of his precocious talents was given by Dr. Burney, author of the 'History of Music,' and is printed in the 'Philosophical Transactions' for 1779, when the infant prodigy was only four years of age. Some anecdotes are also extant, written by the Hon. Daines Barrington, who says, "I first heard little Crotch on the 10th of December, 1778, when he was only three years and a half old." The following notices are extracted from the memoranda which he made on returning home: "Plays 'God save the King' and 'Minuet de la Cour' almost throughout with chords; reaches a sixth with his little finger; cries 'no,' when I purposely introduced a wrong note; delights in chords and running notes for the bass; plays for ten minutes extemporary passages, which have a tolerable connection with each other; seldom looks at the harpsichord, and yet generally hits the right intervals, though distant from each other. His father is an ingenious carpenter of Norwich, and had made an organ. His organ rather of a hard touch. Many of his passages hazarded and singular, some of which he executed by his knuckles, tumbling his hands over the keys. The accuracy of this child's ear is such that he not only pronounces immediately what note is struck, but in what key the music is composed."

As Crotch advanced in years he became a profound theorist and a skilful composer. In 1797, at the early age of twenty-two, he was appointed Professor of Music in the University of Oxford, and the university also conferred on him the degree of Doctor of Music. In 1822 he was appointed Principal of the Royal Academy of Music. He performed in public for the last time in 1834 in Westminster Abbey, during the royal festival, when he presided at the organ on the third day. Dr. Crotch composed a very large number of pieces for the organ and pianoforte, the opera of 'Palestine,' and some pleasing vocal pieces, among which may be mentioned the fine ode for five voices, 'Mona on Snowdon calls.' He also published 'Elements of Musical Composition and Thorough-Bass,' 1812, and 'Specimens of various Styles of Music of all Ages,' 3 vols.

Dr. Crotch, during the latter years of his life, resided at Taunton, Somersetshire, with his son, the Rev. W. R. Crotch, master of the free grammar-school. He died December 29, 1847, when sitting at the dinner-table.

CROZIER, CAPTAIN FRANCIS RAWDON MOIRA, second in command of the ill-fated Franklin expedition, was born at Banbridge, county Down, Ireland. He entered the navy in June 1810, and, under the command of Sir Thomas Staines, he sailed in the Briton to the Pacific, and visited Pitcairn's Island, which was found peopled by the descendants of the mutineers of the Bounty. In 1824 he was appointed master's-mate of the Fury, and he accompanied Parry in three of his voyages to the Polar Sea.

In 1826 Mr. Crozier was made lieutenant, and was employed on the coasts of Spain and Portugal till December 1835, when he sailed with Captain (now Sir) James Ross, to search for the missing whalers in Baffin's Bay. His reputation for science, seamanship, and fertility of resource, secured his promotion; and he commanded the Terror in the expedition under Sir J. Ross for the exploration of the antarctic regions, which sailed in 1839, and was absent three years. In March 1845 he was re-commissioned to the Terror, and sailed with Franklin to discover the North-West Passage: since which time he has not been heard of. He was in the prime of life on his departure, and died probably in his fiftieth year. He was a Fellow of the Royal and Astronomical societies, and was distinguished as much for devotion to duty as for love of science.

CRUDEN, ALEXANDER, the author of the well-known Concordance, was born at Aberdeen in 1701. He studied at Marischal College, but whilst there, his conduct was marked by eccentricities similar to those which characterised his later years, and, as it was found necessary to abandon his intention of becoming a minister of the Church, he came to London in April 1724, and subsisted by giving lessons in Greek and Latin. Afterwards he obtained a situation as tutor, and in that capacity resided for some time in the Isle of Man. In 1732 he opened a bookseller's shop under the Royal Exchange, and occupied his leisure hours in the preparation of his 'Concordance of the Old and New Testament,' which appeared in 1737. It was dedicated to Queen Caroline, and Cruden had calculated sanguinely on her majesty's favour. The queen died however just after the publication of his book, and the disappointment brought out his latent insanity. He was removed to a private lunatic asylum at Bethnal-green, where he was confined from March 23 to May 21, 1738, when he escaped. He persisted in asserting that he was of sound mind, and brought an action against the keeper of the asylum and others; but as might be supposed, the jury was directed by the judge to find a verdict for the defendants.

Cruden published an appeal to the public, under the title of 'Mr. Cruden greatly Injured on account of a Trial between Mr. Alexander Cruden, bookseller to the late Queen, plaintiff, and Dr. Monro, Matthew Wright, John Oswald, and John Davis, defendants, in the Court of Common Pleas, in Westminster Hall, July 17, 1739, on an action of Trespass, Assault, and Imprisonment . . . . with an account of several other Persons, who have been most unjustly confined in Private Madhouses. The whole tending to show the great necessity there is for the Legislature to regulate Private Madhouses in a more effectual manner than at present,' 8vo, 1739. Cruden, who appears to have been treated while in the asylum with great brutality, now found employment as a reader of printers' proof-sheets, and in the occasional preparation of indexes. Among others he is said to have compiled the elaborate index to Newton's 'Milton.'

He now published the first part of a strange kind of autobiography, under the title of the 'Adventures of Alexander the Corrector.' A second time it was deemed necessary to place him under temporary restraint at Chelsea; and again he brought an action in the Court of King's Bench against the parties who had restrained him, with as little success as before. On obtaining his liberty he quietly returned to his ordinary occupations. Subsequently he published the second part of his Adventures, in which he gave the history of his second confinement, or 'Chelsea Campaign,' as he calls it in his title-page; and also an account of the trial, and endeavoured in vain to obtain an audience of the king, in order to present a copy of the two parts. He also, as he says, "pleaded very hard that the honour of knighthood might be conferred upon him," the object being "to fulfil the prophecy about being made a member of parliament for the city of London." He seems to have actually got himself nominated (April 30, 1754) as a candidate for the city; but he acknowledges that few hands were held up for him. In 1755 he published the third part of his Adventures, in which he relates the ill-success of a motion he made in person for a new trial; of his applications for knighthood, and for admission into the House of Commons; but the chief part is taken up with a 'History of his Love Adventures, with his Letters, &c., sent to the amiable Mrs. Whitaker, a lady of shining character and of great eminence,' in which he was as unlucky as in other matters. Impressed with a belief that he had a mission to reform the public manners, he went to preach to the prisoners in Newgate, and then made a journey to Oxford in order to preach to the students at the university. Disgusted at the reception he met with, he abandoned preaching, but arming himself with a large sponge, he went about the streets removing any expressions on the walls which appeared to him offensive to decency; and when the affair of Wilkes and No. 45 of the 'North Briton' was exciting so much public ire, his loyalty led him to the active use of his sponge in effacing the offensive number. His insanity seems to have expended itself in this harmless manner. He continued to pursue his ordinary employments, and found time to enlarge and revise his Concordance. He also published 'Alexander the Corrector's Humble Address;' and other pamphlets relating to the reformation of manners, the American war, &c., all marked by strong indications of insanity. He died at Islington in November 1770. Cruden's 'English Concordance' was far more complete and valuable than any preceding one, and it still retains its value. Three editions of it were published during Cruden's lifetime, the last and the best in 1769; it has since gone through innumerable editions of all degrees of correctness: one of the most esteemed is that of 1810.

CUBITT, THOMAS, was born in 1788, and was the son of a labouring man at Buxton, a village in Norfolk. Thrown early on his own resources, and denied the advantages of what is called a liberal education, he nevertheless rose into eminence by skill and industry combined with integrity, and amassed a large fortune by the improvements which he effected in the architecture and sanatary arrangement of London. His father died while he was still a youth. The trade to which he was brought up was that of a carpenter. He worked at the bench for some time, and then went out to India in the capacity of ship's carpenter. Having accumulated some small amount of money during his voyage out and home again, he became a master-carpenter and then a builder in Gray's-Inn-Road. He was here engaged to build the Metropolitan Institution in Finsbury-Circus. About 1823 he contracted for the improvement of the property of the late Duke of Bedford in the neighbourhood of Russell and Tavistock squares, and a year or two later entered into a similar engagement with the late Marquis of Westminster and Mr. Lowndes for erecting mansions on their property between Knightsbridge and Westminster. The skill with which he laid out and built what is now frequently called 'Belgravia,' recommended him to the late Mr. Kemp, who employed him to build Kemp Town at Brighton. He subsequently laid out and built Clapham Park, and Southern Belgravia, including Warwick and Eccleston squares at Pimlico. Mr. Cubitt was one of the first persons to propose a comprehensive scheme of draining London by carrying the sewerage to a point in the river Thames considerably below the city. He was also the author of other sanitary plans for the prevention of nuisances from smoke, &c., and the appropriation of open spaces in the suburbs of London as parks for the people. When her Majesty and Prince Albert determined on rebuilding Osborne in the Isle of Wight, the work was entrusted to Mr. Cubitt. For several years Mr. Thomas Cubitt held the honorary post of examiner of candidates for district surveyorships, and at one time was president of the Builders' Society. Himself originally a working man, he felt and laboured for the working classes. Thus he erected a workman's library and school-room near his establishment at Thames Bank, and devised a plan for supplying their families with the comforts of life from his own premises. On one occasion, when his large works at Thames Bank were burnt down, thinking nothing of his own loss, he commenced at once a subscription for replacing the tools of his workmen. He died rather suddenly at Denbies, Surrey, December 26, 1855, having just finished his mansion there, and completed his contracts in Belgravia. His brother, Mr. Alderman William Cubitt, formerly his partner in Gray's-Inn-Road, was sheriff of London in 1847, and has represented Andover in parliament since that date.

CUCKOO-FLOWER. [CARDAMINE, *S.* 1.]

CULLEN, Scotland, a royal and parliamentary burgh and sea-port in the parish of Cullen, on the northern coast of Banffshire, in 57° 42′ N. lat., 2° 50′ W. long., about 13¼ miles W. from Banff. The population of the parliamentary burgh in 1851 was 1697, that of the royal burgh was 3165. The town is built on the western acclivity of a hill which slopes to the margin of the sea, and is nearly in the centre of the Bay of Cullen. The burgh is governed by 19 councillors, including a chief magistrate, three bailies, and a dean of guild; and with Elgin, Banff, Inverury, Kintore, and Peterhead, returns one member to the Imperial Parliament.

Cullen consists of two parts, the New Town, which stands on an elevation, and the Sea Town or Fish Town, which is situated on the shore, and inhabited chiefly by fishermen. In New Town the houses are good and the streets are regularly laid out and lighted with gas. The Sea Town is a collection of mean irregularly built houses. The harbour is good, though the depth of water at the pier head is only 8½ feet at neap tides. A few vessels belong to the port, varying from 40 to 100 tons. Besides the parish church, which is of considerable antiquity, there is another church of the Establishment, and a Free church. The Cullen hotel is a large building, to which are attached the assembly-room, a court hall, used for the sheriff and justice of peace courts, and the council chamber of the burgh. One third of the inhabitants of the town are engaged in the fisheries. The deep-sea fishing for cod, skate, and ling commences in February and ends in May. The June fishings are for haddocks, which are dried into speldings; the herring fishing occupies July and August. In the bay is a salmon fishery. The principal imports are coals, salt, and staves, with barley for distillation at a distillery in the neighbourhood; the exports are herrings, dried fish, oats, and potatoes. Boat building is carried on to a considerable extent. There is a parochial library. Cullen was erected into a royal burgh by Robert the Bruce, though traditionally its corporation privileges are said to be derived from Malcolm Canmore. The town was burned down in 1645 by Montrose. The Earl of Seafield is landlord of the whole parish.

CULROSS. [PERTHSHIRE.]

CUMBRAE. [BUTESHIRE.]

CUMBRIAN ROCKS. The succession of rocks, as pointed out by Professor Sedgwick in the Cumberland hills, is as follows:—

1. Skiddaw Slate, usually without fossils, but containing *Graptolites* in one locality.
2. Coniston Limestone, abounding in fossils.
3. Coniston Flagstone and Grit.

These rocks find their representatives in those called Cambrian in North Wales. These latter rocks are included by Sir Roderick Murchison in his 'Silurian System.' As the nomenclature of these rocks is still a disputed question, we subjoin the account of them published by Mr. Jukes, in his work on 'Physical Geology.'

"Cambrian or Cumbrian Rocks.—The word 'rocks' is used here instead of 'system,' or 'formation,' because we cannot yet precisely tell the value of the Cambrian division. Cambrian means the rocks of Wales; Cumbrian those of Cumberland and Westmoreland. In Wales these rocks consist of certain thick sandstones, gritstones, and conglomerates, with interstratified beds of green or green and purple slates. It is in the uppermost of the slate beds of this Cambrian group that the great Penrhyn and Llanberrie slate quarries are opened. They contain no fossils. These rocks are found to have a thickness of upwards of 20,000 feet in some places in North Wales; but as the base of them is never exposed, we know not how much greater thickness they may possess, nor what is below them. One portion of this division has been provisionally called the 'Barmouth and Harlech Sandstone Group.' Their upper boundary is a purely arbitrary line along the top of a certain set of beds drawn by the officers of the Geological Survey of Great Britain, under the direction of Sir H. T. De la Beche, C.B.; their reason for drawing it being simply that no fossils have as yet been found below that line, whereas fossils are pretty abundant in many places above it. It must not be forgotten that Professor Sedgwick (of whose peculiar department we are now speaking, he being the one geologist who has single-handed done far the most to unravel the structure of these older rocks) dissents from this placing of the boundary of the Cambrian Rocks; and himself places it much higher, so as to include the beds we shall subsequently speak of, as Lower Silurian, dividing his system into Upper and Lower Cambrian. There can be no doubt that if we neglect the fossils, and look only to the physical structure and position of the rocks of Wales, Professor Sedgwick is right. There can be no reason for drawing the boundary where it has been drawn, and along no other geological horizon in North Wales, except the fact that fossils have been found in all the rocks above that line of division, and in none of those below. Whether they may not hereafter be found is another question. If we go to Cumberland, Professor Sedgwick there describes the Cambrian, or, as he there calls them, Cumbrian Rocks, as likewise consisting of upper and lower, and gives the following abstract of them:—

		Feet.
Cumbrian, Upper	Coniston Flagstone . .	1500
	Coniston Limestone . .	300
	Slates and Porphyry . .	10,000
Cumbrian, Lower—	Skiddaw Slate . . .	6000

He describes these however as all fossiliferous, which, by the rule lately mentioned, would exclude them from being considered as Cambrian at all, more especially as the fossils of the upper beds are such as palæontologists seem agreed to consider of Silurian age. It is highly probable that the Skiddaw Slates are of the same age as the Barmouth and Harlech Sandstone Group of North Wales, which likewise contains the best roofing-slates of that country. In that case, according to the classification adopted by the Geological Survey, the Skiddaw slates would be considered Cambrian, and all above them as Silurian. The reader will see from these statements that this part of the classification of the stratified rocks is far from being settled. There is however no dispute about the things themselves; the rocks are all known, and their order completely ascertained; the uncertainty is merely as to the name by which certain portions of them shall be called."

CUMIDINE. [CHEMISTRY, *S.* 2.]

CUMMINGTONITE, an American mineral belonging to the hornblende series. It is fibrous, of an ash-gray colour, with a slight silky lustre. It is found at Cummington and Plainfield, in Massachusetts. (Dana, *Mineralogy*.)

CUMNER. [BERKSHIRE.]

CUNITA, a genus of plants belonging to the natural order *Labiatæ*. It has a 13-nerved calyx, ovate, tubular, equal, 5-toothed, the throat villous inside. The corolla having the tube equalling the calyx, naked inside, and the limb bilabiate; the upper lip erect, flattish, usually emarginate; lower lip spreading, trifid, with nearly equal entire lobes, the middle lobe rather the largest and emarginate. The stamens 2, erect, exserted, without any rudiments of the upper two; filaments glabrous, toothless; anthers 2-celled, cells parallel, or at length divaricate. The style shortly bifid at the apex; the lobes nearly equal, subulate, minutely stigmatiferous at top; the achenia dry and smooth. The flowers small, white, or purplish. The species are herbs, shrubs, or under-shrubs.

C. Mariana, native of Canada to Carolina, on dry mountains, is a branched herb with short glabrous branches, but pubescent at the nodes. The corolla is about twice as long as the calyx, and is pubescent inside, and of a red colour. It is employed medicinally, where it grows, in slight colds and fevers, with a view to excite perspiration.

C. microcephala is also used medicinally in coughs and colds, in Brazil, where it grows. It has a procumbent stem, with scarcely pubescent branches; the leaves petiolate, oblong, or obovate, obtuse, quite entire, or subsinuately serrated, narrowed at the base, glabrous, and flat. The corolla is white; the throat villous inside.

There are several species of this genus, none of which are of any known use except those above mentioned.

CUPAR-ANGUS. [PERTHSHIRE.]

CUPULE, a kind of cup or involucre surrounding certain kinds of fruit, and composed of bracts more or less grown together. In the oak the cup of the acorn is the cupule; in the hazel-nut it is the husk; in the beech and chestnut the prickly shell; and in the hornbeam the lobed bract.

CURASSOW. [CRACIDÆ.]

CURRAN, JOHN PHILPOT, was born on July 24, 1750, at Newmarket, in the county of Cork, Ireland. His parents were respectable, but not wealthy; his father having been an officer to a manorial court, and possessing the advantages of a classical education. His mother, perceiving early indications of talent, was in hopes of his becoming a clergyman, and efforts were accordingly made to procure him a suitable education. Being Protestants, they first procured him some instruction from the Rev. Nathaniel Boyse, the resident clergyman, with whom he maintained a continued friendship. He was next sent to the Free Grammar-School at Middleton, and afterwards entered as a sizar in Trinity College, Dublin. After acquiring a considerable proficiency in classical learning at that university, he abandoned his first intention of entering the church, and determined to adopt the profession of the law. Accordingly, having passed through the university with great credit, he went to London, and entered himself at the Middle Temple in 1773. Here his straitened means occasioned him some inconveniences, but he studied law with considerable assiduity, and practised oratory at some debating societies, where he is said to have displayed his talent for energetic and sarcastic speaking. In one of the vacations, between the terms, he returned to Ireland, and married a daughter of Dr. Creagh in 1774. With her he received a small portion, which somewhat smoothed the remainder of his term of probation, and, in 1775, he was called to the Irish bar. His success was almost immediate. His style was precisely suited to the Irish courts; humourous, discursive, often flowery and poetical, vehemently appealing to the feelings, never wearying by dry legal arguments, but when urging them enlivening their dryness by occasional witty or satirical illustrations, and he soon obtained a leading business. His social habits also operated in his favour, and though he had already adopted a political belief in opposition to the reigning government, he was a general favourite even with his political opponents, while his independent bearing to the judges won him the favour of the public. The fearlessness of his addresses however sometimes brought its inconveniences. As counsel in an action for assault by the Marquis of Doneraile on a poor old Roman Catholic clergyman, he had styled Mr. St. Leger, one of the witnesses for the defence, "a renegado soldier, a drummed-out dragoon:" a duel followed, when he declined returning Mr. St. Leger's fire, and the affair ended. He had been always a warm politician, and in 1782 he was returned to parliament as member for Kilbeggan, on the interest of a Mr. Longfield. As a specimen of the state of the Irish parliament, we may mention that soon after entering the House of Commons he found himself differing in political opinions with his patron, and as he had no way of vacating his seat he coolly offered to buy another seat, to be filled by any one Mr. Longfield might choose to appoint. That gentleman declined the offer; but in the succeeding parliament Mr. Curran bought a seat for himself. In the House of Commons he soon took a leading part, generally acting with Mr. Grattan and the few liberal members who then had seats. His speeches were of a very similar character to those he made at the bar, and he was often appointed to make the reply from his readiness and happy facility in retorting charges or damaging the positions of his opponents. He supported the formation of the Irish Volunteers in 1788, and the unconditional appointment of the Prince of Wales to the regency on the occasion of the king's illness in 1789, and his attacks on the government led to a duel, first with Mr. Fitzgibbon, afterwards Earl of Clare, and then with Major Hobart, in which Mr. Curran was the challenger, in both of which neither party was injured. It was in 1794 and the few subsequent years that Mr. Curran's reputation attained its climax. In the House of Commons, Mr. Curran, Mr. Grattan, and others, had been continually pointing out to the government that their measures were driving the people towards rebellion. The warnings were unheeded, and in 1794 Mr. Hamilton Rowan was indicted for a seditious libel issued in the form of an address to the volunteers of Ireland from the society of United Irishmen (not the same as the rebellious societies which aftewards took this name), of which he was secretary. Mr. Curran was his counsel, and made an eloquent and vigorous defence, but Mr. Rowan was convicted and sentenced to imprisonment; and after the breaking out of the rebellion in 1798 he was the counsel generally employed by the accused, among whom the most remarkable were the two brothers Sheares, Theobald Wolfe Tone, and Napper Tandy. He had retired from the Irish House of Commons before the introduction of the measure for the Union, of which he strongly disapproved, and which he ever continued to lament. The insurrection of 1803 brought trouble into his family; Robert Emmet, one of its leaders had formed an attachment for Miss Sarah Curran, which was returned; and his correspondence with her, with his visits, sometimes secretly, to her father's house, led to a suspicion of Mr. Curran's loyalty, and to the searching of his house. He instantly waited upon the Attorney-General Standish O'Grady, and the privy council, by all of whom his perfect want of complicity was instantly admitted. Mr. Emmet had named him one of his counsel, but he did not act. Mr. Emmet was convicted and executed; his fate and his love adventure form the subject of two of Moore's 'Irish Melodies.' Upon the death of Mr. Pitt, in 1806, the Whig ministry under Lord Grenville created Curran Master of the Rolls in Ireland. This appointment did not give him satisfaction; it withdrew him from politics, and as his mind was not judicial, he felt himself out of place: he thought he had been neglected, and his health declined. He held the office till the early part of 1813, when he resigned; and he died in London on October 14, 1817. Mr. Curran in the course of his life wrote a considerable amount of verse of more than ordinary merit, but which bears no comparison with his eloquent speeches.

CURSITOR BARON. This office, or rather sinecure, was abolished by the statute 19 & 20 Vict. c. 86, which also makes provision for the performance of its almost nominal duties.

CUSHAT (*Columba dilopha*). [COLUMBIDÆ.]

CYAMELIDE. [CHEMISTRY, *S.* 2.]

CYANOGEN, CHLORIDE OF. [CHEMISTRY, *S.* 1.]

CYANURIC ACID. [CHEMISTRY, *S.* 1.]

CYCLADIDÆ, a family of Lamellibranchiate *Mollusca*. It is a group of fresh-water mollusks, whose shells resemble those of *Kellia* or of *Astarte*, but whose soft parts present structures conspicuously distinguishing them from the tribes to which either of those genera belongs.

The shells are more or less tumid, equilateral or inequilateral, thin, as in our British forms, or thick, as in the foreign *Cyrenæ*; smooth or concentrically striated and furrowed, and covered with an epidermis. The hinge is furnished with cardinal and lateral teeth, and the ligament is external

The animals have plain-edged mantles open in front, siphonal tubes produced, and either partially separated or completely united to their unfringed extremities, and a large linguiform foot. They live buried in the mud of slow streams, lakes, ponds, ditches, and springs. Our native species are all ovoviviparous. They breed readily in confinement, and often exhibit considerable activity, ascending the sides of the vessel in which they are placed. (Forbes and Hanley.) This family contains two British genera, *Cyclas* and *Pisidium*.

Cyclas has the shell equivalve, thin, suborbicular, more or less inflated, slightly inequilateral, closed, smooth, or concentrically striated; cardinal teeth, one in the right and two in the left valve; lateral teeth developed; ligament external.

C. rivicola has the shell oval, globose, striated; umbones obtuse; dorsal area with a small lunular impression; ligament manifest.

The ordinary length of the finer specimens is 10½ lines, and its breadth about two-thirds of an inch.

The tubes of the animal are tinged with rose or tawny, and when fully protruded are nearly equal, the branchial, if either, being longest.

The foot is large, white, and linguiform; the mantle white; the labial palps long, triangular, and strongly striated. It is sluggish in its habits.

Forbes and Hanley give the following localities:—The most prolific is the river Thames; it is found likewise in the New River (Baily); the Trent (Jenyns); the Lea (S. H.); the canals about Leamington, in Warwickshire (Thompson); streams in Yorkshire (Bean). In a pond at Enville, Staffordshire, a young specimen (Jeffreys). It has not been taken either in Scotland or Ireland. On the continent it occurs in Germany, France, and Belgium; and as a fossil is found in the Pleistocene Fresh-Water Beds of the south of England.

C. cornea, Linn. Shell suborbicular, almost smooth; umbones obtuse; ligament inconspicuous. There is a subglobose variety (apparently the *Stagnicola* of Mr. Sheppard), which is flattened towards the ventral margin, and has the pellucid and swollen umbones peculiarly prominent. The dimensions of the larger typical form are six lines and a quarter in length, and five lines in breadth; of the variety five lines and a half in length, and four and three-quarters in breadth.

The animal is white, its sub-elongated siphonal tubes tinted with pale flesh-colour. Mr. Jenyns observes that the superior tube is sub-conic, with a small aperture, the inferior cylindric and truncate, with a wider aperture.

This very common species is a general inhabitant of rivers, ponds, and ditches throughout the country. It appears to thrive equally well both in running and in stagnant water. (Jenyns.)

It is also generally distributed throughout Europe, and occurs fossil in fresh-water strata of the pleiocene age in the valley of the Thames.

C. caliculata has the shell more or less rhombic; umbones narrow, more or less prominent, capped.

This species is apparently less infrequent in the north than in the more southern parts of England. Mr. Alder has found it near Newcastle; Mr. Bean at Scarborough (where it is not scarce); Mr. Thompson at Lichfield; and Captain Brown records the vicinity of Manchester and the lakes of Westmoreland for its localities. Montagu met with it in Devonshire and Wiltshire; Mr. Jenyns at Bookham Common in Surrey, and more sparingly in Cambridgeshire; and Mr. H. Strickland at Hornsea in Yorkshire. Mr. Jeffreys has taken it in the Clumber Lake, Nottinghamshire, and in the neighbourhood of Bristol. In Ireland it is also rare. "On the Continent it occurs in Sweden, Germany, Belgium, France, and Italy. The *C. partumeia* of Say, in despite of the ventricosity of the adult, is very closely allied, especially in outline, to this species, and may be regarded as its transatlantic representative." (Forbes and Hanley.)

Pisidium has the shell equivalve, thin, usually tumid, sub-oval, inequilateral, smooth or concentrically striated; hinge with one tooth in the right and usually two in the left valve; also lateral teeth; ligament external, inserted at the shorter side.

The species are very small bivalves, living in similar localities with *Cyclas*, and not uncommon even in drains through meadows.

P. pusillum. Shell rounded, oval, not greatly inequilateral, not distinctly striated; valves not swollen, always a little compressed below; umbones usually broad, and but little projecting. This is by far the commonest of the smaller *Pisidia* in this country. It is found abundantly in ponds and ditches. It inhabits generally northern and central Europe.

P. pulchellum. Shell small, striated (not grooved); umbones simple and without appendages. There are many varieties of this shell. It has a great tendency to assume a multiplicity of forms. The average size is a line and a half long, and a line and a quarter broad. It is very common in many parts of Great Britain.

The other British species of this genus are *P. Henslowianum*, *P. nitidum*, *P. cinereum* and *P. obtusale*.

CYRILLACEÆ, *Cyrillads*, a natural order of Exogenous Plants. The order consists of shrubs with evergreen simple leaves without stipules. The flowers usually in racemes. The calyx 4-5-parted. It has 5 distinct petals, with an imbricated æstivation. The ovary is 2-3-4-celled, always composed of some number of carpels different from that of the calyx, corolla, and stamens; solitary pendulous ovules, a short style, the stigma with as many lobes as there are cells of the ovary. The fruit is a succulent capsule or a drupe; the seeds inverted; the embryo in the axis of a very large quantity of albumen, with a very long superior radicle. This order is related to *Olacaceæ* and *Pittosporaceæ*. All the species are inhabitants of North America. Nothing has been recorded of any uses to which they are applied.

CYTHERE, a genus of entomostracous *crustacea*, belonging to the legion *Lophyropoda*, the order *Ostracoda*, and the family *Cytheridæ*. The species are found very commonly in Great Britain. [BRANCHIOPODA.] Mr. Rupert Jones, in his 'Monograph of the Entomostraca of the Cretaceous Formation of England,' describes five fossil species belonging to this genus. [ENTOMOSTRACA.] The same author describes ten species of this genus as fossil in the Permian Rocks of England.

Cythereis is a genus separated from the group of species known as *Cythere* by Mr. R. Jones. It has the following characters:—The animal is unknown. Carapace-valves or shell of an almost regular oblong shape, the dorsal and ventral margins lying nearly parallel to each other. Surface of a very irregular appearance, being wrinkled, ridged, and beset with tubercles, and crenulated or strongly toothed on the margins.

Dr. Baird has described three recent species, whilst nine fossil forms have been described by Mr. Jones from the chalk.

Bairdia is a group of species formerly referred to *Cythere*, and separated by M'Coy. The valves externally are convex and smooth, sometimes finely pitted or spined, never ribbed or granulated; the hinge is simple.

This genus has no recent species. Six species have been found in the chalk.

Cytherella, a genus separated by Jones from *Cythere*. It embraces species of *Cytherina* of other authors. The carapace valves are oblong, and vary in the convexity and smoothness of the surface; the right valve is larger than the left, and its contact margin thicker than that of the opposite valve. Six fossil species have been described from the chalk.

(Rupert Jones, *Monograph of the Entomostraca of the Cretaceous Formations of England*; W. King, *A Monograph of the Permian Fossils of England*, both published by the Palæontographical Society; Baird, *Natural History of the British Entomostraca*—Ray Society.)

D

DACRIDIUM, a genus of Gymnogenous Plants belonging to the natural order *Taxaceæ*. One of the species, *D. taxifolium*, the Kakaterra-Tree of New Zealand, acquires a height of 200 feet. From its branches may be manufactured a beverage resembling in antiscorbutic qualities the well-known spruce-beer.

DADYLE. [Chemistry, *S.* 2.]

DAGUERRE, LOUIS JACQUES MANDÉ, was born in 1789 at Cormeille in the department of Seine-et-Oise, France. At the outset of life he obtained a situation in a government office, but he early quitted that employment, and became a pupil of M. Degoti, scene-painter at the opera. As a scene-painter, Daguerre in a few years surpassed his instructor, and placed himself on a level with the first professors of that art in Paris, while he quickly extended the capabilities of the art by various ingenious contrivances, which he invented for producing increased pictorial effect. He also assisted M. Prévost in the preparation of his panoramic views of the great cities of the world. The experience he thus acquired suggested to M. Daguerre the idea of producing a kind of scenic exhibition, in which the illusion should be more perfect than in the panorama, and he invented, in conjunction with Bouton, a method of so throwing coloured lights and shadows upon the view, as to produce the appearance of changes of season, day and night, storm and sunshine, &c. This they termed a Diorama, and when exhibited, July 1822, in a circular structure erected for the purpose in Paris, the success was complete. The diorama in fact made what the Parisians term a sensation, and no long time elapsed before Messrs. Bouton and Daguerre erected a similar building in London, to which each picture was removed, when it had been exhibited for its season in Paris. For some seventeen years picture followed picture, each rivalling its predecessor, but in 1839 a fire destroyed the building, and the view then exhibiting in it. Daguerre's loss was very great, and the building was not re-erected, as the public interest in dioramas, which had now lost their novelty, was beginning to flag.

M. Daguerre had before this been directing his attention to a matter which was destined to secure for him a more permanent reputation than his scenery or his dioramas. This was the mechanical production of fac-simile delineations of objects by the chemical action of light. As early as about the middle of the 16th century, Fabricius had discovered the property which salts of silver possess of changing colour when exposed to the action of light, and this property had been the subject of many experiments by scientific men. Sir Humphry Davy, among recent chemists, had sought by various applications of this property to obtain copies of simple objects, but though he succeeded in doing this, he was unable to prevent them from being effaced when exposed to the light. In France M. Niepce began about 1814 to pursue a similar course of experiments, and he succeeded in rendering the images he obtained insensible to the subsequent action of the light; but his discovery remained very incomplete when Daguerre commenced similar experiments. About 1829 Niepce and Daguerre joined in the prosecution of their investigations. Niepce died in 1833, before they had made any decided approach to success. But Daguerre persevered, and at length his zeal and rare ingenuity met with an ample reward. He discovered in fact a method by which he was able so to prepare metallic plates, that by placing them in the darkened chamber of a camera-obscura, they received a distinct impression of the images thrown upon them by the lens of the camera, which he was enabled by a subsequent process to render indelible. Some account of the steps by which he arrived at this grand discovery, the method adopted for producing, rendering visible, and fixing this sun-picture, is given elsewhere. [Photogenic Drawings; Photography, *S.* 1.] It will be enough to say that with remarkable patience and ingenuity he surmounted every difficulty, and eventually produced his discovery, as to its principles, perfect. Other experimentalists had in this country and elsewhere been at work, unknown to Daguerre, at the same idea, but to M. Daguerre is due the priority of publication of the discovery, and no doubt also the priority of discovery, as far as the producing sun-pictures upon metallic plates is concerned. What has proved to be the more generally applicable process of photography, was as unquestionably the result of the independent investigations of our own countryman, Mr. Talbot; but, as was to be expected, both the processes as now practised are very different from what they were when originally promulgated by their inventors or discoverers.

Great was the excitement among both learned and unlearned when in January 1839 M. Arago gave, at a sitting of the Académie des Sciences, an account of the new method by which, as was said, the sun himself became the artist, and some of the delineations, with all their wonderful delicacy of detail, were exhibited. At the same time Daguerre made a public exhibition of numerous pictures produced by what he termed the 'Méthode Niepce perfectionnée.' An examination of the merits of the new method was, at the suggestion of M. Arago, promptly ordered by the French government to be made, and in consequence of the favourable nature of the report, M. Daguerre was in June 1839 nominated an Officer of the Legion of Honour; and the project of a law was on the same day presented to the Chambers—by whom it was readily adopted—which accorded to M. Daguerre, on condition of the full publication of his method, an annuity for life of 6000 francs, and one of 4000 francs to the representative of M. Niepce. The rapid extension and improvement of the process of Daguerre (or the Daguerreotype, as it soon came to be generally called) after its being thus freely made public property, was due perhaps more to others than to M. Daguerre, who however never ceased to labour at its improvement during the remainder of his life. He died July 12, 1851, at Petit-Brie-sur-Marne, where a handsome monument has been erected by subscription to his memory.

M. Daguerre is the author of two short works—'Histoire et Description des Procédes du Daguerréotype, et du Diorama,' 8vo, Paris, 1839; and 'Nouveau Moyen de préparer la Couche Sensible des Plaques destinées à recevoir les Images Photographiques,' 8vo, Paris, 1844.

(Arago, *Rapport à l'Académie des Sciences;* A. de Lacaze, art. *Daguerre* in *Nouv. Biog. Gén.*)

DALBERGIA, a genus of Plants belonging to the natural order *Fabaceæ*, named in honour of Nicholas Dalberg, a Swedish botanist. It has a campanulate calyx, 5-toothed; a papilionaceous corolla, the petals of the keel connected to the apex; 8-10 stamens, sometimes all monadelphous, with the tube or sheath cleft in front, sometimes divided into two equal opposite bundles. It has a stipitate membranous compressed legume, which is flat, oblong, and tapers to both ends. The seeds, which vary from 1 to 3, are compressed and remote. The species are sometimes trees, but usually climbing shrubs, with impari-pinnate leaves.

D. Sissoo, has five alternate leaflets, glabrous above, pubescent beneath. It is a native of Bengal, where the timber is much prized, and is known by the name of Sissoo.

D. monetaria, another of the species, yields a resin very similar to Dragon's Blood.

There are about 22 species of this genus, none of which are of any known use except those mentioned.

DALKEITH, Edinburghshire, Scotland, a market-town and burgh of barony in the parish of Dalkeith, six miles S.E. from Edinburgh by road, and eight miles by the Edinburgh and Hawick railway. The population of the town was 5086 in 1851. The affairs of the burgh are administered by 15 trustees. The town stands on an elevated piece of ground, between the rivers North Esk and South Esk, and consists of one principal thoroughfare, and several small streets. The town is clean and generally well built; it is lighted with gas, and well supplied with water. Felt and beaver hats, straw hats, and woollen stuffs are manufactured, and there are corn-mills, a brewery, and a tan-work. The corn-market held here is one of the most important in Scotland. The parish church is an old Gothic building in the principal street. Attached to it is an ancient chapel containing the recumbent statues of an Earl of Morton and his lady. Adjoining this choir is the mortuary chapel of the Buccleuch family. A splendid new church, in the early English style of architecture, was built in 1840 by the Duke of Buccleuch. It is cruciform, and has a steeple 167 feet high. An elegant episcopal chapel is situated within the grounds of Dalkeith palace. The Free Church, United

Presbyterians, and Independents, have places of worship. In the town are two libraries and a savings bank. Dalkeith palace, the seat of the Duke of Buccleuch, is an extensive structure, surrounded by a splendid park and grounds. The mansion contains many fine paintings. The North Esk and South Esk unite their waters in the park, a little way beyond the palace, which is situated on an elevated peninsula formed by the two streams. The regality of Dalkeith belonged to the Grahams in the reign of David II. It afterwards passed into the hands of the Earls of Morton, and about two centuries ago was purchased by an ancestor of the Buccleuch family. Charles Edward spent two nights at Dalkeith after the battle of Preston Pans, and the palace has been visited by George IV. and Queen Victoria.

DALRYMPLE, JOHN, was born in the year 1804 at Norwich, where his father was a surgeon in general practice. He studied his profession under his father, in Edinburgh and in London. He commenced practice as a surgeon in London in 1827. During the latter part of his career he devoted himself entirely to ocular surgery. He died in 1852. As a surgeon-oculist he was better known for his work on the 'Anatomy of the Human Eye,' which was published in 1834. He was not however known only as a surgeon, but also as a naturalist and accurate microscopic observer. Amongst his papers on these subjects the following are the most important: 'On a Peculiar Structure in the Eye of Fishes,' published in the 'Magazine of Natural History,' sect. 2, vol. ii.; 'On the Vascular Arrangement of the Capillary Vessels of the Allantoid and Vitelline Membranes in the Incubated Egg' ('Transactions of the Microscopical Society,' vol. i.); 'On the Family of *Closterinæ*' ('Annals of Natural History,' vol. v.) In 1849 he read a paper before the Royal Society on a hitherto undescribed infusory animalcule allied to the genus *Notorumata* of Ehrenberg. This paper was interesting as confirming the discovery of the sexuality of the rotiferous animalcules, which had been made by Brightwell. This paper was published in the 'Philosophical Transactions,' and in 1850 Mr. Dalrymple was elected a Fellow of the Royal Society.

Mr. Dalrymple was one of the surgeons of the Royal London Ophthalmic Hospital. He was a Fellow of the Royal College of Surgeons of England, and in 1851 was elected a member of the council of that body.

DAMAGES. The stat. 1 Geo. IV. c. 87, enabling a landlord to recover damages in the action of ejectment by which he recovers possession, although not repealed, is superseded by provisions to the same effect in the 'Common Law Procedure Act,' 1852.

DAMAN. [DAMAUN.]

DANÆACEÆ, a small natural order of Plants related to the Ferns. They have all the habit of Dorsiferous Ferns, but their spore-cases are ringless and combined in masses, splitting irregularly by a central cleft. The species are all tropical. It embraces the following genera:—*Kaulfussia*, *Angiopteris*, *Danæa*, *Eupodium*, *Marattia*, and about fifteen species. *Angiopteris erecta* is said to be employed in the Sandwich Islands to perfume cocoa-nut oil. The rhizome of a species of *Marattia* is eaten by the Sandwich Islanders.

DANAITE. [MINERALOGY, *S.* 1.]

DANBURITE. [MINERALOGY, *S.* 1.]

DANEWORT. [SAMBUCUS.]

DARNEL. [LOLIUM.]

DATE-PALM. [PHŒNIX.]

DAVILLA, a genus of Plants belonging to the natural order *Dilleniaceæ*. It has 5 very unequal sepals, which increase after flowering; from 1 to 6 petals, with linear filaments dilated upwards. The single carpel is testaceous, from 1 to 2-seeded, inclosed in the two inner concave valve-like sepals. The seeds are solitary, enveloped in an arillus, which is only open at the apex.

D. elliptica has a shrubby erect much branched stem, with hairy branchlets. The leaves are elliptical, obtuse at each end, entire, between crustaceous and leathery, rough and hairless above, downy and netted beneath; the petiole villous on the under side. The racemes are hairy and bracteolate; the sepals silky. The petals from 1 to 6, somewhat obcordate. This plant is an astringent, and furnishes the vulnerary called Sambaibinha in Brazil.

D. rugosa is also a native of the forests of Brazil, and has a twining stem with hairy twigs. The leaves are oblong, remotely and obsoletely serrated, rough and hairless above, shaggy beneath on the principal veins. The petioles are very shaggy beneath. The peduncles and pedicles hairy. It has two or three petals. Like the former species it is an astringent, and is used in South America in swellings of th[e] legs and different parts of the body.

DAVYNE. [MINERALOGY, *S.* 1.]

DE LA BECHE, SIR HENRY THOMAS, an eminen[t] geologist. He was the only son of Colonel Thomas de l[a] Beche, of Halse Hall, Jamaica, and represented the old famil[y] of De La Beche, who lived at Aldworth, near Reading, in the 13t[h] and 14th centuries. Sir Henry was born near London in 179[6]. He went to Jamaica when young, where his father died, an[d] whilst returning to Europe his mother and her young so[n] suffered shipwreck. On reaching England they lived a[t] Charmouth and Lyme Regis, where the young De la Bech[e] seems to have acquired his first taste for geology. He wa[s] educated at the military school at Great Marlow, which wa[s] afterwards removed to Sandhurst. He entered the army i[n] 1814. In 1817 he became a Fellow of the Geologica[l] Society; he afterwards became Secretary and Foreig[n] Secretary of this society, and eventually, in 1847, President. In 1818 he married. Before this event he had begun t[o] investigate the geology of Devon, Dorset, and Pembrokeshire. He now travelled on the Continent, and dwelt for some tim[e] in Switzerland. Here in 1820 he produced one of his earlies[t] scientific papers, 'On the Temperature and Depth of the Lak[e] of Geneva.' This was first published in the 'Bibliothèqu[e] Universelle,' and afterwards in the 'Edinburgh Philosophical Journal.' The researches which led to the publication o[f] this paper exercised an important influence on all his subsequent career. He subsequently returned to England, and renewed his labours on the geology of Wales and Devonshire. In conjunction with the late Rev. Mr. Conybeare, Dean of Llandaff, he first made known the singular form of the *Plesiosaurus*. This was done in a paper published in 1823 in the 'Transactions of the Geological Society,' and entitled 'On the Discovery of a new Fossil Animal, forming a link between the Icthyosaurus and Crocodile.'

In 1824 Mr. de la Beche visited his paternal estates in Jamaica. Here he made himself remarkable for attempting to introduce ameliorations in the condition of the slave. He suffered considerably from the Act of Emancipation. Whilst in Jamaica he lost no opportunity of pursuing his favourite science, and a paper published in 1826 in the 'Transactions of the Geological Society,' on the 'Geology of Jamaica,' was the result. Having returned to England, his papers on the geology of Dorset, Devon, and Wales, became very numerous, besides others on the general principles of geological inquiry. Such were his papers on the 'Classification of European Rocks,' 'On the Excavation of Valleys,' 'On the Geographical Distribution of Organic Remains,' 'On the Formation of Extensive Conglomerate and Gravel Deposits,' and many others. In 1831 he published his 'Geological Manual,' which went through several editions, and was translated into French and German soon after its appearance in England. In this year he also projected a plan of forming a geological map of England, in which all the details of the various formations should be accurately laid down. He began this gigantic undertaking on his own responsibility, and commenced a map of Cornwall. This resulted in the government instituting the Geological Survey, at the head of which he was placed. Whilst working out his plans he became possessed of a large collection of specimens of rocks and mineral substances used in the arts. This collection served as the nucleus of the Museum of Practical Geology, London, which was at first deposited in a house in Craig's Court. In 1834 he published 'Researches in Theoretical Geology,' and in 1835, 'How to Observe: Geology.' In 1845 the Geological Survey and Museum of Practical Geology were united, and the building in Jermyn Street, Westminster, erected for the reception of the rapidly increasing collection of the latter. Sir Henry succeeded in attracting to this institution a number of ardent young men of science, amongst whom we may mention the late Professor E. Forbes, and through their labours this institution rapidly became one of the most important scientific establishments in the country. In 1851 courses of lectures were given by the various members of the corps, and under the name of the Government School of Mines, they are carried on with increasing vigour and usefulness under the presidency of Sir Henry's successor, Sir Roderick Murchison.

For several years previous to his death, Sir Henry had suffered from a gradually increasing paralytic disorder, which, although it prevented him using his limbs, left his fine intellect almost unimpaired. Day after day it was evident that his frame became feebler, but his attention to the interests of the school he had founded did not diminish, and till within two days of his death be performed the active duties of his responsible position. He died on the 11th of April 1855.

The distinguishing feature of Sir Henry's mind was its eminently practical character. The establishment of the Geological Survey and the School of Mines was a proof of this. Wherever his knowledge could be made available for practical purposes, his services were at the command of the public. Thus we find him becoming a member of the Health of Towns Commission and also of the Commission of Sewers. He was chairman of one of the juries of the Great Exhibition in 1851. With Sir Charles Barry he formed one of a committee to select building-stone for the New Houses of Parliament. He was associated with Dr. Lyon Playfair in reporting to the government on the coals suited to the steam-navy, also with Dr. Playfair and Mr. Smyth in reporting on the gases and explosions in collieries. He was elected a Fellow of the Royal Society in 1819, in 1848 be bad conferred on him the honour of knighthood, and in 1853 he was elected a corresponding member of the Academy of Sciences of Paris.

DEBENHAM. [SUFFOLK.]

DEBT, ACTION OF. The peculiarities connected with this action, which led to the use in ordinary cases of the action of *assumpsit*, have for all practical purposes ceased to exist. Wager of law having been abolished, and the pleadings in personal actions greatly simplified, nothing remains indeed to distinguish the action of *debt*, technically so called, from any other action for breach of contract. (Blackst. 'Comm.,' Mr. Kerr's ed., vol. viii. p. 162.)

DEDDINGTON. [OXFORDSHIRE.]

DEDHAM. [ESSEX.]

DEFAMATION. The jurisdiction of the Ecclesiastical Courts, or, as Blackstone says, of "a petty surrogate in the country" to punish "for railing or contumelious words" *pro salute animæ*, by means of the "brutum fulmen of ecclesiastical censures," having long been a subject of considerable ridicule, though frequently of grievous oppression to the poor, has at last been abolished by the statute 18 & 19 Vict. c. 41.

DELAROCHE, PAUL, an eminent French painter, was born at Paris in 1797. Early intending to follow art as a profession, he at first studied landscape, and was in 1817 an unsuccessful candidate for the Academy prize in landscape-painting. Convinced that landscape-painting was not his vocation, he entered the atelier of Baron Gros, under whose guidance be made rapid progress in the study of the figure. Gros had himself in a great measure thrown off the classic trammels which his master David had fixed on French art, and Delaroche entirely emancipated himself from their thraldom. But be did not, like Delacroix, go to the opposite extreme. He still adhered to the old laws, and many of the conventionalities of art. Choosing his subjects to a great extent from modern history, and painting without much regard to academic attitudes and arrangements, he yet sought to maintain something of the old sobriety and dignity of the historic style, and hence when his superiority in his chosen line came to be generally recognised, and Delaroche was the acknowledged chief of a school, that school received the name of the 'Eclectics,' in contradistinction to the Romantic School of Delacroix and the Classic School of David and his followers.

Paul Delaroche in 1819 and the following years exhibited some paintings of scriptural subjects, but it was not till 1824 that the earliest of that class of works by which he achieved his fame appeared; these were, 'St. Vincent de Paul preaching in the presence of Louis XIII.;' and 'Jeanne d'Arc interrogated in prison by Cardinal Beaufort,' which produced a considerable impression. In 1826 M. Delaroche exhibited the first of his very remarkable paintings from English history—'The Death of Queen Elizabeth.' This picture was purchased for the gallery of the Luxembourg, and is thought by French critics to display a wonderful knowledge of English history and English character. It is really the worst of his English pictures, and renders with abundant exaggeration the coarse notion of Elizabeth which alone continental artists and poets seem capable of conceiving: some of the draperies are, however, very well painted, as indeed his draperies mostly are. When M. Delaroche a few years later (1831) again trod on English ground be was a good deal more successful; his 'Children of Edward IV. in the Tower,' being of its class a very excellent picture; it is well known in this country by engravings. But of a far higher order was his next great English picture, 'Cromwell contemplating the Corpse of Charles I.' He has here imagined a circumstance in itself sufficiently probable, and be has treated it with a calm dignity worthy of the theme. M. Delaroche has been often charged with sacrificing his principal subject to the accessories by his excessive care in the rendering of them, but here the attention is at once arrested by the thoughtful head of the Protector, directed to the lifeless form be is brooding over, and it never wanders from the victim and the victor. The sombre colour and gloomy shades are entirely in unison with the prevalent impression. Simple as is the idea of the picture, it would perhaps be difficult to name another modern painting which so thoroughly succeeds in carrying the mind of the spectator into the very presence of the man represented. This fine picture was purchased by the late Earl of Ellesmere, but M. Delaroche painted, we believe, more than one repetition of it; it has been very popular also as an engraving.

His other more important pictures from English history are the 'Execution of Lady Jane Grey' (1834); 'Charles I. in the Guard-Room, insulted by the Parliamentary Soldiers' (1837), also purchased for the collection of the late Earl of Ellesmere, and well engraved by A. Martinel; 'Lord Strafford on his way to the Scaffold receiving the Blessing of Archbishop Laud' (1837), a companion picture to that of 'Cromwell contemplating the Corpse of Charles,' and equally well known by the engravings, but certainly far less impressive as a work of mind, and inferior in its technical qualities; the original is in the collection of the Duke of Sutherland. M. Delaroche also painted some illustrations of Scott's novels.

Among the subjects from French history may be named 'Une Scène de la St. Barthélemy' (1826); 'Le Cardinal de Richelieu sur le Rhône, conduisant au supplice Cinq Mars et de Thou,' and a companion, 'Le Cardinal Mazarin mourant' (1831), both of which, as pictures, and in the engravings by F. Giraud, were very popular; 'La Mort du Duc de Guise' (1835), one of his best pictures; 'La Reine Marie-Antoinette après sa Condamnation à Mort;' and finally his universally popular pictures of 'Napoleon at Fontainbleau,' and 'Napoleon crossing the Alps,' of which he was required to paint several repetitions and smaller copies. His other pictures and portraits are very numerous.

Perhaps the most remarkable of Delaroche's productions however is his painting of the hemicycle of the Palais des Beaux Arts, in which he has represented the great painters, sculptors, and architects, from the earliest time down to the present. From the centre, where Apelles, Phidias, and Ictinus are enthroned as the representatives of the arts in ancient Greece, and marshalled under figures which symbolise the principal eras in the history of art, the great sculptors and architects are ranged in groups, the painters occupying the extremities. The artists in some instances chosen, and those in more instances omitted, from this artistic Wallhalla, will probably raise a smile on the lips of the student of the history of art; but the work itself cannot fail to excite admiration, it is so elevated in style, treated with so much sobriety and refinement, and is so simple and effective in arrangement and execution. This great work employed the painter during the years 1837-41. A very beautiful version of it (in which M. Delaroche had introduced some alterations) on canvas, of considerable size, but of course small in comparison with the original, formed the chief attraction at the exhibition of French paintings in London in 1854.

M. Delaroche is justly regarded by the French as one of their greatest painters. His pictures never reach the highest order of art. They are rather melodramatic than epic or tragic. They are suggestive always of a certain kind of stage effect. You see that the painter is aiming at the actor's trick—that be is seeking to 'make a point.' But allowing for this, it must be granted that M. Delaroche was almost all his countrymen pronounce him to have been. He had undoubted genius, if it was not of the highest order; he was a master of his art; and be was always truthful, conscientious, correct in drawing, on the whole satisfactory as a colourist, and tells his story with admirable perspicuity.

M. Delaroche was named member of the Institute in 1832, and subsequently professor at the Ecole des Beaux Arts, in which capacity he educated a large number of pupils, several of whom have obtained eminence. He was created an officer of the Legion of Honour in 1834. He died Nov. 4, 1856, at Paris.

DELEGATES, COURT OF. All appeals to the Crown in council are now heard and determined by the Judicial

Committee of the Privy Council, which consists of the Lord President of the Council, the Lord Chancellor, the Chief Justices, and Chief Baron, the Master of the Rolls, and Lords Justices of the Court of Appeal in Chancery, the Judge of the High Court of Admiralty and of the Court of Probate, and certain other persons nominated by the Crown. In ecclesiastical causes, Bishops who are Privy Councillors are members of the committee. The proceedings of this tribunal, which is a Court of Record, have been regulated by various statutes (3 & 4 Will. IV. c. 41; 6 & 7 Vict. c. 38). The Judicial Committee has authority in various other matters, as to which see PATENTS, *S.* 2; JUDICIAL COMMITTEE, *S.* 2. (Blackst. 'Comm.,' Mr. Kerr's ed., vol. vi. p. 225.)

DENIZEN. Letters of Denization are now disused, aliens generally having recourse to the simpler and more advantageous certificate of naturalisation granted by the Secretary of State. [ALIEN, *S.* 1.]

DENTEX, a genus of Fishes belonging to the Family *Sparidæ*. It has the following characters:—Body deep, compressed; dorsal fin, single; head large; teeth conical, placed in a single row, four in the front above and below, elongated, and curved inwards, forming hooks; teeth on the branchial arches, but none on the vomer or palatine bones; nose and suborbital space without scales; branchiostegous rays 6. There are several species of this genus.

D. vulgaris, the Four-Toothed Sparus, is regarded as a native of England. Only one specimen, however, seems to have been taken in this country, and that by Mr. Donovan in 1805 off Hastings. It is a very common fish in the Mediterranean, and is the *Dentex* of the Romans. It is remarkable for the great length of the four anterior teeth in each jaw. It acquires sometimes a large size weighing from 20 to 30 pounds, and measuring 3 feet in length. Mr. Donovan's specimen weighed 16 pounds. "A more voracious fish," says Mr. Donovan, "is scarcely known; and when we consider its ferocious inclination and the strength of its formidable canine teeth, we must be fully sensible of the great ability it possesses in attacking other fishes even of superior size, with advantage. It is asserted, that when taken in the fisherman's nets, it will seize upon the other fishes taken with it, and mangle them dreadfully. Being a swift swimmer it finds abundant prey, and soon attains to a considerable size. Willughby observes that small fishes of this species are rarely taken, and the same circumstance has been mentioned by later writers. During the winter it prefers deep waters, but in the spring or about May it quits this retreat, and approaches the entrance of great rivers, where it deposits its spawn between the crevices of stones and rocks.

"The fisheries for this kind of *Sparus* are carried on upon an extensive scale in the warmer parts of Europe. In the æstuaries of Dalmatia and the Levant, the capture of this fish is an object of material consideration, both to the inhabitants generally as a wholesome and palatable food when fresh, and to the mercantile interests of those countries as an article of commerce. They prepare the fish according to ancient custom, by cutting it in pieces and packing it in barrels with vinegar and spices, in which state it will keep perfectly well for twelve months."

DENTINE. [TISSUES, ORGANIC, *S.* 1.]

DEODAND. Juries and judges having (as stated in the 'Penny Cyclopædia,' vol. viii. p. 411) alike condemned this species of forfeiture, the law has been altered by the statute 9 & 10 Vict. c.6 2, and deodands are now entirely abolished.

DEPOSITIONS (*in Criminal Cases*). The statute 11 & 12 Vict. c. 42, has prescribed with great care and exactitude the mode in which the depositions of witnesses are to be taken in criminal cases. The statute requires a deposition to be put in writing, to be read over to the witness, and to be signed by him. Unless these formalities are complied with, and the deposition has been taken in presence of the accused, and he has had full opportunity of cross-examination, it is not admissible in evidence against him.

DEPOSITIONS (*in Equity*). Evidence is now taken in Chancery by deposition before an officer called an Examiner, not by written interrogatories, but *orally*, in the presence of the parties, the witness being subject to cross-examination and re-examination. This new system, in imitation of that public examination of witnesses pursued in courts of common law, which is justly considered a great test of truth, was introduced as part of the practice of the Court of Chancery by the stat. 15 & 16 Vict. c. 86. (Blackstone's 'Commentaries,' Mr. Kerr's ed., vol. iii. p. 520.)

DEPPING, GEORGE BERNARD, was born at Münster, May 11, 1784. Having completed his educational course, he visited Paris in 1803, when, forming acquaintances there, and observing the facilities which the city afforded for the prosecution of literary studies, he determined to make it his permanent residence. The rest of his life was spent there in the uneventful career of a busy littérateur.

For many years M. Depping mainly occupied himself in preparing juvenile and popular works chiefly on geographical subjects, in translating, and in writing for magazines and encyclopædias. His first important original work was one written for a prize offered by the Institute on the 'Expédition Maritime des Normands en France au Dixième Siècle.' It won the prize, was printed in 1826, and revised in 1844: it is a work of sterling value, and contains the fruits of extensive researches in Scandinavian literature. A more important work, for which this had prepared the way, was his 'Histoire de la Normandie,' from the Conqueror to the re-union of Normandy with France (1066 to 1204), 2 vols. 8vo, 1835. Among his other more important works may be named—'Histoire du Commerce entre le Levant et l'Europe, depuis les Croisades jusqu'à la Fondation des Colonies d'Amérique,' 2 vols. 8vo, Paris, 1830; 'Les Juifs dans le Moyen Age, Essai Historique sur leur État Civil, Commercial, et Littéraire,' 8vo, 1840; 'Règlements sur les Arts et Métiers, rédigés au Triezième Siècle, et connus sous le nom de Livre des Métiers d'Etienne Boileau,' &c., 4to, 1837; 'Geschichte des Kriegs der Münsterer und Kölner . . . 1672-1674,' 8vo, Münster, 1840: 'Correspondance Administrative sous le Règne de Louis XIV.' (forming vols. i. to iii. of the 'Collection des Documents Inédits de l'Histoire de France'), 4to, 1850-53; 'Romancero Castellano,' 1 vol. 12mo, Paris, 1817, and, greatly enlarged, 2 vols. 12mo, Leipzig, 1844. Some of the above works have been translated into German and Dutch, while several of his juvenile works have been translated into most of the European languages. M. Depping wrote many of the more important articles in the 'Biographie Universelle,' 'L'Art de Vérifier les Dates,' &c. He died in Paris, September 5, 1853.

DERMATINE. [MINERALOGY, *S.* 1.]

DESIGN, SCHOOLS OF. [SCIENCE AND ART, DEPARTMENT OF, *S.* 2.]

DESMIDIEÆ, a group of organised beings regarded by some naturalists as Animals and by others as Plants. The botanists who have adopted them into the vegetable kingdom have regarded them as *Algæ*, and allied to the *Diatomaceæ*. Some however who admit the vegetable characters of *Desmidieæ* deny them to *Diatomaceæ*. Dr. Lindley admits the *Desmidieæ* as a sub-order of the *Diatomaceæ*, which he characterises as crystalline angular fragmentary bodies, brittle, and multiplying by spontaneous separation. Amongst this group of beings the *Desmidieæ* are characterised as being 'cylindrical.' The following is the definition of this family as given by Mr. Ralfs in his 'British Desmidieæ,' a work which has greatly increased our knowledge of these obscure beings: "Freshwater figured, mucous, and microscopic *Algæ*, of a green colour. Transverse division mostly complete, but in some genera incomplete. Cells or joints of two symmetrical valves, the junction always marked by the division of the endochrome, often also by a constriction. Sporangia formed by the coupling of the cells and union of their contents." It will be seen from this definition that Mr. Ralfs regards these beings as plants. The principal points on which he relies for establishing this position are the occurrence of conjugation and swarming, and the presence of starch amongst the *Desmidieæ*.

The occurrence of a union or conjugation of the two filaments for the production of spores, has long been known amongst certain forms of *Confervæ*. This has been seen by many observers to occur amongst the *Desmidieæ*. In the *Euastrum rupestre* (*fig.* 3 represents the genus) Nägeli describes this process. Two individuals are placed close together, and push out short processes, which meet, and by the absorption of the wall constitute a canal, into which the entire contents of the two cells thus connected enter, and combine together to form one mass which constitutes a single cell. This process is not always identical in different species. In *Closterium* (*fig.* 6) the middle of the cell-membrane dehisces with a transverse fissure, and the entire contents from two contiguous opened cells coalesce into a single round or angular mass. Siebold says, with regard to the spores or green bodies which result from the union of the cells, that they are not in all cases developed into a single *Closterium* like spores; but that, as in the case of other *Algæ*, such as *Vaucheria* and *Œdogonium*, there are two sorts of spore-formations, and that under certain circumstances these green bodies represent a germ, capsule, or sporangium, in which, by a process of division, several young *Closteria* come to be perfected. The union of the cells of *Didymoprium Borreri* is seen in *fig.* 1.

The process above described appears to be one entirely confined to the vegetable kingdom, as it has never been observed amongst unicellular organisms, which are regarded as decidedly animal.

The process of swarming is one which, although a few years ago its distinguishing feature would have been regarded as entitling the organism exhibiting it to a place in the animal kingdom, is by Mr. Ralfs and other English naturalists regarded as purely vegetable. It has been observed in many species of *Confervaceæ*, more especially in *Achlya prolifera* and *Conferva ærea*. The following is M. Agardh's account of this curious phenomenon in the latter plant. After describing the green matter in the joints, he says:—"The granules of which it is composed detach themselves from the mass one after another, and having thus become free they move about in the vacant space of the joint with an extreme rapidity. At the same time the exterior membrane of the joint is observed to swell in one point till it there forms a little mamilla, which is to become the point from which the moving granules finally issue. By the extension of the membrane for the formation of the mamilla, the tender fibres of which it is composed separating, cause an opening at the end of the mamilla, and it is by this passage that the granules escape. At first they issue in a body, but soon those which remain, swimming in a much larger space, have much more difficulty in escaping; and it is only after innumerable knockings (titubations) against the walls of their prison that they succeed in finding an exit. From the first instant of the motion, one observes that the granules or sporules are furnished with a little beak, a kind of anterior process always distinguishable from the body of the sporule by its paler colour. It is on the vibrations of this beak that the motion, as I conceive, depends; at least I have never been able to discover any cilia. However I will not venture to deny the existence of these; for with a very high power of a compound microscope one sees the granules surrounded with a hyaline border, as we find among the ciliated *Infusoria* on applying a glass of insufficient power. The sporules during their motion always present this beak in front of their body, as if it served to show them the way; but when they cease to move, by bending it back along the side of their body, they resume the spherical form; so that before and after the motion one sees no trace of this beak. The motion of the sporules before their exit from this point consists principally in quick dartings along the walls of the articulation, knocking themselves against them by innumerable shocks; and in some cases we are almost forced to believe that it is by this motion of the sporules that the mamilla is formed. Escaped from their prison, they continue their motion for one or two hours; and retiring always towards the darker edge of the vessel, sometimes they prolong their wandering courses, sometimes they remain in the same place, causing their beak to vibrate in rapid circles. Finally they collect in dense masses, containing innumerable grains, and attach themselves to some extraneous body at the bottom or on the surface of the water, where they hasten to develop filaments like those of the mother plant." This process, to which the name swarming has been given, has been observed by Mr. Ralfs, Dr. Hassall, and others in various species of *Desmidieæ*, more especially in *Sphæroplea crispa* and *Draparnauldia tenuis*. No similar movements to these have been anywhere observed amongst the ova of the animal kingdom.

The presence of starch in the *Desmidieæ* is a third point relied on by Mr. Ralfs as distinguishing the vegetable kingdom. The existence of this substance is easily ascertained by the well-known reaction of iodine upon it. Meyen first discovered this substance in the *Algæ*, and Mr. Ralfs and others have confirmed the correctness of his observations. At the same time it should be stated that starch, although not found present in the tissues of the lower animals, has recently been detected in the brain of man by Mr. Busk ('Microscopical Journal,' vol. ii. p. 105). This may lead to the discovery of the existence of this substance more generally in the animal kingdom than has been hitherto supposed.

The following reasons are given by Mr. Dalrymple, after giving an account of the structure of *Closteria*, for placing the species of this genus amongst animals:—

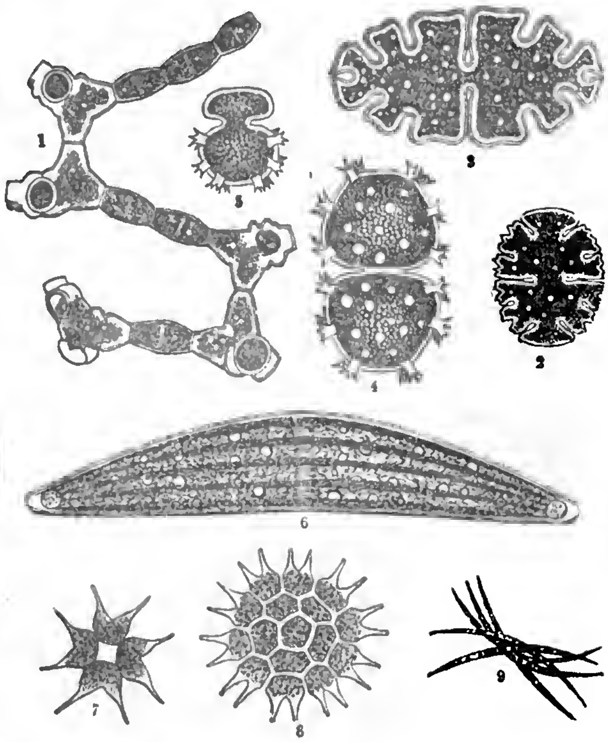
1st. That while *Closterium* has a circulation of molecules greatly resembling that of plants, it has also a definite organ unknown in the vegetable world, in which the active molecules appear to enjoy an independent motion, and the parietes of which appear capable of contracting upon its contents.

2nd. That the green gelatinous body is contained in a membranous envelope, which, while it is elastic, contracts also upon the action of certain reagents, whose effects cannot be considered purely chemical.

3rd. The comparison of the supposed ova with cytoblasts and cells of plants precludes the possibility of our considering them as the latter, while the appearance of a vitelline nucleus, transparent but molecular fluid, a chorion, or shell, determines them as animal ova. It was shown to be impossible that these eggs had been deposited in the empty shell by other *Infusoria*, or that they were the produce of some Entozoon.

4th. That while it was impossible to determine whether the vague motions of *Closterium* were voluntary or not, yet the idea the author had formed of a suctorial apparatus forbade his classing them with plants.

On these reasons, Mr. Ralfs remarks, that the peculiar organ—the terminal globules—of the *Closteria* are as much vegetable as animal. That the throwing off the contents of the cell through chemical reagents, is as much vegetable as animal. "If fresh water touches *Griffithsia setacea*, the joints burst and spirt out their contents." That the supposed ova contain starch, and are therefore vegetable. That he cannot discover that the orifices at the extremities of some of the *Desmidieæ* are tubes, or that they possess a suctorial power.



1. *Didymoprium Borreri*, with the cells uniting to form the green matter. 2. *Micrasterias crenata*. 3. *Euastrum oblongum*. 4. *Xanthidium armatum*. 5. The same with a frond acquiring a new segment by division. 6. *Closterium Lunula*. 7. *Pediastrum simplex*. 8. *Pediastrum Boryanum*. 9. *Ankistrodesmus falcatus*.

The *Desmidieæ* are all of an herbaceous green colour, and from this circumstance are easily discovered amongst the other microscopic beings with which they occur. They are mostly inhabitants of fresh water. Mr. Thwaites records two or three species from brackish water. They are remarkable for the very definite outline which their forms assume, especially in the genera *Micrasterias* (*fig.* 2), *Euastrum* (*fig.* 3), *Xanthidium* (*fig.* 4), and *Pediastrum* (*figs.* 7, 8). Their most obvious characteristic however is their evident division into two valves or segments. The point of union between the two segments is in general very definitely marked. In *Pediastrum* and *Scenedesmus* it is less obvious than other genera. It is at this point of union that the cell opens and discharges its contents. "An uninterrupted gradation," says Mr. Ralfs, "may be traced from species in which these characters are inconspicuous to those in which they are fully developed: thus in *Closterium* and some species of *Penium* there is no constriction; in *Tetmemorus*, in some *Cosmaria*, and in *Hyalotheca*, it is quite evident, although still but slight; in *Didymoprium* and *Desmidium* it is denoted hy a notch at each angle; but in *Sphærozosma*, *Micrasterias* (*fig.* 2), and some other genera, the constriction is very deep, and the connecting portion forms a new cord between the segments, which appear like distinct cells, and are so considered by Ehrenberg and others." He further adds, "That the frond in *Euastrum* (*fig.* 3) and allied genera is really a constricted cell, and not a binate one, will, I am persuaded, be apparent to any one who traces the gradations mentioned above."

The manner in which the cells of the *Desmidieæ* are multiplied, is by means of repeated transverse divisions. This process may be seen in *Euastrum*, the new segments appearing at the constricted part of the original segments. At first the new segments appear as two roundish hyaline bodies formed of the substance of the connecting tnbe. These lobules increase in size, acquire colour, and gradually put on the appearance of the old portions. As they increase in size the original segments are pushed away from each other, and at length an entire separation takes place, each old segment taking with it a new segment to supply the place of the old one. This process is seen going on in *fig.* 5. This process is repeated again and again, so that the older segments are united snccessively, as it were, with many generations. This multiplication however has its limits, for the time comes when the segments gradually enlarge whilst they divide, and at length the plant ceases to grow. When this occurs no more segments are produced, the internal matter changes its appearance, increases in density, and contains starch-grannles. The spore is now formed, which is to give birth to a new individual, and the old one perishes. The separate cells formed by this process of segmentation must be regarded as continuations of the same individual. They are like the grafts and buds from a tree; they continue the individual.

The reproduction of the *Desmidieæ* seems to take place in two ways: first, by the formation of granular contents in the cell, which have the power of moving, burst the cell, and prodnce the pheuomena of swarming above referred to; and secondly, by the formation of a sporangium, or case containing spores, after the union or conjugation of the cells before described. The sporangia assume a variety of forms, and are sometimes covered with spines, and Mr. Ralfs says, "That the orbicular spinous bodies so freqnent in flint are fossil sporangia of *Desmidieæ*, cannot, I think, be doubtful, when they are compared with figures of recent ones."

Movements of the cell-contents of *Desmidieæ*, similar to the cyclosis of higher plants, have been observed by Dalrymple, Bailey, and others. These movements consist of definite currents of the cell-contents, passing in two opposite directions, the one along the side of the cell, and the other along the periphery of the gelatinons mass in their interior. Labarzewski, a German observer, states that these currents are intermittent, lasting each time for about seven seconds.

The part fulfilled by the *Desmidieæ* in creation is little known. They undoubtedly purify the water in which they live in the same manner as other plants, and furnish food to a number of fresh-water animals. As they do not attach themselves to external objects they are seldom found living iu running streams. They are sometimes found in the beds of large rivers, and several species are eumerated by Drs. Lankester and Redfern, in their report on the 'Microscopical Characters of the Water of the Thames.' The best places for procuring them are small shallow pools which do not dry np in the summer. Mr. Ralfs says, however, that the same species never occur in the same pools two years in succession. They prefer open moors and exposed places, and are rarely found in woods, shady places, or deep ditches. They are seldom found in turbid water of any kind. In this respect they are the opposite of their congeners the *Diatomaceæ*, which almost as a rule are fonnd where the *Desmidieæ* are not.

The best way of procuring them for examination is to take a piece of linen, lay it on the ground in the form of a bag, aud then, by the aid of a tin box or ladle, scoop up the water, and strain it through the bag. After this process has been repeated a few times, the specimens of *Desmidieæ* will be found in great abundance on the linen, which, if kept moist, will allow of the growth and development of these beautiful objects for many months.

The study of this family will undoubtedly amply repay the naturalist for years to come. Comparatively little is known of the species beyond the continent of Europe. The following is an analysis of the genera found by Mr. Ralfs in the British Islands:—

*

Plant an elongated jointed filament. Sporangia orbicular, smooth.

1. *Hyalotheca.*—Filament cylindrical. Two species.
2. *Didymoprium.*—Filamsnt cylindrical, or sub-cylindrical. Joints with two opposite or dentate projections. (*Fig.* 1.) Two species.
3. *Desmidium.*—Filament triangular, or quadrangular; joints connected by a thickened border. Two species.
4. *Aptogonum.*—Filament triangular or plain, with foramina between the joints. One species.
5. *Sphærozosma.*—Filament plane, margins incised or sinuated; joints with junction-glands. Two species.

**

Frond simple from complete trausverse division, distinctly constricted at the junction of the segments, which are seldom longer than broad; sporangia spinons or tuberculated, rarely if ever smooth.

6. *Micrasterias.*—Lobes of the segments incised or bidentate. (*Fig.* 2.) Thirteeu species.
7. *Euastrum.*—Segments sinuated, generally notched at the end, and with inflated protuberances. (*Fig.* 3.) Eighteen species.
8. *Cosmarium.*—Segments in front view neither notched nor sinuated; in end view elliptic, circular, or cruciform. Thirty-three species.
9. *Xanthidium.*—Segments compressed, entire, and spinous. (*Figs.* 4 and 5.) Six species.
10. *Arthrodesmus.*—Segments compressed, and having only two spines or mucros. Two species.
11. *Staurastrum.*—End view angular, radiate, or with elongated processes which are never geminate. Forty species.
12. *Didymocladon.*—Segments angular, each angle having two processes, one inferior and parallel with the similar one of the other segment, the other superior and divergent. One species.

***

Frond simple, from complete transverse division, generally much elongated, never spinous, frequently not constricted at the centre. Sporangia smooth.

13. *Tetmemorus.*—Frond straight, constricted at the centre, and notched at the ends. Three species.
14. *Penium.*—Frond straight, scarcely constricted at the centre. Eight species.
15. *Docidium.*—Frond straight, much elongated, constricted at the centre, truncate at the ends. Seven species.
16. *Closterium.*—Froud crescent-shaped or arcuate, not constricted at the centre. (*Fig.* 6.) Twenty-two species.
17. *Spirotænia.*—Frond straight, not constricted at the centre; endochrome spirally twisted. Two species.

****

Cells elongated, entire, fasciculated.

18. *Ankistrodesmus.*—Cells aggregated into faggot-like bundles. (*Fig.* 9.) One species.

*****

Frond composed of few cells, definite in number, and not forming a filament. (Sporangia unknown.)

19. *Pediastrum.*—Cells arranged in the form of a flattened star, their outer margin bidentate. (*Figs.* 7 & 8.) Eleven speciss.
20. *Scenedesmus.*—Cells oblong or fusiform, entire, placed side by side in a single row, but during division into two rows. Six species.

(Ralfs and Jenner, *British Desmidieæ;* Sisbold, *On Unicellular Plants and Animals*, in *Mic. Journal*, 1853; Meneghini, *On the Animal Nature of Diatomaceæ*, translated by Ray Society, 1854; A. Braun, *On Rejuvenescence in the Plant*, translated by Ray Society, 1854; Lindley, *Vegetable Kingdom;* Nägeli, *Gattungen einzelliger Algen physiologisch und systematisch bearbeitet*, Zurich, 1849; Cohn, *On the Natural History of Protococcus pluvialis*, translated by Ray Society, 1854.)

DETINUE. In this action the defendant could, until recently, in all cases retain the chattels which the plaintiff sought to recover, on payment of the damages awarded by the jury as the alternative of not giving them up to the owner. If the plaintiff, therefore, was desirous of recovering the very chattel itself, he was obliged to seek relief in a court of equity, which, on the palpable ground of the remedy at law being insufficient, interfered, and compelled the defendant to make a specific delivery to the plaintiff of his property. It is no longer necessary to resort to the Court of Chancery for this purpose, the Superior Courts of Common Law having now the same powers as the Court of Equity to enforce the specific delivery of the chattels recovered in the action of detinue. ('Common Law Procedure Act,' 1854.)

DEXTRIN. [CHEMISTRY, *S.* 1; TISSUES, ORGANIC, *S.* 1.]

DIALLAGE. [AUGITE.]

DIANÆA. [PULMOGRADA.]

DIASPORE. [MINERALOGY, *S.* 1.]

DIASTASE. [CHEMISTRY, *S.* 1.]

DIATOMACEÆ, or **DIATOMEÆ**, a group of organised beings which naturalists have placed in the animal and vegetable kingdoms, according as they have regarded their structures as most allied to the one kingdom or the other. These organisms consist of a single cell, and are remarkable for possessing a hard shell-valve or frustule, which is composed of silex or flint, and which remains permanent after its organic tissues have perished.

The following is a definition of this group of beings by one of the most recent writers on this subject;—Plant a frustule; consisting of a unilocular or imperfectly septate cell, invested with a bivalve siliceous epidermis. Gemmiparous increase, by self-division; during which process the cell secretes a more or less siliceous connecting membrane. Reproduction, by conjugation, and the formation of sporangia. (W. Smith.)

The *Diatomaceæ* are endowed with the power of motion; and when this function was supposed to be peculiar to the animal kingdom, it is not to be wondered at that the first observers of these organisms referred them to the animal kingdom. Ehrenberg, in his great work on the 'Infusorial Animalcules,' greatly enlarged our knowledge of this family, and added to the forms that were already known. He regarded them, as well as the *Desmidieæ*, and other beings which are now generally referred to the vegetable kingdom, as animals. The following are the principal points on which he relied for assigning to them this position:—

1st. The *Diatomaceæ* exhibit a peculiar spontaneous movement, which is produced by certain locomotive organs.

2nd. A large number of them have in the middle of the lateral surface an opening about which round corpuscles are situated, which become coloured blue when placed in water containing indigo, just as many of the Polygastric *Infusoria.*

3rd. The shells of the *Diatomaceæ* resemble in structure and conformation those which are seen in the *Mollusca* and other animals.

These arguments are met on the other side by the statement, that spontaneous movement is now known not to be specially animal, as the spores of many *Algæ*, and their entire fronds are known to be actively motile. In the next place the colouring of the interior by indigo also takes place in truly vegetable structures.

The complex structure of the minute siliceous frustules of the *Diatomaceæ* is a fact that has struck many observers. It certainly is without a parallel in the vegetable kingdom. Schleiden in his 'Principles of Scientific Botany,' after giving a minute analysis of the siliceous structure of *Navicula viridis* (*fig.* 6 represents this genus), says, "Such an artificial and complicated structure amongst plants has no explanation and is entirely without significance. In all true plants we find the silica present in a very different form, as minute scales or drops, and distributed through the substance of the cell-wall." Again, in another place he says, "This curious structure is wholly without analogy in the vegetable kingdom, and cannot be derived from the laws of vegetation with which we are at present acquainted."

More recently Professor Meneghini has come forward as an advocate of the animal nature of *Diatomaceæ*. In a very lucid and remarkable essay, published at Venice in 1845, he says:

"If we suppose them to be plants, we must admit every frustule, every navicula, to be a cell. We must suppose this cell with walls penetrated by silica, developed within another cell of a different nature, at least in every case where there is a distinct peduncle or investing tube. In this siliceous wall we must recognise a complication certainly unequalled in the vegetable kingdom. It would still remain to be proved that the eminently nitrogenous internal substance corresponded with the gonimic substance, and that the oil-globules could take the place of starch. The multiplication would be a simple cellular deduplication (sdoppiamento), but it would remain to be proved that it takes place, as in other vegetable cells, either by the formation of two distinct primitive utricles or by the introflection or constriction of the wall itself. Finally, there would still remain unexplained the external motions and the internal changes, and we must prove Ehrenberg's observations on the exterior organs of motion to be false. But, again, admitting their animal nature, much would remain to be investigated, both in their organic structure and their vital functions; excepting this, so far as we know, we have only one difficulty to overcome, that of the probably ternary non-azotised composition of the external gelatinous substance of the peduncles and investing-tubes. But as the presence of nitrogen is not a positive character of animal nature, so the absence of it is not a proof of vegetable. And in order that the objection should really have some weight, it would be well to demonstrate that this substance is isomeric with starch. For then, supposing all the arguments in favour of the animal nature of *Diatomeæ* were proved by new and more circumstantial observations, this peculiarity, if it deserve the name of objection, might still be regarded as an important discovery. We should then have in the animal as well as in the vegetable kingdom a ternary substance similar to that forming the basis of the vegetable tissue."

Of the chemical composition of the *Diatomaceæ* little satisfactory has at present been made out. Professor Frankland of Manchester, according to the Rev. W. Smith, whose work on the British *Diatomaceæ* is one of the last that has hitherto been published, has found that a large amount of iron exists in the state of a silicate or protoxide in the siliceous frustules, which probably accounts for the brown or yellow colour of these organisms. On the application of tincture of iodine the internal membrane contracts on its contents, and converts these from a golden-yellow to a bright green. On the addition of sulphuric acid they exhibit a deep brown hue.

The fact which is most relied on to support the vegetable nature of the *Diatomaceæ*, by those who advocate this view, does not appear to have been known to Meneghini, and that is the conjugation of the cells of which they are composed in the same manner as in the *Desmidieæ*. [DESMIDIEÆ, *S.* 2.] This discovery was made by Mr. Thwaites, and observed in species of *Eunotia* (*fig.* 1), in *Epithemia gibba* and *E. turgida* (*fig.* 19), *Fragilaria pectinalis*, and other species. This process takes place as follows:—Two individuals closely approximated dehisce in the middle of their long diameter, whereupon four protuberances arise, which meet four similar ones in the opposite frustule. These indicate the future channels by which the endochrome of the two frustules becomes united, as well as the spot where subsequently the double sporangium is developed (*figs.* 8, 19). From the sporangium the new individuals are developed. This process is precisely analogous to what takes place in the *Desmidieæ*, so that the frustules of the Diatoms must be regarded as cells of the same individual. "If we duly consider this fact," says Mr. Thwaites, "how much does it exalt the lower tribes of plants in our estimation! since we may contemplate an individual plant of them not as the single phyton—not as the single frond—not as the single cell—but it may be as the aggregate of thousands of these;—view it occupying as much space and exercising as great an influence in the economy of nature as the largest forest-tree!"

The mode by which the cells are multiplied amongst the *Diatomaceæ* appears to be strictly in accordance with what occurs generally in the vegetable kingdom. This process is one of self-division. The first step is the fission or division of the internal cell, "probably by the doubling-in of its membranous wall, and consequently the separation of the endochrome, or cell-contents; the central vesicle or cytoblast also dividing into two parts, which remove to a little distance from each other; these movements being simultaneous with a retrocession of the epidermal valves and the formation of the siliceous connecting-membrane already described. In the centre of the enlarged frustule, in exact apposition to the original valves and closely applied to them, there are now found two new valves, covering the surface of the cell-membranes along the line of fission. The divided portions of the endochrome spread themselves along the membrane which is embraced by the new valves, and there result two half-new frustules bound together by the connecting-membrane, generated during the process we have described.

"During the healthy life of the Diatom the process of self-division is being continually repeated; the two half-new frustules at once proceed to divide again each into two frustules, and thus the process continues. I have been unable to ascertain the time occupied in a single act of self-division, but supposing it to be completed in twenty-four hours, we should have, as the progeny of a single frustule, the amazing number of one thousand millions in a single month; a circumstance which will in some degree explain the sudden or at least rapid appearance of vast numbers of these organisms in localities where they were but a short time previously either unrecognised or only sparingly diffused." (Smith, p. 25.)

From a drawing by Mr. West.

The structure of the siliceous portion of the *Diatomaceæ* is the most remarkable part of their organisation. The following is Meneghini's account of this organ:—

"Every Diatom is formed of a siliceous shield and a soft substance therein contained. According to Kützing, this shield consists of pure silica, or, in some cases, perhaps, of silica combined with alumina. Nägeli further says that the silica is deposited in the outside of an organic membrane, which he believes to be of a vegetable nature. In fact, an organic membrane ought to exist, for the silica could not become solid except by crystallising or depositing itself on some pre-existing substance. On the other hand, we cannot admit, with Nägeli, that it has been deposited externally, for in many genera, and especially in the *Achnanthidia*, the siliceous shield is covered with a very delicate dilatable membrane, itself containing silica, as is proved by its sustaining unchanged the action of fire and acids. Therefore, comparing this shield with other organic formations whether animal or vegetable, containing in like manner either silica or some other so-called mineral element, we may reasonably consider it to be formed of an organic tissue permeated by silica. This permeation may occur either in the wall of a simple cell, as is seen in the epidermal cells of many plants, or within minute cells, as in various plants and animals. The action of heat or of acid, in these cases, destroying the organic matter and leaving the silica untouched, does not alter the apparent form of the organ, because the skeleton remains unaltered.

"Externally to the shield Kützing observed a thin stratum which he denominated cement, which may be made visible either by desiccation or by calcination; and produces either a simple opacity, or lines, points, and maculæ, sometimes irregularly disposed, sometimes regularly. He supposes it to be a silicate of iron or of alumina. Independently of the chemical materials which it may contain, this outside integument seems to me the more important, inasmuch as even without resorting to the means indicated by Kützing, I observe it to be constant, not merely in the species enumerated by him, but also in many others, and I could almost assert that it exists in all. For to me it appears to correspond with that fine membrane of the *Achnanthidia* above mentioned, which, according to Kützing's own observations, is always visible whenever the two new individuals (into which every Diatom is resolved in its multiplication by deduplication) (sdoppiamento) begin to separate. The lines and points supposed to belong to the subjacent shield belong very frequently to this kind of covering.

"The shield itself is formed of at least four pieces, or valves, united together in a four-sided figure—a tetragon. The mode of union is unknown. But the existence of a kind of articulation which permits an opening and closing, like the valves of a shell-fish described by Corda in a species of *Surirella*, has been denied by other observers. Be this as it may, whether spontaneous after death or induced by external means, this separation does take place in a regular manner. Now, if we suppose an organic cell with a wall permeated by silica, and with a four-sided figure, we can easily suppose that all the sides will mechanically support each other. Moreover, we shall meet with numerous facts by a different kind of analogy, namely, that with solid animal tissues belonging either to the internal skeleton or the external tegument.

"The four valves are equal in length, but in many species and genera one pair exceeds the opposite pair in breadth. In order to establish an uniform language it is convenient to term those primary valves or surfaces which exhibit along the middle the line of division in the act of deduplication, which, since it is formed here in a normal manner, runs parallel to the other two surfaces, denominated lateral. Along the primary surfaces we frequently see longitudinal lines, which terminate at the two extremities in small apertures. From their internal surface there project into the cavity linear marks variously formed but always longitudinal; these are termed vittæ.

"The lateral surfaces have frequently a round aperture of greater or smaller size in the centre, and from this a fissure extends towards each extremity. This fissure either loses itself gradually or expands into the regular terminal apertures. When this occurs each of these surfaces is divided into two distinct valves. On these lateral surfaces we observe the striæ, lines, and transverse costæ, no less admirable for their beautiful appearance than for their constant regularity in number, direction, and proportion. When many individuals are united together to form one compound being, like a polyp for instance, it is always by the lateral surfaces that they touch each other; and since all other characters sometimes fail, we can affix to them the denomination 'lateral' from this principal one.

"Besides the vittæ before mentioned, in some general (*Biddulphia*, *fig.* 15, *Climacosphenia*, *Terpsinoë*) there are other solid substances in their internal cavities: these are variously arranged.

"These essential peculiarities of the shield may perhaps be regarded as indicating a complex structure, very different therefore from what would be prescribed by a simple cellular wall. Ehrenberg deduces from it an argument to compare it with the shell of *Mollusca*. The *Arcellinæ* may be cited among the *Infusoria*. Kützing states, in reply, that among vegetable cells there is found a peculiar conformation of the walls, with prominences, depressions, points, lines, papillæ, and perforations, disposed in a regular manner; he refers to grains of pollen, as an instance. He might have added the more appropriate instance of the *Desmidieæ*, which would be very closely allied to the *Diatomeæ*, if the latter, like the former, could be referred to the vegetable kingdom. If not equal in constancy and regularity, the *Desmidieæ* display a greater degree of complication; and we must remember the different nature of their substance, for in the vegetable cell, when lime or silica predominates, the wall becomes uniform and regular (?) (uniforme ed irregolare)."

The siliceous epiderm presents an extraordinary variety of forms, which in every genus and species offer the best possible means of distinction and identification: striæ, or lines frequently moniliform, dots arranged in a radiate or concentric manner, and minute divisions presenting perfectly hexagonal outlines, are amongst the most frequent occurrences. Great difference of opinion exists as to the nature of these. Mr. Smith says, "I am disposed to regard them all as modifications in the arrangements of the silex of the valve, arising from the mode of development peculiar in each case to the membrane with which the silex is combined." He also denies that there are any perforations in the valve, as supposed by Ehrenberg and Kützing. These foramina are also denied by Schleiden. Mr. Smith denies also that the valves are externally covered with any organic membrane.

The delicacy of the markings on many of the *Diatomaceæ* render them objects peculiarly adapted for testing the powers of the object-glasses of the microscope. The following table, drawn up by Messrs. Sollitt and Harrison of Hull, to whom microscopy is indebted for having first pointed out this method of testing the powers of the microscope, was presented by them at the meeting of the British Association at Hull in 1853:—

Focal length of object glass.	Species.	Striæ in inch.	Angle of Aperture.
$\frac{1}{2}$	*Navicula strigilis* . .	34·000	40°
$\frac{1}{4}$	*N. Hippocampus* .	42·000	60°
	N. Spencerii. . .	50·000	70°
	N. liniata . . .	60·000	80°
	N. angulata . . .	60·000	80°
$\frac{1}{8}$	*N. strigosa* (large) .	70·000	90°
	N. strigosa (small) .	80·000	95°
	Ceratoneis Fasciola	90·000	110°
	Navicula sigmoidea	105·000	120°
$\frac{1}{12}$	*N. arcus*	130·000	150

The *Diatomaceæ* possess the power of moving. "The cells have no special organs for these movements. But as, in consequence of their nutritive processes they take in and give out fluid matters, the cells necessarily move when the attraction and the emission of the fluids is unequally distributed on parts of the surface, and is so active as to overcome the resistance of the water. This motion consequently is observed more particularly in those cells which, in consequence of their taper forms, easily pass through the water; these cells moreover move only in the direction of their long axis. If one half of a spindle-shaped or ellipsoidal cell chiefly or exclusively admits material, the other half, on the contrary, giving it out, the cell moves towards the side where the admission takes place. But, as in these cells both halves are physiologically and morphologically exactly alike, so it is that it is first the one and then the other half which admits or emits, and consequently the cell moves sometimes in one, sometimes in the opposite direction." (Nägeli.)

This is perhaps as satisfactory an explanation of these movements as can be given in the present state of our knowledge. All observers agree that they can find no evidence to support Ehrenberg's notion of a pedal or motile organ projected from the interior of the siliceous shield. The Rev. W. Smith has also detected cyclosis in the *Diatomaceæ*. "A distinct movement," he says, "of the granular particles of the endochrome, closely resembling the circulation of the cell-contents in *Closterium Lunula*, noticed by Mr. Ralfs [Desmidieæ], and which I have frequently detected in the same species, has occasionally fallen under my notice in some of the larger forms of *Diatomaceæ*." He has observed it in *Surirella biseriata*. (*Fig.* 4.) "This circulation," he continues, "has not however the regularity of movement so conspicuous in the *Desmidieæ*, and is of too ambiguous a character to furnish data for any very certain conclusions, save one, namely, that the Diatom must be a single cell, and cannot contain a number of separate organs, such as have been alleged to occupy its interior; since the endochrome moves freely from one portion of the frustule to another, approaching and receding from the central nucleus, unimpeded by any intervening obstacle."

The *Diatomaceæ* are the most abundant and extensively distributed of unicellular organisms. They are found in the ocean, at the mouths of rivers, in brackish waters, in rivers, lakes, ponds, ditches, pools, and cisterns. In fact, wherever a few drops of water are allowed to remain exposed to the air, we may expect to find forms of *Diatomaceæ*. Their forms are not less abundant than their presence. In the first volume of his 'Synopsis of the British Diatomaceæ,' the Rev. W. Smith has described upwards of 220 species, and the second will contain nearly 100, so that the number of species known in Great Britain is considerably above 300. The facility with which their forms are preserved, give to these objects a great advantage, and a handful of sand from the sea or mud from a river in the most remote district of the world may be expected to reward the observer with an abundance of new forms. They occur in great abundance in the river Thames, and its mud affords a large variety of the frustules of those which have ceased to exist. In a report on the 'Microscopical Examination of the Thames and other Water,' by Drs. Lankester and Redfern, upwards of forty species were observed.

The mode of collecting living specimens for observation is simply to allow the water in which they exist to stand for a few hours, when, by carefully decanting the water, a portion remains at the bottom of the vessel more turbid than the rest, and which generally contains in large numbers the objects sought for.

In describing showers of coloured dust which have occurred in various parts of the world, Ehrenberg has demonstrated that various forms of *Diatomaceæ* have been found present. In some seasons these organisms occur in such numbers in the waters of rivers as to give to their banks a peculiar physical aspect. In the autumn of 1841 the stones and pebbles in the nearly dried-up bed of the Annan, in Dumfriesshire, presented an appearance as though they were white-washed. The substance which gave the stones this appearance could be scraped off, and looked like some form of calcareous matter. On submitting this powder to the microscope, Dr. Lankester found that it consisted entirely of the siliceous shields of a species of *Synedra*. (*Fig.* 5.) In the first volume of the new series of the 'Transactions of the Microscopical Society,' Mr. Shadbolt has given an account of the examination of portions of mud given him by Mr. Busk from Port Natal. This mud was recent, and from the nature of the specimens in it, Mr. Shadbolt thinks it probable that it was obtained not far from the mouth of some river. In this mud he made out fifty-five distinct species of *Diatomaceæ*, twenty of which he has described as entirely new species. In the 'Microscopical Journal' for July, 1853, Mr. Brightwell of Norwich has described nine new species of one genus—*Triceratium*. Six of these are recent. He says, "We have detected nearly all the recent species described in this memoir in material obtained from the surface of the large sea-shells of the genera *Hippopus* and *Haliotis* before they have been cleaned. Many of them in this state are covered with small zoophytes, minute algæ, and other parasites; and by a careful examination of these, *Triceratia* and other *Diatomaceæ* have been obtained."

One of the most singular positions in which Diatoms are found is in the guano brought from America and Africa. Their history is curious. They must first have been swallowed by fish and subsequently by birds; their shields, however, have been able to withstand this double process of digestion, and they are found in large numbers in every pure specimen of guano. Some of the forms which have been thus presented to the naturalist are entirely new, and are amongst the most singular of the family. It has been suggested that the silex thus introduced into the guano may contribute to its fertility, as it is well known that this substance is present in the stems of all our cereal grasses, and is necessary to their growth.

If they occur thus abundantly in recent deposits, it would be expected that they should be found in many of the older formations of the earth's surface. This is very extensively the case; although it may be doubted whether, from the fact of their being occasionally found in igneous rocks, that they were amongst the first organisms on the earth's surface. Ehrenberg has been able to detect their presence in some of the earliest rocks of the Palæozoic series. How *Diatomaceæ* may be present in igneous rocks has been suggested by Dr. Hooker. During his voyage with Sir James Ross in the Antarctic Ocean he says, "This order occurred in such countless myriads as to stain the sea everywhere of a pale ochreous-brown, in some cases causing the surface of the ocean, from the locality of the ships, as far as the eye could reach, to assume a pale-brown colour." This immense mass of organisms perishing are producing a sub-marine deposit, or bank, of vast dimensions, resting on the shores of Victoria Land, and hence on the sub-marine flanks of Mount Erebus, an active volcano upwards of 12,000 feet high. "Knowing as we do that *Infusoria*, *Diatomaceæ*, and other organic constituents, enter into the formation of the pumice and ashes of other volcanoes, and are still recognisable in those minerals, it is perhaps not unreasonable to conjecture that the subterranean and subaqueous forces which kept Mount Erebus in activity, may open a direct communication between this Diatomaceous deposit and its volcanic fires."

Ehrenberg has described a large number of forms of *Diatomaceæ* from the oolite, cretaceous, and other secondary rocks. A formation occurring in Barbadoes, and described by Sir Robert Schomburgk in the 'Reports of the British Association' for 1847, furnished him with an entirely new group of beings apparently related to this family. The following is Sir Robert's account of this discovery:—

"In the white marls and other rocks of Scotland district, Professor Ehrenberg of Berlin discovered a new and great group of siliceous-shielded animalcules, which, in a report read before the Royal Academy of Sciences, he described as *Polycystina*. The regular apertures and articulation of the minute shells which cover these animalcules distinctly bespeak an independent animal structure and development. They possess large apertures at the extremity of the body, which has no analogy among plants, but occur very commonly among animals. These siliceous loricated organic forms from the rocks in Barbadoes differ alike from *Polygastrica* and *Polythalamia*, but develop an important relation to these two groups, which Professor Ehrenberg considers, not upon conjecture but from actual investigation, to form two separate types. They approach most nearly in systematic arrangement to *Polythalamia*, and would occupy a separate group among animals possessed of vessels but without a heart and pulsation, and provided with a simple tubular intestinal canal. The forms developed in the highest degree in that division would be *Holothuriæ* and *Echinoideæ*.

"The minute forms of organic life in the rocks of Barbadoes, as far as investigated by Professor Ehrenberg in February, 1847, consist of the following groups:—

	Species.
Polycystina	282
Polygastrica	18
Phytolitheria	27
Geolithia	27
Polythalamia	7
	361

Of these more than 300 are new forms.

"The great discovery of the *Polycystina*, which might be almost called a new class, since they amount to upwards of 280 species, a larger number of specific forms than is contained in some classes of animals, may guide us to form an idea of the geological age of the rocks in Scotland district, by comparing these forms with similar fossil animalcules from rocks upon the age of which geologists have agreed. Ehrenberg considers that the *Polycystina* from the rocks of Barbadoes resemble more the animalcules from rocks of the secondary period than the tertiary."

Amongst the varieties of quartz rock the mineralogist recognises, under the name of tripoli and polishing powder, certain pulverulent and earthy forms of silex. On placing these substances under the microscope they are found to be entirely composed of the siliceous frustules of *Diatomaceæ*. The polishing powder or slate (polirschiefer) found at Bilin in Bohemia is used for the purpose of producing a polish on fine surfaces. The angularity and hardness of the frustules of the Diatoms well adapt them to this purpose.

Another deposit in which the *Diatomaceæ* have been found in great abundance is the Bergmehl of Sweden [BERGMEHL, *S.* 1.] The Diatoms found by Ehrenberg in this formation are principally species of *Navicula*. (*Fig.* 6.)

Amongst the tertiary deposits, beds of *Diatomaceæ* are very common. They have been observed in Italy, in Germany, and in several of the States of America. "The city of Richmond in Virginia is said to be built upon a stratum of Diatomaceous remains, 18 feet in thickness." (Smith.) Professor Gregory of Edinburgh has recently described, in the 'Transactions of the Microscopical Society,' a Diatomaceous earth, discovered about two years ago by the Duke of Argyle in the Isle of Mull. It constitutes a bed, resembling marl in appearance, lying in a rough piece of ground between Loch Baa and the sea. The lake is about 30 feet, the land about 40 feet, above the sea-level. At one part there is a hollow, which in winter used to become a small loch, in summer only a stagnant pool, and in draining this the bed of marl was discovered. The bed rests upon gravel, which appears to belong to the diluvial period, and the Diatomaceous earth is probably of recent origin. Professor Gregory has examined the contents of this earth with great care, and has given a list of upwards of 130 species, which he has been able to make out ('Quarterly Microscopical Journal,' January, 1854). Of these upwards of twenty are altogether new species, or species that are new in a British locality.

From these facts it will be seen that the subject of fossil *Diatomaceæ* promises an almost boundless field for further inquiry. It appears that we may say of these organisms, what we can say of no other family or group of organised beings, that once created they exist for ever. Myriads of species of soft-bodied animals have perished, never to be recognised, but each individual cell of the Diatom leaves its siliceous wall as a record of its existence—a record that the ordinary forces of nature seem to have little or no power in obliterating.

We now turn to the subject of arrangement. It would of course be impossible here to give any account of individual species, and systematic arrangements are being constantly modified by new discoveries. The following is an arrangement of the families or tribes by Kützing:—

Tribe I. STRIATÆ.

Order I. *Astomaticæ*.

Without a central opening on the secondary valve.

* Transverse striæ unbroken.

Family 1. *Eunotieæ*.
Family 2. *Meridieæ*.
Family 3. *Fragilarieæ*.

** Striæ broken (interrupted) in the median line.

Family 4. *Meloseireæ*.
Family 5. *Surirelleæ*.

Order II. *Stomaticæ*.

With the central opening.

α *Monostomaticæ*.

Having a median aperture on only one of the two secondary surfaces.

Family 6. *Cocconeideæ*.
Family 7. *Achnantheæ*.

β *Distomaticæ*.

With a median aperture on each secondary surface.

Family 8. *Cymbelleæ*.
Family 9. *Gomphonemeæ*.
Family 10. *Naviculeæ*.

Tribe II. VITTATÆ.

Order I. *Astomaticæ*.

Without central opening on secondary side.

Family 11. *Licmophoreæ*.
Family 12. *Striatelleæ*.

Order II. *Stomaticæ.*

With a large distinct aperture.

Family 13. *Tabellarieæ.*

Trihe III. Areolatæ.

Order I. *Disciformes.*

Family 14. *Coscinodisceæ.*
Family 15. *Anguliferæ.*
Family 16. *Tripodisceæ.*

Order II. *Appendiculata.*

Doubtful forms.

Family 17. *Biddulphieæ.*
Family 18. *Angulatæ.*
Family 19. *Actinisceæ.*

The Rev. W. Smith, in his 'Synopsis of the British Diatomaceæ,' gives the following arrangement of the genera:—

Tribe I. Frustules naked; not imbedded in gelatine nor inclosed in membranaceous tubes.

Sub-Tribe 1. Connecting membrane deciduous; frustules solitary, or during self-division in pairs; rarely in greater numbers, adherent or free, dispersed, or aggregated into a mucous stratum.

22 Genera—

Epithemia (*fig.* 19)	16 species.
Eunotia (*fig.* 1)	7 species.
Cymbella	6 species.
Amphora	8 species.
Cocconeis	6 species.
Coscinodiscus	3 species.
Eupodiscus (*fig.* 2)	5 species.
Actinocyclus	1 species.
Arachnodiscus	1 species.
Triceratium (*fig.* 3)	3 species.
Cyclotella	4 species.
Campylodiscus	7 species.
Surirella (*fig.* 4)	20 species.
Tryblionella	6 species.
Cymatopleura	5 species.
Nitzschia	23 species.
Amphiprora	5 species.
Amphipleura	2 species.
Navicula (*fig.* 6)	36 species.
Pinnularia	24 species.
Stauroneis	10 species.
Pleurosigma (*fig.* 7)	26 species.

Sub-Tribe 2. Connecting membrane subpersistent; frustules after self-division attached by a gelatinous cushion, or dichotomous stripes.

7 Genera—

Synedra (*fig.* 5)	24 species.
Doryphora	2 species.
Cocconema (*fig.* 8)	4 species.
Gomphonema (*fig.* 9)	12 species.
Podosphenia	5 species.
Rhipidophora	3 species.
Licmophora	2 species.

Sub-Tribe 3. Connecting membrane evanescent, or obsolete; frustules after self-division united into a compressed filament.

12 Genera—

Meridion (*fig.* 10)	2 species.
Bacillaria (*fig.* 11)	1 species.
Himantidium	7 species.
Odontidium	4 species.
Denticula	4 species.
Fragilaria	3 species.
Eucampia	1 species.
Achnanthes (*fig.* 12)	6 species.
Diadesmis	3 species.
Rhabdonema	2 species.
Striatella (*fig.* 13)	1 species.
Tetracyclus	1 species.

Sub-Tribe 4. Connecting membrane subpersistent; frustules after self-division united into a zigzag chain.

6 Genera—

Diatoma (*fig.* 14)	4 species.
Grammatophora	2 species.
Tabellaria	2 species.
Amphitetras	1 species.
Biddulphia (*fig.* 15)	4 species.
Isthmia	2 species.

Sub-Tribe 5. Connecting membrane subpersistent as a siliceous annulus; frustules after self-division united into a cylindrical filament.

3 Genera—

Podosira	2 species.
Melosira (*fig.* 16)	6 species.
Orthosira	6 species.

Tribe II. Frustules invested with a gelatinous or membranaceous envelope.

Sub-Tribe 6. Frond indefinite; mammillate; frustules scattered.

1 Genus—

Mastogloia	3 species.

Sub-Tribe 7. Frond definite; compressed or globular; frustules scattered.

2 Genera—

Dickieia (*fig.* 17)	3 species.
Berkeleyia	1 species.

Sub-Tribe 8. Frond definite; filamentous; frustules in rows.

3 Genera—

Encyonema	2 species.
Colletonema	4 species.
Schizonema (*fig.* 18)	16 species.

Sub-Tribe 9. Frond definite, filamentous; frustules fasciculated.

1 Genus—

Homœcladia	3 species.

(Smith, *Synopsis of British Diatomaceæ*, vols. i. & ii.; Meneghini, *On the Animal Nature of Diatomeæ*, translated by Ray Society; Kützing, *Species Algarum*; Siebold, *On Unicellular Plants and Animals*, translated in *Quarterly Journal of Microscopical Science*, vol. i.; Pritchard, *A History of Infusorial Animalcules, Living and Fossil*; Dujardin, *Histoire Naturelle des Zoophytes Infusoires*; Hassall, *British Fresh-Water Algæ*; Ehrenberg, *Die Infusions-Thierchen*; Hooker, *British Flora*, vol. ii.; Agardh, *Conspectus Criticus Diatomacearum*; Papers in vols. i. & ii. of *Quarterly Journal of Microscopical Science*, by T. Thwaites; *Reports of British Association*; Professor J. W. Bailey in *Smithsonian Contributions to Knowledge*.)

DIBDIN, REV. THOMAS FROGNALL, the most conspicuous English writer on Bibliography in the earlier half of the nineteenth century, was born at Calcutta in 1776. His father, Captain Thomas Dibdin, the commander of a sloop of war in the Indian Ocean, was the elder brother of Charles Dibdin, the celebrated naval song-writer. [Dibdin, Charles.] Both he and his wife, whom he had first met in the East Indies, died on their passage home in the year 1780, and Frognall Dibdin first landed on the English shore an orphan of four years old. His mother's brother, Mr. Compton, took charge of him from that age to man's estate; and of other relations he saw so little, that, he tells us in his 'Reminiscences,' he conversed with his famous uncle Charles but once in his life, though Charles lived till 1814, when Frognall was eight-and-thirty. He was sent to St. John's College, Oxford, but quitted the university without taking a degree, and studied the law under Mr. Basil Montagu, whose office he left to practise in the unusual character of a provincial counsel at Worcester.

Finding no prospect of success, he soon abandoned the law for the church; and a passage in his 'Reminiscences,' in which he describes his studies, furnishes the key-note of much of his subsequent career. "In Greek Testaments my little library was rather richly stored. I revelled in choice copies of the first Erasmus, and of the first Stephen, and defied any neighbouring clergyman to match me in Elzevirs and in Tonson." In London, to which he speedily returned, and where he became a preacher at some fashionable chapels at the west-end, he was less known in the clerical than in the literary or rather the bookselling world. At that time, the 'bibliomania,' as it was called, or fancy for purchasing rare and curious books at extravagant prices, was advancing to a height which it had never before attained in England or elsewhere. It reached its culminating point at the celebrated sale of the library of the Duke of Roxburghe, in June 1812, where a copy of an early edition of Boccaccio, printed by Valdarfer, at Florence, in 1471, was sold to the Marquis of Blandford, afterwards Duke of Marlborough, for the sum of 2260*l.*; and it was afterwards discovered that an imperfect copy of the same book was in the Sunderland library at Blenheim, at the very time of the purchase, but had three times over escaped being mentioned in the catalogue.

Dr. Dibdin proposed, at a dinner party at Baron Bolland's, even before the Valdarfer was sold, the establishment of a club, to dine together in honour of Bibliography. The club was established under the name of the Roxburghe Club: and he became the first vice-president. This club afterwards adopted the rule that each of its members should every year reprint a book, to be presented to every member; and this practice seems to have led to the establishment of the numerous printing and publishing clubs now in existence, more liberal in their regulations than the original. The rise and progress of the bibliomania was stimulated and recorded by different publications of Dr. Dibdin: an 'Introduction to the Greek and Roman Classics,' in 1802; a dialogue, entitled 'Bibliomania,' in 1809, which was reprinted, with great enlargements, in 2 vols., in 1811; and the 'Bibliographical Decameron,' in three large vols., in 1817. A new edition of Ames's 'Typographical Antiquities' was also commenced by him, and carried as far as four volumes, between 1810 and 1819; and a minute account of the rare books in Earl Spencer's library, under the title of the 'Bibliotheca Spenceriana,' which occupied four volumes, and was extended by the 'Ædes Althorpianæ,' a description of Earl Spencer's seat at Althorp; and by an account of the Cassano library purchased by him; in the whole, seven volumes. In 1818, Dr. Dibdin made a tour abroad, to purchase books for the same patron, and the result was, a 'Bibliographical, Antiquarian, and Picturesque Tour in France and Germany,' 3 vols. 8vo, 1821. These works, particularly the 'Bibliographical Decameron' and the 'Tour,' present beautiful specimens of typography and engraving, produced at an expense which the author was never weary of proclaiming. In 'The Library Companion; or, Young Man's Guide and Old Man's Comfort in the Choice of a Library' (1824), he apparently aspired at producing something of more general and permanent use; but the result was disastrous. The flippant and frivolous character of his remarks, and the inaccurate and superficial character of his information, were commented upon in so severe a tone by some of the leading reviews, in particular the 'Quarterly' and the 'Westminster,' that his reputation never recovered the shock. In the preceding year he had obtained, by the patronage of Earl Spencer, his first preferment in the church—the living of Exning, near Newmarket; he was afterwards appointed to the rectory of St. Mary, Bryanstone Square, London; and his publications for some years were chiefly of a theological character. He returned to the field of bibliography in his 'Reminiscences of a Literary Life' (2 vols. 1836), and in his 'Bibliographical, Antiquarian, and Picturesque Tour in the Northern Counties of England and in Scotland' (3 vols. 1838). He also made, not long before his death, a tour in Belgium, of which he also intended to publish an account. He died on the 18th of November, 1847, after a long illness, of paralysis of the brain. His latter years had been much clouded with pecuniary difficulties.

Many of the publications of Dr. Dibdin have already been enumerated, but it will be necessary to recur to some of them to afford a fuller notion of their character. The most important is the 'Typographical Antiquities of Great Britain.' The meritorious work of Ames on that subject, professing to give an account of all the works printed in England from the introduction of the art to the year 1600, had been expanded from one volume to three by Herbert, who made such extensive additions that the work might justly be regarded as no longer Ames's, but his own. There was still room for extensive improvement on Herbert—a very simple alteration even in the arrangement would have much increased its value to nearly all who consulted it. The titles of the books are disposed under the names of the printers: had they been disposed instead, according to Panzer's plan, in his 'Annals of German Literature,' in the plain order of date, a host of particulars would have presented themselves in combination which are now scattered and inaccessible. It would have been far from uninteresting to observe what books issued from the press in England during the year in which Henry broke up the monasteries, in which Mary lighted the fires of Smithfield, or in which Shakspere first came to London. Dibdin has preserved the old arrangement, and has so much augmented the matter that the four volumes of his edition, which was left imperfect, carry the record no further than the middle of the second volume of Herbert's three. Some of the matter which he has added is of interest, in particular his more minute account of the productions of Caxton, but much is mere idle surplusage—biographies of book-collectors of the 18th century, illustrated with their portraits, which have nothing whatever to do with the history of printing in the 15th and 16th centuries. Much too of the additional matter for which he has obtained credit is taken from the manuscript notes which Herbert had prepared for a second edition, and inserted in a copy of his work which is now in the British Museum. It is to be hoped that the whole subject will be resumed ere long by some competent scholar, with the numerous additional materials now at his command in our public libraries, when, with some industry and intelligence, a work may be produced which will interest not only the bibliographer but all who have a tincture of feeling for literary matters. The 'Bibliotheca Spenceriana,' from its containing particulars of many books not accessible to the public in general, is often used as a work of reference: but those who have consulted it the oftenest regard it with the most distrust. Such was Dr. Dibdin's habit of inaccuracy, that in two accounts of the origin of the Roxburghe Club, to him a matter of great importance and interest, given in two of his works, the dates are utterly irreconcileable. In the 'Decameron' (vol. iii. p. 69), he distinctly states that the dinner at which he proposed it was on the 4th of June; in the 'Reminiscences' (p. 367), he states no less distinctly that it was "on the evening before the sale of the 'Boccaccio' of 1471, which took place on the 17th of June, 1812." It may easily be conceived that his accounts of the dates of rare books are not to be depended on till after they have been verified. It may be remarked also that his way of describing a book has too little of the scholar and the man of letters, and too much of the bookseller and the bookbinder. The width of the margin, and the kind of leather in which a book is coated, attract as much of his attention as the particulars which all copies of the book have in common. The 'Tours' are a singular compound of anecdotes of rare interest mixed up with the most idle and irrelevant matter. The 'Decameron' is by far the best of Dr. Dibdin's works, as comprising the least of detail and the most of anecdote; and it is written in many portions with a degree of care and spirit often wanting in his other works. The 'Reminiscences' afford singular proof that, although the author of an 'Introduction to the Classics,' his acquaintance with some of them was more than usually deficient. On the whole, though his bibliographical works abound with much that the reader wishes away, they are indispensable in any large library of English literature. His other productions, which are numerous, will be found mentioned in his own 'Reminiscences.'

DICHROITE. [Mineralogy, *S.* 1.]

DICK, THOMAS, LL.D., was born in 1772. He was educated for the Christian ministry in connection with the Secession Church of Scotland, and was a preacher in connection with that body in the early part of his career, but it is as a popular writer on physical science that he is best known to the world. The works by which he first became generally known were the 'Christian Philosopher,' and the 'Philosophy of Religion.' These were followed by works on the 'Improvement of Society by the Diffusion of Knowledge,' the 'Mental Illumination of Mankind,' 'The Philosophy of a Future State,' a 'Treatise on the Solar System,' 'Celestial Scenery,' 'The Sidereal Heavens,' 'The Practical Astronomer,' and an essay on 'Christian Beneficence, contrasted with Covetousness,' written in competition for the prize which was conferred on Dr. Harris for his work, entitled 'Mammon: or Covetousness the Sin of the Christian Church.' Dr. Dick was a man of singularly unobtrusive disposition, and was content to labour perseveringly for the public instruction, although his immediate reward was but small. His principal works were reprinted at low prices, and had extensive circulation, yet the author derived little pecuniary benefit from them. A public subscription on his behalf, as an acknowledgment of the benefits he had conferred upon society, was projected a few years since by some of his admirers, but realised a very small amount, most of it being raised in the town of Dundee, where the subscription was commenced. Dr. Dick's works have been reprinted and very extensively sold in the United States. Dr. Dick resided in the small village of Broughty-Ferry, on the left bank of the river Tay, in Forfarshire. Besides instructing the public by his pen, Dr. Dick had been in the habit of accepting occasional appointments to preach in neighbouring churches, and also to deliver popular lectures on scientific subjects. A few years ago a small pension was granted to him by the government in acknowledgment of his services in the advancement of popular science. He died July 29, 1857.

DICTYOGENÆ, a class of plants, proposed by Lindley, and adopted in his 'Vegetable Kingdom.' It embraces a number of orders standing between the larger classes of Exogens and Endogens. They have a monocotyledonous embryo, but they have also a broad net-veined foliage, which usually disarticulates with the stem. The following are the natural orders of *Dictyogenæ*:—

Flowers unisexual. Perianth free. Carpels 00; one seeded	*Triuridaceæ.*
Flowers unisexual. Perianth adherent. Carpels consolidated; several seeded .	*Dioscoreaceæ.*
Flowers bisexual. Carpels several, quite consolidated. Placentæ axile. Flowers hexapetaloideous	*Smilaceæ.*
Flowers bisexual. Carpels several, quite consolidated. Placentæ parietal. Flowers 3-6-petaloideous	*Philesiaceæ.*
Flowers bisexual. Carpels several, half consolidated. Placentæ axile. Flowers 3-petaloideous	*Trilliaceæ.*
Flowers bisexual. Carpels solitary, simple, many-seeded, with long-stalked anatropal seeds, and a basal placenta . .	*Roxburghiaceæ.*

DIDYMIUM. [Chemistry, *S.* 1.]

DIDYMOPRIUM. [Desmidieæ, *S.* 2.]

DIEGO, SAN. [Canada, *S.* 2.]

DIGENITE, a native Sulphuret of Copper.

DILMAN, a town in Persia, is situated on the caravan route from Tabriz to Erzerum, 70 miles W. from Tabriz, 10 miles W. from the north-west angle of Lake Urumiyeh, and has about 15,000 inhabitants. It is situated in the wide and fertile plain of Selmas, which stretches westward from the lake to the base of the Kurdistan Mountains. The town is surrounded by gardens and orchards, and has clean streets. The plain about it is inhabited by Nestorians, Armenians, Catholics, Kurdish Leks, and Russian emigrants. About 4 miles to the westward is the old town of Dilman, a great portion of which is in ruins. From the number of mounds in the neighbourhood it seems to have been once of considerable extent, and it is described by St. Martin as being a very ancient Armenian city. (Colonel Sheil, in *London Geographical Journal*, vol. vi.)

DINORNIS, a genus of birds probably extinct, the remains of several species of which have been found in New Zealand.

In November, 1839, Professor Owen exhibited, at a meeting of the Zoological Society of London, the fragment of the shaft of a femur, 6 inches in length, and 5½ inches in its smallest circumference, with both extremities broken off. This bone of an unknown struthious bird of large size, presumed to be extinct, was put into the Professor's hands for examination, by Mr. Rule, with the statement that it was found in New Zealand, where the natives have a tradition that it belonged to a bird of the eagle kind, which has become extinct, and to which they give the name Movie or Moa. Similar bones, it was said, were found buried on the banks of the rivers.

After a minute description of the bone, Professor Owen made the following statement:—"There is no bone of similar size which presents a cancellous structure so closely resembling that of the present bone as does the femur of the ostrich; but this structure is interrupted in the ostrich at the middle of the shaft, where the parietes of the medullary or rather air-cavity, are smooth and unbroken. From this difference I conclude the struthious bird indicated by the present fragment to have been a heavier and more sluggish species than the ostrich; its femur, and probably its whole leg, was shorter and thicker. It is only in the ostrich's femur that I have observed superficial reticulate impressions similar to those on the fragment in question. The ostrich's femur is subcompressed, while the present is cylindrical, approaching in this respect nearer to the femur of the emeu; but its diameter is one-third greater than that of the largest emeu's femur with which I have compared it. The bones of the extremities of the great *Testudo elephantopus* are solid throughout; those of the crocodile have no cancellous structure like the present bone. The cancellous structure of the mammiferous long bones is of a much finer and more fibrous character than in the fossil. Although I speak of the bone under this term, it must be observed that it does not present the characters of a true fossil; it is by no means mineralised; it has probably been on or in the ground for some time, but still retains most of its animal matter. It weighs 7 ounces 12 drachms avoirdupois.

"The discovery of a relic of a large struthious bird in New Zealand is one of peculiar interest, on account of the remarkable character of the existing Fauna of that island, which still includes one of the most extraordinary and anomalous genera of the struthious order; and because of the close analogy which the event indicated by the present relic offers to the extinction of the Dodo of the island of the Mauritius. So far as judgment can be formed of a single fragment, it seems probable that the extinct bird of New Zealand, if it prove to be extinct, presented proportions more nearly resembling those of the Dodo than of any of the existing *Struthionidæ*. Any opinion however as to its specific form can only be conjectural. The femur of the Stilt-Bird (*Himantopus*) would never have revealed the anomalous development of the other bones of the leg; but so far as my skill in interpreting an osseous fragment may be credited, I am willing to risk the reputation for it on the statement that there has existed, if there does not now exist, in New Zealand, a struthious bird nearly if not quite equal in size to the ostrich."

It was not long before an opportunity occurred of testing this very remarkable statement, and of proving the sagacity of the naturalist who had thus staked his reputation upon his conviction of the truth of the general principles of the science of comparative anatomy. Professor Owen received a communication from the Rev. W. Cotton describing several other remains of animals of the same kind, and in 1843 a collection, comprising vertebræ and bones of the hinder extremities, pelvis, &c., were transmitted by the Rev. W. Williams to the dean of Westminster (Dr. Buckland); and in 1846 many specimens were sent to England by Dr. Mackellar, Mr. Percy Earle, and Colonel Wakefield. These were placed in the hands of Professor Owen, and form the subject of his first and second 'Memoirs on the Dinornis,' in the 'Zoological Transactions,' vol. iii.

In these Memoirs Professor Owen pointed out that the bones which had been thus sent over from New Zealand contained the remains of no less than nine species of a remarkable group of birds, which he at first supposed belonged to the family of *Struthionidæ*. Subsequent examination however has led Professor Owen to the conviction that, although wingless, these birds have as little connection structurally and physiologically with the ostriches as with any other group of recent birds.

From an examination of the various bones thus collected, Professor Owen was enabled to point out that the fragment of bone which he had first received belonged to a species of the genus not only much larger than any of the other species indicated by these remains, but larger than any form of existing bird. To this species he gave the name of *Dinornis giganteus*, and found that the height of this bird must have been from 10 feet to 10 feet 6 inches. The other species described were—*D. ingens*, attaining a height of 9 feet; *D. struthoides*; *D. didiformis*, 4 feet; *D. dromæoides*, 5 feet; *D. struthioides*, upwards of 6 feet. In addition to these were described—*D. curtus*, *D. crassus*, *D. otidiformis*, and *D. casuarinus*. Thus these remains showed the existence of a number of birds, varying in size from the almost flightless Bustard to birds of the size of the Dodo, the Emeu, and the Ostrich, and one larger than all.

On a subsequent examination of the bones of *D. ingens* and *D. dromæoides*, Professor Owen discovered a back toe which he had seen nowhere in the other species, and for these he proposed the generic name *Palapteryx*. To these two was afterwards added a third species, *P. geranoides*. Dr. Mantell gives the following account of a further discovery of the remains of birds in New Zealand:—

"In 1846 and 1847 my eldest son, Mr. Walter Mantell, of Wellington, who had resided several years in the colony, explored every known locality of these fossil bones within his reach in the North Island, and went into the interior of the country, and located with the natives, for the purpose of collecting specimens, and of ascertaining whether any of these gigantic birds were still in existence, resolving, if there appeared to be the least chance of success, to penetrate into the unfrequented regions, and obtain a live Moa. The information gathered from the natives offered no encouragement to follow up the pursuit, but tended to confirm the idea that this race of colossal bipeds was extinct, the last individuals having in all probability, like the Dodo, been exterminated by human agency within a comparatively recent period; or that if any of the species whose bones occur in a fossil state are still living, they will prove to be of comparatively small types, related to the *Apteryx*, the living diminutive representative of the stupendous ostrich-like birds which once trod the soil of New Zealand. My son succeeded however in forming the most interesting collection of these remains hitherto obtained. It comprised between 700 and 800 bones belonging to birds of various species and genera, and differing considerably in magnitude and age, some belonging to very young individuals, in which the epiphyses of the long bones are distinct from the shaft, while others are those of adult and aged birds." The chief part of this collection is now deposited in the British Museum.

The locality from which these specimens were obtained is thus described by Mr. Mantell:—"Near Waikoriati, 17 miles north of Otāgo, there is a headland called Island Point, about three-quarters of a mile in length and 150 in height; it consists of sandy clay distinctly stratified and traversed by dykes of columnar trap, the columns being at right angles to the sides of the veins. In a little bight, south of Island Point, on the side of the bar which unites that headland to the mainland at the entrance of the River Waikoriati in front of the native Kaika, named Makuku, is situated the exposed parts of the so-called turbary deposit, whence bones of Moas and other birds of various kinds have been obtained in such number and perfection. This bed is about 3 feet in depth and not more than 100 yards in length, and lies immediately on a stratum of tertiary blue clay; its inland boundary is obscured by vegetation, and appears to be of a very limited extent; the bed is entirely submerged, and only visible when the tide has receded. It consists almost wholly of decayed vegetable matter, and its surface is studded with the undisturbed roots of small trees, which appear to have been burnt to the ground at some remote period. It is a light, sandy, elastic earth, of a blackish-brown colour, and emits a strong fetid odour when first collected; from the large quantity of animal matter it contains I conceive it was originally a swamp or morass, in which the New Zealand Flax (*Phormium tenax*) once grew luxuriantly. It is now covered by a thin layer of sand when exposed at low water. . . Although bones of several species of Moa, especially of the largest kinds, have been collected from this locality in considerable numbers and in great perfection, yet as the bed is rapidly diminishing from the inroads of the sea, there is great reason to fear that it will be entirely washed away, without yielding to the palæontologist all the desired information respecting the extinct animals whose relics it enshrines; for the natives and whalers are well aware of the interest attached to the bones by Europeans, and they seize indiscriminately on any specimen exposed by the receding tide, and if it cannot be readily extracted they break it off, and thus many a valuable relic has been destroyed. Their cupidity and avarice have too been so much excited by the large rewards injudiciously given by casual visitors, that the cost of specimens has increased to an unreasonable amount."

In their general aspect the bones which have been obtained from these spots closely resemble those obtained from the ossiferous caverns in Germany. Professor Owen gives an analysis of their chemical composition, and from this infers that they may have been recently deposited. Mr. Mantell obtained bones also from North Island:—"On the western shore of the North Island, about sixty miles south-west of New Plymouth, there is a stream called Waingougou, which empties itself into the sea at about a mile and a half south of Waimate in the Ngátirúai ûi district. Part of the neighbouring country is elevated table-land, with deep tortuous gullies, through which the torrents and streams take their course to the sea. That of Waingougou, which is as tortuous as any of them, takes its rise in the neighbouring volcanic ridge, and has evidently at a former period discharged itself far distant from its present embouchure, as is proved by the existence of a line of cliffs which extends inland, and has manifestly been produced by the corroding action of the river. Driven from its course probably by a change in the relative level of the land and sea, the stream has formed its present channel, which cuts through a bed of loose conglomerate, 100 feet thick, overlying a deposit of finely-laminated sand, which covers a thick stratum of blue clay full of shells. The conglomerate consists of pebbles and large boulders of an infinite variety of volcanic rocks; the clay is the lowermost visible bed; the shells it contains are marine, and resemble species existing in the South Pacific Ocean; but I suspect many will be found specifically distinct from any recent forms. Between the two bluffs near the embouchure of the river there is a sand-flat about 200 yards across, and this on my first visit was strewn with bones of men, moas and other birds, and two species of seals. I had some deep openings made near the foot of the ancient cliff on the top of which is the Pa or native village of Ohawetokoloko, and at the same level as the flat on which I had observed the strewn fragments of bones I came to a regular ossiferous deposit. The bones however though perfect were as soft and plastic as putty, so that if grasped strongly they changed as it were by magic into pipeclay; and it was necessary to dig them up with great care, and expose them to the air and sun to dry, before they could be packed and removed. . . Unfortunately the natives soon caught sight of my operations, and came down in swarms, men, women, and children, trampling on the bones I had carefully extracted and laid out to dry, and seizing upon every morsel exposed by the spade. My patience was tried to the utmost, and to avoid blows I was obliged to retreat and leave them in the possession of the field; and to work they went in right earnest, and quickly made sad havoc. No sooner was a bone perceived than a dozen natives pounced upon it, and began scratching away the sand, and smashed the specimen at once. It was with great trouble, and by watching the opportunity of working in the absence of the Maoris, that I procured anything worth having."

The remains thus procured by Mr. Mantell were placed at the disposal of Professor Owen by Dr. Gideon Mantell, who was thus enabled to supply many deficiencies in his former descriptions of these remarkable birds. They afforded specimens of the bones of *Dinornis curtus*, *D. didiformis*, and *D. casuarinus*; also of *Palapteryx ingens*, variety *robustus*, and of a new species, *P. geranoides*. Notwithstanding the great number of bones that have thus been examined, one fragment only of the wings or humerus has been detected. This indicates the rudimentary condition of the wings in these birds. The humerus found Professor Owen regards as belonging to a species of *Palapteryx*. The following is a summary of the nature of this collection by Professor Owen:—"There are not less than 190 phalanges of the toes referrible to five or six species of *Dinornis*, *Palapteryx*, and *Notornis*, and there are 8 tarso-metatarsals, with the articular surface for a very strong hind toe, and of a conformation more nearly resembling those of the Dodo than of the *Dinornis* and *Palapteryx*, but shorter and thicker in proportion, and appertaining to the same bird as the tibia and fibula described in my Memoir of 1843 under the name of *D. otidiformis*. The proximal articulation of this remarkable form of tarso-metatarsal exactly fits the distal end of the tibia figured, and also that of a corresponding fractured tibia in Mr. Mantell's collection; which also contains the proximal end of another tibia, a fibula, an entire femur, and distal ends of two other femora, of the same species. The large surface for the hind toe; the strong calcaneal process forming a complete bony canal for the flexor tendons at the back part of the proximal end of the tarso-metatarsal; the perforation above the interspace between the outer and middle metatarsals for the tendon of the adductor muscle of the fourth toe, and the more posterior position of the condyle for the inner toe—all concur to indicate the generic distinction of the bird to which it belonged from either *Dinornis* or *Palapteryx*; and I propose to distinguish the new genus by the name of *Aptornis* and the present species *A. otidiformis*." ('Zool. Trans.' iii. p. 347.)

With the remains of the bones found on the banks of the river Waingougou were mixed the fragments of egg-shells. The eggs to which the fragments belonged were supposed to be about the size of a tea-cup. In connection with this subject the recent discovery of a large egg in Madagascar is interesting.

In a report to the French Academie de Sciences, M. Isidore Geoffroy St. Hillaire described three enormous fossil eggs from Madagascar, and some bones belonging to the same bird. The captain of a merchant-vessel trading to Madagascar one day observed a native using for a domestic purpose a vase which much resembled an egg, and upon examination proved to be one. The native stated that many such were to be found in the interior of the island, and eventually procured the eggs and bones exhibited by M. St. Hillaire. The largest of these eggs is equal in bulk to 135 hens' eggs, and will hold two gallons of water. M. St. Hillaire proposes the name of *Epiornis* for the monster biped of which these marvellous eggs and bones are the first evidence brought under the notice of naturalists. Casts of these eggs have been sent to this country, and are to be seen in various museums.

Amongst the bones sent home by Mr. Mantell, the remains of a new genus, *Notornis*, were found. It belongs to the same family as the *Brachypteryx* and the *Rallidæ*, and the interest that attaches to it in this relation is the fact that Mr. Mantell succeeded in obtaining a single living specimen. Many persons had reported the existence of a wingless bird as large as a fowl, and with red beak and legs, with a cry sounding like 'Keo Keo.' The following is Dr. Mantell's account of the discovery of this bird:—"On my son's second visit to the southern part of the Middle Island (as Government Commissioner for the settlement of native claims), he fell in with some sealers who had been pursuing their avocations along the little frequented islets and gullies of Dusky Bay on the south-western shores, and from them obtained the skin of a recent specimen of *Notornis Mantelli*. It appeared that when frequenting the coasts in search of seals and other game, these men observed on the snow, with which the ground was then thickly covered, the foot-tracks of a large and strange bird, and after following the trail for a considerable distance, they caught sight of the object of their search, which ran with great speed and for a long while distanced their dogs, but was at length driven up a gully in Resolution Island, and captured alive. It uttered loud screams, and fought and struggled violently; it was kept alive three or four days on board the schooner and then killed, and the body roasted and eaten by the crew, each partaking of the dainty, which was said to be delicious. The skin, with the skull and bones of the feet and legs, was preserved, and fortunately obtained by my son while in good condition, and thus perhaps the last of the race of Mohos was preserved for the naturalists of Europe. Upon comparing the head of the bird with the fossil crania and mandibles, my son was at once convinced of the specific identity of the recent and fossil specimens; and so delighted was he by the discovery of a living example of one of the supposed extinct contemporaries of the Moa, that he wrote to me and stated that the skull and beaks were alike in both, and that the abbreviated and feeble development of the bones and plumage of the wing were in perfect accordance with the indications afforded by the humerus and sternum found by him at Waingougou and now in the British Museum, as pointed out in the 'Zoological Transactions,' vol. iii. To the natives of the pahs, or villages, my son visited on his homeward route to Wellington, the *Notornis* was a perfect novelty, and excited great interest. No one had seen such a bird, but all agreed that it was the traditional Moho or Takahé, which they had believed was utterly extinct.

"This beautiful bird is about two feet high, and much resembles in its general form the *Porphyrio melanotus*, but it is larger and stouter, and generically distinct; the characters predicated by Professor Owen from the fossil remains being clearly marked in his recent volume. The beaks are short and strong, and as well as the legs were of a bright scarlet in the living animal. The neck and body are of a dark purple colour, the wings and back being shot with green and gold. The wings are short and rounded, and remarkably feeble both in structure and plumage. The tail is scanty, and white beneath. The specific identity of the recent and fossil *Notornis* is confirmed by Mr. Gould, who has published a coloured figure the size of the original in a supplementary number of his splendid work on the 'Birds of Australia.'"

In addition to the bones of the animals mentioned, remains of other birds were found in the Mantellian collection. These were of a species of nocturnal Parrot, belonging to the genus *Nestor*, of a probably extinct species of *Apteryx*, of a species of Albatross allied to *Diomedea chlororhynchus*, and also of the Penguin.

For the structure of the *Apteryx* and its relations to other birds, see the article STRUTHIONIDÆ.

In 1851 Professor Owen received from Governor Grey a large collection of specimens from New Zealand of the bones, and more especially the skulls, of several of the species, which he described in a fifth memoir presented to the Zoological Society. An almost perfectly restored skeleton of the *Dinornis giganteus* exists in the Museum of the College of Surgeons. Professor Owen concludes one of the memoirs referred to with the following general remarks:—"The extraordinary number of wingless birds and the vast stature of some of the species peculiar to New Zealand, and which have finally become extinct in that small tract of dry land, suggest it to be the remnant of a larger tract or continent over which this singular Struthious Fauna formerly ranged. One might almost be disposed to regard New Zealand as one end of the mighty wave of the unstable and ever-shifting crust of the earth, of which the opposite end, after having been long submerged, has again risen with its accumulated deposits in North America, showing us in the Connecticut Sandstones of the Permian period the foot-prints of the gigantic birds which trod its surface before it sank; and to surmise that the intermediate body of the land-wave along which the *Dinornis* may have travelled to New Zealand has progressively subsided, and now lies beneath the Pacific Ocean."

(Owen, *Memoirs on the Dinornis; Zoological Transactions*, vol. iii.; Owen, *Proceedings of Zoological Society*, in *Annals of Natural History;* Mantell, *Petrifactions and their Teachings.*)

DIOMEDEINÆ, a family of birds, to which the Albatrosses belong. The characters of the genus *Diomedea* are given under ALBATROSS. In that article three species of this genus are referred to. We now give a complete list of the species of this important genus:—

Diomedea exulans, Linn. This bird is abundant between 30° and 60° S. lat., and equally numerous in all parts of the ocean bounded by those degrees; its range, however, extends much farther south, even to within the antarctic circle.

D. melanophrys, Temm. It is the most abundant species of the southern seas; equally numerous in every part between the 30th and 60th degrees.

D. cauta, Gould. This species was procured by Mr. Gould off the south coast of Van Diemen's Land.

D. chlororhynchos, Lath. It occurs between 30° and 60° S. lat., in both the Atlantic and Pacific Oceans.

D. culminata, Gould. This bird is rather abundant both in the Pacific and Atlantic Oceans, between 30° and 50° S. lat.

D. fuliginosa, Gmel. It occurs in all parts of the ocean between 30° and 60° S. lat.; equally common off Van Diemen's Land, Cape Horn, and the Cape of Good Hope.

D. brachyura, Temm. Found in the North Pacific Ocean.

D. gibbosa, Gould. An inhabitant of the North Pacific Ocean.

D. olivaceorhyncha, Gould. China seas (?).

Mr. Gray, in his 'Genera of Birds,' also gives *D. spadicea* as a species. He also makes *D. gibbosa* (Gould) synonymous with *D. nigripes*, Audubon, 'Orn. Biog.,' vol. v. p. 327, and adopts the latter name as having the priority.

DIOPSIDE. [AUGITE.]

DIPHTHERITE. [MATERIA MEDICA, *S.* 2.]

DISRAELI, ISAAC, was born at Enfield, Middlesex, in 1766. His father, Benjamin Disraeli, was the descendant of a family of Spanish Jews, who, driven from the Peninsula in the 15th century by the persecutions of the Inquisition, had settled in Venice, and there, to mark their race, had exchanged the Gothic Spanish name they had hitherto borne for that of Disraeli—"a name never borne before or since by any other family" (the name was originally written D'Israeli; but in his later years the subject of this memoir was in the habit of omitting the apostrophe). He had come over to England from Italy in 1748, and made a considerable fortune by commerce. He married in 1765 "the beautiful daughter of a family" of his own race "who had suffered much from persecution." She was a person of strong sense but no imagination, whose ruling feeling was "a dislike for her race." The only child of this union was the subject of our notice. His sensitive and poetical character as a boy puzzled both his parents, and, in particular, occasioned continual discord between him and his mother. His father destined him for commerce; but from the first he showed a decided aversion to an active life. Educated first at a school near Enfield, and then at Amsterdam, where the only advantage he received was that derived from access to a large library, he was not more than eighteen when, in spite of all that his father could say or do, he signified his intention of being a literary man. "He had written a poem of considerable length, which he wished to publish, against commerce." His father naturally opposed this intention, and accordingly "he enclosed his poem to Dr. Johnson with an impassioned statement of his case, complaining that he had never found a counsellor or literary friend. He left his packet himself at Bolt Court, where he was received by Mr. Francis Barber, the doctor's well-known black servant, and told to call again in a week." When he did call the packet was returned to him unopened, with a message that the doctor was too ill to read anything. The doctor, in fact, was then on his death-bed. In 1788 Disraeli's father sent him to travel in France. On his return, finding Peter Pindar's satires in everybody's mouth, he ventured anonymously to publish by way of corrective some verses "On the Abuse of Satire," which Walcot attributed to Hayley. About this time he became acquainted with Mr. Pye, afterwards poet laureate, who was of service to him in many ways, and who persuaded his father to allow him to follow his own inclinations. Accordingly from about 1790, without any further opposition on the part of his family, and with sufficient means supplied by his father (who survived till 1819, when he was nearly ninety years of age), he was free to devote himself entirely to literature. His first efforts were in poetry and romance. His early verses are forgotten; but a volume of romantic tales, including one called 'The Loves of Mejnoun and Leila,' published by him some time before the close of the 18th century, reached a second edition. But though he had much poetic taste, he was not fitted to be a poet or creative writer; and he was not long in finding out that his true destiny was "to give to his country a series of works illustrative of its literary and political history"—in other words, to prosecute researches in literary history and gossip. It was in the year 1790 that he published anonymously a little volume entitled 'Curiosities of Literature.' The success of this volume determined him to prosecute the walk which he had there entered upon. Accordingly, with the exception of the volume of romance above alluded to, and we believe, one other anonymous publication, all Mr. Disraeli's further productions during his long life consisted of the fruits of his literary and historical researches. These researches were prosecuted partly in the British Museum, where he was a constant visitor at a time when the readers who had access to its treasures were not more than half-a-dozen daily; partly in his own library, which, especially in the end of his life (when he resided on his own manor of Bradenham in Buckinghamshire) was very extensive. The results of these researches were put forth from time to time either as additions to his 'Curiosities of Literature' (which thus eventually attained, in the eleventh edition published in 1839, the bulk of six volumes); or as independent publications. Among the independent publications may be mentioned his 'Essay on the Literary Character' originally published in 1795; his 'Calamities of Authors,' his 'Quarrels of Authors, or Memoirs of Literary Controversy,' and his 'Inquiry into the Literary and Political Character of James the First'—works originally published between 1812 and 1822, and since then published collectively under the title of 'Miscellanies of Literature;' and his 'Life and Reign of Charles the First,' published in five volumes at intervals between 1828 and 1831. In acknowledgment of this last work he was made D.C.L. by the University of Oxford. He contemplated a 'Life of Pope,' and also 'A History of the English Free-thinkers,' and had collected materials for both; but a paralysis of the optic nerve which attacked him in 1839 prevented him from executing either. With the assistance of his daughter he selected from his manuscripts three volumes, which were published in 1841 under the title of 'Amenities of Literature.' His last years were spent in revising and re-editing his former works; and he died in 1848 at the age of 82. "He was," says his son, from whose memoir, prefixed to a new and posthumous edition of his 'Curiosities of Literature,' we have derived the foregoing particulars, "a complete literary character, a man who really passed his life in his library. Even marriage produced no change in these habits: he rose to enter the chamber where he lived alone with his books, and at night his lamp was ever lit within the same walls." In his old age his appearance was mild and venerable; he had then become rather corpulent.

DISS. [Norfolk.]

DIVORCE. The subject of the law of divorce has for several years engaged the attention of the legislature, and a commission having been appointed to consider the question, made a report which was presented to both houses of Parliament by command of Her Majesty in 1853. The statute 20 & 21 Vict. c. 85, which came into operation on the 11th day of January, 1858, has carried the recommendations of the commissioners into effect. For information as to the previous state of the law, see Divorce.

In the first place the jurisdiction in matters of divorce and causes matrimonial is taken away from the Ecclesiastical Courts, by which it was formerly exercised, and transferred to a new court, called the 'Court for Divorce and Matrimonial Causes,' the jurisdiction of which is exercised in the name of the Sovereign. The judges in this court are the Lord Chancellor, the Lord Chief Justice of the Court of Queen's Bench, the Lord Chief Justice of the Court of Common Pleas, the Lord Chief Baron of the Court of Exchequer, the senior puisne judge in each of the three Common Law Courts, and the judge of the Court of Probate. The last-mentioned functionary is entitled the 'Judge Ordinary of the Court of Divorce and Matrimonial Causes,' and he is invested with power to determine alone all matters, except petitions for dissolving or annulling marriage, application for new trials, bills of exception, special verdicts, and special cases.

The Act abolishes the old decree of divorce *à mensâ et thoro*, but enables the judge to pronounce a sentence of 'judicial separation,' which is nearly the same thing, and which sentence may be obtained either by husband or wife, on the ground of adultery or cruelty, or desertion without cause for two years or upwards. Desertion was not a ground for legal separation under the old system, which only offered to the party wronged such remedy as was afforded by a decree for the restitution of conjugal rights. The great advantage which the sentence of judicial separation has over the old divorce *à mensâ et thoro*, consists, however, in this, that from the date of the sentence, and whilst the separation continues, the wife is considered as a *feme sole* with respect to property of every description which she may acquire, or which may devolve upon her. The wife is also a *feme sole* for the purposes of contract, and may sue and be sued alone, so that her husband during the separation is free from all liability which she may incur. The marriage tie does indeed continue to subsist, as was the case in divorces *à mensâ et thoro*, but the injustice which frequently arose from that anomalous kind of relation has been effectually removed. Applications for the restitution of conjugal rights may still be made as before. The state of separation may be put an end to, either by the reversal of the decree or by the mutual consent and actual cohabitation of the parties, but in the latter case the property of the wife acquired subsequently to the separation is still "held to her separate use," subject to any agreement which the husband and wife may have entered into while separate.

Applications for judicial separation and restitution of conjugal rights may be made to the judges of assize, whose sentences are subject to appeal to the Court in London.

The Ecclesiastical Courts would in no case whatever dissolve a marriage once lawfully contracted. They would pronounce a marriage void *ab initio*, on the ground of some antecedent incapacity of the parties to contract, such as relationship within the forbidden degrees, a previous marriage, corporal imbecility, or mental incompetency. The total dissolution of a legal marriage could only be decreed by a special Act of the legislature, and in order to obtain this, it was necessary first to have obtained a decree of divorce *à mensâ et thoro*, in the Ecclesiastical Courts, and in almost all cases a verdict in a court of law in an action of *crim. con.* It is the object of the new Divorce Act to simplify this cumbrous and expensive process, and the new Court of Divorce is accordingly clothed with power to entertain petitions for divorce, either on the part of the husband or wife, and to pronounce a decree of dissolution or otherwise, according to the justice of the case. The husband may petition on the ground of the wife's adultery, the wife on the ground that her husband has been guilty of incestuous adultery, adultery with bigamy, adultery combined with cruelty or desertion for two years, or adultery combined with rape or unnatural crimes; simple adultery on the part of the husband not being sufficient to enable the wife to obtain a dissolution of the marriage. Connivance or collusion or the condonation of the petitioning party are grounds for refusing to interfere. On a dissolution being decreed, the husband may be compelled to make a suitable provision, when necessary, for the wife. When a husband petitions for dissolution of marriage, he may at the same time claim damages from the adulterer, who must be made a respondent. The damages are ascertained by the verdict of a jury, the old action of *crim. con.* being abolished by the statute. The adulterer may also be condemned in the costs of the whole proceedings.

After a decree of dissolution has been duly pronounced, either party is at liberty to contract a new marriage. Out of respect, however, to the religious scruples of a part of the community, clergymen of the established church are not compelled to solemnise marriages of persons who have been released from the bonds of a former matrimony. In case of a general refusal on the part of the clergy to celebrate marriages under such circumstances, parties so situated may of course marry with the other formalities by which that contract may be solemnised.

DÖBRENTEI, GABOR or **GABRIEL**, an Hungarian author and antiquary of distinguished merit, was born at Nagy-Szöllös, in the county of Veszprim, in 1786. He showed very early not only a remarkable zeal for the Hungarian language and literature, but a singular social talent for enlisting others in his views. At Oedenburg, a town not far within the frontier from Austria, and chiefly inhabited by Germans, he succeeded in getting up an Hungarian literary society, of which he became the secretary; and under his superintendence, when a youth of nineteen, a volume of 'Transactions' was published. At twenty he studied at Wittenberg and Leipsic, and in 1807 was recommended by Kaziuczy, then the almost acknowledged head of Hungarian literature, to the post of tutor to Count Louis Gyulay, a nobleman of Transylvania, which made him for some years a resident in that country. With the literary contributions of some of his Hungarian and Transylvanian friends, and the pecuniary contributions of the Transylvanian magnates, he set on foot and edited a magazine, the 'Erdélyi Muzéum,' of which the first number was issued at Klausenburg and the remaining nine at Pesth, after which it ceased for want of support; but it contained so many articles of interest that no Hungarian library is considered complete without it. In 1820 Döbrentei removed to Pesth, where he continued to reside for the remainder of his life, in the occupation of several highly-respectable official posts of a legal character, and in such constant literary activity that he became the acquaintance or friend of almost every person of any note connected with Hungarian literature. Indeed almost all the information that has been put in circulation on that subject in England had its origin in Döbrentei. He was the friend and correspondent of Dr. now Sir John Bowring, to whom he supplied much of the information for his 'Poetry of the Magyars;' he also communicated to Miss Pardoe materials for her account of Hungarian literature and authors in her 'City of the Magyar,' and he wrote the article on the subject in the Leipsic 'Conversations-Lexikon,' which, by its being translated in Lieber's 'Encyclopædia Americana,' and the translation reprinted in the Glasgow 'Popular Encyclopædia,' has become familiar to thousands of English readers. As a poetical writer, Döbrentei was not successful; his original poems appear to have been pleasing, and no more; and though his translation of Shakspere's 'Macbeth' was acted at Presburg in 1825, it did not receive such a welcome as to encourage the publication of his versions of the other masterpieces of Shakspere, which were reserved in Hungarian for the more successful pen of a lady, Emilia Lemouton, who is, we believe, the only translatress of our great poet in any language. Döbrentei was more at home in his exertions to establish a 'Casino' at Pesth, an establishment of nearly the same kind as an English club of our own days, but borrowed both in plan and name from Italy, where it is made use of not to render more exclusive the society of the capital, but to enliven the dullness of the provincial towns. He was, after Count Stephen Szechenyi, the most influential person in promoting this institution, and was for some years its secretary, but relinquished the post to take that of one of the secretaries of the Hungarian Academy in 1831, of which he was also a zealous promoter. Kohl, the traveller, bears testimony to the extraordinary influence of these establishments on the whole tone of society even in Hungarian villages, where they were imitated on a small scale. In 1837 Döbrentei received an intimation from the government that his holding the post of secretary to the Academy any longer would be incompatible with his official duties, and he then devoted himself to the editorship of his great work, the 'Régi Magyar Nyelvemlékek,' or 'Ancient Monuments of the Magyar Language,' the first volume of which, a substantial quarto, was published at Buda in 1825, and the fifth was in preparation at the time of Döbrentei's death. His labours on this work were the delight of his life, he pursued them with irrepressible ardour, and on the result his reputation rests securely. When he began, hardly anything was known of the history of the Magyar language for centuries, and a subject that he found in darkness he left environed with light. He was indefatigable in discovering the existence of old correspondence or documents in family archives; when he had once discovered them, he was no less eager in obtaining permission to copy and make use of them, and he was not a man to take easily a refusal. By this combination of qualities he amassed a quantity of materials which nobody before him had ever supposed to exist, and he made such good use of them that the works of subsequent authors are full of constant references to Döbrentei's 'Nyelvemlékek,' which has become one of the principal monuments of Hungarian literature. How the revolution of 1848 affected him we have not seen stated, but it is well known that his friend and fellow-promoter of progress, Count Stephen Szechényi, became a maniac. Döbrentei was still engaged in collecting materials for his great work when surprised by death on the 27th of March 1851, at the age of 65. He was the author of numerous lives of Hungarian worthies, both in the periodicals to which he contributed and in the 'Esmeretch Tára,' or Hungarian translation of the Leipsic 'Conversations-Lexikon,' with original additions to the Hungarian articles, and in editions of Berzsenyi and other authors published under his superintendence, but no extended account of himself appears to have been published since his death.

DOBRUDSCHA, a district in European Turkey, forms the north-eastern part of Bulgaria, and comprises the country north of the eastern rampart called Trajan's Wall, between the Danube on the west and north, and the Black Sea on the east. Trajan's Wall leaves the Danube between Rassova and Czernavoda, and runs across to the Black Sea a little south of Kustenje, a distance of about 35 miles. In its western part the wall skirts a small stream, the Kara-Su (Black Water), that connects several small lakes, and enters the Danube above Czernavoda. At the head of the valley of the Kara-Su, near Bourlak, a line of hills or downs, composed chiefly of a porous limestone rock, runs north and south 164 feet above the level of the Black Sea. Along the coast at Kustenje also there is an uninterrupted range of low hills and cliffs, so that it is certain the Danube never had an outlet across the Dobrudscha in this direction. The formation of a canal from Czernavoda to Kustenje has been long a favourite project; but on the summit-level, which consists of porous limestone, no water ever rests to feed such a canal if it were cut. Besides, the only water communication between these two points that would be of much use would be a ship-canal, or, in other words, the opening of a new bed for the Danube; and this the nature of the ground renders all but physically impossible.

The low undulating down runs northward all through the Dobrudscha, forming a small watershed between the Danube and the sea; on the north it joins a lofty mountainous mass which covers the north of the district between Baba-Dagh and Matchin. On the eastern side the Dobrudscha is marshy, and contains several lakes. There is a great scarcity of drinkable water in this district. It contains however many fertile spots, although in the hot season of the year, like all the countries near it, it resembles a desert. In the spring, on the melting of the snows, the soil is saturated with wet, and in most parts is converted into a sea of mud. The inhabitants are chiefly Bulgarians, Tartars, and runaway Cossaks, who rear sheep and buffaloes. Eagles, bustards, cranes, wild geese, partridges, kites, ducks, wild swans, and wild dogs, are extremely numerous in the Dobrudscha. Along the Danube are the fortresses of Hirsova, Matchin, Isaaktcha, and Tulcha. Tulcha stands at the head of the St. George mouth of the Danube, which forms part of the boundary between the Dobrudscha and Russia. In the interior is the town of Baba-Dagh, between the mountains of that name and Lake Rassein. Kustenje is a mere village. In 1854 a Russian army entered the Dobrudscha. The Turkish army fell back to the fortress of Silistria, where they defended themselves successfully.

DONINGTON. [LINCOLNSHIRE.]

DONINGTON, CASTLE. [LEICESTERSHIRE.]

DONIZETTI, GAETANO, was born September 25, 1798, at Bergamo, in Northern Italy. He studied in the Lyceum of that town, and his father having originally destined him for the law, it was somewhat late before he commenced his musical studies. He received his first instruction at the Musical Institute of Bergamo, of which Simone Mayer was then director. Here he remained three years, and in 1815 removed to Bologna, where his musical education was completed under Pilotti and Mattei. In consequence of some dispute with his father, he entered into the army, and while in garrison with his regiment at Venice in 1818 produced his first opera, 'Enrico di Borgogna.' He continued to write for the theatre, and in 1822 left the army. His earliest pieces are forgotten, or at least are no longer performed, and it was not till 1830, when he produced 'Anna Bulena' at Milan, that he began to take rank with the higher class of musical composers. In the course of these first twelve years of his career he composed 31 operas. During the fourteen years from 1830 to 1844, when his last opera, 'Catarino Cornaro,' was performed, he produced 33 operas, of which several have sunk into oblivion, but others still retain their places on the stages of Italy, Germany, France, and England. Some are especial favourites, and frequently performed. Among these more fortunate productions may be mentioned 'Anna Bolena,' Milan, 1830; 'L'Elisire d'Amore,' Milan, 1832; 'Lucrezia Borgia,' Milan, 1833; 'Marino Faliero,' Paris, 1835; 'Lucia di Lammermoor,' Naples, 1835; 'Betly,' Naples, 1836; 'La Fille du Régiment,' Paris, 1840; 'La Favorite,' Paris, 1840; 'Linda di Chamouni,' Vienna, 1842; 'Don Pasquale,' Paris, 1843; 'Maria di Rohan,' Vienna, 1843. Most of these later operas, besides his usual grace and facility, exhibit strength, solidity, command of the resources of counterpoint, and skill in instrumentation, much superior to his earlier productions. His artistic powers were thus manifestly improving and expanding towards the termination of his musical career. Soon after the performance of his 'Lucia,' which excited great admiration, he was appointed Professor of Counterpoint in the Royal College of Music at Naples, and after the production of 'Linda' at Vienna, he was named chapel-master and composer to the imperial court. In 1845, while in Paris, symptoms of mental decay, arising chiefly from habits of intemperance, began to show themselves, and he was for some time in a lunatic asylum. In October 1847 he was removed to his native town of Bergamo, where he died on the 8th of April 1848. (*Nouvelle Biographie Générale.*)

DONOSO CORTÉS, JUAN, an eminent Spanish statesman and author, was born in 1809, of wealthy parents, at the town of El Valle in Estremadura. He was so precocious that at the age of eleven he studied logic at Salamanca, and had completed his legal studies at Seville long before he was competent to be admitted as advocate at the age of twenty-four. He was known to a large circle of friends at Seville as a promising poet, and an ode which he published on the nuptials of King Ferdinand with Maria Christina was particularly distinguished among all those on the occasion. In 1832, when the temporary revocation by Ferdinand of the decree for the succession of the present Queen Isabel awakened the apprehensions of the liberal party that all progress would be checked, a large number of the principal young men of Madrid waited on Queen Christina to offer her their lives in defence of the rights of her infant daughter, and at their head was Donoso Cortés. From this time he was distinguished by the favour of Queen Christina, and entered upon a political career before he was of age to enter on a legal one. A pamphlet however which he composed under the title of a 'Memoir on the Rights of Isabel the Second,' was suppressed by the advice of his friends as containing ideas so ultra-liberal as to be certain to give offence. He was appointed in the same year to a post in the ministry of Grace and Justice, and in the next published his 'Considerations on Diplomacy and its Influence on the Political and Social State of Europe, from the time of the Revolution of July to that of the Quadruple Alliance.'

In 1835 he was sent as a royal commissioner with General Rodil to bring back to obedience his native province of Estremadura, and acted with such success as to receive the grand cross of Carlos III. and a higher official station; but dissatisfied with the turn that affairs were taking, he resigned his post, and for some time occupied himself in combating the party which supported the revolution of La Granja. He founded the newspaper 'El Piloto,' in which he was assisted by Alcalá Galiano, and was for some time editor of the 'Revista ee Madrid,' a review or rather magazine established on the plan of the French 'Revue des Deux Mondes,' his first article in which was one of a series on 'Spain since 1834.' He delivered in 1837 at the Athenæum of Madrid, a series of lectures on the science of politics, which attracted much attention. He was in France in 1840 at the time of the expulsion of Queen Christina, hastened to offer her his services on her arrival in that country, and is said to have been the author of the manifesto which she issued from Marseille. He afterwards went to Madrid on a commission from her to defend her rights against Espartero, but his efforts were unsuccessful. He then returned to France and occupied himself with the composition of a 'History of the Minority of Queen Isabel II.,' passages of which were published in the 'Revista de Madrid,' and have received high applause from Spanish critics. He returned to Spain in 1844 after the fall of Espartero, and was named plenipotentiary to invite Queen Christina back to Madrid, when his services were rewarded with the title of Marquis de Valdegamas. His pen, which never ceased to be active, was by this time active in an entirely different cause from that in which he had first won his laurels. From an ultra-liberal Donoso Cortés had become a Catholic conservative, and after Balmes, the most distinguished literary advocate of Catholicism in Spain. He was ambassador to Prussia at the time of the revolution in 1848, and afterwards ambassador to France, a country for which he always avowed a strong partiality. It was while holding that post, and very soon after he had officiated as Spanish ambassador at the marriage of Louis Napoleon with a Spanish consort, that he was seized with an attack of pericarditis, which carried him off, after about a month's illness, on the 3rd of May 1853, at Paris.

A select collection of his writings, 'Coleccion Escogida de los Escritos del Excelentisimo Señor Don Juan Donoso Cortés,' was published in two volumes at Madrid in 1848. It comprises none of his poetry but most of his political writings that we have mentioned, and several of his articles from the reviews, which seem, like those of Macaulay, to be considered the brightest ornaments of his literary coronet. For brilliancy of style they are remarkable among the general flatness of Spanish composition, but for soundness of thought they are not, we think, likely to acquire a high reputation in England. One of them, on Pius IX., talks of the "singular privilege which Italy enjoys in conjunction with Spain of drawing towards itself the attention of the civilised world," and goes on to affirm that "the nations always keep their eyes fixed by instinct on the Italian and the Spanish race." There is much that is as questionable on most of the subjects on which he touches.

DOON. [Ayrshire.]

DORCHESTER. [Oxfordshire.]

DORNOCH. [Sutherland.]

DOUBLEDAY, EDWARD, a naturalist of eminence, was born in 1810, and died in London in 1849. The family of Doubleday are honourably distinguished for their devotion to natural history pursuits, and the subject of this notice early distinguished himself by his contributions to the literature of Ornithology and Entomology. His first papers were devoted to the subject of entomology, of which many were published in the volumes of the 'Entomological Magazine.' In the early part of his life he made a tour through the United States of America, and made many important observations on the animals of that country. These he published in a paper 'On the Natural History of America,' in the fifth volume of the 'Entomological Magazine.' On his return from America he was appointed one of the curators of the British Museum. The large collections in this institution afforded him abundant materials for increasing his knowledge and developing his views of the structure of insects. The results he made known in a variety of papers, but more especially in his work 'On the Genera of Diurnal Lepidoptera.' This work, which was published in parts and left unfinished at the author's death, consisted of descriptions, with coloured illustrations of great beauty and accuracy by Mr. Hewitson, of all the genera of butterflies. This family of insects was studied by Mr. Doubleday with the greatest industry, and his contributions to our knowledge of their forms are the most valuable of his labours. He devoted also considerable attention to ornithology, and assisted his brother Henry in publishing a work on this subject. He also contributed a paper 'On the Occurrence of Alligators in East Florida,' to the 'Zoologist.' A list of his papers will be found in the second volume of Agassiz's 'Bibliographia Zoologica,' published by the Ray Society.

DOWNHAM. [Norfolk.]

DRACONINA, a sub-family of Saurians belonging to the family *Agamidæ*, the tribe *Strobilosaura*, and the sub-order *Pachyglossæ* of Dr. J. E. Gray's arrangement. The family of Agamas, or *Agamidæ*, is thus defined by Dr. Gray:—"Teeth implanted on the end of the jaws. Tongue short, depressed, apex entire or slightly nicked. Eyelids connivent, valvular. Feet, for walking. Toes all free, unequal; the thumb of the hind feet on the same plane as the other toes; the little toes lower down on the ankle than the thumb. The thumb is anterior and internal, and the great toe of the hind feet occupies the same position, the thigh and foot being bent forwards. This is proved by analogy; this toe being the one that is clawless in the *Gecko*, which have the clawless thumb, and in *Anolis*, where the thumb and great toes are simple, and not dilated beneath, like the other toes."

The synopsis of the genera of this family, according to the 'British Museum Catalogue,' is as follows:—

I. Body compressed. Living on trees.

A. Femoral and pre-anal pores none. Scales imbricate. Asiatic.

a. Ribs elongated, exserted, supporting wing-like lateral expansions. Throat with 3 pouches.

1. *Draco*.—Ears naked. Nostril below the face-ridge.
2. *Dracocella*.—Nostril above the face-ridge.
3. *Dracunculus*.—Ears covered with scales.

b. Ribs simple. Back crested.

* Toes 4 or 5. Ears exposed.

4. *Sitana*.—Males with an elongated pouch. Females without any pouch.

** Toes 5—5. Tail with elongated keeled scales beneath. Scales of back small, often with scattered larger ones.

† Ears hidden under the skin.

5. *Lyriocephalus*.—Head lyrate. Muzzle with a round tubercle in front. Scales unequal.
6. *Ceratophora*.—Head square. Muzzle with a prolonged horn-like process. Scales unequal.
7. *Otocryptis*.—Head squarish. Muzzle nearly flat, simple. Eyebrows bluntly angular behind.

†† Ears exposed.

8. *Gonyocephalus*.—Scales of the belly smooth, of the back unequal. Eyelids angular, produced.
9. *Dilophyrus*.—Scales of the belly smooth; of the back equal. Eyebrow rounded, simple.
10. *Tiaris*.—Scales of the belly keeled, of the back unequal. Eyebrows and parotids unarmed.
11. *Acanthosaura*.—Scales of the belly keeled, of the back unequal. Eyebrows and parotids armed.

*** Toes 5—5. Tail with broad rhombic keeled scales beneath. Scales of back uniform.

12. *Bronchocela*.—Nuchal crest simple. Scales in descending series.
13. *Salea*.—Nuchal crest double. Scales large, in longitudinal series.
14. *Calotes*.—Back crested. Scales in ascending series. Head swollen behind, with one or two ridges of spines.

**** Toes 5—5. Tail with truncated keeled scales beneath. Scales small, keeled, in cross rings.

15. *Chelasonia*.—Parotids swollen, armless. Throat lax. The nape and back with a low crest. Tail rather compressed. Face-ridge rounded, with small scales.
16. *Charasia*.—Parotids swollen, with some spines above. The nape and back with a low crest. Tail tapering. Face-ridge distinct, with enlarged imbricated scales.
17. *Gindalia*.—Parotids rather swollen, with 2 or 3 spines above. Nape and back not crested. Tail tapering, round. Face-ridge indistinct.

B. Femoral pores distinct.

a. Scales rhombic, placed in rings. Toes fringed on each side. Back crested. Throat lax, folded across.

18. *Lophura*.—Back and tail with a fin-like crest, supported by bony rays. Head squarish.
19. *Phrysignathus*.—Back and tail with a crest of compressed scales. Head swollen behind.

b Scales irregular, imbricate. Australian.

* Neck with a frill-like expansion on each side.

20. *Chlamydosaurus*.—Head rhombic.

** Neck simple.

21. *Hatteria*.—Back and tail crested. Head elongate. Pre-anal pores numerous. Scales small.
22. *Lophognathus*.—Back crested. Head elongate. Pre-anal pores 2—2. Femoral pores 2—2.
23. *Diporophora*.—Back keeled. Head short. Pre-anal pores 1—1. Scales rhombic, of belly larger.
24. *Amphibolurus*.—Back crested, with longitudinal series of larger keeled scales. Femoral pores numerous.
25. *Grammatophora*.—Back not crested, with cross rows of larger scales. Femoral pores numerous.

II. Body depressed. Back with imbricate scales. Throat with a cross fold. Terrestrial.

a. Pre-anal pores distinct. Femoral pores none. Ears exposed.

* Pre-anal and abdominal pores in several rows.

26. *Laudakia*.—Tail with rhombic keeled scales. Parotids spinose.
27. *Stellio*.—Tail with rings of large spinose scales. Parotids spinose.

** Pre-anal pores in a single line. Abdomen poreless.

28. *Agama*.—Parotids spinose. Scales rhombic, keeled.
29. *Trapelus*.—Parotids unarmed. Scales minute. [AGAMA.]

b. Pre-anal and femoral pores none.

* Ears exposed. Body and limbs with large spinose tubercles.

30. *Moloch*.—Neck with a convex tubercle above.

** Ears hidden. Scales small, granular. Back not crested.

31. *Phrynocephalus*.—Angle of mouth simple. Toes toothed on the sides.
32. *Megalochilus*.—Angle of mouth fringed. Toes fringed on the sides.

c. Femoral pores distinct. Pre-anal pores none. Ears exposed. Scales small, granular. Back not crested.

33. *Uromastyx*.—Tail broad, depressed, with complete rings of spinose scales.
34. *Saara*.—Tail broad, depressed, with scales of the upper part of the rings spinose; of lower, armless.
35. *Leiolepis*.—Tail round, elongate, tapering, with whorls of smooth scales.

The genera and species of the family *Draconina* are as follows:—

1. *Draco*.—Head small. Nostril in a scale, rather tubular on the side of the face-ridge. Tympanum of the ear visible, opaque, white. They live on trees, walking with agility with their wings folded on their sides, but they expand them and use them as a parachute when they throw themselves from the tops of trees. They spread out their pouches as they lie on the trunks of the trees. Scales unequal, some larger, keeled. Nape crested. For skeleton of *Draco*, see DRAGON.

D. volans, Linn., the Flying Lizard. It is the *D. major* of Lamarck, *D. viridis* of Daudin, *D. Bouroniensis* of Lesson, and the *D. Daudini* of Duméril. The scales of the back are rather broad, generally smooth; of the throat granular, of the same size; the lateral pouches of the males moderate, rounded at the end, covered with ovate keeled scales: the throat black-spotted; wings gray, fulvous, or brown, spotted and marbled with black, sometimes forming four or five oblique black bands near the outer edge: the sides with a series of large broad keeled scales.

D. Timorensis, the Timor Flying Lizard. It is the *D. viridis Timorensis* of Schlegel. It has flat scales, rather large, smooth, unequal, with a row of rather larger keeled scales upon and on each side of the vertebral line; wings reddish, brown-spotted; lateral pouches (of male) moderate, rounded at the end, covered with large keeled scales; sides with an interrupted series of large keeled scales.

D. fimbriatus, Kuhl, the Fringed Flying Lizard. Scales of the back small, equal, mostly smooth; the throat with many circular spaces, covered with large granular scales; head white, brown-netted; lateral pouches of male elongate, angular, acute, covered with large keeled scales; wings with short whitish longitudinal lines; sides with a series of small triangular keeled scales, placed in groups of two or three; nostrils sub-superior. For figure of *Draco fimbriatus*, see DRAGON.

2. *Dracocella.*—Head small, covered with small unequal scales; the nostrils roundish, in a scale, erect, vertical on the face-ridge; tympanum exposed, and opaque.

* Nape crested.

D. Dussumieri, Dussumier's Dragon, has moderate scales, rather rhombic; the sides with a series of rather larger scales, placed in roundish groups; orbit with a small bony point at back and front angle; wings with large brown spots near the body, and largely marbled near the outer edge; a black band across the throat; base of the pouch blue-black; the limbs moderate.

** Nape not crested.

D. Nacuratopogon, the Red-Throated Dragon. The orbit with a small bony point above, upon the front and back edge; scales of the back equal, smooth, the sides with a series of large keeled scales; nape not crested; a large round black spot on each side of the base of the pouch; wings brown-spotted; the limbs elongate.

3. *Dracunculus.*—Head quadrangular, covered with small unequal scales; nostrils lateral, on the face-ridge; tympanum hid under the skin, covered with scales. Weigmann described *D. lineatus*, as having but five exserted ribs, but the specimens in the British Museum, like the other dragons, have six on each side.

* Nape not crested, with a longitudinal fold.

D. quinquefasciatus, the Banded Flying-Lizard. Wings with five cross bands; scales of the back keeled; nape with a longitudinal fold, not crested; nostrils superior, erect; ears covered with many equal granular scales.

** Nape crested. Ears slightly concave.

D. lineatus, the Lined Flying-Lizard. Head gray, white-spotted; wings dark-banded, with small white longitudinal lines; the sides and throat bluish-black, with large white spots; the ears indistinctly marked, covered with three flat scales; base of the tail rounder above, with a slight crest on each side.

D. ornatus, the Banded-Head Dragon. Gray; head black, cross-banded; chin black, dotted; wings gray, reticulated with black, and with broad black bands at the edge; scales rhombic, of the middle of the back larger, keeled, of the sides smaller, smooth; ears covered with small equal granular scales; tail slender, compressed, with five keels above and two stronger keels beneath, rather depressed at the base, with five slight keels above.

D. maculatus, the Spotted-Winged Dragon. Gray, black-spotted; wings black-spotted; throat gray; pouch of the male elongate; scales of the back rather unequal, rhombic, keeled, of the sides rather smaller; sides with a series of large keeled scales; ears rather sunk, with unequal flat scales; tail slender, with a central keel above and five more small ones on the sides; base dilated, with five nearly equidistant equal keels above.

D. spilopterus, Weigmann's Flying-Lizard. Wings reddish near the body, with large brown spots, yellow near the edge; throat yellow, black-spotted. This may be the same as the former species, but the wings are subelliptic, and the scales do not exactly agree.

DRAGON-FLY. [LIBELLULA, *S.* 1.]

DRAGONET. [CALLIONYMUS.]

DRAKÆA, a genus of plants belonging to the natural order *Orchidaceæ*. *D. elastica* has a single flower placed at the end of a slender smooth erect scape from 12 to 18 inches long, and its labellum, which is hammer-headed and placed on a long arm with a moveable elbow-joint in the middle, is stated by Mr. Drummond to resemble an insect suspended in the air and moving with every breeze.

DREELITE. [MINERALOGY, *S.* 1.]

DRONFIELD. [DERBYSHIRE.]

DROZ, FRANCIS-XAVIER-JOSEPH, was born at Besançon on the 31st of October, 1773. Having visited Paris for a few months in 1792 he witnessed the massacres of September; after which he returned to Besançon, and enlisted as a volunteer during the national enrolments. His comrades, according to the fashion of the times, elected him as their captain. But after a short service of little better than three years, he quitted the army for ever in 1796, and devoted the rest of his life to study. About the same time he obtained by his family influence the appointment of Professeur de Belles Lettres to a public school in his native town; and in 1799 he published his 'Essai sur l'Art Oratoire.'

In 1802 his school having been suppressed, he went to Paris, where he settled definitively, and became connected with Villemain, Cabanis, and all the leading literati of the time. By the advice of Cabanis, he published his 'Lina,' a work of fiction in 1804, to attract attention to his philosophical writings. In 1806 appeared his 'Essai sur l'Art d'être Heureux,' which was followed by an 'Eloge de Montaigne,' in 1811, for which a medal was awarded to him. From 1816 to 1820 he wrote for several newspapers, inculcating his temperate views of moral philosophy, but refraining from politics. He then joined Picard in writing his 'Mémoires de Jacques Fauvel,' a tame imitation of Gil Blas; the work appeared in 1823. The next year he carried off the Montyon prize for his treatise 'De la Philosophie morale, ou des différents Systèmes sur la Science de la Vie.' In 1825 he was elected a member of the French Academy.

He had long desired to hold a professorship, and at length in 1832 he was appointed to lecture, by authority, at the Institute, on Moral and Political science. In 1839 he published his best work, 'L'Histoire du Règne de Louis XVI.' His gentle and unambitious life came to a close on the 4th of November, 1850, when he died as peaceably as he had lived. Although his works are written in a very unpretending style, they will be found well stored with suggestive ideas, and all the principal critics of his country have mentioned them with esteem.

DUCK-WEED. [LEMNA.]

DUFRENITE. [MINERALOGY, *S.* 1.]

DUFRENOYSITE, a mineral, consisting of an arseniuret and sulphuret of lead. It occurs in dodecahedrons of a dark steel-gray colour in the Dolomite of St. Gothard. The specific gravity is 5·55.

DULWICH COLLEGE. Under ALLEYN, WILLIAM, in the 'Penny Cyclopædia,' vol. i., p. 347, an account was given of the college of his institution. As the value of the property with which he had endowed it had enormously increased, it had been long felt that the income was no longer employed in accordance with the donor's intentions. An Act was therefore passed, 20 & 21 Vict. c. 84, for its better management. According to this Act, the educational branch of the college is very largely extended; two schools are established, an upper and a lower school, in which the classical and modern languages, mathematics, history and geography, physics, chemistry, civil engineering, and other departments of knowledge are to be taught to daily scholars, on the payment of a small fee, with no limit to the number except the amount of funds required and the means of accommodation. A certain number of boys, to be elected by competition (at present not to exceed twenty-four, but to be increased when there are sufficient funds), are to be foundation scholars, to be provided with board and lodging free; and there are eight exhibitions of 100*l.* a year each provided for the scholars of the upper school, tenable for five years while studying at an English university or for a profession; and twelve of 40*l.* for boys of the lower school, tenable for four years for the like purposes.

The life interests of the present master, warden, fellows, and poor brothers and sisters are provided for; but for the future management nineteen governors are to be chosen; namely, two each to be elected by the four parishes of St. Saviour's, Southwark; St. Giles, Camberwell; St. Luke, Middlesex; and St. Botolph, Bishopsgate, to hold office for seven years; and the remaining eleven to be appointed by the Court of Chancery, without any other restriction than that one must be resident in Dulwich. There is to be an upper and a lower master of the schools, a resident chaplain, and an organist for the chapel, which is to be maintained as a place of worship for Dulwich. The net income of the college is to be divided into four equal parts: three to be devoted to the purposes of education, and the remaining fourth to the support of aged men and women, at present (1858) not to exceed twenty-four, and to be chosen in equal proportions from the four parishes above named.

Provision is also made for the maintenance and preservation of the picture gallery. If a surplus should arise from this fund, it is to be applied in providing instruction in drawing and designing for such of the boys in the two schools as evince an inclination and capability for their acquisition.

DUMB-CANE. [CALADIUM, *S.* 1.]
DUMBLANE. [PERTHSHIRE.]
DUNDAS. [CANADA, *S.* 2.]

DUNMANWAY, Cork, Ireland, a market-town and the seat of a Poor-Law Union, is beautifully situated on the river Bandon near its head, in 51° 43′ N. lat., 9° 5′ W. long., distant 33 miles W.S.W. from Cork, 190 miles S.W. from Dublin. The population in 1851 was 2222. Dunmanway Poor-Law Union comprises 15 electoral divisions, with an area of 103,917 acres, and a population in 1851 of 20,517.

The town is situated on level ground almost entirely surrounded by lofty and rugged hills. The greater part of the town was built by Sir Richard Fox, who also obtained for it a charter as a market-town. There are two churches for Episcopalians, a Roman Catholic and a Wesleyan Methodist chapel, and a district Bridewell. A Charter school was endowed by Sir Richard Fox. The market is held weekly; fairs are held in May, July, September, and October.

DUNSE. [BERWICKSHIRE.]
DUNSTER. [SOMERSETSHIRE.]

DUPERRÉ, VICTOR GUY, a baron of the empire and a French admiral, was born at La Rochelle on the 20th of February, 1775. He commenced his maritime career in the merchant navy, and went to India, but returned to France after a voyage of eighteen months; and war having broken out, he entered the republican service in 1795. During the next ten years he took part in many single ship-fights with the English, until he was promoted to the staff on board the Veteran, commanded by Prince Jerome Bonaparte, in 1804. In September, 1806, he became captain, and took the command of the Sirène frigate. In March, 1808, whilst off the coast of Bretagne, in company with the Italienne, Duperré was chased by two ships and three frigates, and whilst making for the port of L'Orient, his passage was intercepted and he had to sustain for an hour and twenty minutes an unequal combat with two of the enemy's ships, keeping up a constant fire at once from both broadsides. Though repeatedly summoned to surrender, he contrived to bring off his frigate; an act of skilful intrepidity which did not escape the notice of Napoleon, who promoted him to the rank of ship captain. He performed several brilliant exploits in the Indian Ocean in 1808 and 1809, after which he became a baron of the empire and contre-amiral, August 20, 1810. In September, 1823, he was appointed to command the French squadron lying before Cadiz, and contributed to the capture of that city. In 1826 he became commander in chief of the combined fleet in the Antilles.

In 1830 he was summoned to Paris in February by the government of Charles X. to be consulted respecting the meditated expedition against Algiers. In his reply, Duperré represented the undertaking as extremely perilous and uncertain, but in spite of his representations it was resolved upon, and the absolute command of the naval forces was confided to him. This fleet set sail on the 25th of May, 1830. It consisted of 103 ships of war, and 572 vessels belonging to the merchant service, and other craft, the whole having on board 37,331 men and 4000 horses. After encountering many difficulties from the nature of the coast and contrary winds, Duperré appeared before the batteries of Algiers on the morning of the 13th of June. The signal share taken by Duperré in the siege and capture of this formidable fort, induced Charles X. to raise him to the peerage, July 14th, 1830, a few days before his own fall. This appointment was revoked by the government of July; but on the 13th of August, 1830, the same government made him an admiral, and restored his peerage. He became minister of the naval department November 22, 1834; and was afterwards recalled twice to the same office under different administrations. He resigned this office on account of declining health, February 7, 1843, and died November 2, 1846.

DUPONT DE L'EURE, JACQUES-CHARLES, was born at Neubourg, department de l'Eure, on the 27th of February 1767. He was an advocate, practising in Normandy, when the revolution began in 1789, and was made a judge in one of the law-courts of Louviers in 1792. In 1798 he was a member of the Council of Five Hundred, and on the 18th Brumaire was driven out by the bayonets of Murat. He belonged to the Corps Legislatif in 1813, and the following year was elected a deputy of the new Chamber. During the governments of Louis XVIII., of Charles X., and of Louis Philippe, he attached himself without deviation to the cause he had at first adopted of constitutional reform, and on more than one critical occasion took the lead of the liberal party. After the revolution of July 1830, Dupont de l'Eure became a commissioner of the law in the provisional government in his own department, and soon after, yielding to the entreaties of Lafitte, he accepted the office of Minister of Justice; but his principles and want of flexibility were suited neither to his colleagues nor to his sovereign, so that he resigned his portfolio on the 27th of December, 1830, and resumed his place in the ranks of the opposition. After the fall of Louis Philippe in February 1848, Dupont de l'Eure became, against his own wish, a member of the provisional government. He died in 1855, at the age of eighty-eight. A firm but by no means a violent republican, he was generally respected as a consistent and honest politician.

DUTENS, JOSEPH-MICHEL, the son of Michel-François, was born at Tours on October 15, 1765. He was entered when eighteen at the École des Ponts et Chaussées, and at twenty-two years of age he left it with the brevet of engineer. In 1800 he printed his first work at Evreux, 'Des Moyens de naturaliser l'Instruction et la Doctrine,' and in the same year published a topographical description of the arrondissement of Louviers, in the department of Eure. In 1804 he gave to the world his first work on political economy, an analytical exposition of its fundamental principles. In 1818 he was commissioned by the government to travel in England in order to obtain a knowledge of the canal system there, and he extended his labours to all the great commercial works of the country, the results of which were published at Paris in 1819 in 'Memoirs on the Public Works of England.' The work is divided into two parts; the first is devoted to engineering, describing the canals, the works of art employed in their construction, the cost of making, the expense of maintaining, and the system of working; the second is principally to develop the mode of concession of public works in England, and its advantages in a country where the energies of association are in almost all cases employed instead of the intervention of the government.

Desirous of enabling his country to profit by his studies in England, Dutens published in 1829 a 'History of the Interior Navigation of France,' in which he gives a detailed description of the geographical features of France, and an account of its rivers and canals; with an analysis of the agricultural and industrial products of France, showing their value if made available by a net-work of canals, sketching a scheme of what should be the principal branches, and discussing the financial condition which would ensure its success. In 1835 Dutens published his greatest work, the 'Philosophy of Political Economy; or a new Exposition of the Principles of this Science,' in 2 vols. 8vo. It was an expansion with considerable modifications of his previous work, and occasioned much opposition from the economists of the school of Adam Smith. Blanqui says, "it is only a new edition of the doctrines of Quesnay, but with less of advancement in respect to commercial freedom and duties." The severe criticisms occasioned M. Dutens to publish in 1837 a defence of his work, and a second in 1839; and the contest was still going on when the Académie des Sciences elected him a member of their body. He then published in 1842 his 'Essai comparitif sur la formation et la distribution du Revenue de la France en 1815 et 1835,' a work which contains the best statistical resumé of the productive riches of France, and has received and deserves high praise. In his last issued work, 'Des pretendues erreurs dans lesquelles, an jugement des modernes economistes, seraient tombés les anciens economistes relativement au principe de la richesse nationale,' in which he defends the theory of Quesnay, Turgot, and their followers, that manufactures and commerce do not constitute the wealth of a country, but that this advantage is only due to agriculture. M. Dutens died in 1848.

(*Nouvelle Biographie Générale.*)

DUTROCHET, RENÉ-JOACHIM-HENRI, a distinguished French botanist and natural philosopher. He was born at the Chateau de Néon, Poitou, on the 14th of November 1776, and died at Paris on the 4th of February 1847. He was the son of a military officer, who emigrated, and whose property was confiscated. Young Dutrochet in 1799 entered as a private the military marine, but afterwards deserted. In 1802 he commenced at Paris the study of medicine. He made a brilliant career as a student, was created doctor in 1806, and in 1808 was appointed physician to Joseph Bonaparte, king of Spain. He became principal physician to the Hospital of Burgos, which was then devastated with typhus. He displayed here great energy and skill. In 1809 he returned to France, and gave himself up to the study of those natural sciences for which his medical education fitted him. The tendency of Dutrochet's mind was to develop the laws which regulated the existence of organic beings, and many of his researches have had a permanent influence on the development of the departments of science to which they relate. His name is best known to physiologists from his researches on the passages of fluids through animal and vegetable membranes. The laws which he observed to regulate these phenomena he applied to the explanation of the functions of absorption and excretion in the animal and vegetable body. The passage of a fluid from without inwards he called 'endosmosis,' and the passage from within outwards 'exosmosis.' His views on this subject were published in a work which appeared both in London and Paris in 1828, with the title 'Nouvelles recherches sur l'Endosmose et l'Exosmose, suivies de l'application expérimentale de ces actions physiques à la solution du problème de l'irritabilité végétale et à la determination de la cause de l'ascension des tiges, de la descente des racines.' The phenomena comprehended under the terms endosmose and exosmose were rightly described by Dutrochet, but he was hasty in tracing their cause to electricity, and failed to see that they were parts of a much more general set of phenomena than he had described. His other papers are very numerous, and were on a variety of subjects not immediately related. Thus we find his inquiries embraced amongst other things the following subjects: a New Theory of Voice; a New Theory of Harmony; on the Family of Wheel-Animalcules; History of the Egg of the Bird; on the Envelopes of the Fœtus; Researches on the Metamorphosis of the Alimentary Canal in Insects; on the Structure and Regeneration of Feathers; on the Height of the Meteor which projected Aerolites at Charsonville in 1810; on the Growth and Reproduction of Plants; on the Special Directions taken by certain parts of the Plants. The results of all his labours and a connected view of the subjects to which he devoted his attention, he gave in a volume entitled 'Mémoires pour servir à l'Histoire Anatomique et Physiologique des Végétaux et des Animaux.'

DUVERNOY, GEORGES-LOUIS, a distinguished anatomist and zoologist. He was born at Montbelliard, then a dependency of the duchy of Würtemburg, now an arrondissement in the department of Doubs in France, on the 6th of August, 1777, and died at Paris on the 1st of March, 1855. His father practised as a physician at Montbelliard, and he was brought up to the same profession. He commenced his studies at Stuttgart in 1792; but the principality of Montbelliard having been ceded to the French in 1793, he was compelled to finish his studies at Strasbourg. He subsequently went to Paris, where he graduated in 1801. In 1802 he was associated with M. C. Dumeril in reporting the lectures of Georges Cuvier, then in the zenith of his reputation. The 'Leçons d'Anatomie comparées' were concluded and published in 1805. On the completion of this labour he married, and, as natural science afforded him little hope of support for a family, he retired to his native town to practise his profession. In 1809 he was recalled to Paris, and named by De Fontanes joint professor of zoology in the faculty of science. Again, however, he returned to practise his profession in Montbelliard, and for nearly twenty years this distinguished zoologist pursued its harassing and laborious duties. In 1827 the chair of natural history in the faculty of science in Strasbourg was offered him: this he accepted; and from this time to his death we find him pursuing with unwearied industry zoological researches. In 1837 he was offered the chair of natural history in the College of France, vacated by the death of his great master, Cuvier. This chair he accepted, and held till 1850, when the death of De Blainville having created a vacancy in the chair of comparative anatomy he was appointed to it, and held it for four years. Duvernoy's contributions to zoological science are extremely numerous. In his writings and lectures he was more remarkable for the accuracy and extent of his knowledge than for the novelty and originality of his views. He was an industrious compiler, and was an extensive contributor to the 'Dictionnaire des Sciences Naturelles,' and also to the 'Dictionnaire Universelle d'Histoire Naturelle.'

DYNASTES, a genus of Coleopterous Insects belonging to the section *Pentamera*, sub-section *Lamellicornes*, and family *Dynastidæ* of M'Leay. The species have the body very large and thick, the outer edge of the jaws sinuated or toothed, and the lower jaws corneous and toothed. The genus *Dynastes* embraces the largest and most robust forms of the insect kingdom. They are nevertheless quite harmless. None of the species are found in this country, and only one in France. The largest forms are found in the tropical parts of India and South America. The habits of these insects are much the same wherever found. They bury themselves by day in holes in the ground, or in the decaying trunks of trees. At night they are seen flying about the trees. The females are more numerous than the males, and do not possess the horns, which give the males so remarkable an appearance. The more remarkable species of this genus are the Elephant and Hercules Beetles. The latter is of a glossy black colour. In the males the thorax is developed into a thick and curved horn, which is bent downwards at the tip, and a similar horn projects from below which points upwards, so as to come in contact with the former. The entire length of this beetle is 6 inches.

DYSART. [FIFESHIRE.]

DYSCLASITE, a Mineral consisting of hydrous silicate of lime. It occurs in white fibrous masses, consisting of delicate fibres of a whitish or yellowish or bluish colour. It has a hardness of 4·5, and a specific gravity of from 2·28 to 2·36. It is easily gelatinised in hydrochloric acid. It is found in the trap of the Faroe Islands. A variety called *Okenite* is from Greenland.

DYSDERA, a genus of Spiders. The species have 6 eyes, placed in a curve resembling a horse-shoe open in front; the mouth-claws very large, and produced in front; the maxillæ straight, and dilated at the place of insertion of the palpi. The type of the genus is *D. erythrina*, which is not an uncommon species in Great Britain. It is mostly found under stones.

DYSODIL. [COAL, *S.* 2.]

DYSLUITE. [MINERALOGY, *S.* 1.]

E

EARTH-WORM. [ANNELIDA.]
EASINGWOLD. [YORKSHIRE.]
EAST INDIES. [INDIAN EMPIRE, *S.* 2.]
EASTBOURNE. [SUSSEX.]

EBELMEN, JACQUES-JOSEPH, French chemist, was born July 10, 1814, at Beanme-les-Dames, in France. Having passed successively through the colleges Henri IV. and Besançon, he in 1831 entered the École Polytechniqne, and in 1833 passed from it to the Ecole des Mines. His ability and attainments early attracted notice; in 1840 he was appointed assistant, and in 1845 chief professor of analysis at the École des Mines; in 1841 he was made one of the secretaries of the 'Annales des Mines,' and experimental chemist at the École Polytechnique. A wider field was however opened before him by the appointment in 1847 of director of the Manufacture-Royale of Sèvres. To the duties of this office he applied all his energies. New and improved modes of operation, and the latest chemical discoveries, were employed with a view to economise the cost and improve the quality of the manufactnre, while the most able designers and painters were called in for the purpose of obtaining the best models and the richest ornamentation; and under his direction the porcelain of Sèvres acquired a reputation fully equal to that it had ever held, while the establishment was regarded as a model for the excellence of its arrangements. M. Ebelmen was a member of the commission sent by the French government in 1851 to the Great Exhibition, London. In the beginning of March 1852 M. Ebelmen was named engineer-in-chief of the mines, but he survived the appointment only a few days, dying on the 31st of March, 1852, in his thirty-eighth year.

Ebelmen was regarded with great hope for his combination of sound and minute scientific knowledge with practical administrative ability, and extensive powers of generalisation; and his early death was generally regretted. He contributed a great many papers to the 'Annales des Mines,' the 'Annales de Physique et de Chimie,' and the 'Bulletins de l'Académie des Sciences.' Among the more important were some npon the composition of coal-gas, and its employment in metallic manufactnres; and several npon the composition of rocks, the artificial reproduction of minerals, &c., of which we may mention—'Sur les Produits de la Décomposition des espèces Minérales de la famille des Silicates,' 1845; 'Sur une Nouvelle Méthode pour obtenir des Combinaisons Cristallisées par la voie sèche, et sur ses applications à la réprodnction des espèces Minerales,' 1847; 'Sur la Décomposition des Roches,' 1848, and particularly 'Sur les Altérations des Roches stratifiées sous l'influence des agents atmospheriqnes et des eaux d'infiltration,' 1851. The more important of his 'Mémoires' have been collected and published nnder the care of M. Salvetat with the title of 'Recueil des Travanx Scientifiqnes de M. Ebelmen,' 2 vols. 8vo, Paris, 1855.

(M. Chevreul, *Notice sur M. Ebelmen; Nouvelle Biographie Générale.*)

ECCLESHALL. [STAFFORDSHIRE.]

ECCLESIASTICAL COMMISSIONERS. The Ecclesiastical Commissioners are a body corporate, created by the statute 6 & 7 Will. IV. c. 77, for certain purposes and with certain powers therein named. The great inequalities in the extent and income of the dioceses of England and Wales, in the duties and receipts of the cathedral and collegiate bodies, and in the extent of parishes and the annual value of the benefices of the Church of England, after long and angry comments gave rise in 1835 to the issue of two commissions, directing the persons named therein to consider the state of the dioceses with reference to the amonnt of their revenues, and the more equal distribution of episcopal duties; and of the several cathedral and collegiate churches, with a view to the suggestion of such measures as might render them conducive to the efficiency of the Established Church; and further, to devise the best mode of providing for the cure of souls with special reference to the residence of the clergy on their respective benefices. These commissioners made four reports, recommending various alterations, and the appointment of permanent commissioners, for the purpose of preparing and laying before the sovereign in council such schemes as should appear to them to be best adapted for carrying those recommendations into effect; the Crown being empowered to make orders ratifying such schemes, having the full force of law. The statute above mentioned was passed in consequence; and under its provisions a great many beneficial alterations have been and are being effected. The recommendations contained in the four reports of the original commissioners have also been carried out, with certain modifications and amendments, to which the sanction of Parliament was required and obtained (see 1 & 2 Vict. cc. 30, 106, 108; 2 & 3 Vict. cc. 9, 14; 3 & 4 Vict. c. 113; 4 & 5 Vict. c. 39; 6 & 7 Vict. c. 77; 10 & 11 Vict. cc. 98, 108; 13 & 14 Vict. c. 41; 16 & 17 Vict. c. 50). The chief features of the alterations thus effected are the equalisation of the territorial extent of the dioceses, the creation of the new sees of Ripon and Manchester, and the union of the sees of Gloucester and Bristol. The revenues of the sees have also been equalised, by augmenting the income of the smaller out of the revenues of the larger. Cathedral and collegiate bodies have also been regulated. The powers and constitution of the Ecclesiastical Commissioners have been amended by the stat. 3 & 4 Vict. c. 113, s. 78; and by the appointment of Church Estates Commissioners, who are *ex officio* members of the Ecclesiastical Commission (13 & 14 Vict. c. 94; 14 & 15 Vict. c. 104; 19 & 20 Vict. c. 74); and, lastly, by the transfer to them of the powers of the Church-Building Commissioners.

ECCLESIASTICAL COURTS. Until recently the Ecclesiastical Courts, in addition to their merely spiritual functions, had cognisance of three kinds of civil causes, namely, causes *pecuniary*, causes *matrimonial*, and causes *testamentary*.

The first of these heads included matters relating to the non-payment of tithes, and of ecclesiastical dues and fees, and also matters of spoliation, dilapidation, and neglect of repairing the church and things thereto belonging. The statutes under which the tithes have been commuted and replaced by rent-charges, recoverable by distress like ordinary rents, have virtually abolished suits for tithes in the Courts Christian, and their jurisdiction in other causes *pecuniary* has thus been in other ways reduced to a very small compass. The statute 20 & 21 Vict. c. 85 has entirely abolished the jurisdiction of these Courts in causes *matrimonial* [DIVORCE, *S.* 2], the privilege of granting marriage licences being alone preserved to them. And the Act of the same session (20 & 21 Vict. c. 77) has transferred their jurisdiction in causes *testamentary* to a Civil Court, proceeding according to the course of the Common Law. [PROBATE, *S.* 2). Little therefore now remains of the Ecclesiastical Courts except the name, their most important functions having been transferred to other tribunals.

ECHENEIS, a genus of fishes belonging to the section of Sub-Brachial *Malacopterygii* and the family *Echeneidæ*. The body is elongated, covered with very small scales; a single dorsal fin placed opposite the anal; the head very flat, covered with an oval disc formed by numerous transverse cartilaginous plates, the edges of which are directed backward; the mouth wide, with numerous small recurved teeth on both jaws, the tongue, and the vomer. (Yarrell.)

The species of this genus are not numerous. Cuvier enumerates four, and another has been described from the West Indies. They are all easily recognised by the peculiar adhesive disc on the top of the head, by means of which they attach themselves to other fishes, the bottoms of vessels, or other objects floating in the sea. The object of this contrivance is not very well ascertained.

E. remora, the Common Remora, or Sucking-Fish, is found in the Mediterranean Sea, and was known to the Greeks and Romans. Dr. Turton once took a specimen of this species riding on a cod-fish in Swansea Bay. The following is Mr. Yarrell's description of the sucking apparatus:—

"The disc of the adhesive apparatus in the specimen now described, with seventeen transverse laminæ, was one-third of the whole length of the fish, not including the caudal rays; the breadth one inch and one quarter. The margin is free, flexible, and of considerable breadth, to secure perfect contact with the surface to which it is opposed; the parallel laminæ are represented as only slightly elevated: the degree of adhesion is in proportion to the power used to raise the inner surface of the disc in a direction perpendicular to the plane of contact. * * * * The vertical direction of the moveable laminæ is effected by sets of muscles going off obliquely right and left from two elongated bony processes, one on each half of each of these moveable divisions. The contraction of these muscles acting upon these levers, raises the external edges of the parallel divisions, increasing the area of the vacuum; and it will be observed that the points of the moveable transverse divisions to which the muscles are attached, are nearer the middle line than the outer edge, by which the chance of interfering with the perfect continuity of the free margin, and thereby destroying the vacuum, is diminished. All the bony laminæ, the outer edges of which are furnished with rows of minute tooth-like projections, are moved simultaneously, like the thin vertical divisions of our common window-blinds, by means of the mechanical contrivance on the framework. The longer muscles placed nearer the outer oval edge are probably instrumental in preserving the contact of the more flexible margin, and the serrated external edges of the parallel laminæ help to preserve the degree of elevation obtained: the adhesive power as before observed, is in proportion to the area of the vacuum."

ECHEVERIA, a genus of Plants named after M. Echeveri, author of the drawings in the 'Flora Mexicana.' It belongs to the order *Crassulaceæ*. It has a 5-parted calyx, the sepals erect, united at the base. Petals united at the base, erect, thick, stiffish, thickest at the middle nerve, and nearly trigonal at the base, acute. Stamens 10, shorter than the petals, and adnate to them at the base. Scales 5, short, obtuse. Carpels 5, ending each in a subulate style. The species are succulent shrubs, natives of Mexico. None of the species are used in the arts or medicine, but their handsome leaves and showy flowers give them a place in every collection of plants. The genus is closely allied to *Sedum*, and many of the species resemble that genus.

ECHINODERMATA. [ASTERIAS; STELLERIDIANS.]

ECHIODON, a genus of Apodal Malacopterygious Fishes belonging to the family *Murænidæ*. The head is oval; jaws furnished with large cylindrical teeth in front; other smaller teeth on the palatal bones and on the vomer. Gill-apertures large; branchiostegous membrane with seven rays. Body smooth, without scales, elongated, compressed. Dorsal and anal fins nearly as long as the body; all the rays soft; no ventral fins; anal aperture near the head.

This genus was constituted to receive a very remarkable fish found by Dr. J. L. Drummond on the beach at Camclough, near Glenarm, in the county of Antrim, Ireland. It was described by the late Mr. W. Thompson in part iii. vol. ii. of the 'Transactions of the Zoological Society.' This fish has anomalous characters, and Mr. Thompson had some difficulty in assigning it its proper position. The total length of the fish was 11 inches. As Dr. Drummond's specimen is the only one on record, nothing is known of the habits of the fish.

ECPHYMOTES (Fitzinger), a genus of Saurians belonging to the family of the *Iguanidæ*. It possesses the teeth and pores of the genus *Polychrus*, but with small scales on the body only. The tail, which is large, has great scales, which are rhombic and carinated. The head is 4-sided, and covered with small plates. The form is a little short and flattened, like that of some of the *Agamæ*, rather than like the slender shape of *Polychrus*. There are four species—*E. Fitzingerii* and *E. undulatus*, natives of Brazil; *E. obtusirostris*, native of Mexico; and *E. acutirostris*, a native of Brazil.

ECTOZOA (from ἐκτός, without, and ζωός, living), animals found living upon the external parts of other animals. This term is applied to distinguish the forms of animal life which are parasitic upon the surface of other animals from those which inhabit their interior. [ENTOZOA.] Whilst those which inhabit the interior of animals have so much resemblance to each other that naturalists place them together in an order which is called *Entozoa*, those which are found on the surface are very dissimilar, and belong to distant and dissimilar families. The term *Ectozoa* is therefore not one expressing any affinity between the animals included in it, but simply refers to their habitation.

The *Ectozoa* as well as *Entozoa* are found frequently associated with the diseased states of the animal bodies on which they are found, and much discussion has arisen as to whether they are the true causes of the diseases which they accompany. Thus much is certain, that whether they originate or not the diseased state of the body on which they are found, when allowed to increase they become themselves a source of diseased conditions, which disappear as soon as they are destroyed.

This is a general law equally applicable to parasitic plants as well as to animals. So that it would appear that, although their first attacks may be invited by a diseased condition of the plant or animal on which they are found, they may be productive of destructive effects by an unnatural and unhealthy increase. Every species of plant and animal appears to be subject to the attacks of special forms of parasitic plants and animals; and with regard to the latter they may be either inside or outside, so that we have not only *Ectozoa* and *Entozoa*, but *Ectophyta* and *Entophyta*. [ENTOPHYTA.]

Under the term *Epizoa* a number of animals have been placed together whose claims to be regarded as a section of the great family *Crustacea* are now generally recognised. These are found more especially on the bodies of fish, infesting their skin, eyes, and gills. They are very numerous, and the larger number of them belong to the family *Lerneadæ*. [LERNEADÆ.] They must be regarded as the *Ectozoa* of aquatic animals. The bodies of the *Cetacea* are frequently the chosen residence of many species of *Cirripeda*. [CIRRIPEDA.] These ecto-parasitic habits seem to be partaken of by some of the Vertebrate Animals, as we find the *Remora* [ECHENEIS, *S.* 2.] and other fish attaching themselves to the bodies of animals by an apparatus adapted for the purpose.

Land animals are subject to the attacks of various forms of *Ectozoa*, more especially those belonging to the Articulate tribes of animals. The following is a list of the creatures to which man is subject in various parts of the world:—

Phthirus inguinalis (Leach), the Crab-Louse; *Pediculus Capitis* (Nitzsch), Head-Louse; *Pediculus Vestimenti* (Nitzsch), Body-Louse; *Pediculus Tabescentium*, Burmeister [ANOPLURA, *S.* 2); *Sarcoptes Scabiei* (Latreille), Itch-Insect [ACARIDÆ]; *Dermanyssus Boryi* (Gervais); *Ixodes Americanus* (De Geer), Tick; *Argas Persicus* (Fischer); *Pulex penetrans* (Gmelin), Chigoe; *Pulex irritans* (Linn.), Common Flea [PULEX]; *Cimex lectularius* (Linn.), Bed-Bug [BUG]; *Œstrus Hominis* (Say), Gad-Fly [BOTS].

Other creatures are occasionally found taking possession of the surface of the human body. In diseased conditions the common fly has been known to deposit its ova in various parts of the body, and many of the insects which are parasitic upon the lower animals will take up their abode on the human body. This is the case with the various forms of the *Anoplura*, which are a peculiar species on almost every species of animal on which they are found, so also with the species of the genera *Pulex* and *Cimex*.

(Leidy, in *Flora and Fauna within Living Animals*.)

EDELFORSITE. [MINERALOGY, *S.* 1.]

EDENDERRY. [KING'S COUNTY.]

EDGEWORTH, MARIA, the daughter of Richard Lovell Edgeworth, by his first wife, was born on January 1, 1767, at Hare Hatch, near Reading, in Berkshire. In the year 1782 her father went with his family to reside on his paternal estate at Edgeworthtown, until when, except for a few months in her childhood, his daughter had never been in Ireland. From that time however Edgeworthtown became her abode for the remainder of her long life, with the exception of occasional visits of a few weeks only to England, Scotland, and France, and for about two years at Clifton in attendance on her sick step-mother. The neighbourhood of Edgeworthtown did not afford much congenial society, the family of the Earl of Longford at Pakenham Hall, that of the Earl of Granard at Castle Forbes, and that of a Mr. Brookes, being the only ones whom they visited; and Pakenham Hall, she says, was twelve miles distant, with "a vast Serbonian bog between us, with a bad road, an awkward ferry, and a country so frightful, and so overrun with yellow weeds, that it was aptly called by Mrs. Greville, 'the yellow dwarf's country.'"

Miss Edgeworth was principally educated by her father, as all his other children were. They all lived on the most confidential terms with him, and she was very early selected as his business assistant, copying letters, receiving rents, and welcoming his tenants, while his office of magistrate gave her still further opportunities of observing the manners and habits of the peasantry around her. These occupations soon led to her becoming a co-operator with her father in literary productions. The first was a series of 'Essays on Practical Education,' published in 1798; and 'Early Lessons,' which had been commenced by Mr. Edgeworth and his second wife, was continued by him and his daughter; the 'Parent's Assistant' was also a joint production, as was the 'Essay on Irish Bulls,' published in 1803. But Miss Edgeworth's fame rests upon her novels, which were produced without assistance, though they always had the benefit of her father's revision while he was living. The series commenced with 'Castle Rackrent,' published in 1801, and closed in 1834 with 'Helen.' In the interval there appeared 'Moral Tales,' 'Belinda,' 'Leonora,' 'The Modern Griselda,' 'Popular Tales,' 'Tales of Fashionable Life,' 'Patronage,' 'Frank,' 'Harrington,' and 'Ormond,' with some minor tales. Her last production was 'Orlandino,' a children's tale, published by the Messrs. Chambers in 1847.

The novels of Miss Edgeworth were published some years ago in a collected series. The manners which they describe, especially those of fashionable life, belong in some degree to a past generation. But her delineations of character, more particularly of Irish character, are so true to nature, and there is such a vein of quiet humour and practical good sense running through them all, that amidst the more exciting plots and strong situations of the novels of our own time, the more important may be referred to as worthy of a lasting place in our literature.

Miss Edgeworth passed a quiet but useful life with her family; she maintained an extensive correspondence with many friends and literary acquaintances, and at length died May 21, 1849, at the venerable age of 83.

EGG. [REPRODUCTION, *S.* 2.]

EICHHORN, CARL FRIEDRICH, son of Johann Gottfried Eichhorn, obtained considerable celebrity as an able and learned jurisconsulist. He was born at Jena on the 20th of November 1781. After passing through the usual course of academic and legal training, he was named in 1805 Professor of German Law at Frankfurt-on-the-Oder. In 1811 he removed to Berlin, and in 1817 to Göttingen, in each place holding the same chair as at Frankfurt. Ill-health however compelled him in 1828 to resign, and to retire to an estate he possessed near Tübingen. Having somewhat recovered, he was in 1831 again summoned to Berlin, and along with his professorship he received an appointment in the ministry of foreign affairs. At length in 1833 he resigned his professorship, and devoted himself entirely to his official duties and to writing. About this time he was made a member of the Prussian council of state, and of the commission of legislation. He died in July 1854.

Carl Eichhorn was one of the most erudite expounders of the ancient Germanic law, of its origin, its growth, and its various bearings. As the associate and fellow-labourer of Savigny, though taking a somewhat different branch of the subject as the main object of his investigations, and as holding the chair of German law for so many years, Eichhorn exercised an important influence on the study of law in Prussia. His principal writings are—'Deutsche Staats-und Rechts-geschichte,' 4 vols. 8vo, Göttingen, 1808-18, which work has passed through eight editions; 'Grundsätze des Kirchenrechts der Katholischen und Evangelischen Religions-partei in Deutschland,' 2 vols. 8vo, Göttingen, 1831-33; and 'Einleitung in das Deutsche Privatrecht, mit Einschluss des Lehnrechts.' In conjunction with Savigny and Goschen he also carried on the 'Zeitschrift für geschichtliche Rechtswissenschaft,' Berlin, 1815-1843.

EIFEL, a wild highland region in the Prussian Rhein-Provinz, extends along the left bank of the Rhine between Bonn and Coblenz. Its proper geographical boundaries are the Rhine on the east, which divides it from the Westerwald; the deep valley of the Moselle on the south, which separates it from the Hochwald and the Hunsdruck, north-eastern offshoots of the Vosges; the Our or Ourthe, the Ardenne hills, and the Meuse on the west; and the great flat plain of the Lower Rhine on the north. The name however is confined to the region that stretches eastward from the sources of the Our and the Roër to the Rhine. At the head of these rivers lies an extensive highland called *Veen*, or *Fanges* (from the Celtic 'fancq' for bog)—a dreary waste covered with turf-bogs, morasses, and reeds, and rising between 1500 and 2000 feet high, with a length of about 16 miles every way, which connects the Eifel with the Ardenne, and offsets of which stretch nearly to the Meuse below Aix-la-Chapelle.

The Eifel is a rugged, desert, and in parts swampy table-land, with a general elevation of 1400 to 1600 feet above the Rhine. Its slopes are scored in all directions by deep glens and valleys, which are traversed by tributaries of the three great rivers named above. The flat surface of the table-land with the exception of some rather extensive forest-tracts, presents a wild moor covered with a thin barren soil; but here and there rise up abruptly naked crags and basaltic cones of various elevations, some of them richly wooded, with wide-spread layers of ancient lava between. The general components of the region are clay, flint, limestone, and slate; but the hills and rocks that flank the valleys, ravines, and glens of the Eifel are in many instances composed of basalt or capped with it; indeed the Eifel almost everywhere bears traces of violent convulsions and volcanic eruptions at some long-distant period. Extinct volcanoes, cauldron-shaped depressions, tarns of circular shape filling up ancient craters and locally called 'Maare,' mineral-springs, lava-streams, columnar basalt, fossil zoophytes and shells, proving submergence under some ancient waters, are among the natural curiosities of this interesting region.

Amongst the highest points in the Eifel the following may be mentioned:—The Hohen-Acht, above Adenau, 2434 feet above the sea; Nürberg, which is also near Adenau, and is crowned with the ruins of an extensive feudal castle, 2251 feet; Kelberg, near the source of the Els, 2098 feet; Michaelsberg, near Münstereifel, 1860 feet; and the Schneifel, or Snow-Eifel, in the circle of Prüm, in the wildest part of the region, 2100 feet.

The Eifel has a length from east to west, between the Rhine and the Our, of about 50 miles. Along the left bank of the Rhine, north of Andernach, it extends for about 20 miles; but in the interior the breadth is in some places more, in others less than this. Rivers flow from it in all directions. On the northern slope near Münstereifel (a small town in the government of Cologne with about 1600 inhabitants), rises the Erfft, which flows with rapid course down into the low country, and enters the Rhine at Grimlighausen, a short distance above Düsseldorf. The Röer, or Ruhr, also flows down the northern slope, rising in the mountains between Malmedy and Montjoie; after reaching the low country it runs north-north-west past Düren and Julich, and, entering Belgian Limbourg, joins the Meuse on the right bank at Ruremonde, after a course of above 80 miles. Both of these rivers sweep down stones and gravel from the highlands; they are subject to frequent and sudden swells, and abound in fish. Their water-power is turned to some advantage in driving machinery. Before it leaves the Eifel the Roër receives on its right bank the Urst, which rises near Blankenheim, and passes *Gemünd*, a small town in the government of Aachen with about 1000 inhabitants, who manufacture woollen-cloth and leather. Not far from the source of the Roër rises the Warge, which flows westward past Malmedy, and throws itself into the Ambleve, a feeder of the Ourthe, in the Belgian province of Liège. The Ambleve itself rises a little south of the Warge, which it joins a little below Malmedy. *Malmedy*, a town in the government of Aachen, stands on the Warge, and has about 4000 inhabitants. It is a quaintly-built place: the houses and gardens are all in the Dutch style. The town is famous for its manufacture of sole-leather: there are above fifty tanyards. It has also mineral springs; manufactures of woollen-cloth, lace, soap, potash, and glue. *Montjoie* stands in a marshy country between two high hills on the left bank of the Roër, and has a population of 3000, who manufacture woollen-stuffs, leather, and iron. A large, strong, and gloomy castle above the town is said to occupy the site of a hunting-seat erected here by Charlemagne: it is a fine specimen of a feudal fortress.

On the southern slope flows the Our, which passes Reuland and forms below this small town the boundary between Rhenish Prussia and the Dutch province of Luxemburg to its mouth in the Sure, a feeder of the Moselle. The Sure receives also from the Eifel the Prüm, which rises in the wildest part of the district. Just above its junction with the Sure the Prüm is joined by the Nims. The town of *Prüm* is in the government of Trèves. It is situated to the south of the Schneifel at the foot of a beautifully wooded hill, and has 2100 inhabitants. Its name is taken by corruption from that of the Benedictine Abbey of Ad Pratum, founded here in the 8th century, and in which Pepin, natural son of

Charlemagne, and the emperor Lothaire were monks: the latter died here A.D. 853. The abbey buildings were destroyed by fire in 1769, with the exception of a small portion which is now a school; the church near it, which is built in the Italian style, replaces the magnificent church of the abbey, of which no vestige remains. The road from Aix-la-Chapelle to Trèves passes through Prüm, and coincides at some points with the old Roman road from Trèves to Cologne, of which there are many traces south of Prüm. Near *Bitburg*, the ancient Bædæ Vicus, a town of about 2000 inhabitants, midway between Prüm and Trèves, a Roman villa, in excellent preservation, and two Roman milestones, set up in the reign of Hadrian, have been disinterred.

Southwards also, and from near the source of the Roër, flows the Kill directly into the Moselle a little below Trèves. At Gerolstein, a picturesque little town of 600 inhabitants, on its left bank, the river runs between cliffs of limestone and dolomite. Near the town are an old castle, a dry crater, the surface of which is cultivated, several old lava streams, caverns, basaltic rocks, and mineral springs. Fossil shells and corals are found strewed over the fields at Auberg, in the neighbourhood of Gerolstein. Olivine and glassy felspar are found about the dry crater of Dreiser Weiher, about six miles east of Gerolstein.

Further east, but still on the Moselle slope of the Eifel, flow the Lieser, the Ues, and the Elz. The Lieser passes Daun and Witlich (2600 inhabitants), and enters the Moselle at the town of Lieser, which has a population of about 1000. At the village of Daun, which has an old castle (the family residence and birth-place of Marshal Daun, who led the Austrian armies in the Seven Years War), there are three maare, or crater lakes, separated from each other by a narrow partition of slaty rock. To the southward of Daun and on the left bank of the river, is the village of Manderscheid, famous for its old castle and for the beautiful maare in its neighbourhood. On the hill of Mosenberg near it are four volcanic cones of slag, from one of which a lava stream descends to the valley of the Lieser. The Meerfelder maare is about 100 fathoms deep, and the Pulver maare, one of the largest and most beautiful of the crater lakes in the Eifel, is 330 feet deep in the centre. The village of Strötzbusch is built in a dry crater.

The Ues or Iss, which has an old Celtic name, rises near Kelberg, and enters the Moselle at the pretty village of Alf. It flows with many windings and contortions down a valley distinguished for its varied scenery, for the umbrageous foliage of its woods, for its conical hills, and basaltic cliffs. The junction of the clay-slate and lava is distinctly seen at several parts of the valley. In the vale of the Issbach, as the Germans call this small river, are iron-works and the mineral baths of Bertrich.

The Elz rises not far from the source of the Ues, and flows south-east down a wooded gorge, in which it makes innumerable windings, bounding from side to side against the cliffs that screen it on either hand, and enters the Moselle at the little village of Mosel-Kern. The Elz forms some pretty cascades, and passes the castles of Pyrmont and Elz. The Elz-Schloss is one of the most picturesque and best preserved old feudal fortresses in Europe; it begins to yield to decay but is still inhabited. On the opposite rock stands the rival castle of Trutz-Elz, erected by the Bishop of Trèves, against the lords of Elz. The castle of Pyrmont was burnt by the Swedes in 1641. Between the mouths of the Ues and the Elz, on the left bank of the Moselle, stands the town of *Kochem*, prettily situated on a hill, with two old castles frowning from the adjacent heights. Although a pretty object from the Moselle it is a very dirty place. Population about 2500.

On the eastern slope flow the Nette and the Ahr. The Nette rises to the east of Adenau, and runs first to the south-east and then eastward into the Rhine a little above Andernach, which town has been already noticed. [ANDERNACH.] The Ahr (Aar) rises near Blankenheim and running eastward through a valley abounding with wild and most picturesque scenery, past Altenahr and Ahrweiler, enters the Rhine between Remagen and Sinzig. In the upper part of its course the Ahr is joined on the left bank by the Adenan near the small village of Dumpelfeld. On the basalt-capped hill of Landskrone in the Ahrthal, are ruins of a castle built by the emperor Philip of Hohenstaufen in A.D. 1205. The Ahr is celebrated for its minnows, trout, and craw-fish. A fine road runs up the valley and in parts is carried by tunnels through the rocks. *Adenau*, is a small town of 1200 inhabitants, at the foot of the Hope-Acht. *Ahrweiler*, is a pretty walled town entered by four gates, and has about 2500 inhabitants, who are chiefly engaged in the growth of the vine. It is the centre of the wine trade of the valley, and has a beautiful gothic church erected in the 13th century.

The Brohlbach, a small feeder of the Rhine, enters that river at Brohl, a small village, midway between the mouths of the Nette and the Ahr. The stream at Brohl drives a paper-mill and several trass-mills, in which the volcanic tufa, quarried in the neighbourhood, is ground for export to Holland; the tufa, reduced to dust, is used by the Dutch for subaqueous cement (tras or trass), as it hardens under water. In the tufa quarries in the valley of the Brohl, land shells and trunks of trees reduced to the condition of charcoal, are found imbedded. Mineral waters, resembling Seltzer, are got from springs in the valley of the Brohl. A little north of Brohl is the castle of Rheineck, recently purchased and repaired by Professor Bethmann Hollweg, of Bonn. *Sinzig* is a small ill-built walled town of about 1600 inhabitants, with an interesting gothic church, erected in the beginning of the 13th century; an adjoining chapel contains a natural mummy, which was carried away to Paris when the French extended their frontier to the Rhine, but was restored at the peace. Sinzig occupies the site of the ancient *Sentiacum*, near which the cross with the inscription 'In hoc Signo vinces,' upon it, it is said, appeared to Constantine when marching towards Italy against Maxentius. The ancient Roman road along the left bank of the Rhine nearly coincides with the present diligence road between Bonn and Coblenz. *Remagen*, a small place of 1400 inhabitants, occupies the site of the ancient *Rigomagus*. Roman antiquities have been found here.

About 5 miles inland from the mouth of the Brohl, is the large and beautiful crater-lake of Laach, or Laacher-See, which is 666 feet above the Rhine, of nearly elliptic shape, 2 miles long and about a mile and a half broad; its depth increases towards the centre where it is 214 feet deep. The lake is hemmed in on all sides by a ridge of hills covered with wood down to the water's edge. It is supposed to occupy the crater of a volcano. A stream of carbonic acid gas issues from an opening on the north-east side of the lake; and in a neighbouring pit bodies of birds have been found killed by the noxious vapour, which circumstance has given rise to a popular notion similar to that connected with Avernus in Italy, that no bird can fly over the Laacher-See. The lake is fed by numerous springs beneath its surface, which keep its basin always full. Its waters are clear, deep-blue in colour, very cold, but never freeze; and abound in fish. It has no natural outlet, but its superfluous waters are carried off by an underground emissary nearly a mile long, cut in the 12th century by the Benedictine monks of the now ruined abbey of Laach, which is a little south-west of the lake. The shores of the lake are covered with masses of scoriæ, cinders, ashes, pumice, and other volcanic products. Laach abbey, or Kloster-Laach as it is called, was suppressed at the time of the first French revolution. Part of the old buildings that remain is now converted into a farm-house; the church, a beautiful specimen on a small scale of the round-arched gothic, erected in the early part of the 12th century, has been purchased in order to its preservation by the Prussian government. The gardens of the abbey, the lake, and village of Laach, are favourite places of resort with the inhabitants of Coblenz. Between the lake and the Nette are the famous millstone quarries of Nieder-Mendig which have been worked in the hard porous lava for 2000 years. The lava stream in which these quarries lie is 5 miles long and 3 miles broad. The lava separates into gigantic columns, some of which are left by the quarrymen to support the roof; there are vast caverns in it, probably the result of ancient excavations. At *Mayen*, a picturesque old town, on the Nette, with about 3000 inhabitants, defended by a castle and surrounded by walls and gardens, there are several millstone quarries, a paper-mill, tan-yards, and mineral springs. To the geologist, the botanist, and lover of the picturesque, all the southern and eastern part of the Eifel is extremely interesting. Besides the Lacher-See no less than 27 maare, marking as many extinct craters, exist between the Nette and the Ahr.

The climate of the table-land of Eifel is damp, and much colder than that of the plain of the lower Rhine; cold mists very frequently hover over it. In all Prussia there is no district so poor in arable land as the Eifel. The rugged surface of the region is covered with wild heath or swampy bog, the thin coating of the soil not affording nourishment for the roots of the trees. Some parts of it however, as before stated, are clothed with forests. This is especially the case in the districts covered with volanic deposits. The chief species of forest trees are beech, oak, and fir, which are grown for the supply of fuel and timber. The valleys and glens are all inhabited, and in these the population is gathered into small towns, villages, and hamlets, most of which have sprung up under the frowning protection of some feudal castle, and a few in the neighbourhood of ancient monasteries. On the rapid slopes along the Ahr valley and towards the Rhine, vines and fruit trees yield valuable crops; here every piece of cultivated land is covered with walnut, apple, pear, or cherry trees. The wine of the Ahrthal is of excellent quality. The commune of Rübenach draws a revenue of 10,000 francs annually from Coblenz for cherries alone. Walnuts are a favourite crop on the hills but not in the valley bottoms, where it is said, the leaves of the walnut tree injure the soil. The nuts are preserved for oil. Apples and pears are sliced and strung upon pack-thread to serve as vegetables with meat in winter. The fruit of the valleys of the Eifel is good generally; but the apples and pears grown on the Moselle slope are particularly delicious, and not surpassed by those of any region in Europe. The corn crops of the region are necessarily restricted in quantity; the deficiency is supplied from the neighbouring districts.

The region of the Eifel is exposed to a phenomenon called Wolkenbruch, or Cloud-Burst, being a sudden discharge of water, which brings sudden destruction on everything that it may strike; trees are rooted up and hurled down by suddenly formed torrents; cattle, houses, soil, and crops are swept away. A cloud-burst of this description destroyed the greater part of Münstereifel in 1818.

The principal roads through the region of the Eifel are those from Aix-la-Chapelle to Trèves, and from Coblenz to Bonn; the high road up the left bank of the Moselle from Coblenz to Trèves, and the new road up the Ahrthal to Trèves. There are also numerous cross-roads, but most of them are bad. The great Roman road made by Agrippa from Trèves to Cologne traversed the western part of the Eifel. Along it were numerous post houses (mutationes) and six 'mansiones,' serving as military posts and hotels. Bædæ Vicus, now Bitburg, was one of these 'mansiones.' *Zulpich* (population 1200), near the Nassel, a feeder of the Erfft in the plain, at the northern base of the Eifel, was another of the mansiones, and was called *Tolbiacum*. The road is still in a perfect state at Zulpich. Remains of an aqueduct, which ran parallel to the road, and along its whole length, to supply the stations with water, are still visible at ten or a dozen different places between the two cities. The road along the left bank of the Rhine, between Remagen and the precipitous projection of Rolandseck, which is composed of prismatic basalt, and is crowned with the ruins of an old castle, is cut in the rock. In making this part of the road several Roman remains were found. Connected with Rolandseck is the circular crater of Rodersberg, which is a quarter of a mile across and 100 feet deep; its sides, which are composed of tufa and scoriæ, are cultivated. The castle of Godsberg, a town of about 1000 inhabitants, a short distance north of Rolandseck, is an interesting object on the road and from the Rhine. Between Godsberg and Bonn, at the north-eastern extremity of the Eifel, are the coal and alum mines of Friesdorf. The coal is of the kind called lignite or fossil wood, and has evidently resulted from the subsidence of some primeval forest; fossil fishes, fresh-water shells, and very fine potters' clay are also found in these beds.

As the Eifel is a popular and not an administrative division of Rhenish Prussia, we have no means of stating its population. The region is divided between the three governments of Aachen, Coblenz, and Trèves. The inhabitants are less polished than their lowland neighbours, in their dress rather slovenly than neat, and their houses are in general rudely constructed. Iron and lead mines are worked near Gemund. The manufactures are unimportant, with the exception of leather. The chief exports are millstones, trass, wine, and fruit. The inhabitants are almost all Roman Catholics. Eifel is said to be an old German name for the Ardenne, of which region the Eifel is in reality a part.

EJECTMENT. The action of ejectment [EJECTMENT] in which *John Doe* was generally the nominal plaintiff, and *Richard Roe* the nominal defendant has been abolished, and a new and simpler mode of proceeding substituted for it. *John Doe's* suit was attended with one great disadvantage: it could only be followed out during term; so that, if a right to lands in Yorkshire accrued on the 1st of June, the person entitled was unable to bring his adversary into court before the following November, or in case of a defence, to proceed to trial before March in the following year. The fictions on which the old action was founded were also considered objectionable, and accordingly, when the procedure of the Superior Courts of Common Law was reconstructed in the year 1852, a new mode of proceeding for the recovery of land was created, which however possesses the one distinguishing peculiarity of the old action, that in it no question can be raised except that of *title*.

This new action is commenced by the issue of a writ, directed to the persons in possession by name, and to all persons entitled to defend the possession of the property claimed; and commands the persons to whom it is directed to appear within sixteen days to defend the possession of the property claimed, a notice being added, that, in default of appearance, they will be turned out of possession. This writ is served on the tenant in possession, or, in case of a vacant possession, by posting a copy thereof upon the door of the dwelling-house, or other conspicuous part of the property. Every tenant served with a writ must give immediate notice thereof to his landlord, under the penalty of forfeiting three years' rack rent of the premises held by him. The object of giving the landlord notice is, that he may be permitted to defend, which he has a right to do, for frequently the tenant has no interest in the premises beyond the temporary possession. A mortgagee, a devisee in trust, or an heir, will also be permitted to defend the possession; for possession has now become the very essence of property, twenty years' uninterrupted possession constituting a title good against all the world.

If no appearance be entered, the claimant obtains judgment to recover possession of the land claimed; to which he by the writ asserts his right. By entering an appearance, the tenant, or the landlord, or any other person admitted to defend, denies that right. The parties are then at issue on the question of *title;* and the next thing to be done is for the claimant to prove his alleged right to a jury on the trial, which must take place, in all ordinary cases, in the county where the property is situated; the proceedings at and after the trial being the same as in ordinary actions.

Such is the modern way of trying the *title* to lands and tenements. It is founded on the same principle as the ancient writs of assize, being calculated to try the mere *possessory* title to an estate; and has succeeded to those real actions, as being infinitely more convenient for attaining the end of justice. It has on the same principle been rendered a very easy and expeditious remedy to landlords whose tenants are in arrear, or who hold over after their term has expired or been determined. The Common Law Procedure Act (re-enacting 4 Geo. II. c. 28) enables a landlord who has a right of re-entry in case of non-payment of rent, when half a year's rent is due and not sufficient distress is to be had, to serve a writ of ejectment on his tenant, or fix the same upon some notorious part of the premises, which shall be valid, without any formal re-entry or previous demand of rent. And a recovery in such ejectment is final and conclusive, both in law and equity, unless the rent and all costs be paid or tendered within six calendar months afterwards. The same statute (re-enacting 1 Geo. IV. c. 87), enables a landlord, on serving a writ of ejectment on a tenant holding over after his term has expired or been determined, to give him notice that he will be required to give bail (if ordered so to do by the court or a judge), conditioned to pay the costs and damages to be recovered in the action. If bail is thereafter ordered to be given, and the tenant fails to do so, the claimant obtains immediate judgment for recovery of possession and for his costs. In ejectments also between landlord and tenant the claimant may go on, after proving his right to recover, to give evidence of the mesne profits, and the jury shall thereupon give their verdict on the whole matter, both as to the title and mesne profits; so that in such cases a second action for mesne profits is unnecessary. Besides these remedies a landlord may, in cases where the rent or value of the premises does not exceed 50*l.*, and no fine has been paid, proceed in the County Court (19 & 20 Vict. c. 108, ss. 50-56). And if the rent does not exceed 20*l.*, and no fine has been paid, he may proceed summarily before the justices in petty sessions. (1 & 2 Vict. c. 74.)

EKEBERGITE. [MINERALOGY, *S.* 1.]
ELÆOLITE. [MINERALOGY, *S.* 1.]
ELAIDIC ACID. [CHEMISTRY, *S.* 2.]
ELALDEHYDE. [CHEMISTRY, *S.* 2.]
ELANUS. [FALCONIDÆ.]
ELAPHUS. [DEER.]

ELASTIC TISSUE. The elements of Elastic Tissue are cylindrical or band-like fibres with dark contours, very minute, and when present in large numbers they exhibit a yellowish colour. Hence it has been called Yellow Tissue. The fibres acquire sometimes little cavities in particular spots, which give these fibres a striated appearance, as seen in the giraffe. The elastic tissue is rarely found in large masses, but is very frequently mixed with areolar tissue, either in single fibres or in networks of various kinds. The organs into which this tissue enters, and constitutes their special feature, are :—

1. The elastic ligaments, in which the tissue, with only a slight admixture of connective tissues and hardly any vessels and nerves, exists, so to speak, in a pure form. Of these we have examples in the ligamentum subflava of the vertebræ, the ligamentum nuchæ, the ligament of the larynx, and stylo-hyoid ligament.

2. The elastic membranes which appear either in the form of fibrous networks or of fenestrated membranes, and are found in the walls of the vessels, especially in those of the arteries, in the trachea and bronchia, and in the fascia superficialis.

(Kölliker, *Manual of Histology*, translated by Busk and Huxley for the Sydenham Society.)

ELECTION. The proceedings on the election of knights and burgesses to the Commons House of Parliament have formed the subject of several recent statutes; all of them, more or less, directed to obtaining what is called 'purity of election.' With this view, the elections, alike in counties and boroughs, must now be completed in *one* day, so that neither time nor opportunity may be allowed of extensively tampering with the voters. The merely formal proceedings are still taken under the original Reform Acts; but the *bribery oath* can no longer be administered to a voter. In order, however, to restrain bribery, treating, and intimidation, the returning officers are now required annually to appoint *election auditors*, through whom alone can accounts in respect of the election be paid by the candidates. Stringent provisions have been made for inquiring into charges of corrupt practices, by Committees of the House, sworn to the performance of their duties. Bribery, if proved, involves the disqualification of the elector, and the unseating of the member chosen, if the charge is brought home to him. The candidate is required to appoint his own agents, in writing, so that they may be known; and to send all accounts and a note of all his disbursements to the election auditor; which, when audited and paid through the auditor are to be published in the local newspapers. It may be added here, however, that both the method of proceeding at elections, and the principles which ought to guide legislation on that subject are at present quite undetermined, the recent Acts of Parliament being only of temporary operation and of an experimental character. (Blackstone's 'Commentaries,' Mr. Kerr's edition, vol. i. p. 166.)

ELECTRIC TELEGRAPHS. In the previous Supplement a full account of the discovery and of the application of the electric telegraph was given. [TELEGRAPH, ELECTRIC.] All that remains now is to complete the account by a statement of its more important improvements, and more especially of the widely-extended transmission of messages by submarine telegraphs, bringing the most distant countries into almost immediate connection.

At the present time almost every important town in Great Britain, with the exception of Inverness in the far north, and Falmouth in the south-west, is furnished with means of telegraphic communication to other towns. As fast as any new railways, whether trunk or branch lines, are opened, so surely is the telegraph now laid down; insomuch that the length of telegraph is nearly coincident with the length of rail. The exceptions to this rule are so few as scarcely to disturb the simplicity of the rule itself. From Cornhill, from Charing Cross, from the government offices, and from numerous other places in the metropolis, messages are every day being quickly flashed to Aberdeen in one direction, to Liverpool in another, to Dover in a third, to Southampton in a fourth, to Plymouth, to Milford Haven, to Holyhead—indeed, to almost all of our outports, and to nearly every inland town of any commercial pretensions. A system is everywhere acted on that the principal railway stations shall at the same time be telegraph stations, some of the wires being for public use, and the others for railway use. The charges have been gradually lowered, to the great advantage of all parties; and the messages now sent are of countless variety—the price of funds, the state of the markets, orders to purchase, the arrival of ships, the receipt of important news, the Queen's speeches, the result of elections, the divisions in a debate, the running of a race, the progress of the Court while travelling, the state of the weather, the verdict of an important trial, the sending for a doctor, the detection of a thief or murderer, inquiries after health, announcements of illness or of death, inquiries after lost luggage—these are only some of the open or confidential communications intrusted to the copper wires.

In most parts of England the wires, as from the commencement of the system in this country, are supported on poles at a height of several feet from the ground; but in a few cases, such as along the mail-coach road from London to Dover, a subterranean arrangement has been adopted: the wires being encased in a wooden trough, and deposited a foot or two beneath the surface of the ground. This arrangement is also adopted in the streets of London, and of other large towns.

An interesting use of the sub-way telegraph may be here noticed. In proportion as the use of Greenwich time has become familiar on all the English railways, so has it become important to ascertain this time with precision, in such a way as to enable all the station-clocks to be regulated thereby. This is one purpose of the new time-ball in the Strand. The Electric Telegraph Company, the South-Eastern Railway Company, and the Astronomer Royal, have acted in conjunction in the establishment of this plan. A subterranean wire has been carried from the Observatory, through Greenwich Park, and across Blackheath to the Lewisham station of the North Kent Railway; thence to the London Bridge station; and thence to the Telegraph office in the Strand. At the top of this office has been erected a hollow shaft, up the interior of which the electric wire is carried, and a large light ball, capable of moving eight or ten feet vertically, slides easily up and down near the top of the shaft. At ten minutes before one o'clock each day the ball is raised nearly to the top of its shaft or spindle; and at five minutes before one it is raised quite to the top. At one o'clock precisely, exact to a single second, the great or master-clock at Greenwich Observatory puts in action a small piece of mechanism which sends an electric shock through the wire to the Strand; the wire at this end is connected with another piece of mechanism, which releases the ball and allows it to fall suddenly. The ball falls upon a kind of piston in an air-cylinder, so as to break the force of the concussion. As this ball is 130 feet above the level of the Thames; as it is six feet in diameter, exhibits bright colours, and falls through a considerable space, its descent can be seen for a great distance on all sides; and all who choose to regulate their clocks and watches by this standard can do so. An electric clock with four dials, illuminated at night, has been put up on a pillar in front of the office; it indicates Greenwich time at all hours. The various railway stations receive their time from the Strand office, which is the medium of communication from the Greenwich Observatory. There can be little doubt that these arrangements will contribute powerfully to the adoption of Greenwich time in church clocks and other public clocks. So useful is this considered to be, that a plan has been under consideration for erecting an electric time-ball on the summit of the South Foreland; the descent of such a time-ball, at one o'clock each day, could be witnessed by the captains of ships many miles out in the Channel, who could regulate their chronometers by this means, as the time-ball would show Greenwich time. It was also proposed that the electric current should fire off a gun at the same time and place, so that the sound might be heard if the descent of the ball could not be seen.

In the English telegraphs, the wires employed are usually about one-sixth of an inch diameter, covered by a galvanic process with a thin coating of zinc, to prevent oxidation. Four miles of such wire weigh about a ton. The supporting posts are about sixty yards apart, with connecting pieces of porcelain or other non-conducting material, so that the wire may not touch the wood itself; the connecting pieces themselves being sheltered from rain by a small overhanging roof. At intervals of a quarter of a mile are winding-posts, with apparatus for screwing up the wires to the proper degree of tightness, and joining the several lengths together. The great number of wires which we see along the chief lines of railway are not all necessary for transmitting one message; a single wire will effect this; but many are required to keep up correspondence of different kinds, and with various stations.

The 'needle telegraph,' as it is called, is still the one generally used in this country; that is, one in which, instead of pressing down the keys of a finger-board, the manipulator works two handles; these handles govern two needles or indices, the relative positions of which indicate letters and words. The action of the machines was sufficiently described in our former article. [TELEGRAPHS, ELECTRIC.] Improvements have been since introduced, but the principle is in its general features such as Messrs. Cooke and Wheatstone made it many years ago. The Electric Company have purchased many patented inventions and machines, to be used subsidiary to the needle-telegraph.

Much as there has been of litigation in England concerning electric telegraphs and their patentees, it bears no comparison with that of the United States, where the system is developed with so much more completeness. The telegraphs principally employed in that country are those of Morse, Bain, and House; and it is chiefly the owners of Morse's patent rights by whom the legal proceedings have been carried on. In one trial in 1851 the evidence extended over a thousand printed pages; and in several other trials it extended to many hundred pages—containing the opinions of a vast number of persons concerning the priority of certain inventions. Between 1837 and 1849, Professor Morse took out seven patents, under the powers of which many thousand miles of telegraphic wire have been laid down.

Bain and Morse both employ a method which, for familiar illustration, may be characterised as nearly the same; and we will therefore briefly describe Bain's. Let us suppose a message to be sent one hundred miles, from one station to another. The letters of the message are separately transmitted, by means of a key-board or a set of handles; or at least a series of impulses, which may be made to represent letters. At the other end of the wire, a small needle or metallic point has slight reciprocating movements given to it by the impulses: and it presses upon a strip of chemically-prepared paper which slowly moves onward by means of clock-work. At the instant of contact, the paper becomes discoloured by a chemical action between it and the iron; these discolorations appear in the forms of dots and short lines, certain combinations of which are understood to represent the letters of the alphabet. A permanent record of the message is thus preserved—in a cypher which requires to be translated into English for the use of all except the telegraph officers.

There are many patented systems in England, Germany, and America, bearing some analogy to those of Bain and Morse. Mr. Rogers, of Baltimore, substitutes a pen for a needle or point, a brass disc for a paper strip, and a kind of ink for the chemical preparation in the paper. The pen is dipped in the ink, which becomes decomposed on contact with the brass; a superficial stain is produced on the metallic surface, which is easily obliterated by friction. In some of the contrivances, a strip of plain paper is bedded upon a cushion of some soft substance; and the dots and lines are effected by indentations with a blunt point on the paper, instead of chemical stains in the paper itself.

House's printing telegraph, in use on many of the American lines, is a beautiful contrivance; for it actually prints the message with ink in the familiar Roman character. When the impulse for each letter has been sent along the wire, it affects the movements of a type-wheel, which is made to press against a slip of blackened paper; beneath this is a strip of white paper; and an impression of the Roman letters becomes transferred to the white paper. Letters can be thus transmitted and printed at the rate of a hundred and fifty or two hundred in a minute. Mr. Bakewell and other inventors in England have put in practice printing telegraphs more or less resembling this by Mr. House.

It is said that House's system is capable of transmitting more words in a minute than either of the other two principal American systems; but to balance it a great deal of time is consumed in adjusting the instrument. There is a fallacy in some of the statements respecting the rapidity of telegraphing which deserves to be borne in mind; Mr. Bain's 'fast method' enables one thousand letters to be transmitted per minute; but the process of preparing the message requires about as much time as the transmission by the ordinary method. It is said, that in the ordinary every-day working, the American rate of transmission averages from seventy-five to a hundred letters per minute. On one particular day in the spring of 1852, Bain's line transmitted 500 messages, besides 5000 words of foreign news, from Boston to New York.

Remarkable and valuable as is the degree of rapidity already attained, there are many reasons to wish for still greater speed in transcribing the messages than that at present attainable. To effect this end, Mr. Bain introduced a method different from those above mentioned. He prepared continuous slips of paper, about a quarter of an inch in width, and perforated them with holes and slits, to represent the dots and lines of his alphabet; the passing of a metal point, alternately over the paper and over the holes in the paper, broke and re-made the galvanised circuit with great rapidity; and in order to aid the work, Mr. Bain invented an ingenious machine for punching the holes in the paper. The actual transmission was very rapid: but by the time the punching and the subsequent translation into English were completed, not much time was gained over the ordinary methods.

In relation to the wires linking Great Britain with other countries, the submarine principle has been brought very remarkably into operation. Beginning at the north, and working half round the island, we first meet with the Portpatrick and Carrickfergus cable (24 miles) dipping between the North Channel of the Irish Sea, and connecting Scotland with Ireland. At one end it joins two land-telegraphs, one from Portpatrick through Stranraer to Ayr and the centre of Scotland; the other through Stranraer to Dumfries and the net-work of British lines. At the other end the cable is connected with wires running along the Irish railways. Without any difficulty a message is sent from London to Ireland *viâ* Dumfries without regard to circuitousness of route; for the electric current recks little of distance. Next comes the Holyhead and Dublin cable (64 miles), joined at one end to the Welsh and English lines of telegraph, at the other end to the Irish lines. In the south is the Hants and Isle of Wight cable, not very important commercially, but establishing electric communication with her Majesty's marine residence at Osborne: it is connected at Hurst Castle with a land-wire running through Lymington to the Brockenhurst station, and at the other end with a land-wire passing through Yarmouth to Osborne. Farther east is the Dover and Calais cable (22 miles), connected at the two ends with the systems of telegraphs belonging to England and France respectively. Another is the Dover and Ostend cable, connecting England with the Belgian and European wires generally. Lastly, there is the Orfordness and Hague cable, joined at one end to a land-wire running to the Ipswich station, and connected at the other with the Dutch telegraphs. All these cables are thicker than that intended for the Atlantic, presently to be described; and all have had occasional mishaps; but taking them collectively, they afford a remarkably complete series of channels through which messages may be exchanged between Great Britain and all the neighbouring countries. The salt-water, the storm-tossed ocean, have been pretty nearly conquered by the ingenious men engaged in these operations; and now the English public hear with as little surprise of messages or *telegrams* (to use a new word concerning which Greek scholars have been carrying on a fierce battle) brought under water as if brought on dry land.

Directing attention next to the continent of Europe, we find telegraphic wires ramifying in all directions. Nations were never more struck with the wonders of the electric telegraph than on the occasion of the death of the Czar Nicolas in 1855. On the 2nd of March the Earl of Clarendon announced in the House of Lords that the Czar had died at St. Petersburg at one o'clock on that same day. Two distinct messages had been received, one *viâ* Berlin and the Hague, the other *viâ* Berlin and Ostend, both communicating a message telegraphed to Berlin from St. Petersburg, and all in four hours after the actual death. Not only have the dreary wastes of Russia been brought within the civilising influence of the bit of copper wire, but lines in all directions have been laid, with or without regard to railways. Nearly all the chief cities in Europe are now linked together. Circuitous as is the route from London to Trieste, going through Belgium, Prussia, several minor German States, Saxony, Bohemia, Austria, and Istria, the connection is nevertheless complete; and telegrams are twice a-month transmitted to us relating to Indian affairs, brought to Trieste from Alexandria. Italy, in railways and in telegraphs, is in arrear of Austria; and Spain is lower on the list than Italy. Turkey, to the great astonishment of many of the Osmanlis, has been made a sharer in the fast-going, high-pressure operations of the age: she possesses an electric telegraph, extending from the Austrian frontier to Constantinople; and messages can now be flashed from London to the seat of the Ottoman empire. During the Russo-Turkish war, an electric cable 300 miles in length was sunk in the Black Sea from Varna in Bulgaria to Kamiesch in the Crimea, there to be available to the allied generals engaged in the operations around Sebastopol: it was one of the many contributions of peaceful industry to dread war. The Czar Alexander and the Sultan Abdu-l-Medjid, now that hostilities have ceased between them, might, if so disposed, exchange friendly telegrams; for there is an uninterrupted copper wire extending all the way from the capital of the one to that of the other, passing in its route through Berlin, Dresden, and Vienna. Nay, if business or pleasure suggested it, a dozen emperors and kings, seated in a dozen capitals, might exchange greetings all in one day, or perhaps in an hour or two, and might make a score of petty princes sharers in the achievement.

We pass now to the routes for traversing the Mediterranean by telegraph. The two islands of Corsica and Sardinia, belonging to two energetic sovereigns, have been connected by telegraph with the French and Sardinian continental dominions: land-wires on the islands themselves, and submerged cables from Sardinia to Corsica and from Corsica to France. This being done, the grand question arose—how to span the broad Mediterranean, so as to connect Europe with regions far beyond. Glancing at a map, we see that the southern end of Sardinia makes a tolerably near approach to the northern coast of Africa, at a point in the pachalic of Tunis. We also see that Sicily, Malta, the Ionian Islands, and Candia, form spots of dry land which might be used as resting places for separate lengths of submarine cable, should commercial and other reasons justify the adoption of such plans. A company, aided by the Sardinian Government, has been formed, which has laid down a submarine cable on the first of these two routes. From Sardinia to Malta, and from Malta to Corfu, it was found that the water is of much less depth than in the line of route from Sardinia to Africa; and as these islands lie in the way towards the Levant and Egypt, an enterprise was commenced to connect the various islands by a chain of telegraphic links. The whole of this line, 450 miles from Sardinia to Malta, and 350 miles from Malta to Corfu, has been completed; and there is a project on the part of the Austrian Government to extend their land-telegraph from Trieste to Ragusa, to lay down a submarine cable from Ragusa to Corfu, there to join the line just described, and thence to extend it to Alexandria, with or without stopping at any intermediate island. The Mediterranean cables, actual or proposed, may thus be classed in four groups: from Spezzia in the Genoese State to Cagliari in Sardinia, promoted and supported by the Sardinian Government; from Cagliari to Africa, by the French Government; from Cagliari to Malta and Corfu, by the English Government; and from Trieste to Corfu and Alexandria, by the Austrian Government.

Next, a few words must be said concerning the rival projects for connecting Asia with Europe by telegraph. Supposing all the attempts in the Mediterranean to succeed (and succeed they probably will after a time), there will be one terminus of electro-communication on the north coast of Africa, another at Corfu, and a third at Constantinople; and the question then arises—how best to apply the system to Asia. Two projects have been competing for public favour during 1857 and 1858—the Red Sea and the Euphrates routes. The first of these comprises a submerged cable along the Red Sea, to be connected at Aden either with a land-wire or a submarine cable to India; while the other starts from Syria or from Asia Minor, and follows the valley of the Euphrates through Mesopotamia to the Persian Gulf and the Indian Ocean, thence to be prolonged, whenever convenient, to India. The promoters of the Red Sea telegraph advocate its merits somewhat in the following way. There would be a land line of 240 miles from Alexandria to Suez; and then a submerged cable of 4200 miles from Suez to Kurrachee in India in two lengths, joined at Aden as a resting-point. Between Suez and Aden there would be three resting-points on land, at Cosseir, Juddah, and Camaran; while there would be three others between Aden and Kurrachee, at Ras Shurmah, the Kooria Mooria Islands (now a British possession), and Ras el Had, in the Imaum of Muscat's territory. The promoters say that 700,000*l.* in money, and one year in time, would complete this great enterprise; but that if the Indian Ocean section, from Aden to Kurrachee, were suspended for the present, and the Red Sea portion only attended to, 300,000*l.* in money, and eight months of time, would suffice to establish a telegraph from Alexandria to Aden. The promoters urge that they have obtained the necessary firmans from the Turkish and Egyptian Governments; that a cable plunged into the sea is freed from the difficulties of territorial politics; that plans are already made by other parties to connect Alexandria with Europe by a cable from Austrian and Sardinian ports; and that, even should these projects fail, the Red Sea Telegraph Company would undertake to lay down a cable of 800 miles from Alexandria to Constantinople—in either case ensuring complete telegraphic communication from London to India. On the other hand, the Euphrates Company propose a land-wire of 1200 miles, starting from Constantinople, stretching south-eastward across Asia Minor, and thence to the Euphrates, or to Baghdad on the Tigris; then a river-cable to the Persian Gulf, and lastly, a submarine cable to Kurrachee at the mouth of the Indus—the two cables together being about 1600 miles, or 2800 miles of electric line from Constantinople to Kurrachee. The estimated coast is 400,000*l.*, and the time of completion six or eight months.

Having thus noticed the various projects for establishing electro-telegraphic lines to India, we must now say a few words concerning what has been effected in India. In 1852 Dr. O'Shaughnessy, after a series of preliminary experiments, was empowered by the East India Company to establish a magnificent series of telegraphs in that country. During the remainder of that year, and the whole of 1853, he was employed in procuring from England the immense quantity of material required, and all the working apparatus. He commenced the actual construction shortly before the end of the year just named, and on the 24th of March, 1854, he sent a message through 800 miles of wire from Calcutta to Agra. Proceeding energetically with his labours, Dr. O'Shaughnessy was able to announce that, on the 1st of February, 1855, only about fourteen months after his commencement, he had finished the whole trunk line from Calcutta through Agra, Delhi, and Lahore, to Attock on the Indus; a branch from Agra to Bombay; and another from Bombay to Madras—the whole extending to 3050 miles, and including 41 offices or telegraph stations. During the remainder of the year 1855 the lines were extended from Attock to Peshawur on the Afghan frontier, from Rangoon to Meeaday on the Burmese frontier, and from Bangalore to Ootacamund—extending the total length to 4000 miles. During 1856, and so much of 1857 as was uninterrupted by war, other lines were executed, raising the length to more than 5000 miles. Throughout Central India the engineer was opposed by enormous difficulties; there was no metalled road; there were few bridges; the jungles are in many places deadly for at least half the year; and there was no police for the protection of the wires. More than seventy principal rivers have been crossed, some by cables, others by wires extended between masts; the Toonbuddra crossing was two miles wide, and that of the Soane more than three miles. Throughout three-fourths of the distance from Calcutta to Madras the telegraph is more substantial than any known in Europe or America; for 174 miles the wire is borne on masonry pillars capped with granite; while for 332 miles it is supported on superb granite slabs, each 16 feet high. The whole expense has, nevertheless, been kept within 50*l.* per mile.

Viewing the state of telegraphy on the other side of the Atlantic, we come to that which almost baffles calculation. In the United States the railways have been ramified in all directions, but the telegraphic wires have far outstripped them in length. The Americans, having millions of acres that belong to no one, or that are of very slight value, set up their telegraphic poles and stretch their wires in spots where no such achievements are dreamed of in England. Across swamps, through forests, over rivers, across prairies, over mountains—nothing stops them, and as the engineers and companies care little about strength or symmetry, the telegraphs are set up with wonderful cheapness. Cheapness of telegraph leads to cheapness of telegram; and the Americans avail themselves much more than the English of this sort of silent converse.

Atlantic Telegraph.—The effort to establish a telegraphic communication between England and the United States so far transcends every previons undertaking of the kind that we deem it advisahle to describe the operations in some detail, and for this purpose avail ourselves of a communication with which we have been favoured hy a gentleman intimately acqnainted with the whole course of the proceedings.

A company having heen formed in 1856 for the purpose of connecting the two countries by a line of electric telegraph, under the title of the Atlantic Telegraph Company, and the reqnisite capital having heen suhscribed, the Governments of Great Britain and the United States agreed not only to pay each to the Company a suhsidy of 10,000*l.* a year, for 25 years, hut to assist the undertaking, by fnrnishing the men and ships which shonld he required in the laying of the cahle. The preparation and perfection of the electrical details of the work were left in the hands of Mr. Wildman Whitehouse. Three gentleman who had practical experience in the work of marine telegraphy, Mr. Canning, who submerged the Newfoundland cable, Mr. Woodhouse, who connected Balaklava and Varna dnring the Russian war, and Mr. F. C. Webb, who had the charge of the line between Orfordness and the Hague, were associated with Mr. C. Bright, in preparing the engineering appliances for the suhmergence of the cahle, the mannfacture of the paying out machinery being intrusted to Mr. Henry Clifford, under the superintendence of Mr. C. Bright. A company which had been incorporated hy the legislatnre of Newfoundland in 1854, under the denomination of the "New York, Newfoundland, and London Telegraph Company," transferred all their rights to the Atlantic Company, secnring to them the exclusive privilege of landing a cahle npon the Newfoundland shores dnring fifty years, and upon the coasts of Nova Scotia during twenty-five years. Patent rights in apparatus which wonld be required in working the line, were also secured to the company hy Messrs. Whitehouse and Bright.

Before the actual operations of the undertaking were entered upon it was deemed very important that the capahility of transmitting an electrical current through a coated conducting wire as long as the Atlantic is wide, should be put to the test of direct experiments. Mr. Whitehouse had already availed himself of several opportunities furnished hy the chance of lengths of cahle heing under construction, which had separate wires imhedded in the insulating gutta percha mass; the wires being so joined at their extremities upon the occasion of the experiments as to form continuous lines of condnction. In 1855 he was enahled to operate at Greenwich with an extent of 1146 miles. In the following year, with the co-operation of the Magnetic Telegraph Company, arrangements were made for the crowning trial in the persence of Professor Morse, he chancing to be in England at the time. The wires of this company extended nnder ground, and through the sea, from London through Dumfries to Dublin, along a course of 660 miles. They are also so numerous, and so connected with a wide system of ramifications, that, npon need, a length of some six thousand miles can he formed. Upon a pre-determined night, that of the 9th of Octoher, ten gutta percha-covered insulated wires, each more than 200 miles long, were connected into a continuous circuit of more than 2000 miles. The conclave of experimentalists met at the offices of the company in Old Broad Street, London. A pair of Mr. Whitehonse's indnction-coils were used to excite the wires, and the current was made to act through one of Professor Morse's ordinary recording instruments. Signals were distinctly telegraphed through the two thousand miles of wire at the rate of 210, 241, and 270 per minute! This result was deemed eminently successful, and as proving beyond all fair ground of question, that the transmission of an electric signal through a coated wire laid across the hed of the Atlantic was perfectly within the powers of science; for thongh the greater part of the cahle employed in this experiment was suhterranean rather than subaqueous, it is now well known to the initiated in these matters, that the two cases are, as nearly as possihle, identical in all their essential characteristics and conditions.

During the preparation for the construction of the Atlantic cables, and indeed even more availably dnring its mannfactnre, Mr. Whitehouse was engaged in putting several important matters concerning the rationale of electrical action to the rigid questioning of experiment. Many of the results which were elicited through these investigations are of surpassing interest, and require to be alluded to as contrihuting notable passages to the pages of the history of electrical science. Foremost among the lahours of the experimentalist, however, necessarily stood the completion of his instrumental means of research. He very soon fonnd that the instruments which had heen previously in nse as measures of electrical force and speed were quite inadeqnate for the examinations he had entered upon. He conseqnently set himself to work seriously to remedy the defect.

The nsual method whereby the force of an electrical current had heen estimated hitherto, had heen the placing a freely suspended magnetic needle near to, or within, a many-spired coil of the conducting wire. The degree of the magnetic needle's deflection from its position of equilihration, was then held to give the acting force of the current. This answered very well so long as only continuons currents of moderate intensity were under examination. When, however, the experimentalist came to deal with sudden and interrupted currents of high intensity, such as the streams are which the Atlantic telegraphists have to deal with, no steady deflection could be prodnced. The needle jerked fitfully and violently backwards and forwards with so much caprice that it defied the adroitness of the most skilful observer to get any intelligible indication of force out of its position or movements. This determined Mr. Whitehonse to dispense altogether in his investigations with the fitful and unstable needle, and to call in to his assistance, in its stead, that power which is fixed and stable beyond all other forces that are known to man. He resolved that he would literally *weigh* the available strength of the current; that he would put its strength in the scale, make terrestrial gravity determine the amount, and send in a record of the same in grains. The ingenions piece of apparatns wherehy he accomplished this curious feat of *weighing* electrical action, Mr. Whitehouse named, when he had perfected the mechanical details of its construction, his *Magneto-Electrometer*.

Mr. Whitehouse's instrument for measuring the force of electrical cnrrents consists of a delicate steel-yard suspended at each side hy springs similar to those which are used for the support of the pendulums of clocks. The short end of the steel-yard is armed with a har of soft iron, and at a short distance heneath this is placed another har of soft iron, snrrounded by a coil of fine silk-covered copper wire, and therefore capable of heing converted into a magnet whenever a current of electricity is flowing through the coil. The strength of the artificially formed magnet depends on the power of the current which flows through the coil, and consequently a greater or less weight can be tilted up on the long arm of the steel-yard accordingly as the short arm is more or less powerfully attracted. By shifting weights along the steel-yard, by changing these weights for others of different mass, and by lifting the steel-yard itself to different distances from the artificially magnetised har, so wide a range of mechanical adjustment is commanded that degrees of attraction can he accurately estimated from those capahle of tilting up hut a small fractional part of a grain, to those which can lift many thousands of grains.

Mr. Whitehouse also prepared an instrument which enahled him to compare the velocity of transmission of different currents of electricity through the same wire, or of the same current through different wires. This instrument consists of a pendulum, heating true seconds, connected with a voltaic hattery, and of a ribbon of chemically prepared paper unrolled from a drum hy a train of clock-work. The pendulum hangs upon a pivot, which is vertically one of the poles of the voltaic battery, and its rod is prolonged upwards into a sort of crest, which comes into contact with a spring right and left, as it swings to and fro. The springs, when not touched hy the pendulnm, press upon a metallic pillar, which is itself the other pole of the voltaic hattery. The crest of the pendnlum lifts the spring, which it tonches for the time, from the pillar. When it lifts the right spring it sends an electrical current out through it and any conducting wire placed in communication, and back throngh the left spring to the central pillar and connected pole of the hattery. When it lifts the left spring exactly the opposite proceeding occurs. The wire which forms the circuit, and which is supposed to he a lengthened one, is curled into a coil near to either extremity, and into each of these coils a har of soft iron is inserted. These bars hecome temporary magnets whenever a current of electricity is passing through the coils, but the precise polarity of either extremity depends on the way the current passes. The extremity, which is a north pole when the current issues from the battery through the right spring of the pendulum apparatus, becomes a south pole when the current issues through the left spring. Near to each temporary magnet is placed a permanent magnet traversing upon a central pivot, in such a way that it can be acted upon and made to traverse backwards and forwards by the reversal of the temporary magnetism. Now when these traversing magnets lie in one position they make a contact, and turn on each a small local voltaic battery in connection with them, causing its current to pass through a style pressed down on the ribbon of paper, so that a visible trace is left upon its surface. When the magnets lie in another direction, they turn the currents of the local batteries off, and cause them to cease to print. As therefore it is the pendulum which reverses the direction of the primary current in the long wire, and so the positions of the temporary magnets, a trace is printed on the temporary ribbon of paper, each alternate second, as the ribbon is drawn along, and an intermediate blank interval is left. But as there are two batteries printing, one at each extremity of the wire, if any appreciable time be occupied by the passage of the current along its extent, and if the two batteries are made to record, side by side, upon the same ribbon, the distance to which the one trace lags back behind the other, *estimated by comparison with the second's-long* trace, will afford a measure of the time. In this way the length of time the electrical current takes to run through the wire from one printing instrument to the other, can be determined with the utmost precision in fractional parts of the printed linear representative of a second. It does not at all matter what the speed is with which the paper ribbon is unwound beneath the printing styles, because the estimate is always a relative one referred at each instant to a particular track made by the beat of the pendulum. When the velocity of transmission in any special wire is to be examined, the apparatus is set to work, and a somewhat lengthened series of observations is printed off. This is then narrowly scrutinised, and any doubtful or suspicious records are rejected, and the mean of all the more trustworthy ones is noted as the result to be adopted.

One of the most important deductions arrived at through the instrumentality of this ingenious apparatus, was the fact that voltaic electricity is capable of producing greater mechanical effects at the extremity of any given wire, than the induced electro-magnetic current, but performs its journey through a long course with inferior speed to its weaker comrade. As is commonly the case in some other matters, the heaviest agent proved to be by no means the most fleet and agile one. Seventy-two pairs of sixteen-inch sand-battery plates lifted 1400 grains on the steelyard of the magneto-electrometer at the end of 600 miles wire, but the current took forty-four hundredths of a second to traverse the distance. Two large electro-magnetic induction coils, excited by a Smee's battery of ten pairs of one hundred square-inch plates, sent forth a current which lifted only 745 grains at the end of the same wire, but which arrived at that end in nineteen hundredths of a second. Simple voltaic electricity is capable of greater mechanical effort, under any given arrangement of conductors, than an induced electro-magnetic current, but the electro-magnetic current travels through lengthened conductors with a considerably superior rate of speed. The electro-magnetic current sent forth from induction-coils possesses a treble velocity of transmission, and realises consequently *a three-fold working speed* as compared with simple voltaic electricity. It was hence obvious that induced, and not voltaic electricity, must be adopted for the wide Atlantic service, where the ultimate commercial success of the enterprise would be mainly dependent upon the number of signals which could be forwarded in any given period.

In the early experiments made to determine the rate of movement of the electrical influence along telegraph-wires, it appeared that it could pass through hundreds of thousands of miles in a single second of time. When however a similar examination was entered upon with telegraph-wires coated with gutta-percha and running beneath the ground and through the sea, instead of being freely suspended in the air, it seemed that scarcely thousands of miles were traversed in a second. Different experimenters, too, arrived at different results for the rate of speed. In a paper read by Mr. Edward Bright, at the meeting of the British Association in 1854, the statement was made that the velocity of currents in ordinary use in subterranean and submarine lines did not exceed one thousand miles per second; this gentleman had also inferred from experiments made in a circuit of 480 miles underground, that the speed of the electric impulse varied with the energy or intensity of the current, and with the nature of the conductor and conditions in which it was placed. When Mr. Whitehouse turned his attention to this question, his investigations amply confirmed the deduction which had been previously drawn. Working with his pendulum-apparatus he found that the mean or average speed of voltaic electricity along a No. 16 gauge copper wire, is about 1400 miles per second. But he also ascertained that that of the induced electro-magnetic current is 4300 miles per second. He determined too that the speed of the voltaic current might be raised under special circumstances to 1800 miles per second, and that that of the induced current might be augmented to 6000 miles per second.

But what could be the cause of these varying rates of speed, and of the retardation in general which the electrical influence was thus proved to suffer when it was constrained to traverse coated underground or sub-marine wires, instead of air-surrounded conductors? Professor Faraday had thoroughly investigated this question so soon as the unexpected fact was disclosed, and was able at once to explain the seeming anomaly. When a conducting wire of metal is stretched as an electrical conductor between posts, and is insulated simply by earthenware holders and the circumambient air, the electrical influence runs along it as a simple stream, and almost without suffering impediment. When, however, the wires are inclosed in a compact sheath of insulating substance, like gutta-percha, and are placed in water or moist earth, the affair is altogether changed. A new agent then comes into play. So soon as the insulated and sheathed wire is electrically excited, the electrical excitement operates upon the near-at-hand outer layer of moisture, and it being a conductor, calls up in it an electrical excitation of an opposite kind. The two electrical forces then pull upon each other through the intervening layer of impenetrable substance, and hold, each the other, fast locked. The inner excited influence keeps the outer reduced force stationary upon the external surface of the insulating sheath. The outer induced force keeps a certain portion of the inner excited one present on the internal surface of the insulating sheath *as a charge*, and so prevents it from moving as freely onward upon its journey as it otherwise would. The submarine telegraph cable is indeed virtually a lengthened out Leyden jar, and is necessarily charged with a certain measure of static electricity whenever a current is passed through it. It is a reservoir or *bottle* for the electricity, which has to be filled and emptied, as well as a channel or *pipe* through which the influence may be poured. When an extent of many miles is concerned, it gets too to be a very capacious bottle in virtue of its length, however narrow its transverse dimensions may be. In the more ordinary practice of artificially induced electricity, the voltaic current is not able to produce a static charge in a Leyden jar. In the case of the coated wire of the electric telegraph it is able to do so, probably in consequence of the comparatively enormous extent of surface which comes to be concerned. Now it is this peculiarity of the action of the coated telegraph-wire which leads to the slower rate at which the electric influence is propagated along its substance. The wire, upon every occasion, must be filled to saturation with the force before any transmission can be effected, and then must be emptied completely before any new transmission can be made. Mr. Whitehouse was able by his delicate instruments to procure a very beautiful illustrative proof that it is as charged Leyden jars, and not simply as conductors, that submarine cables, or subterranean coated wires act. He took fifteen miles of the Atlantic cable, consisting of an internal conducting strand, an external metallic envelope, and an intervening insulating sheath, and he *turned up* the further end into the air, thus leaving the conducting wire entirely insulated that way. He next took 200 miles of the same cable, and arranged it in precisely the same fashion. He now found that he could fill each of these lengths with an electric charge, allow the charges to remain for a few seconds in the wire, and then discharge them back through the nearer end, measuring the force of the discharge, and therefore the amount of influence which had been inductively retained in the wires, by the

magneto-electrometer as it flowed out under a constraint which forced it to pass through the coil. The discharge from the 15-mile length of the wire lifted 1075 grains on the steel-yard of the electrometer. The discharge from the 200-miles length lifted 2300 grains. A current which lifted 18,000 grains upon being simply poured through the coil of the electrometer, lifted 60,000 grains when allowed to flow back as a discharge after having saturated a coated wire 498 miles long. Here it was evident that these wires were acting as reservoirs and not as simple channels, because the longer wire had received the most powerful charge, and had produced the most powerful effects. If the wires had been acting as common conductors, the longer wire would necessarily have produced the weaker and not the stronger effect, on account of the electrical influence being attenuated through its greater extent.

Most electricians had held, previously to the period of Mr. Whitehouse's investigations, that the available force of an electric current is diminished by increasing distance, or in other words by the length of the transmitting medium, in the rates of the square of the distance it has traversed. It was very important that this question should receive immediate and full investigation, because, if the received dogma were true, it was obvious that the difficulty must be very great indeed, of getting any efficient current to present itself on the opposite shore of the Atlantic, it having been started from the eastern or western shore. A current which would be strong enough to produce very decided results at the distance of 500 miles, would be rendered at this greater distance almost evanescent. Mr. Whitehouse accordingly proceeded to test the deduction in two ways. First, by examining the diminution of the current power to produce mechanical effects in consequence of its having made certain extended journeys; and then by closely scrutinising its loss of speed at varying distances. The current from a voltaic battery, consisting of 72 pairs of 16-inch plates, was transmitted to the magneto-electrometer through wires of different lengths. Where the wire was only a few feet long, 25,000 grains were lifted on the steelyard. With a wire 200 miles long 10,650 grains were lifted. With 400 miles, 3250 grains, and with 600 miles, 1400 grains. As many as 5000 experiments were made with wires ranging from 80 to 1020 miles long, to determine the rate of transmission. With a length of wire of 83 miles, the transmission was accomplished in eight-hundredths of a second. With 166 miles in fourteen-hundredths of a second. With 249 miles in thirty-six hundredths of a second. With 498 miles in seventy-nine hundredths of a second, and with 1020 miles in a trifle less than a second and a half. Taking 83 miles as the unit in these results, there were a series of distances represented by the numbers 1, 2, 3, 6, 12. Therefore, if the so-called law of the squares of the distances were correct, the transmission through the 1020 miles of wire ought to have required 144 times as long as the transmission through the 83 miles. When the induced electro-magnetic current was employed in the distances represented by the series 1, 2, and 3, the rates of velocity were represented by the fractional series $\frac{1}{4}$ $\frac{1}{9}$ $\frac{1}{16}$. It therefore appears, from experiments, that nature is more auspicious to the cause of wide ocean telegraphy, than the assumption of theory.

During the experimental investigation of this portion of the subject, a very surprising and an altogether unforeseen result was obtained. In the attempt to ascertain how small a quantity-battery would prove sufficient to effect a charge and transmit a current, through some thousand miles of the Atlantic cable, Mr. Whitehouse had a piece of apparatus prepared consisting of twenty-five pairs of zinc and silver plates, each about the twentieth of a square inch large, and the pairs so arranged that they could hold a drop of acidulated water or brine between them. On charging this lilliputian battery, by dipping the plates into salt and water, messages were sent from it through the thousand miles of cable with the utmost ease; and not only so. Pair after pair was dropped out from the series, the messages being still sent on with equal facility, until at last only a single pair, charged by one small drop of liquid was used. Strange to say, with this single pair, and single drop, distinct signals were effected through the thousand miles of the cable! Each signal was registered at the end of the cable, in a trifle less than three seconds of time. This remarkable experiment demonstrated how slight a current might be made to give very good results, when a conductor as perfectly insulated as the copper strand of the Atlantic cable was made the channel of transmission.

In some of Mr. Whitehouse's early experiments it was found that the induced electro-magnetic current took a second and a half to discharge itself, when it moved through a coated wire 1146 miles long, in consequence of the retarding influence of induction in this lengthened channel. This apparently is a very excellent result—a signal conveyed eleven hundred miles in less than two seconds! It is not enough, however, for the exigent service of Atlantic telegraphy. In spelling out messages, most letters require three or four signals each, consequently with this rate of transmission it would be extremely difficult to send enough words across the Atlantic within twenty-four hours, to enable the company to work their telegraph remuneratively at low rates of charge. The experimenter, therefore, set himself to see whether he could not find some means of quickening the pace of his too lagging messenger. He ultimately accomplished his object by means of an arrangement with electro-magnetic coils which enabled the operator, through the simple reversal of the poles of the magnet to send currents of *different kinds* of electricity, one after the other through the conducting wire. Each successive transmission then served to clear away the lagging residue of the antagonistic current which immediately preceded it. The remains of the old current which clung about the wire pertinaciously, were completely and rapidly put to the rout upon the stream of an opposite kind being thrown in. When positive followed negative, and negative followed positive, in exactly equal proportions, the electrical equilibrium of the wire was continually restored as fast as it was disturbed, and its telegraphic capabilities were in this way steadily maintained. By the use of these alternated electrical currents, seven and eight signals were now distinctly recorded through the 1146 miles of wire in a second, instead of one signal in a second and a half.

When the idea was first entertained that electrical currents would run along coated telegraph-wires with a velocity that was inversely proportional to the squares of the distances traversed, it was also thought that the difficulty might be partially overcome by providing them a wider road to travel along. It was conceived, that if one of two wires of equal length, was six times as large as the other, that wire ought to transmit any given electrical current with a six times greater facility and rate of speed. Hence it was proposed that long wires should always be made larger than short ones. But this proposal became a matter of very great consequence when a cable of sufficient length to span the Atlantic was concerned. A cable possessing only the dimensions of the Dover and Calais one, if extended enough for the Atlantic service would weigh not less than 20,000 tons. But if the Dover and Calais cable were only duly proportioned to its work, the Atlantic cable would be required, by theory, to be considerably larger and heavier, so that not even such a vessel as the Leviathan would be capacious enough to carry more than a small part of it. The weight, too, that would be dependent upon itself and upon the stern of the vessel from which it was being payed out, would in Atlantic depths amount to a considerable number of tons. Mr. Whitehouse, consequently, applied himself with considerable anxiety to determine how far this view was based in fact. He worked with a 300 miles' length of cable which had three insulated wires running along parallel to each other, but distinct, through one mass of gutta-percha, so that he could use a single wire, or a double, or a treble one, at will, combined as one. Some 3000 separate observations were made, and to the experimenter's great relief it proved, that the wire of increased capacity *did not* transmit electrical signals with greater facility or speed than the smaller one. With a length of 166 miles the velocity of the induced electro-magnetic current was eight-hundredths of a second in a single wire. With the double wire it was nine hundredths; and with the trebled wire it was nine and a half hundredths. Increasing the size of the conductor actually *augmented the retardation* of the electrical transmission through it. All Mr. Whitehouse's experiments taken together seemed to warrant the conclusion, that a treble-sized conductor gives nearly a doubled rate of retardation.

When the actual construction of the Atlantic telegraph-cable was commenced, certain important facts had therefore been determined which served as very excellent indications of the principles upon which the manufacture of the apparatus would have to be carried on. It was manifest that gutta percha covered submarine wires transmit the agent entrusted to their conveyance as induction-incumbered Leyden jars, and that consequently the transmission is effected with a velocity which is modified and influenced by external conditions. Also that induced electro-magnetic currents of a certain determinate intensity, travel more quickly than simple voltaic currents, and that the rapidity with which signals are transmitted by the agency of electro-magnetic currents, can be greatly increased by using opposite electricities following each other alternately. It was also clear that the diminution of the speed of movement along induction-embarrassed wires was not in so high a ratio as the squares of the distances traversed; that several distinct waves of transmission might be made to run along the same wire, one after the other, at the same time; that large coated wires transmitted with less facility and freedom than small ones, in consequence of requiring a larger charge to saturate their inductive capacities before they were in a fit state to transmit; and that therefore the small ones were better suited than large ones for employment in wide ocean telegraphy; and that by the use of small wires, very perfectly insulated, and of electro-magnetic induction-coils of powers carefully apportioned to the dimensions of the wires, signals might be transmitted through a distance of 2000 miles with a rapidity amply sufficient for all purposes of revenue to the Company, and of utility to commerce.

It was necessary, then, that an Atlantic cable, which was to furnish a fair promise of success, should have a well insulated conductor, of dimensions of a very moderate size; that it should be so light as to be easily conveyed across the Atlantic, and easily handled during paying out, and yet be so dense as to be able to sink with facility to the depths of the Atlantic, and so strong that it could resist any strain to which it might be exposed during deposition. It was also essential that it should be so flexible that it could be readily coiled up in the store-spaces of the factories, and of the vessels employed in paying out, and rolled over the sheaves of the paying-out apparatus, and yet possessing sufficient inertia and rigidity to allow of its lying in a tolerably straight line when once *in situ* at the bottom of the sea.

The following is the plan which, in accordance with the indications of these multiplied experiments, was finally adopted in preparing a cable for the Atlantic. A strand of seven wires of the purest copper of the No. 22 gauge, was first prepared, it being the sixteenth of an inch in diameter when twisted. The strand of seven wires was adopted in preference to a single wire of the same practical capacity, because the probability of a destruction of continuity was in this way greatly diminished. In case of any accident occurring it was very unlikely that all the seven wires would be broken in exactly the same place, and so long as only one of them remained sound, the electrical transmission could be carried on. The strand itself was subject to a strain which stretched it twenty per cent., without any appreciable injury to its conducting power being discovered. To show that no amount of attenuation, which could possibly be produced by accident, could interfere to any important extent with its utility as a telegraphic conductor, one mile of wire eleven times smaller than the strand, was introduced into a gap made in a 600-miles length of the cable, and the effect produced on the transmitting power of the cable by the interpolation was tested. It proved that the transmitting capacity of the cable was only diminished by one thirty-seventh part.

As the copper strand was prepared, it was rolled upon drums, and then taken from the drums to have three separate coatings of gutta percha applied, until the aggregate diameter was thus brought up to about three-eighths of an inch. The gutta percha used for these coatings was prepared with the utmost possible care. It was first rasped into shreds, and washed, and next pressed through several layers of fine wire gauze, and kneaded for hours in the interior of iron cylinders by steam machinery. It was then squeezed by powerful screws, through dyes, as the strand of copper was gradually drawn along between them, and so made to adapt itself as a compact sheath to the strand. Three several and successive coatings were given to the strand in order that any imperfection left in the first might be compensated and remedied by the next coat applied. The completed core was subjected to a pressure of five tons upon the square inch, by the use of hydraulic power, without the insulating material being at all injured by the force applied.

During the process of the manufacture of this core it was submitted to constant examination to prove both that the continuity of the copper strand continued unimpaired, and also that the insulating power of the gutta percha sheath was as complete as it was required to be. The continuity was proved by passing a voltaic current of *low intensity* from a battery of a single pair of plates, through the strand, and then causing it to record a signal after issuing from the wire. A battery of low intensity was employed for this purpose, because it made the test so much the more severe. A strong battery might have thrown the current through a slight imperfection, which a weak battery might not be able to overcome. The due perfection of the insulation was tried by turning up into the air the end of the length of core about to be examined, and by then connecting one pole of a voltaic battery of five hundred pairs of plates with the nearer end of the length of wire, and the other pole with the earth, a magnetic galvanometer being suspended within a coil continuous with the strand. So long as the insulation of the strand was fairly perfect, the copper wires became charged with the electricity of which but very little could escape, and so no current was produced through the strand, and no defection of any consequence appeared in the magnetic needle. When the insulating sheath, on the other hand, was imperfect, the electrical charge *leaked* through the imperfections to the earth, and so got back to the opposite pole of the battery. In this way a current was set up in the wire to supply the leakage, and the magnetic needle was deflected from its position of equilibrium, the deflection being in proportion to the amount of the current. A strong battery of five hundred pairs of plates was employed in detecting imperfect insulation, in preference to a weak one, because a strong current would force a passage through an imperfection which might be too slight to allow a weak current to make its way. During the progress of the work, a plan was devised which enabled the testing for both continuity of the strand and insulation of the sheath to be carried on simultaneously. A voltaic current can pass through a charged Leyden jar without either the current or the charge being in any practical way interfered with. Therefore the entire length of cable under examination was joined up into a loop or endless ring, and a voltaic battery of five hundred pairs of plates had one of its poles connected with the conducting strand of this ring, and the other pole placed in communication with the earth. A small *insulated* battery of low tension was also introduced into the circuit of the ring, so that its current flowed round continually, from pole to pole, through the strand. An insulated bell was also so placed in the circuit, that any break of continuity dropped a needle, before held magnetically fast, and caused the bell to sound. Another bell instrument was so arranged that it was rung whenever the current from the five hundred cell battery began to run, in consequence of electrical leakage, with undesirable speed. The feeble battery in the circuit rung its bell whenever the circuit was broken. The strong battery out of the circuit rung its bell whenever an outflowing current was set up through the strand, in consequence of the insulating sheath being unable to retain the charge.

During the prosecution of these experiments the very remarkable discovery was made, that the insulating power of gutta percha is very materially affected by temperature. A high temperature seems greatly to impair its insulating capacity, and the recurrence of a low temperature speedily restores it to its original excellence. An opportunity was taken, when a single flake or tier of the completed cable was lying at the bottom of the receptacle in the yard of the manufactory at Greenwich, to watch the changes which the natural variation of temperature during forty-eight hours produced in its conducting capability. When the thermometer stood at 42°, the deflection of the galvanometer needle was barely 3°; but when the thermometer rose to 59°, the deflection of the magnetic needle became 64°. Even passing sunshine and cloud made the tell-tale needle traverse out and in with surprising rapidity. There is fortunately reason to conclude that the bottom of the Atlantic *will* supply the low temperature essential to the good performance of the insulating material. The last soundings taken by Lieutenant Dayman of the Cyclops, have enabled him to determine the deep-sea temperature over a very considerable range, and are abundantly confirmatory of this fact.

The separate lengths of manufactured core were joined into longer extents in a very ingenious way. The gutta percha was scraped from the ends for a short distance, and these were placed in contact. A piece of copper wire was then attached by firm brazing to one side of the joint, and *wound* round the strand until it reached as far on the other side, being there brazed again. A second binding was then effected outside the first in precisely the same way, and several layers of gutta percha placed over the whole by the aid of hot irons. In case of the core on each side of the joint being at any time so dragged that the ends of the strand were broken asunder, this outer investment of wire would unroll spirally without being detached from the strand. Thus the electric continuity of the strand would be preserved even when the strand itself was severed.

Every two miles of the completed core were wound upon channelled drums with deep flanges, iron shod at the rim, so that they could be rolled about and made to perform their own locomotion. When the contents of these drums were used in supplying the cable with more core, one of the ends was attached to the outgoing core of the compressed cable, and so the contents were unrolled from the drum as the external metallic wires were spun round the core. During the unrolling a serving of hemp, saturated with a mixture of pitch and tar, was compactly wound round the core to act as a bed for the external metallic sheath. Then eighteen strands, each of seven wires of charcoal iron, were twisted firmly round the core. The strands and the cable were made by precisely analogous machinery. A large horizontal table, containing seven bobbins on the circumference in the case of the strand machine, and eighteen in the case of the closing or finishing machine, was whirled round by steam power with great rapidity. A central wire, or the core, was drawn up through a hole in the middle of the table, and so invested with a twisted whorl of wires or strands, given off from the bobbins as the table revolved. The strands were used, in completing the cable, instead of solid wires, because by this means greater flexibility and strength, for the material used, were obtained. The external investment of iron was solely designed to protect the coated core from mechanical violence during the act of submergence, and to confer upon it a convenient amount of weight for effecting its sinking in the sea.

Each strand-machine, during the manufacture of the cable, was worked day and night, and in twenty-four hours spun ninety-eight miles of wire into fourteen miles of strand. The several strand-machines at work simultaneously every twenty-four hours transformed 2058 miles of wire into 294 miles of strand. As much as thirty miles of cable have been made within twenty-four hours. At one time all the wire-drawers in England proved to be unable to supply the exacting demands of the machinery, and the works had to pause for a short space. The entire length of wire, iron and copper, spun into this wonderful structure, amounts to 332,500 miles; a length sufficient to engirdle the earth thirteen times! The completed cable weighed from nineteen hundredweight to one ton per mile, and proved to be able to bear with impunity a direct strain of five tons. In the salt water the weight of the cable would, however, not exceed fourteen hundredweight per mile; and as the greatest depth of the Atlantic in which it would have to be laid is only a little more than two miles, and a certain portion of the weight would necessarily be borne by friction against the particles of the water as the rope sunk, it was anticipated that the cable would never, under any circumstances, be required to meet a strain of more than one ton and a half.

The Atlantic cable is to be worked at the bottom of the sea by means of electro-magnetic currents called forth by an instrumental agency of a somewhat complicated kind. First and foremost in this agency, as the primary source of the working influence, stands Mr. Whitehouse's "Perpetual Maintenance Battery." This battery consists of large plates of platinated silver, and amalgamated zinc, mounted in cells of gutta percha. There are several plates, both of silver and zinc, in each cell; but all the zinc plates rest upon a longitudinal bar of metal at the bottom of the cell, and all the silver plates hang upon a similar bar at the top of the cell, so that thus there is virtually but a single stretch of silver, and a single stretch of zinc in operation. This arrangement is made because it enables any portion of either silver or zinc to be removed for repair or renewal without stopping for a moment the operation of the battery. As any one lamina becomes imperfect, it can be taken out from its groove, and replaced. Each cell contains two thousand square inches of acting surface, and is charged with the usual mixture of acid and water, and there are ten such cells combined to constitute the battery that is employed. This combination is so powerful that when the broad strips of copper plate which form the polar extensions are brought into contact or separated, brilliant flashes are produced, accompanied by a loud crackling sound. The points of large pliers are made red-hot in five seconds when placed between them, and iron screws burn with vivid scintillation. These brilliant effects are, however, inconvenient in one particular. They are produced at the expense of the apparatus. The metallic surfaces from which they are emitted, are rapidly burned away during their continuance. In order, as far as possible, to alleviate this injurious effect, contact is made and broken, during the transmission of electrical signals, by means of a key presenting a very large surface of metal. A horizontal bar, flattened at the top, turns backwards and forwards pivotways, and tilts its edges against twenty flat brass springs resembling in form the keys of a piano-forte, ten being on each side. A constant slight leak of the current is also continuously maintained through a curl of platinum wire placed in water. By this contrivance the injurious force of the spark is pretty well absorbed and destroyed. The cost of maintaining this magnificent ten-celled Titan battery at work does not exceed a shilling per hour.

But it has been stated that the voltaic current is by no means a fleet messenger compared with other agents which are at the command of the electrician. Consequently it is not the electric stream generated in this mighty battery which is designed to be actually sent across the Atlantic on the performance of telegraphic service. This primary power is only used to call up and stimulate the energy of a more speedy traveller. The voltaic current, generated in the battery, is transmitted to a piece of complicated apparatus known as Mr. Whitehouse's "Double Induction Coils." These coils are arranged in pairs, and each coil consists, first, of a thick bar of soft iron about five feet long; then of a sheath of gutta percha enveloping the bar; next of several miles of comparatively fine silk-covered copper wire, coiled round the gutta percha sheath and bar; and finally of a mile and a half of silk-covered coarser copper wire coiled round outside the inner coil, but without the two coils having any metallic communication or connection. Now the inside iron bars, here, are intended to be made into temporary magnets by the action of electrical currents circulating through the coils. The outer coil of coarse wire carries the battery-current round the iron to make it a temporary magnet. This coil therefore is the primary or *generating* coil. The inner coil of finer wire has a new independent current set up in it by the instrumentality of the temporary magnet; as the primary current makes a magnet, so the magnet makes a secondary current in the previously quiescent coil, and this secondary and magnetically induced current it is which is sent off brisk enough to perform the work of rushing across the Atlantic. This independent secondary current is therefore the *transmission current*, and the coil in which it is produced is properly the transmission coil. To Mr. Whitehouse the merit is due of winding the secondary transmission coil round the magnet directly, and inside of the generating coil. By this means the magnet has additional inducing power given to it on account of the greater propinquity. The coils are used in pairs, because each one inductively increases the power of its neighbour, and in return has its own energy inductively increased as well. The great beating power of the battery-current is rendered harmless by the size and extent of the primary coil through which it is passed. If at any time, by accident, the current find a short course for itself in consequence of the silk covering of the wire being injured, the accident is immediately indicated by the rapid rise of the temperature of the coil.

The transmission-current generated in the inner wire of the double induction-coil necessarily gets considerably weakened when it has passed through a distance of 1800 or 1900 miles. Consequently it does not form a part of the electrician's plan to set this weakened current immediately to work to print or record the signals transmitted. The weakened transmission-current is merely caused to open and close the outlet of a fresh battery destined to do the printing or recording labour. The strand of the cable is continued into a coil of fine wire, wound about a bar of soft iron. When the transmission-current flows through the coil, the bar becomes a temporary magnet, which has the direction of its polarity determined by the nature of the current (positive or negative) that is sent through the coil. The pole which is north when the transmission-current is positive, becomes south when the transmission-current is negative. Near to the temporary magnet a permanent magnet is so placed that it can traverse backwards and forwards upon a pivot as it is actuated by the temporary magnet. The north pole of the permanent magnet is attracted by the south pole of the temporary one, and *vice versâ;* so that as the polarity of the temporary magnet is reversed, the permanent magnet is caused to traverse. When it traverses one way, it opens the ontlet of the local battery by effecting a contact and canses it to print; when it traverses the other way it shnts off the current of the local battery, so that it is constrained to cease to print.

It is the peculiar advantage of this relay-instrument (as it is called) that the temporary magnet has no other work to do than to turn the permanent magnet upon its almost frictionless pivot. It has no spring to overcome, snch as is more commonly employed in this class of instruments. The arrangement is so sensitive that the apparatns may be pnt in action by a fragment of zinc and a sixpence pressed against the tongue. These relays may indeed be ordinarily heard clicking backwards and forwards, and working automatically when the large indnction-coils are in operation within a few feet of them, actually doing a little business on their own account, although not in commnnication with any cnrrent, and transmitting the same signals and messages as those which are being forwarded through the agency of the indnction-coils. As the poles of the indnction-coil magnets are reversed, the poles of the relay-magnets are actnated different ways. Mr. Whitehouse has made the instruments even more exqnisitely delicate by applying a second permanent magnet, so that it can be made by a screw-adjustment to increase or diminish the attraction acting on the working magnet, either way.

When the printing battery is brought into operation by the relay, already described, it records by the agency of one of Professor Morse's instruments. In this instrument a ribbon of paper is unrolled from a hollow cylinder by a train of clock-work, and as it is nnrolled, a sharp style, magnetically actnated, indents a series of dots or lines npon the paper. When the style is pricked down bnt for an instant, it is a *dot* that is impressed. When it is kept down for more than an instant a lengthened line or *dash* is left, because the paper ribbon is being drawn along beneath the style. In order that the style may be magnetically controlled to inscribe the dash or the dot, it is held np by a strong spring when not in action, and drawn down by a temporary magnet formed by the printing battery current, when in operation. A soft iron bar, enveloped by a coil of the printing battery wire, is stronger than the spring when it becomes a magnet, and drags it down.

The dot and dash-code of Professor Morse is adopted for the Atlantic service, becanse there is but one wire in the cable, which must be made to express, at least, all the letters of the alphabet, and all the numerals; different combinations of the dot and dash can be readily caused to effect this; thus dot and dash, . — is taken to signify a; — . . . to signify b; — . — . for c; — . . d; . for e, and so on. Mr. C. Bright has patented a very ingenious piece of apparatus in which the same elementary symbols are given by sounds issuing from a free and a muffled bell. It is possible that this apparatus will some day be adopted by the Atlantic Company for their service.

Her Britannic Majesty's Government granted to the Company the use of the fine 91-gun ship Agamemnon for paying ont one half of the cable into the Atlantic, and commissioned the paddle-wheel frigate Leopard to act as its tender. The United States Government sent over the magnificent new heavy frigate Niagara to carry the other half, with the paddle-wheel steamer Susqnehanna for a tender. The Agamemnon proved to be singularly adapted for its work in consequence of having one square space as a hold, 49 feet across and 20 feet deep. In this space the 1260 miles of the cable were able to be deposited in a single circular coil. The Niagara was not by any means so well adapted for the service, and had to be considerably altered in her internal arrangements after she came over to England, the cable even then being distribnted into three or four distinct coils. The arrangements made by the engineer for the paying ont, planned that the cable should come up from the hold of the ship, sweeping ronnd a central block occupying the width of the coil, and then wound out and in over four grooved sheaves, geared together by cogs, finally passing along a short distance above the poop-deck, and plunging over a fifth sheave, resting over the stern, into the sea. A friction drum, also geared to the sheaves, was embraced by blocks worked by powerful screws, so that it could be gripped more or less tightly whenever occasion arose. Provision was also made to register electrically the speed with which the paying-out vessels moved through the water, the rate at which the cable was payed ont every instant, and the strain which was thrown npon it. Electrical signals, too, were to be made throngh the cable, from end to end, every second, to prove the maintenance of its continnity. The engineer's calculations fixed from four to five miles an honr as the rate of speed at which it was deemed advisable the paying-out of the cable should be effected. An external guard was placed over the screws of the vessels engaged in the work, to prevent the cable being injured in case any need should arise for returning npon the course to pick up some portion of it that had been already submerged. A small jonrneyman engine was prepared for accomplishing this picking-up labour. Provision was also made for dropping the portion of the cable in the act of being snbmerged to the bottom of the sea on the occurrence of a severe storm, and for bnoying the end until the storm was past, the dropping being accomplished by means of very strong supernnmerary ropes kept ready for the pnrpose.

The end of the month of July was selected for the accomplishment of this wonderful enterprise, becanse Lientenant Manry had ascertained, by the accumnlation of a large series of observations, that the Northern Atlantic is in the most favonrable condition for any work of the kind in this season of the year. There is then the least likelihood of trouble from the presence of either fogs or icebergs, and gales of wind are almost nnknown at the period, excepting jnst off the western coast of Ireland. Lieutenant Manry also marked ont the track the vessels onght to endeavonr to take. Theoretically, the best course lay in the arc of a great circle running directly from Trinity Bay in Newfoundland to Valentia Harbour in Ireland. Bnt all practical navigators are aware that it is altogether impossible to direct a ship along a true great circle track. Snch a track wonld require that the course of the vessel should be altered to an almost infinitely small amount at every successive instant. Whereas in steering by the compass no alteration, of conrse, to any thing less than half a point of the compass is actually trustworthy. Bad steering, unascertainable sets of the cnrrent, and nnavoidable compass deviations, introduce continually errors nearly approaching to this amonnt. Lientenant Maury conseqnently planned a *polygonal* ronte from Valentia Harbour to Trinity Bay, in which there were only six changes of conrse, each one restricted to a quarter of a point of the compass, and in which the departure from a true great circle-path was no more than eight-tenths of a nautical mile. If one ship had sailed in the great circle ronte, and the other in the polygonal route, each moving at the same rate of speed, the one vessel would not have been ont of hail of the other the whole way. The telegraph cable being laid in the polygonal ronte, and then hauled in by windlasses at each end, until it was reduced to a true great circle cnrve, each windlass would only have to wind in 350 fathoms of the cable. The entire length of the cable that wonld be required to connect Valentia Harbonr with Trinity Bay wonld be 1834 statnte miles. The liberal allowance of a superfluous length of 600 miles was therefore made to provide against unforeseen accidents.

In recent years very great improvements have been made in the process of deep sea sounding, chiefly in the first instance through American ingenuity and skill. Mr. Brooke, of the United States navy, has contrived a sounding apparatns, which proves very successful and manageable. The apparatus consists of a cannon-ball threaded npon an iron rod in such a way that when the rod strikes the bottom of the sea the cannon ball is detached from a pair of triggers and dropped, the rod being then drawn up with specimens of the bottom adhering to a hollow cup indented into its inferior surface. Allowance is made for the extent to which transverse currents draw ont the line dnring the descent of the plnmmet, based npon the known rate at which the plummet ought to descend in deep water. It appears from a large series of deep sonndings which have now been taken, that the actual bed of the Atlantic is very mnch, and very abruptly broken np; jagged peaks alternating with precipitous snbmarine vallies. The greatest depth of the Atlantic seems to lie to the south of the banks of Newfoundland, the sounding there indicating a descent of something more than five miles. In the more northern regions the depth is considerably less, especially between the parallels of 48° and 55° north latitude. There is one great zone of the earth, extending from east to west, in which the surface appears to be raised comparatively high. This zone marks the line in which the northern and southern water-sheds meet, alike in the continents of America, Europe, and Asia. It is continued in the Northern Pacific through the Aleutian Isles, and it stretches at the bottom of the Atlantic, as a sort of submarine shelf from Cape Race, in Newfoundland to Cape Clear in Ireland, Newfoundland and the British Islands being really projecting extremities of the higher portion of the shelf. This plateau rests precisely in the course along which the telegraphic cable requires to be stretched, and nowhere sinks to more than a trifle beyond two miles. Besides this, it is covered through a great portion of its course by microscopically minute calcareous and siliceous shields or shells of foraminated and diatom races of creatures, which have been produced in the warm waters of the tropics, and then drifted along by the Gulf stream, until they were finally dropped in this region as a kind of perpetual snow storm, in consequence of passing from water in rapid onward movement, into fluid that is comparatively at rest. These delicate remains of organised existence when brought up by the deep sea plummet prove to be so perfect notwithstanding their fragility, that there can be no doubt the depths where they lie are free from all kinds of mechanical disturbance, and so in the precise condition which must be the most conducive to the safe preservation of an electrical cable once deposited in their recesses. Lieutenant Berryman, of the United States navy, carefully sounded through the extent of this submarine plateau, and described it as being smooth and slightly inclined from end to end. Lieutenant Dayman of H.M.S. Cyclops, revised these soundings shortly before the sailing of the expedition for the submergence of the cable, going over the same track again, and fully confirmed the general facts of the relatively slight depth of the plateau, and the abundant presence of the diatomaceous and foraminated deposits, but he reported a greater degree of density in the depths of different positions than Lieutenant Berryman had conceived.

On the 5th of August, 1857, operations commenced. There were present the 'Agamemnon,' 'Niagara,' 'Leopard,' 'Susquehanna,' 'Willing Mind,' and 'Advice,' six steamers intended to assist in various parts of the operations. The shore-end of the cable was taken on shore from the 'Niagara,' by a number of boats. And then took place a ceremonial inauguration of the enterprise: the Lord-Lieutenant of Ireland receiving the extreme end of the cable, and drawing it into a tent where electrical batteries had been placed, on the beach of Valentia Harbour. The engineer was doomed, however, to a mortifying disappointment. A slight accident happened to the cable on the 6th, but this was repaired, and the ships proceeded. By the morning of the 10th they had got out 200 miles to sea, and the cable conveyed messages to and from the land and the ships with the utmost facility: the persons on shore following the history of the voyage hour by hour. On the 11th, however, the engineer found that 335 nautical miles, or 380 statute miles, of cable had been submerged; and, knowing that that was far too much in proportion to the straight line distance, he concluded there was too much 'slack' or zigzag in the cable's course. A modification in the grip of the machinery was therefore made; and this modification appears to have been unskilfully attended to by one of the subordinates. The cable was stretched too tightly; it snapped, and went to the bottom, at a depth of twelve thousand feet, equal to forty times the height of St. Paul's. Preparations are being made at this time, March 1858, for immediately resuming the attempt. The lost portion of the cable has been replaced; and government ships of Great Britain and of the United States are under orders again to assist in this national enterprise.

Electrical Telegraphs now render useful service in several cities of America. In New York eight bell-towers are connected with each other, and with the central tower over the City Hall by telegraphic wires; this system is used to signalise an alarm of fire. At Boston a comprehensive plan is acted on. A central station has been selected, in which the principal instruments are placed. Two wires take a very circuitous route from this station; one, ingeniously supported on house-tops by insulated standards, extends to all the fire-bell towers in the city, where it acts upon machinery which strikes on a large bell whenever an impulse is transmitted through the wire; the other, much more extensive, proceeds to all the street or ward signal-stations in the city. At each of these signal-stations is a box containing a magnetic apparatus, under the care of a keeper. If a fire break out in any part of the city, a message is sent to the nearest signal-station; the man transmits a signal to the central station, whence an electric impulse is sent to all the bell-towers in the city, the ringing of which conveys the required information. It is obvious that other public information, besides that relating to fires, may be disseminated throughout the city by similar means. There are about fifty miles of wire in this telegraph at Boston. There seems every reason to believe that, now the telegraphic wires follow so many sub-way routes in London, local news will gradually be brought within the scope of the system.

ELECTRICITY OF ORGANIC BEINGS. Plants and animals, under certain circumstances, exhibit electrical phenomena. These however are not so constant or frequent as is sometimes imagined. Considering the connection that is now known to exist between the great forces of nature, as Light, Heat, Chemical Action, and Electricity, it is perhaps matter of surprise that so few electrical phenomena are exhibited by organised bodies.

In Plants it appears that during growth electricity is developed. Pouillet filled several pots with earth, and placed in them different kinds of seeds, and then insulated them. During the process of germination no electric disturbance was discovered, but when the seeds began to sprout a gold-leaf electrometer had its leaves separated at least half an inch from each other. Pouillet concludes that the vegetation on the surface of the earth must produce a vast amount of electricity, and be an active cause of its phenomena in the atmosphere. Other observers have found that, by placing wires in the bark and pith of a growing tree, they have obtained decided indications of the presence of a galvanic current. These exhibitions of electric disturbance are undoubtedly dependent on the chemical changes going on in the plant, and this is one of the many instances in which we find one force in nature representing another. Under the influence of heat and light the chemical and attractive forces are brought into play, and the motile force of the growth of the plant as well as electrical phenomena are the result.

In the Animal Kingdom the same indications of the presence of electricity is afforded during the activity of the vital functions. Matteucci has observed a considerable deflection of the galvanometer when wires were connected with it passing from the liver and stomach of a rabbit. Other experimenters have obtained similar results. It has been supposed that these phenomena were due to the chemical changes going on in the body of the animal, but they cease on the death of the animal. Free electricity is excited by the movements of the human body. This is made evident by rubbing the feet on a woollen rug, when, on applying the hand to a gold-leaf electrometer, the presence of electric disturbance is indicated. Some persons are more liable to this development than others; and Dr. Carpenter says there are persons "who scarcely ever pull off articles of dress which have been worn next the skin without sparks and a crackling noise being produced, especially in dry weather."

Recent experiments of Matteucci and Du Bois-Raymond have shown not only that free electricity is developed in animal bodies, but that there is a true galvanic current both in the muscles and nerves. Galvani attributed the movements, first observed by his wife, induced in a frog's leg by plates of copper and zinc, to a purely animal action. Volta showed that the movements observed by Galvani were dependent on the chemical action developed in the metals. Matteucci observed the peculiar sensibility of the nerves and muscles of the frog to galvanic action, and made use of the leg, prepared as a galvanometer, in many of his experiments. The mode of using it was simply to take the leg of a recently-killed frog with the crural nerve dissected out of the body, but remaining in connection with it. The leg was then inclosed in a glass tube, covered with an insulating varnish, and the nerve allowed to hang freely at its open end. When two points of the nerve thus prepared are brought in contact with any two substances in a different electrical state, the muscles of the frog's leg are thrown into contraction. By this 'galvanoscopic frog' Matteucci was able to detect currents of electricity in the muscles of animals, by cutting into them, and placing one extremity of the nerve deep in the wound and the other at its lips. The experiments of Matteucci were followed up by Du Bois-Raymond, who has arrived at the following conclusions:—1. That galvanic currents may be observed in any limb of any animal whether cold or warm-blooded. These currents in some limbs are directed downwards, in others upwards. They are of different intensity in different limbs; but their intensity and direction are always the same in the same limb of different individuals of the same species. 2. The electro-motive action on which these currents depend does not arise from the contact of heterogeneous tissues, as Volta supposed; for the different tissues, the nerves, muscles, and tendons, in an electric point of view, are quite homogeneous. 3. These currents are produced by the muscles. If any undissected muscle of any animal be brought into the circuit longitudinally, it generally exhibits an electro-motive action, the direction of which depends on the position of the muscle. The current of the whole limb is nothing but the resultant of the partial currents which are engendered by each muscle of the limb. It is therefore a 'muscular current.' 4. The law of the muscular current may be expressed as follows: "Any point of the natural or artificial longitudinal section of the muscle is positive in relation to any point of the natural or artificial transverse section." 5. By means of the above-mentioned law an explanation is afforded of the muscular current appearing in one instance an upward one, in another a downward one, which occurs according as the upper or the under of the two transverse sections is made to touch one of the ends of the galvanometer wire, whilst the other end is applied to the longitudinal section of the muscle. This is true even as regards shreds of muscle consisting of only a few primary fibres, and such as only admit of observation by the microscope. 6. The nerves are possessed of an electromotive power which acts according to the same law as the muscles. Whilst still in organic connection with the muscles, and forming part of a circuit in which the muscles give rise to a current, the nerves simply play the part of an inactive conducting body, provided their own current be prevented from entering the circuit.

There are certain animals which possess the power of accumulating electric force within their bodies, and of discharging it at will in a violent form, and with the exception of some insects and *Mollusca* which have been said (though this is doubtful) to communicate sensible shocks, these animals are all included in the class of Fishes. About seven species of this class, belonging to five genera, are known to possess electric properties, and it is curious that these genera belong to tribes very dissimilar from one another, and that, though each has a limited geographical range, one species or other is found in almost every part of the world. Thus, the three species of *Torpedo*, belonging to the Ray tribe, are found on most of the coasts of the Atlantic and Mediterranean, and sometimes so abundantly as to be a staple article of food. The *Gymnotus*, or Electric Eel, is confined to the rivers of South America. The *Silurus* (more correctly the *Malapterurus*), which approaches more nearly to the Salmon tribe, occurs in the Niger, the Senegal, and the Nile. The *Trichiurus*, or Indian Sword-Fish, is an inhabitant of the Indian Seas; and the *Tetraodon* (one of the genus allied to the *Diodon*, or Globe-Fish) has only been met with on the coral banks of Johanna, one of the Comoro Islands. These fishes have not all been examined with the same degree of attention, but it seems probable that the phenomena which they exhibit, and the structural peculiarities with which these are connected, are essentially the same throughout.

The peculiar characteristic of all is the power of giving to any living body which touches them a shock resembling in its effects that produced by the discharge of a Leyden jar. This is of very variable intensity in different species and individuals, and at different times. The *Gymnotus* will attack and paralyse horses, as well as kill small animals; and the discharges of large fish (which are 20 feet long) sometimes prove sufficient to deprive men of sense and motion. The effects of the contact of the *Torpedo* are less severe, and soon pass off; but the shock is attended with considerable pain when the fish is vigorous. The electrical organs appear to be charged and discharged to a certain extent at the will of the animals. Their power is generally exerted by the approach of some other animal, or by some external irritation; but it is not always possible to call it into action, even in vigorous individuals. It usually diminishes with the general feebleness of the system, though sometimes a dying fish exerts considerable power. All electrical fishes have their energy exhausted by a continued series of discharges; hence it is a common practice with convoys in South America to collect a number of wild horses and drive them into the rivers, in order to save themselves, when they pass, from being injured by the fish. If excessively exhausted, the animals may even die; but they usually recover their electrical energy after a few hours' rest.

The *Torpedo*, from its proximity to European shores, has been most frequently made the subject of observation and experiment; and the following are the most important results of the investigations which have been made upon it by various inquirers:—That the shock received by the organs of sensation in man is really the result of an electric discharge, has now been fully established. Although no one has ever seen a spark emitted from the body of one of the fish, it may be easily manifested by causing the *Torpedo* or *Gymnotus* to send its discharge through a slightly interrupted circuit. The galvanometer is influenced by the discharge of the *Torpedo*, and chemical decomposition may be effected by it, as well as magnetic properties communicated to needles. It seems essential to the proper reception of the shock, that two parts of the body should be touched at the same time, and that these two should be in different electrical states. The most energetic discharge is procured from the *Torpedo* by touching the back and belly simultaneously, the electricity of the dorsal surface being positive, and that of the ventral negative; and by this means the galvanometer may be strongly affected, every part of the back being positive with respect to every part of the opposite surface. When the two wires of the galvanometer are applied to the corresponding parts of the two sides of the same surface, no influence is manifested; but, if the two points do not correspond in situation, whether they be both on the back or both on the belly, the index of the galvanometer is made to deviate. The degree of proximity to the electric organ appears to be the source of the difference in the relative state of different parts of the body; those which are near to it being always positive in respect to those more distant. Dr. Davy found that, however much Torpedoes were irritated through a single point, no discharge took place; and he states that, when one surface only is touched and irritated, the fish themselves appear to make an effort to bring the border of the other surface, by muscular contraction, into contact with the offending body; and that this is even done by fœtal fish. If a fish be placed between two plates of metal, the edges of which are in contact, no shock is perceived by the hands placed upon them, since the metal is a better conductor than the human body; but if the plates be separated, and while still in contact with the opposite sides of the body, the hands be applied to them, the discharge is at once rendered perceptible, and it may be passed through a line formed by the moistened hands of two or more persons, the extremities being brought into relation with the opposite plates. The electrical phenomena of the *Gymnotus* are essentially the same with those of the *Torpedo;* but the opposite electrical states are found to exist, not between the dorsal and ventral surfaces, but between the head and tail; so that the shock is most powerful when the connection is formed between these two extreme points.

It has been ascertained by experiment, that the manifestation of this peculiar power depends upon the integrity of the connection between the nervous centres and certain organs peculiar to electrical fishes. In the *Torpedo* the electrical organs are of a flattened shape, and occupy the front and sides of the body, forming two large masses, which extend backwards and outwards from each side of the head. They are composed of two layers of membrane, between which is a whitish soft pulp, divided into columns by processes of the membrane sent off so as to form partitions like the cells of a honeycomb; the ends of these columns being directed towards the two surfaces of the body. The columns are again subdivided horizontally by more delicate partitions, which form each into a number of distinct cells; the partitions are extremely vascular, and are profusely supplied with nerves, the fibres of which seem to break up into minuter fibrillæ to form plexuses upon these membranes. The fluid contained in the electrical organs forms so large a portion of them, that the specific gravity of the mass is only 1·026, whilst that of the body in general is about 1·060; and from a chemical examination of its constituents, it seems to be little else than water, holding one-tenth part of albumen in solution, with a little chloride of sodium. The electrical organs of *Gymnotus* are essentially the same in structure, though differing in shape, in accordance with the conformation of the animal; they occupy one-third of its whole bulk, and run along nearly its entire length; there are however two distinct pairs, one much larger than the other. The prisms are here less numerous, but are much longer; for they run in the direction of the length of the body, a difference which is productive of a considerable modification of the character of the discharge. In the *Silurus* there is not any electrical organ so definite as those just described; but the thick layer of dense cellular tissue, which completely surrounds the body, appears to be subservient to this function; it is composed of tendinous fibres interwoven together, and of an albuminous substance contained in their interstices, so as to bear a close analogy with the cellular partitions in the special organs of the *Torpedo* and *Gymnotus*. The organs of the other known electrical fishes have not yet come under the notice of any anatomist.

In all these instances the electrical organs are supplied with nerves of very great size, larger than any others in the same animals, and larger than any nerve in other animals of like bulk. They all arise in the *Torpedo* from a ganglionic mass situated behind the cerebellum, and connected with the medulla oblongata, to which the name of 'electric lobe' has been given; the first two of them issue from the cranium in close proximity with the fifth pair, and have been regarded as belonging to it, although their real origin is different; whilst, from the distribution of the third electrical nerve to the stomach, after sending its principal portion to the electrical organ, it would seem analogous to the eighth pair or pneumogastric.

The electrical nerves in the *Gymnotus* are believed to arise from the spinal marrow alone; and those of the *Silurus* are partly intercostals and partly belong to the fifth pair. The integrity of the nerves is essential to the full action of the electrical organs. If all the trunks be cut on one side, the power of that organ will be destroyed, but that of the other may remain uninjured. If the nerves be partially destroyed on either or both sides, the power is retained by the portion of the organs still in connection with the centres. The same effects are produced by tying the nerves as by cutting them. Even slices of the organ entirely separated from the body, except by a nervous fibre, may exhibit electrical properties. Discharges may be excited by irritation of the brain when the nerves are entire, or of the part of the divided trunk distributed on the organ; but on destroying the electric lobe of the brain the electric power of the animal ceases entirely, although all the other ganglionic centres may be removed without impairing it. It is remarkable, however, that after the section of the electrical nerves Torpedoes appear more lively than before the operation, and actually live longer than others not so injured, which are excited to discharge frequently. Poisons which act violently on the nervous system have a striking effect upon the electrical manifestations of these fish; thus, two grains of muriate of morphia were found by Matteucci to produce death after about ten minutes, during which time the discharges were very numerous and powerful; and strychnia also excited powerful discharges at first, succeeded by weaker ones, the animals dying in violent convulsions. When the animals were under the influence of strychnia it was observed that the slightest irritation occasioned discharges; a blow given to the table on which the animal was placed being sufficient to produce this effect. If the spinal cord were divided, however, no irritation of the parts situated below the section called forth a shock. It has also been ascertained by Matteucci that the electric power is suspended when the *Torpedo* is plunged into water at 32°, and is recovered again when it is immersed in water of a temperature from 58° to 68°; and that this alternation may be repeated several times upon the same fish. But if the temperature be raised to 86° the *Torpedo* soon ceases to live, and dies while giving a great number of violent discharges. (Carpenter.)

From these facts it is evident that the electric force is developed as the result of nervous agency. From this it has been sometimes hastily inferred that the electric and nervous forces are identical. This, however, is not more probable than that the contractile force of the muscles is identical with the nervous force. The best explanation of the phenomena appears to be the correlation of these forces. They are convertible forces, the one being capable of generating the other; the force generated being always the representative of the force generating it. The uses of these electric organs it is somewhat difficult to explain. The *Gymnotus* eats very few of the fishes which it kills by its shocks, and this is the case with the Torpedoes. Dr. John Davy conjectures that the electric discharges decompose the water, and supplying oxygen assist in respiration. Dr. Carpenter suggests that this peculiar action may assist the digestion of the fish, as animals killed by electricity are more digestible. The electrical condition of the animal itself he also thinks may conduce to the easy digestion of its food.

Bence Jones, ***Abstract of Du Bois-Raymond's Researches in Animal Electricity.***)

ELEOTRIS, a genus of Acanthopterygious Fishes belonging to the family *Gobiodæ*. Like the Gobies the species have flexible spines in the first dorsal fin, and an appendage behind the vent, but they have the ventral fins separate and six gill-rays. The species are inhabitants of the fresh waters of warm countries, and conceal themselves in the mud.

E. dormatrix, the Sleeper, is a large fish. It is found in the West Indian marshes. Other species have been found in Africa, India, and the Mediterranean.

ELIDONE. [SEPIADÆ.]

ELLENBOROUGH. [CUMBERLAND.]

ELLENBOROUGH, LORD. Edward Law was born November 16, 1750, at Great Salkeld, in the county of Cumberland. He was the fourth son of Dr. Edmund Law, bishop of Carlisle. He received his rudimentary education at the residence of his maternal uncle, the Rev. Humphrey Christian, who then resided at Docking in Norfolk. He was removed thence in 1762 to the Charter-house School, London, and placed on the foundation. In 1768 he was entered of St. Peter's College, Cambridge. After taking his degree of B.A. he removed to London, and became a student of law at the Inner Temple. Having been called to the bar, and acquired by a short preparatory practice the needful technical knowledge, he soon took his place among the chief members of the profession. He was engaged as the leading counsel in the defence of Warren Hastings, 1788 to 1795, and in this famous trial acquired great distinction both as a lawyer and a speaker. In Westminster Hall he had Erskine and other able rivals to contend with, and never rose to the first lead as a pleader, but he became the admitted leader of the Northern Circuit. His rise in the profession was remarkably rapid. In 1801 he was appointed attorney-general and knighted, and in the same year he was elected a member of the House of Commons. In April 1802 Sir Edward Law succeeded Lord Kenyon as lord chief justice of the court of King's Bench, and was created a peer by the title of Baron Ellenborough, of Ellenborough in Cumberland, by patent dated April 10th, 1802. He was afterwards made a privy councillor. In the House of Lords in 1805 he strenuously opposed any concession to the Roman Catholics. On the trial of Lord Melville in 1806 Lord Ellenborough voted against him. In 1813 he was nominated one of the commissioners to inquire into the conduct of the Princess of Wales. In 1814 he was one of the judges who presided at the trial of Lord Cochrane, and in 1818 on the trial of Hone. [HONE, WILLIAM, *S.* 1.] In November of the same year he retired from the bench. He died December 13, 1818, at his residence in London. He married in 1782, and was succeeded in the title by his eldest son, who is now Earl of Ellenborough. Lord Brougham, in his 'Historical Sketches of Statesmen,' makes the following remarks on his character as a judge:—"The Term Reports bear ample testimony to the vigour of this eminent individual's capacity during the eighteen years that he filled the first place among the English common-law judges. . . . . He was somewhat irascible, and sometimes even violent. But no one could accuse him of the least partiality. His honest and manly nature ever disdained as much to trample overbearingly on the humble as to crouch meanly before the powerful. . . . . He despatched business with great celerity, and for the most part with success. But causes were not sifted before him with that closeness of scrutiny, and parties were not suffered to bring forward all they had to state with that fulness and freedom, which alone can prevent misdecision, and ensure the due administration of justice."

ELLESMERE, EARL OF. LORD FRANCIS LEVESON GOWER was born in London, January 1, 1800. He was the second son of the first Duke of Sutherland, and brother of the present Duke. He was educated at Eton College, and afterwards at Christ Church, Oxford. He left the university in 1820, in which year he was returned as M.P. for Bletchingly in Surrey, since disfranchised by the Reform Act. At a time when the German language was little studied in England he distinguished himself by a translation of the 'Faust' of Göthe, in two volumes, which was more than once reprinted before the author resolved to withdraw it from circulation. It has now been several years out of print. The 'Faust' was followed by 'Translations from the German, and Original Poems, by Lord Francis Leveson Gower,' 8vo, London, 1824. This small volume consists of translations of seven lyrical poems by Schiller, one by Göthe, one by Salis, and three by Körner, and of thirteen original poems. He was M.P. for Sutherlandshire from 1826 to 1830. In 1827 he was made a lord of the treasury. From January 1828 to July 1830 he was chief secretary for Ireland, and from July to November 1830 he was secretary at war. After the death of his father in 1833, having received as his inheritance the Bridgewater estates, which his father had inherited from the last Duke of Bridgewater, he assumed the name of Egerton. From 1835 to 1846 Lord Francis Egerton was M.P. for South Lancashire. In the autumn of 1839 he commenced a voyage in his own yacht up the Mediterranean Sea. He wintered at Rome, whence he sailed for Malta in April 1840, and having landed on the coast of Syria, made a tour in Palestine. In 1841 he was elected rector of the university of Aberdeen. In 1843 he published 'Mediterranean Sketches, by Lord Francis Egerton,' 12mo. In this volume the poem called 'The Pilgrimage' records some of the most interesting impressions of his tour in Palestine. It is followed by extracts from his journal and by a few poems. A new edition of these poems, with several additions, was published in 1856, 'The Pilgrimage, and other Poems,' 4to. In 1846 he was created Earl of Ellesmere and Viscount Brackley, titles nearly corresponding to those held by Lord Chancellor Egerton, who, at the time of his death, held the title of Viscount Brackley, and had previously held that of Baron Ellesmere. The Earl of Ellesmere was elected President of the Asiatic Society in 1849. In 1855 he was created a knight of the Garter, and in the same year became colonel-commandant of the Lancashire yeomanry cavalry. He was also deputy-lieutenant of Sutherlandshire. He died Feb. 21, 1857.

Besides the works before mentioned, the Earl of Ellesmere published the 'Camp of Wallenstein, and other Poems;' the tragedies of 'Catherine of Cleves and Hernani;' 'The Sieges of Vienna by the Turks, from the German of K. A. Schimmer, and other sources,' 16mo, 1847; 'Military Events in Italy, transcribed from the German,' 12mo, 1851; 'Life and Character of the Duke of Wellington,' 12mo, 1852; 'History of the Two Tartar Conquerors of China, from the French of J. P. D'Orleans,' 8vo, 1854.

The Earl of Ellesmere, at his residence, Bridgewater House, Cleveland Square, London, had one of the very finest galleries of paintings possessed by any individual in the kingdom. He inherited the chief portion of it as a part of the property of the Duke of Bridgewater, but he made some additions to it himself, and in a very handsome manner he made it accessible to the public. We ought to mention that his lordship presented to the nation his celebrated portrait of Shakspere, known as the Chandos Shakspere, with a view to its forming a portion of the projected National Gallery of Portraits.

ELLIOTT, EBENEZER, the Corn-law Rhymer, was born March 17th, 1781, at the New Foundry, Mashro', near Rotherham, Yorkshire. His father, a clerk at the foundry, was an ardent politician, and a stern ultra-calvinistic dissenter of the Berean sect; and he employed his "brother Berean, Tommy Wright, the Barnesley tinker" to baptise his son—as the poet relates in his 'Autobiography,' published soon after his death in the 'Athenæum' (January 12, 1850). The elder Elliott (also an Ebenezer) was accustomed to preach in his own room every fourth Sunday, to persons of a similar persuasion, who used to come twelve or fourteen miles to hear him; and on the week-days he "delighted to declaim on the virtues of slandered Cromwell and of Washington, the rebel," as he pointed to prints of them which hung on the walls; and here, as Elliott wrote, "is the key which will unlock all the future politics" of the Corn-law Rhymer. The young Ebenezer was regarded as a dull child, loved to be alone, made little progress at school, where he could never master grammar, or attain to vulgar fractions, was a frequent truant, and seemed to be a confirmed dunce; and eventually, out of sheer hopelessness, was sent by his father to work in the foundry. At the foundry work, however, he was thought to be even clever, but with the workmen's skill he acquired also the workmen's evil habits, and for a while gave way to intemperance. But from sinking into thoroughly vicious courses his early love of nature saved him. A copy of Sowerby's 'English Botany,' lent him by an aunt, led him to collect botanical specimens, and after a while he became interested in poetry that treated of his favourite flowers, and of country scenes. He soon became a diligent reader, studying "after Milton, Shakspere —then Ossian, then Junius," and so on, while "of Barrow," he says, "I was never weary; he and Young taught me to condense." In time too he began to write verses himself, though his early efforts, he confesses, were very unsuccessful; and he set himself doggedly to learn in his own way grammar and even French, but could master neither. Meanwhile he was not neglecting his ordinary duties. His father had been induced to purchase the foundry business on credit, and from his sixteenth to his twenty-third year Elliott "worked for his father as laboriously as any servant he had, and without wages, except an occasional shilling or two for pocket-money." It was while thus engaged that he composed (in his seventeenth year) his first published poem, the 'Vernal Walk;' this was followed soon after by 'Night,' 'Wharncliffe,' and others: and Elliott, between his rhymes and politics, began to be a local celebrity. He had the good fortune to form the acquaintance of Southey, who was earnest in giving him the full benefit of his own wide experience in poetical studies, and Elliott was in after years proud of proclaiming that Southey taught him poetry. Happily for his lasting fame, he did not let his respect for the genius or his gratitude for the kindness of the laureate lead him to become an imitator, or to tame down his wild notes to the orthodox tunes. Between 'Wharncliffe' and the 'Corn-law Rhymes,' he published in 1823 'Love,' and another poem, accompanying them with a 'Letter to Lord Byron.'

Elliott's father was too much hampered by the liabilities he had incurred, and his want of capital, to carry on the foundry with success. After a time young Elliott commenced business at Rotherham on his own account; but failing there he removed to Sheffield, where in 1821 he, at the age of forty, recommenced the battle of life as a bar-iron merchant, with a borrowed capital of 100*l*. Here he had a series of commercial successes, built himself a handsome residence in the suburb of Upper Thorpe, and carried on a flourishing business till the great panic of 1837, when heavy losses caused him to contract the scale of his dealings. He finally withdrew from business in 1841, and retired to a pretty country residence he had built for himself on an estate of his own at Great Houghton, near Barnesley, and there he resided at ease in his circumstances, the centre and oracle of a circle of admiring friends, till his death, which occurred on the 1st of December, 1849, having lived to see the great change effected in the commercial policy of the country which he had laboured so earnestly to bring about.

Elliott says of himself, in the 'Autobiography' already quoted: "There is not in my poetry one good idea that has not been suggested to me by some real occurrence, or by some object actually before my eyes, or by some remembered object or occurrence, or by the thoughts of other men, heard or read." And this is evidently true. All his poetry—all the true and living part of it at least—was suggested by some passing event, or was written to serve some temporary purpose. None of it is the result of a long meditated design, or the completely formed issue of a vivid and vigorous imagination; or, on the other hand, the unpremeditated melody of a heart imbued with happy thoughts and fancies —singing as the wild-bird sings. Nevertheless it is true poetry, albeit often very harsh and rugged. It is the passionate protest against wrong—the fiery remonstrance with the wrong-doer—spurning the cold incumbrance of prose, and finding its only sufficient utterance in the unrestrained flow of poetry. The great public evil that came nearest home to his own hearth, that, as it seemed to him, which was inflicting dire mischief on the labouring classes of his own neighbourhood, and which was undermining the prosperity of the manufactures of his native place, and as he believed, of the country generally, was the Corn-Laws; and he resolved to set forth the mischiefs those laws were producing, and the greater dangers they were threatening. He had not been long settled at Sheffield when his 'Corn-Law Rhymes' began to appear in a local paper, and their effect on the hard Yorkshire artisans was immediate and lasting. And their influence was assuredly well-earned. Rude and rugged in language, intensely bitter, even savage in their indignation, often, as might be expected, inconsiderate and sometimes unjust in their denunciations, they yet showed everywhere a thoroughly honest hatred of oppression, and fellow-feeling with the oppressed and suffering. With quite a Crabbe-like familiarity with the poverty of the poor, they displayed a far warmer, deeper, and more genial sympathy. The wrath and the pathos, too, uttered in the most impassioned and the most direct words, were yet conveyed in genuine music, which made its way at once to the heart.' When from a local they appealed to the general public they were equally successful.

The 'Corn-law Rhymes,' published in a single volume with 'The Ranter,' at once made Elliott's name famous. Men of all shades of opinion joined in the admiration. The language was occasionally objected to, but it was generally felt that the language was really a part of the man. Noticing the objection in the preface to a new edition of the Rhymes, Elliott asked, "Is it strange that my language is fervent as a welding heat, when my thoughts are passions that rush burning from my mind like white-hot bolts of steel?" But this, while a sufficient explanation of what reads so like excessive vehemence, serves really to take off the edge of his poetic declamation, while it destroys the impression of his prose, as placing within the category of passion what ought to be the result of reason. Elliott followed his 'Corn-Law Rhymes' by publishing in 1829 the 'Village Patriarch,' another but longer corn-law rhyme, much the best of his longer pieces, and one which, with many faults, shows that he was capable of producing a great work, could he have subjected his mind to the necessary discipline. 'Love,' 'They Met Again,' 'Withered Wild Flowers,' 'Kerhonah,' a dramatic fragment, and numerous beautiful little pieces, in which descriptions of the scenery of his much-loved Yorkshire formed the most attractive part, followed; and in 1834 he published his collected works in three volumes. Three or four more editions of his poetry were called for during his life, and to the last he continued to write rhymes, epigrams, songs, and short snatches of ver e, which usually appeared from time to time in the corner of a local newspaper, or the pages of 'Tait's Magazine.' Since his death two volumes of his inedited remains have appeared under the title of 'More Prose and Verse, by the Corn-law Rhymer,' but they contain nothing that can materially add to his reputation.

Two memoirs of Ebenezer Elliot have been published, written by Sheffield friends: but his biography remains to be written; and it is greatly to be desired that a fitting biography should be written of one who is emphatically the poet of Yorkshire—of its moors and streams, its towns and townsmen—the poet of the corn-law struggle, and the poet of the poor.

ELMES, HARVEY LONSDALE, son of James Elmes, was born near Chichester, about the year 1814. He was sent to school at Mortlake, in Surrey, and subsequently was taken into the office of his father, who had removed to London. At the age of twenty-one he joined his father in partnership, and together they designed and superintended buildings in Park-street and the South Mall, St. James's Park. His independent fame dates from his success in the competition for the building of St. George's Hall, Liverpool; his design having been chosen from the drawings of eighty-six competitors. He was then aged twenty-three. The building was at first intended for a music-hall only, and a foundation-stone was laid on the 28th of June 1838, though not quite on the present site. A competition for the Assize Courts shortly succeeded the other; and in this also Elmes was successful, there being seventy-five competitors. It was however decided to erect one grand edifice, and for this a fresh design by Elmes was approved of in 1841, when the work at length commenced. It was carried on under the architect's direction till the year 1847, when he was obliged to succumb to the encroachments of a fatal malady, and, after a brief sojourn at the Isle of Wight, he quitted England for Jamaica, with the hope of restoration in a warm climate, but died at Spanish Town, November 26, 1847, in the 33d year of his age. He had delegated the superintendence of his great work during his expected absence to his friend Mr. R. Rawlinson, Mr. Cockerell having agreed to attend to architectural detail. Under the first of these gentlemen the hall was arched over, contrary to many predictions which the architect had borne the brunt of—feeling probably that what had been accomplished in the works of the Romans should be allowed to present no insurmountable difficulty in the present century. The present decorative character of the interior, and some of the external accessories, are due to Mr. Cockerell, who also designed the sculpture of the pediment.

To understand the importance of Elmes's great work, it would be necessary to review the history of architecture, and especially the adaptation of Greek models, during the course of some years preceding the date of the St. George's Hall design. The proper use of ancient models had been completely lost sight of, and especially as to Greek architecture. In many parts of the kingdom buildings were erected, supposed to be classical, but which realised neither art nor the lower quality, the very imitation. Thus an idea had begun to prevail that the Greek system was so limited in its scope, whilst at variance with modern requirements, as to be in itself the cause of the failure in certain ambitious productions. Elmes however repeated the proof how that it is possible to use the works of preceding minds, and yet to realise the grandest new conception. Considered as to the attributes of art, Elmes's work is more Greek than many modern buildings which may exhibit even accurate reproduction. The design may well be claimed by this country as amongst the noblest efforts of architecture in Europe.

After years spent most worthily in the pursuit of art, Elmes had not realised anything commensurate with the extent and merit of his exertions. An average of 450*l.* a-year, subject to deductions for travelling, clerks, office and other heavy expenses, was all that one who had the highest gifts, received from that work which forms the chief adornment of a rich provincial town; and after his death a subscription was raised to provide a moderate income for his wife and child.

ELODIANS. [TORTOISES.]

EMBERIZIDÆ, a family of birds belonging to the order *Insessores* and the tribe *Conirostres*. The most distinguishing genus of the family is *Emberiza*. It comprises however other genera. The general relations of this family are given under FRINGILLIDÆ. We shall confine ourselves here to the British genera of this family known under the name of Buntings.

Plectrophanes.—Beak short, thick, conical, the edges of both mandibles slightly curved inwards; upper mandible smaller than the lower, with a small palatal knot. Nostrils basal, oval, partly hidden by small feathers. Wings long and pointed; the first and second quill feathers of nearly equal length, and the longest in the wing. Legs with the tarsi of moderate length; anterior toes divided; lateral toes equal in length; hind toe strong; claw elongated, and nearly straight.

P. Lapponica (Gould), the Lapland Bunting. It is the *Emberiza Lapponica* and *E. calcarata* of other writers. Though a native of the arctic regions, Mr. Yarrell records five instances of its being taken in Great Britain. It is found in Siberia and near the Uralian chain. Towards winter a few migrate as far as Switzerland. It inhabits the Faroe Islands, Spitzbergen, Greenland, and Iceland in summer, and thence westward to Hudson's Bay. Sir John Richardson says, that about the middle of May, 1827, they appeared in very large flocks at Carlton House, and a few days later made their appearance at Cumberland House. The eggs are usually seven, and of a pale ochre-yellow spotted with brown.

P. nivalis, the Snow-Bunting. It is the *Emberiza glacialis*, *E. montana*, *E. nivalis*, and *E. mustelina* of authors; and the Tawny-Mountain- and Snow-Bunting of English writers. It was at one time supposed they were different species, but this arose from the great variety of plumage to which these birds are subject. The predominant colour of their plumage is white, hence the name Snow-Bunting. This bird arrives in this country in the end of September and the beginning of October, and extends from the north of Scotland to the south of England. This bird is rather larger than the last.

Emberiza.—Beak conical, strong, hard, and sharp-pointed; the edges of both mandibles curving inwards; the upper mandible narrower and smaller than the under one, and its roof furnished with a hard bony and projecting palatal knob. Nostrils basal and round, partly hidden by small feathers at the base of the bill. Wings of moderate size; the first quill shorter than the third, which is the longest in the wing. Feet with three toes before and one behind, divided to their origin; claws rather long, curved, and strong.

E. miliaria, the Common Bunting, is the most common species of this genus. It remains in the British Islands throughout the year; and on acconnt of its very familiar preseuce in corn-fields, is frequently called the Corn-Buntiug. It builds its nest in April, and lays four or five eggs of a reddish-white or pale purple-red ground, streaked and spotted with dark purple-brown. It feeds on the seeds of the grasses, of the *Polygona*, of sorrels, and of cereal plants; also on Coleopterous Insects.

In both sexes of this species the upper parts are of a light yellowish-hrown streaked with hlackish-brown, each feather being of that colour along the shaft; lower parts pale yellowish-gray, each feather of the fore neck tipped with a triangular spot of brownish-black, the fore part of the hreast and the sides with more elongated and fainter spots.

E. schœniclus, the Reed-Bnuting. It is also called, according to MacGillivray, Black-Headed Bnnting, Reed-Sparrow, Water-Sparrow, Ring-Buuting, Riug-Bird, Ring-Fowl, and Chnck. It frequents marshy places, where it is seen perching on willows, reeds, sedge, and other aquatic plants. It feeds on insects, seeds, and small *Mollusca*. The nest is placed among aquatic plants, and is composed of stalks and blades of grasses, bits of rushes, and the like. The eggs are fonr or five in numher, of a yellowish-gray, with tortuons or angular lines, and irregular spots of black. This hird is easily distinguished from the other species by its hlack head and white throat.

E. citrinella, the Yellow Bunting, or Yellow Ammer. It is also called in English Yellow Yelding or Yolding, Yellow Yowley, Yellow Yite, Yeldrock Skute, and Devil's Bird. It is a permanent resident in Great Britain, in cultivated and wooded districts, where it is well known. The hack and wings are bright red, the central part of each feather hrownish-black. The nest is composed of coarse grasses and twigs, neatly lined with fiue grass, fihrous roots, and hairs: it is placed on the ground or in the lower part of a hush. It lays four or five eggs purplish-white, marked with linear and angular streaks and a few irregular dots of hlack.

E. Cirlus, the Cirl-Bunting. This hird is not so common in this country as the last, which it greatly resembles. It was first distiuguished as a British hird by Colonel Montagu. It is a native also of the south of Enrope, and is more frequent in the south of England than in the north.

E. hortulana, the Ortolan Bunting. A very few specimens only of this hird have heen taken in England. It is common in the southern conntries of Europe, and migrates as far northward as the Baltic.

(MacGillivray, *Manual of British Birds;* Yarrell, *History of British Birds.*)

EMIGRATION. One of the most remarkahle facts in the history of Great Britain is the rapid increase of the population. The positive increase in our own kingdom has heen pointed out in the article CENSUS. While the popnlation of France and Germany has increased within the last fifty years in a very small degree; while iu Spain, Portngal, and Italy it has probably decreased; Great Britain has increased from 10,800,000, as given in the censns of 1801, to 20,900,000 in that of 1851; and in the middle of 1856, the Registrar-General estimated the population of England and Wales alone at 19,044,000: Ireland is omitted, as there was no census of 1801. In addition to this increase, swarms have been thrown off to which the ancient migrations from the North are insignificant in their total amount, though the emigration has been less striking from its being not an irruption but a gradual progress. In forty-two years, from 1815 to 1846 inclusive, during which an account of avowed emigrants has been taken, 4,470,319 persons, male and female, have left the shores of the United Kingdom; and these have heen enahled to form what may now be termed three mighty empires, subordinate to our own, in Australia, North America, and Sonth Africa; independent of the branch streams which have flown off to Ceylon, the West and East Indies, Gniana, and other British possessions. The United States of America is the only dominion that can afford anything like a parallel, and even that is indehted to us for 2,703,782 persous, who have proceeded thither, the greater proportion of whom have heen from Ireland, and chiefly from the years beginning with 1847. The annual average of emigration from 1815 to 1846, was 52,255; from 1847 to 1856, it was 279,816. It should be added, however, that from 1815 to 1824 no records were kept of the emigration to South Australia and New Zealand; but it was certainly under 1000 a year. In the 'Penny Cyclopædia' (vol. ix. p. 377; article EMIGRATION) we gave a tahle of emigration to 1836, which we now complete to 1856:—

Years.	North American Colonies.	United States.	Australia and New Zealand.	Other Places.	Total.
1837	29,884	36,770	5,054	326	72,034
1838	4,577	14,332	14,021	292	33,222
1839	12,658	33,536	15,786	227	62,207
1840	32,293	40,642	15,850	1,958	90,743
1841	38,164	45,017	32,825	2,786	118,592
1842	54,123	63,852	8,534	1,835	128,344
1843	23,518	28,335	3,478	1,881	57,212
1844	22,924	43,660	2,229	1,873	70,686
1845	31,803	58,538	830	2,330	93,501
1846	43,439	82,239	2,347	1,826	129,851
1847	109,680	142,154	4,949	1,487	258,270
1848	31,065	188,233	23,904	4,887	248,089
1849	41,367	219,450	32,191	6,490	299,498
1850	32,961	223,078	16,037	8,773	280,849
1851	42,605	267,357	21,532	4,472	335,966
1852	32,873	244,261	87,881	3,749	368,764
1853	34,522	230,885	61,401	3,129	329,937
1854	43,761	193,065	83,237	3,366	323,429
1855	17,966	103,414	52,309	3,118	177,307
1856	18,378	111,837	44,584	3,755	176,554
Total.	696,561	2,370,655	529,279	58,560	3,655,055

In 1857 the total number of emigrants from the port of Liverpool only, was 155,652; of these 9788 were for the North American colonies; 106,918 for the United States; 32,631 for Australia and New Zealand, and 324 for other places. Of these emigrants England supplied 50,289; Scotland, 8161; Ireland, 71,195; and various foreign countries, chiefly Germany, 6414. The emigration to Anstralia was principally English; that to the United States principally Irish.

Many emigrants, however, proceed to the North American colonies by New York, and no account is taken of the passage either way on the borders between them and the United States. The popnlation thus exported seems scarcely less fertile than at home. We give the latest returns of the population of these colonies which are mainly occnpied by a British population, our youngest and most vigorous:—

IN NORTH AMERICA:		Males.	Females.	Total.
Canada	Western	499,067	452,937	952,004
	Eastern	449,967	440,294	890,261
New Brunswick		99,526	94,274	193,800
Nova Scotia		137,677	138,440	276,117
Prince Edward's Island and Cape Breton		36,137	35,365	71,502
Newfoundland		52,274	44,232	96,506
Bermnda		4,797	6,295	11,092

The nnmbers given for Canada are from the Census of 1851 for Western, and the official retnrn of 1852 for Eastern Canada; the estimated numhers of hoth in January 1857, were 2,500,000. For New Brnnswick they are taken from the Census of 1851, and the official returns of 1853. For Nova Scotia, from the Census of 1851. For Prince Edward's Island, the Census of 1854; estimated in 1857 at 117,000. All have increased since the returns. For Newfoundland the numbers are taken from the Census of 1845, and in 1857 the increase was estimated at 10,000. For Bermnda the authority is the official return of 1853.

IN AUSTRALIA:	Males.	Females.	Total.
New Sonth Wales	147,091	119,098	266,189
Victoria (late Port Phillip)	201,422	104,742	306,164
South Australia	48,843	48,544	97,387
Western Australia	8,536	4,282	12,818
Tasmania	38,506	32,460	70,966
New Zealand	15,035	11,672	26,707

These retnrns all come down to a recent date, 1855-56, except New Zealand, for which the numbers are from the Census of 1851, and is exclnsive of military and aborigines. In Tasmania are inclnded 7740 convicts, 989 troops, and 19 ahorigines. The popnlation of Victoria on Dec. 31, 1855, only three months later than the ahove return, was estimated at 319,379; and on Dec. 31, 1857, at 457,000.

IN AFRICA:		Males.	Females.	Total.
Cape of Good Hope	Western Division	71,021	69,957	140,978
	Eastern Division	48,973	48,147	97,120
Natal		4,142	3,487	7,629

The returns of these colonies are for 1853 and 1854; and in Natal the numhers given are exclnsive of 112,988 settled natives.

In these three divisions of the British colonies, there are now representative governments, the privilege of self taxation, and the right of a free press; in short, a complete reprodnction of the British Constitntion. To other colonies, especially to British Guiana and some of the West India islands, the emigration has heen considerable; but as the emigrants become mixed with an older and in some cases a coloured or foreign population, we cannot trace the British element so clearly. The effect has been so far good, that the inhabitants of the North American and Australian colonies are, with the exception of the United States, among our best customers. It is not remarkable, therefore, that so much attention has been paid of late years to the subject of the transmission of emigrants thither, and of means for enabling them to settle there in comfort. Government, accordingly, has undertaken to a considerable extent the business of regulating emigration. First, an agent-general for emigration was appointed. This officer introduced many judicious plans for rendering the passage of emigrants across the ocean as free as possible from discomfort, and a code of rules was framed to secure this and other objects. The functions of the agent-general for emigration are now exercised by the Land and Emigration Commissioners. Emigrants are also protected by the Passengers' Act. The Act 5 & 6 William IV. c. 5, passed in 1835, having proved insufficient for the purpose, several amended acts were passed, of which the latest is the 18 and 19 Vict. cap. 119, passed in 1855. Its objects are to regulate the number of passengers in each ship, and to provide for their proper accommodation on board; to ensure a proper supply of provisions and water for their use; to provide for the sea-worthiness of the vessels; to secure a sufficient number of boats in case of accidents; and to protect emigrants from the numerous frauds to which at various stages of their undertaking their helplessness and inexperience expose them. If the ship does not sail on the day mentioned in the agreement, the Passengers' Act compels the captain to victual the emigrants just the same as if the voyage had commenced; and they are entitled to remain on board forty-eight hours after the ship reaches her destination.

As a further protection to emigrants, and to enforce the provisions of the Passengers' Act, government emigration agents are appointed for the ports of London, Liverpool, Plymouth, Southampton, Glasgow and Greenock, Dublin, Cork, Belfast, Tralee, Donegal, Ballina, Limerick, Sligo, Waterford, Londonderry, and Galway. These officers act under the immediate directions of the Colonial Land and Emigration Commissioners. They procure and give gratuitously information as to the sailing of ships, and means of accommodation for emigrants; and whenever applied to for that purpose, they see that all agreements between ship-owners, agents, or masters, and intending emigrants, are duly performed. They also see that the provisions of the Passengers' Act are strictly complied with, viz., that passenger-vessels are sea-worthy, that they have on board a sufficient supply of provisions, water, medicines, &c., and that they sail with proper punctuality. They attend personally at their offices on every week-day, and afford gratuitously all the assistance in their power to protect intending emigrants against fraud and imposition, and to obtain redress where oppression or injury has been practised on them.

In the colonies there are Government Emigration Agents at the following places:—

Canada.—Quebec, Montreal, Toronto, and Hamilton.

New Brunswick.—St. John's, St. Andrew's, Chatham (Miramichi), Bathurst, Dalhousie, and Richibucto.

Australian Colonies.—Sydney, Moreton Bay, Melbourne, Geelong, Portland Bay, Hobart Town, Launceston, Perth, Fremantle, Adelaide, and Auckland.

Cape of Good Hope.—Cape Town, Port Elizabeth, and Simon's Town.

The duty of these officers is to afford gratuitously to emigrants every assistance in their power by way of advice and information as to the districts where employment can be obtained most readily, and upon the most advantageous terms, and also as to the best modes of reaching such districts.

The Emigration Commissioners, while they have funds for the purpose, grant passages to New South Wales, Victoria, and South Australia, to persons strictly of the labouring class who may be considered eligible emigrants. The funds are supplied entirely from colonial revenues, and in the administration of them the Commissioners act as trustees for the colonies, and are therefore bound to look exclusively to colonial interests. They do not consider therefore how distress in this country may be best relieved, but how the largest number of emigrants most suited for the wants of the colony may be procured and sent out. In deciding what classes are most suited to the wants of the colonies, the Commissioners are guided by reports and instructions received from time to time from the governments of the respective colonies, either direct or through the Secretary of State. The Commissioners are occasionally also able to grant passages to Western Australia; but they have no funds for assisting persons wishing to emigrate to the North American colonies.

In British Guiana, the Governor, under Ordinance No. 7, of 1854, sect. 4, is authorised by proclamation to name the places from which emigration on bounties is permitted, and to fix the rates of bounty for the introduction of emigrants, under the age of forty, competent and willing to engage in agricultural labour.

Emigration is one of the 'modes of relief' contemplated by the Poor Law Amendment Acts (4 & 5 Wm. IV. c. 76; 11 & 12 Vict. c. 110; 12 & 13 Vict. c. 103; and 13 & 14 Vict. c. 101). In some years a large number of persons have emigrated with the assistance of funds obtained under the Act 4 & 5 Wm. IV. By sect. 62 of that Act owners and rate-payers are empowered to raise money on security of the rates for the purposes of emigration, under the authority of the Poor Law Commissioners. The sum so raised must not exceed half the average yearly rate of the preceding three years, and it must be repaid within five years. The money is advanced to emigrants by way of loan, and is recoverable against persons above the age of twenty-one, who, having consented to emigrate, refuse to do so after the expenses of emigration have been incurred; and the loan is also recoverable if persons who emigrate shall return to this country. By the 12 & 13 Vict. cap. 103, the guardians of any parish or Union are empowered to expend money to the amount of 10*l.* upon the emigration of any poor person belonging to the parish or to any parish in the Union, without the necessity of a parochial meeting to give their consent. But the gross amount expended must not exceed the limit fixed above, and a majority of the Guardians of the parish of the settlement must express their concurrence in writing in the resolution of the Board of Guardians for such expenditure. This written concurrence must be transmitted, together with a list describing the proposed emigrants, to the Poor Law Board, who are to issue their order to confirm the resolution. The 13 & 14 Vict. c. 101, s. 4, enables Boards of Guardians, under similar restrictions, to expend money in and about the emigration of orphan or deserted children under sixteen having no settlement, or whose settlement is unknown. But it requires that no emigration of any such orphan or deserted child shall take place without the consent of such child given in petty session, and unless a certificate thereof under the hands of two justices shall have been transmitted to the Poor Law Board. Certain conditions are inserted by the Poor Law Board in all orders sanctioning the emigration of poor persons, of which the most material is, that the party emigrating shall go to some British colony not lying within the tropics; and the guardians are empowered to expend certain specified sums in the conveyance of the emigrant to the port of embarkation, and on the outfit, including bed, bedding, and clothing.

Under the Irish Poor Law Act, money may be raised for enabling poor persons to emigrate to British colonies; but the money so raised must not exceed one shilling in the pound on the net annual value of rateable property.

The Bounty System derives its name from the mode in which the proceeds of land-sales are applied in obtaining immigrants. In this case persons who introduce persons into the colony receive so much per head, according to the terms of agreement. The contractors engage to find persons willing to emigrate, and undertake to land them in the colony. This system is in force only in some of the Australian colonies. In New South Wales 51,736 persons were introduced from 1831 to 1842 under bounties.

The mode in which unoccupied land is disposed of in the colonies has a most important influence on the condition and welfare of immigrants. By the application of a general principle of law, the waste lands in the British colonies were considered to be vested in the Crown, and that every private title must rest upon a royal grant as its basis. But since 1831 another principle has been acknowledged and observed: that the Crown holds the lands in question for the purposes of the public good, not merely for the existing colonists, but for the people of the British empire collectively. It must be appropriated to public uses and for the public benefit. The Land Sale Act for the Australian Colonies (5 & 6 Vict. c. 36) prohibits land being alienated by her Majesty, or by any one acting under her authority, except by sale, and in the manner directed by the Act.

Down to the year 1831 no regular or uniform system of selling land appears to have been adopted in the British colonies. In place of such system, conditions were attached to the occupation of land under the name of quit-rents, money payments, or the cultivation of the soil; but these conditions were not effectually enforced, and in fact it was generally found impossible to enforce them. Land was profusely granted to individuals in large tracts, and as cultivation was not enforced, and no roads were made through these tracts, they interrupted the course of improvement. Under the old system, lands in the colony of the Cape of Good Hope, amounting to upwards of thirty-one million acres, have been disposed of for less than 46,000*l.* In Prince Edward's Island the whole of the land was granted in one day to absentee proprietors upon terms which have never been fulfilled. The influence of these proprietors with the Home Government prevented such measures being adopted as were calculated to enforce the settlement of the grants, and consequently the greater part of them remained chiefly in a wild state. ('Report of Mr. C. Buller, M.P., to the Earl of Durham, on Public Lands in British North America,' 1838.) This Report contains an account of the system of granting lands in each of the provinces of British North America; and in all of them it appears to have been injurious to the public interests.

In January, 1840, commissioners were appointed under the royal sign manual to act as a Land and Emigration Board. The sale of the waste lands of the Crown throughout the British colonies was regulated by the commissioners, and they applied the proceeds of such sales towards the removal thither of emigrants from this country, when the land-fund was appropriated to this object. This board was a subordinate department of the Colonial Office. But the disposal of the waste lands is now, by various Acts of the imperial and provincial parliaments, vested in the local governments. The regulations vary considerably in their details, but we give a summary of the conditions and prices of the waste lands in the North American, Australian, and Cape of Good Hope Colonies.

Colony.	Mode of Sale.	Price per acre.
NORTH AMERICAN COLONIES:		
Canada (West)	Fixed Price	4*s.* to 20*s.* currency.
Canada (East)	Ditto	2*s.* to 4*s.* ditto, according to situation.
Nova Scotia	Ditto	1*s.* 9*d.* sterling.
New Brunswick	Auction and private sales	2*s.* 6*d.* sterling upset price, and 2*s.* 1*d.* at private sale.
Newfoundland	Ditto	2*s.* currency upset price.
Prince Edward Island	Private contract	5*s.* or upwards, according to situation.
AUSTRALIAN COLONIES:		
New South Wales Victoria Western Australia South Australia Tasmania	By Auction. Country lands not sold at the public sales may afterwards be bought at the upset price as a fixed price.	Lowest upset price, 1*l.* sterling.
New Zealand [Crown lands]	Auction, for town, suburban and rural lands. Fixed price for country lands.	Highest fixed price, 10*s.* an acre.
Cape of Good Hope	Auction, subject to a quit-rent	No fixed upset price.
Natal	Ditto	Lowest upset price, 4*s.* sterling.

In Canada there are detached Clergy Reserves for sale in most of the townships surveyed prior to 1841. These reserves are now vested in the Colonial Government by the 16 Vict. c. 21 (1853), subject to the rights of the clergy. They are now thrown open for public sale. The lands reported by the chief agent for emigration at Quebec to be most worthy the attention of emigrants, are the townships Peel, Wellesley, Maryborough, and Mornington, covering an area of 250,000 acres, in the county of Waterloo. The prices of land in these townships (as of all Clergy Reserves), are regulated by the quality of soil and situation, and average from 8*s.* to 20*s.* currency per acre, one-tenth of the purchase-money being required at the time of sale, and the remainder to be paid in nine annual instalments, with interest. One million acres of land were also appropriated for school purposes by the legislature in 1849, and the school lands in the counties of Bruce, Grey, and Huron are now open for sale to actual settlers upon the following terms:—The price to be 10*s.* per acre, payable in ten equal annual instalments, with interest. The first instalment to be paid upon receiving authority to enter upon the land. Actual occupation to be immediate and continuous. The land to be cleared at the rate of 5 acres annually for every 100 acres during the first 5 years. A dwelling-house at least 18 feet by 26 to be erected. The timber to be reserved until the land has been paid for in full and patented, and to be subject to any general timber duty thereafter. A license of occupation, not assignable without permission, to be granted. The sale and the license of occupation to become null and void in case of neglect or violation of any of the conditions. The settler to be entitled to obtain a patent upon complying with all the conditions. Not more than 200 acres to be sold to any one person on these terms.

In Canada West, the provincial government have recently opened three great lines of road, and laid out for settlement the lands through which they pass; they are styled, 1st, The Ottawa and Opeongo Road, which runs east and west; it will eventually be 171 miles in length, and connect the Ottawa River with Lake Huron. 2nd, The Addington Road, which runs north and south, is 60 miles long, and starts from the settlements in the county of Addington until it intersects the Opeongo Road. 3rd, The Hastings Road, which runs nearly parallel to the Addington Road, is 74 miles long, and connects the county of Hastings with the Ottawa and Opeongo Road. In order to facilitate the settlement of this part of Canada, and to provide for keeping the roads in repair, the provincial government have authorised free grants of land along these three roads, not to exceed in each case 100 acres, upon the following conditions:—That the settler be eighteen years of age. That he take possession of the land allotted to him within one month, and put in a state of cultivation at least twelve acres of the land in the course of four years,—build a house (at least 20 by 18 feet) and reside on the lot until the conditions of settlement are duly performed. Families comprising several settlers entitled to lands, preferring to reside on a single lot, will be exempted from the obligation of building and of residence (except upon the lot on which they live) provided that the required clearing of the land be made on each lot. No title is given to the settler until after these conditions have been performed, and the non-performance of them entails the immediate loss of the assigned lot of land, which will be sold or given to another.

The road having been opened by the Government the settlers are required to keep it in repair. The log house required by the Government to be built is of such a description as can be put up in four days by five men. The neighbours generally help to build the log cabin for newly-arrived settlers without charge, and when this is done the cost of erection is small; the roof can be covered with bark, and the spaces between the logs plastered with clay, and whitewashed; it then becomes a neat dwelling, and warm as a stone house.

The lands in Canada West thus opened up for settlement are capable, both as to soil and climate, of producing abundant crops of winter wheat, of excellent quality and full weight, and also of every other description of farm produce grown in the best-cultivated districts of that province.

In Australia and New Zealand licenses and leases are granted for large tracts of land for pasturage purposes, at very low rents, as to which the holders have certain restricted rights of pre-emption if required for purposes of cultivation; and subject to the right of being taken by the Government if wanted for public purposes.

In all the colonies the rights of the Crown in regard to minerals are preserved; but in most cases leases are granted on payment of a certain rate per cent. on the produce. In Australia licenses to mine and dig for gold on Crown lands are granted at the rate of 10*s.* per month for each individual license, payable in advance; or in case of a lease being granted of a certain portion of land, at a rate of three per cent. on the gross value of the gold procured from Crown lands, and of half that amount on gold obtained from private lands. A 'miner's right' license to search and dig for gold is obtainable on payment in advance of 1*l.* per annum. 'Storekeepers' licenses' at the 'Diggings' are also paid for at the rate of 2*l.* 10*s.* for three months, 5*l.* for six months, and 10*l.* for twelve months.

The Land and Emigration Commissioners are required by their official instructions to prepare and issue "a distinct and compendious account of whatever relates to the agriculture, the commerce, the natural products, the physical structure, and the ecclesiastical and political institutions of each of the colonies in which they offer land for sale." The Commissioners in pursuance of this object issue occasionally a 'Colonisation Circular,' which contains matter calculated to be of essential use to emigrants or persons who intend at some time to settle in the colonies.

EMMET, a name used by early English writers for the Ant. [ANT.]

ENAMEL (*of Teeth*). [TISSUES, ORGANIC, *S.* 1.]

ENCEPHALARTOS, a genus of Plants belonging to the natural order *Cycadaceæ*. The species are found in Africa. Like many of the other forms of Cycadaceous plants they yield starch in their stems, which are prepared by the natives and eaten; hence these plants are known by the name of Caffer-Bread or Kaffir-Bread.

ENCHELIS, a genus of infusorial animalcules. The species *E. sanguinea* and *E. pulvisculus*, according to Meyen, form the Red and Green Snow-Plants which have been described as *Conferva*, and referred to *Protococcus*. [SNOW, RED.]

ENDOSMOSIS, a name given by Dutrochet to the process by which fluids pass from the exterior to the interior of a cell. This process seems to result from two distinct agencies, which are always brought into operation where fluids pass through a membrane. The one is the imbibition of the fluid by the porous cell-membrane, and the other is the mutual diffusion of miscible fluids. From the researches of Matteucci and others there can be little doubt that the passage of a gas or liquid through an animal or vegetable membrane is but the modification of the process of attraction by which fluids are absorbed by solid bodies. This process is carried on with various degrees of force in different materials, and seems to depend on the degree of attraction subsisting between the particles of the solid and those of the fluid. Matteucci found that when glass tubes of about three-quarters of an inch diameter were filled with fine sand previously dried, and introduced without pressure, and were immersed at their lower ends into the following liquids, the action of imbibition raised the liquids in the tubes to the following height:—

Solution of Carbonate of Potash	85 millimetres.
Solution of Sulphate of Copper	75 „
Serum of Blood	70 „
Solution of Carbonate of Ammonia	62 „
Distilled Water	60 „
Solution of Common Salt	58 „
Milk	55 „
White of Egg, diluted with its own volume of water	35 „

In these cases the imbibition took place at first rapidly, then more slowly, and ceased entirely at the end of ten hours. When thick solutions of gum, or starch, or fixed oils were employed, scarcely any imbibition took place, and it was but little more when strong saline solutions were used. The degree in which different fluids pass into different solids will be seen in the following table:—

	Sand.	Pounded Glass.	Saw-dust.
Alcohol	85 mill.	175 mill.	125 mill.
Water	175 „	182 „	60 „

Thus showing that water passed more freely than alcohol into sand, but less freely into saw-dust, and both fluids passed with equal facility into pounded glass. The size of the tubes employed in these experiments and the temperature affected considerably the results. The fluids rose higher in proportion as the temperature increased. This enables us to understand the influence of heat on life by the physical effects it produces.

Not only is the passage of fluids from the exterior to the interior of a cell facilitated by the attraction between the cell-wall and the fluids, but the fluids on either side of the membrane have a tendency to mix with each other, which cannot but assist in this process. Professor Graham has shown that not only have gases an inherent tendency to mix with each other, independent of the laws of gravity, but that this law also applies to the miscibility of liquids. In a Memoir on this subject in the 'Philosophical Transactions' for 1850, he has shown the laws which this diffusion of liquids obeys. Different substances possess this property in different degrees. Thus, when solutions of the following substances were used, of the strength of 20 parts to 100 parts of water, the relative quantities diffused in a given time were as follows:—

Chloride of Sodium	58·68
Sulphate of Magnesia	27·42
Nitrate of Soda	51·56
Sulphate of Water	69·32
Crystallised Cane-Sugar	26·74
Starch-Sugar (Glucose)	26·94
Gum Arabic	13·24

The experiments from which these results were obtained, were performed by inverting a phial containing the solution to be diffused in a large jar of pure water. The diffusion was stopped after seven or eight days, and the amount of diffusion was determined by evaporating the water of the jar to dryness. There can be little doubt that the relative diffusibility of the juices of plants and animals must have an important influence on the changes which go on in the cells during the performance of the functions of the vegetable or animal body. "Thus," observes Dr. Carpenter, "the low diffusibility of albumen obviously tends to the retention of the serous fluids within the tissues; whilst the high diffusibity of urea will favour its escape from them." The following is an account of the process of Endosmosis, and some of the conclusions at which we may arrive, from Dr. Carpenter's 'Principles of Physiology:'—

"If into a tube, closed at one end with a piece of bladder or other membrane, be put a solution of gum or sugar, and the closed end be immersed in water, a passage of fluid will take place from the exterior to the interior of the tube, through the membranous septum; so that the quantity of the combined solution will be greatly increased, its strength being proportionably diminished. At the same time, there will be a counter-current in the opposite direction; a portion of the gummy or saccharine solution passing through the membrane to mingle with the exterior fluid, but in much less quantity.

"The first current is termed Endosmose, and the counter-current Exosmose. The increase on either side will of course be due to the relative velocity of the currents; and the changes will continue until the densities of the two fluids are so nearly alike as to be incapable of maintaining it. The greater the original difference (provided that the denser be not actually viscid, but be capable of mixing with the other), the more rapidly and powerfully will the process be performed. The best means of experimenting upon the phenomena is afforded by a tube, narrow above, but widely dilated below, so as to afford a large surface to the membrane, compared with that of the superincumbent column, which will then increase in height with great rapidity. By bending this tube in the form of a syphon, and introducing into its curve a quantity of mercury, the force as well as the rapidity of the Endosmose between different fluids may be estimated with precision. In this way it was ascertained by Dutrochet, in some of his experiments, that fluid might be raised against a pressure of no less than 4½ atmospheres, or nearly 70 lbs. to the square inch. Although it is not universally true that the activity of the process depends upon the difference in density of the two fluids (for in one or two cases the stronger current passes from the denser to the lighter), it seems to be so with regard to particular solutions, as those of gummy or saccharine matter. No endosmose takes place between fluids which will not mingle, such as oil and water; and very little between such as act chemically on each other. Although an organic membrane forms the best septum, yet it has been found that thin laminæ of baked pipe-clay will suffice for the evident production of the phenomenon; and that porous limestones possess the same property in an inferior degree. Although it may not yet be possible to explain all the phenomena of Endosmose upon physical principles, yet these will go so far towards it that the general conditions of the process may be considered as well understood. Supposing that two mutually diffusible liquids are on the opposite sides of a porous septum, which is not equally penetrable by them, then the one which is most readily imbibed will tend to occupy the capillary passages of the septum, and will thus be brought into contact with the liquid on the opposite side. This contact will permit the diffusion of that which has passed through the pores of the septum; and as fast as that which occupies these pores is removed by diffusion, so fast will it be renewed on the other side,—just as oil continues to ascend through the capillary channels in the wick of a lamp, so long as it is being dissipated by the combustive process at its summit. In this way then an endosmotic current is produced, the force of which will depend upon the diffusion-powers of the two liquids, and upon the difference of the attractive power which the capillary tubes of the septum have for the two respectively.

Thus when a solution of sugar or gum is on one side of the septum, and water on the other, the water is the most readily imbibed; and consequently the chief mixture and diffusion of the liquids, the one through the other, takes place at the surface of the septum in contact with the more viscid liquid. But at the same time this liquid is tending to diffuse itself through the water which occupies the capillary channels of the septum; and as it is not repelled by the septum, but is only attracted by it in a less degree than the water, a portion of it finds its way in a direction opposed to the principal current, and diffuses itself through the water on the other side, thus constituting Exosmose. Thus it happens that the direction of the principal current, or Endosmose, will be determined by the attractive power of the septum for one or the other of the liquids; though the diffusion-power of the liquids through each other will help to determine its force. When alcohol and water, for example, are separated by a septum composed of animal membrane, the endosmotic current will be from the water towards the alcohol, because the former liquid more readily 'wets' the membrane, and consequently tends most strongly to occupy its capillary passages; but on the other hand, when the separation is made by a thin lamina of caoutchouc, the endosmotic current is from the alcohol towards the water, because the former is most readily imbibed by the septum. It has further been ascertained by the experiments of Matteucci, that when an organic membrane is employed as a septum, the rapidity of transmission is considerably affected by the direction in which the endosmotic current traverses the membrane. Thus, when the skin of the Torpedo was employed, with a solution of sugar on one side of it and water on the other, although there was always an endosmotic current from the water to the sugar, yet this current was strong enough to raise the interior liquid to 80° when the water was in contact with the internal surface of the membrane, in the same time that was occupied by its rise to 20° when the external surface of the membrane was turned towards the water. Again, when the mucous membrane of the stomach of a dog was used as the septum, and its external (or muscular) surface was placed in contact with alcohol, the passage of water from the other side took place with such rapidity as to raise the liquid in the tube to 130°; whilst if the internal (or mucous) surface of the membrane were placed in contact with the alcohol, and the muscular surface with water, the current was only sufficient to raise the liquid 6 degrees in the same time; so that it is evident that the transudation of water takes place much more readily from the mucous lining of the stomach towards the outer side of the viscus than in an opposite direction, in virtue simply of the physical properties of the membrane. In fact, according to Professor Matteucci, the cases are very rare in which, with fresh membranes, Endosmose takes place with equal readiness, whichever of the two sides is exposed to the water.

"The direction which is most favourable to Endosmose through skins is usually from the internal to the external surface, with the exception of the skin of the frog, in which the endosmotic current, in the single case of water and alcohol, takes place most readily from the external to the internal surface. But when stomachs and urinary bladders are employed, the direction varies much more, according to the nature of the liquids employed. This variation appears to have some relation to the physiological conditions in which these membranes are placed in the living animal: thus, the direction most favourable to Endosmose between water and a saccharine solution, is not the same for the stomach of a ruminant as for that of a carnivorous animal: as yet however no positive statement can be made on this subject. When membranes are employed that have been dried or altered by putrefaction, we either do not observe the usual difference arising from the position of the surfaces, or Endosmose no longer takes place; thus affording another indication that it is to the physical condition of the perfectly-organised membrane that we are to look for many of the peculiarities which are noticeable in the transudation of fluids through them. The exosmotic current does not bear any constant relation to the endosmotic, as may be easily comprehended from the preceding explanation; for if the liquids have a strong tendency to mutual diffusion, and the difference in attractive power which the septum has for them respectively is not great, each may find its way towards the other, and a considerable exosmose may ensue, with very little change of level. The amount of the exosmotic as of the endosmotic current, varies with the direction in which it traverses the membrane; thus, when sugar, albumen, or gum, was employed in solution, its transudation towards water took place most readily from the internal towards the external surface of all the skins examined by Matteucci, a fact which is not without its significance, when it is remembered that it is in this direction that the secretion of mucus takes place on the skins of fishes, frogs, &c.

"Applying these considerations to the phenomena of imbibition of liquids into the tissues and canals of the living body, we shall have to inquire how far they are capable of being accounted for on physical principles which have been now brought forward. It has been maintained by some that absorption is a purely vital operation, because it does not occur save during the continuance of life. But this is not true, since imbibition will take place into dead tissues, though more slowly than into some parts when living; and the difference of rate seems to be fully accounted for by the difference of the condition between a mass of tissue, all whose fluids are stagnant, and another in which an active circulation is taking place. Thus, as Matteucci has shown, if the hind legs of a frog recently killed be immersed for some hours in a solution of ferrocyanide of potassium, it will be found that every part of the viscera is so penetrated with the salt, that by touching it with a glass rod moistened with a solution of chloride of iron, a more or less deep blue stain is the result. Now, the same effect is produced much more speedily in a living frog; and it is easily proved that the imbibition takes place in the latter case into the blood-vessels, and that the salt is conveyed to the remoter parts of the body by the circulation, instead of having slowly to make its way by transudation through the tissues, as in the dead animal. But further, not only does the movement of blood in the vessels promote the diffusion of liquid, which has been already observed, it also increases the rapidity of the absorption itself in a very extraordinary degree. Thus, if a membranous tube, such as a piece of small intestine, or of a large vein of an animal, be fixed by one extremity to an opening at the bottom of a vessel filled with water, and have a stop-cock attached at the other extremity, and be then immersed in water acidulated with sulphuric or hydrochloric acid, it will be some time before the acid will penetrate to the interior of the tube, which is distended with water; but if the stop-cock be opened, and the water be allowed to discharge itself, the presence of the acid will be immediately discovered (by tincture of litmus) in the liquid which flows out, showing that the acid has been assisted in its penetration of the walls of the tube by the current traversing its interior. Thus, the continuance of circulation is obviously one of the most patent of all the conditions of absorption, and the difference in the rate of the process in the dead and living organisms, placed under the same circumstances, may be accounted for in great part, if not entirely, by the stoppage of the circulation in the former. All the circumstances which are laid down by physiologists as favouring absorption are in strict accordance with the physical principles which have been now explained. These circumstances are—1. The ready miscibility of the liquids to be absorbed with the juices of the body. 2. The penetrability of the tissue through which the absorption takes place. 3. The absence of previous distention in the tissues or canals towards which the flow takes place. 4. The elevation of the temperature within certain limits. 5. The vascularity of the tissues, and the rate of movement of the blood through the vessels. And the results of experiments upon recently-dead membranes which retain almost exactly the same physical conditions as those which they possessed during life, but have entirely lost their vital properties, seem most decidedly to indicate that the relative facility with which different substances are absorbed, and the direction most favourable to their passage through the tissues, are determined in great part by the physical relations of those tissues (and of the vessels which traverse them) to the liquid which is seeking to enter them. In this way, then, many of the phenomena of selective absorption are probably to be explained, especially in plants and the lower animals. The special absorbent vessels, however, of *Vertebrata* seem to possess properties which can scarcely be thus accounted for." ('Principles of Physiology.') [ABSORPTION.]

ENDYMION, a genus of plants belonging to the class of Endogens, the order *Liliaceæ*, and the tribe *Hemerocallideæ*. It has a tubular bell-shaped perianth, composed of six connivent leaves, with reflexed points combined below. The stamens are inserted below the middle of the perianth; the filaments decurrent.

E. nutans, the English Blue-Bell. It is also the *Scilla nutans*, the *Hyacinthus non-scriptus*, and *Agraphis nutans* of various botanical writers. It has linear leaves, with nodding racemes, the flowers bell-shaped, cylindrical; the apex of the sepals revolute; the bracts 2. This is a very common plant, flowering in May in the woods and thickets of England. It is also common in France and Belgium. The flower-stalk is about a foot high. The leaves are shorter than the flower-stalk. The flowers are generally blue. A white variety is however occasionally seen.

ENFRANCHISEMENT. The enfranchisement of copyholds, to facilitate which a great many acts of parliament have been passed, has at length, by the statute 15 & 16 Vict. c. 51, been rendered compulsory alike on the lord as on the tenant, on terms which are to be determined in case of difference by the Copyhold Commissioners nominated by the statutes. From the annual reports of these commissioners, which are laid before parliament, it would seem that the holders of copyhold property are gradually availing themselves of the facilities afforded by the statutes; so that in course of time the old tenure by copy of court-roll will become rare, and perhaps unknown. This is one of the many instances showing the tendency of modern legislature to simplify and cheapen the transfer of real property. (Blackstone's 'Commentaries,' Mr. Kerr's edition, vol. vii. p. 146.)

ENGRAULUS. [ANCHOVY.]

ENNISTYMOND. [CLARE.]

ENTOPHYTA (from ἔντον and φυτόν), a term applied to plants found living within animal bodies. The term *Epiphyta* has been applied to those forms of plants which live upon the external parts of organised beings whether plants or animals. It is however difficult to draw the line between these two classes, because it frequently happens that a plant whose spores are deposited in the interior of an animal body, in the course of growth finds its way to the surface. The term Epiphyte has also been employed to designate those higher forms of plants, more especially the *Orchidaceæ* which are found growing on other plants, so that the term Entophyte is more especially used to designate those cryptogamic plants which grow on the skin or mucous membranes of animals. These will be more particularly referred to here. At the same time it should be observed that a large number of cryptogamic plants are found in the living tissues of other plants, and claim to be regarded as Entophytes in relation to the vegetable kingdom.

The study of *Entophyta* has been invested with considerable interest, since by the aid of the microscope so many of these plants have been detected accompanying various diseased conditions of the animal body. Although they have been perhaps more carefully investigated in the human body, it has been for a long time a familiar fact that many of the lower animals are attacked by these plants in states of disease. Thus the cultivators of the silk-worm have observed the growth of a species of *Botrytis* in the organs of that animal, producing great destruction amongst them, and the occurrence of this fungus is known by the name of Muscardine. [MUSCARDINE, *S.* 2.] Caterpillars have been brought to this country from New Zealand, Australia, and China, as curiosities, from the bodies of which a species of *Clavaria* or *Sphæria* of considerable size is found to project. A species of *Polistes*, a kind of wasp, has been observed in the West Indies to be subject to the attacks of a fungus which appeared on the surface of its body in the form of a growth as large as itself. The common house-fly is often seen in the autumn of the year adhering helplessly to a pane of window-glass from the growth of a fungus on its body, which has not been free from the suspicion of producing even so formidable a disease as cholera. Gold-fish, when kept in confinement, as well as water-salamanders and sticklebacks, have been observed to be covered with a fungus (*Achlya prolifera*) before death.

These facts, and many others, have from time to time attracted attention, which, having been followed up by diligent observations with the microscope, have led to the discovery of a very large class of vegetable bodies taking up their ordinary residence within or upon animal surfaces.

A question has been raised as to whether these plants are the natural products of the bodies on which they are found, as other plants are of the soil in which they grow, or are introduced from some foreign and extraneous source. From the observations that have been made up to the present time, it appears that these plants are truly in their natural positions in the localities in which they are found, and that they only multiply or become sources of disease when the bodies on which they grow get into a disordered state. In the same manner the ova of animalcules seem constantly present in the air and water, only awaiting the proper combination of circumstances to be developed in prodigious numbers. The circumstances which predispose to the growth of these Entophytes upon the body, are not better known than those which predispose the body to receive certain contagions. A failure of the ordinary vital powers to carry on the healthy processes of life seems ordinarily to be the inviting cause of such a development of these plants as would constitute a disease.

All the observations that have been made on this important subject have been brought together by M. Robin in his work on the 'Natural History of the Parasitic Vegetables which grow on Man and on Living Animals' (Paris, 1853). The following is a classification of these plants:—

I. ALGÆ.

Class *Isocarpeæ*.
 Sub-Class I. *Diatomeæ*.
  Genus *Psorospermia*, 11 species.
 Sub-Class II. *Malacophyceæ*.
  Tribe *Gymnospermeæ*.
   Order I. *Eremospermeæ*.
    Sub-Order I. *Mycophyceæ*.
     Family *Cryptococceæ*.
      Genus *Cryptococcus*, 2 species.
  Tribe *Palmelleæ*.
      Genus *Merismopœdia ventriculi*.
     Family *Leptothriceæ*.
      Genus *Leptothrix*, 2 species.
      Genus *Cladophytum comatum*.
      Genus *Arthromitus*, 2 species.
  Tribe *Leptomiteæ*.
      Genus *Leptomitus*, 6 species.
      Genus *Mouliniea*, 3 species.
  Tribe *Laprolegnieæ*.
      Genus *Saprolegnia ferax*.
      Genus *Enterobryus*, 4 species.
      Genus *Eccrina*, 2 species.
    Sub-Order III. *Tiloblasteæ*.
     Family *Oscillarieæ*.
      Genus *Oscillaria*.
      Genus *Zygnæma cruciatum*.
   Order II. *Cryptospermeæ*.
     Family *Chætophoreæ*.
      Genus *Chætophora meteorica*.

II. FUNGI.

Division I. *Arthrosporci*.
  Tribe *Torulacei*.
    Genus *Trichophyton*, 3 species.
    Genus *Microsporon*, 3 species.
    Genus *Sporendonema musca*.
  Tribe *Oidiei*.
    Genus *Achorion Schœnleinii*.
    Genus *Oidium*, 3 species.
  Tribe *Aspergillei*.
    Genus *Aspergillus*, 8 species.
Division II. *Trichosporei*.
  Tribe *Oxycladei*.
    Genus *Dactylium oogenum*.
    Genus *Botrytis Bassiana*.
  Tribe *Sporotrichei*.
    Genus *Sporotrichum*.
  Tribe *Isariei*.
    Genus *Isaria*, 12 species.
Division III. *Cystoporei*.
  Tribe *Columellati*.
   Section *Ascophorei*.
    Genus *Mucor Mucedo*.
Division IV. *Chirosporei*.
  Tribe *Coniopsidei*.
   Section *Phragmidiei*.
    Genus *Puccinia favi*.
 Sub-Division *Endoclivei*.
   Section *Spheronomei*.
    Genus *Laboulbenia*, 2 species.

Tribe *Sarcopsidei.*
Genus *Stilbum Buquetii.*
Division V. *Thecasporei.*
Tribe *Sphæriacei.*
Genus *Sphæria*, 8 species.
Genus *Kentrosporium*, 2 species.

The following is a list of the distribution of the species of the above genera in the various localities of the animal body.

I. Man and the *Mammalia.*
A. The Skin.
Trichophyton tonsurans. Malmsten. (On Hairs.)
T. sporuloides. Ch. Robin.
T. ulcerum. Ch. Robin. (On Ulcerated Skin.)
Microsporon Audouini. Gruby. (Hair Follicles.)
M. mentagrophytes. Ch. Robin. (Roots of the Hair.)
M. furfur. Ch. Robin. (Skin.)
Mucor mucedo. Linnæus.
Achorion Schœnleinii. Remak. (The Hair and the Hair Follicles.)
Aspergilli species. Pacini et Meyer. (Auditory Passage.)
Puccinia favi. Ardsten.
B. On the Mucous Membrane.
Cryptococcus cerevisiæ. Kützing. (Intestines.)
C. guttulatus. Ch. Robin. (Rabbit.)
Merismopædia ventriculi. Ch. Robin.
Leptothrix buccalis. Ch. Robin.
Oscillaire (?) of the Intestines. Farre.
Leptomitus urophilus. Mont. (Bladder.)
Leptomitus of Hannover. Ch. Robin. (Pharynx and Œsophagus.)
Leptomitus of the Epidermis.
Leptomitus of the Uterus.
Leptomitus of Uterine Mucus.
Leptomitus of the Eye.
Oidium albicans. Ch. Robin. (In Thrush.)
Fungus of the Lungs. Bennett.
Fungus of the Nasal Mucus.

II. Birds.
A. Of the Respiratory Organs.
Aspergillus candidus. Michele. (The Air-Cells and the Lungs.)
A. glaucus. Fries.
A. nigrescens. Ch. Robin.
A. strix nyctea. J. Müller and Retzius.
Mouldiness of the Lungs of the Jackdaw. Meyer.
B. The Eggs.
Dactylium oogenum. Montague.
Sporotrichum (*Nematogonum*) *brunneum.* Schenk.

III. Reptiles.
A. The Eggs.

IV. Batrachians.
A. The skin. *Saprolegnia ferax.* Kützing (*Achlya*, Nees von Esenbeck).

V. Fishes.
A. The Skin.
Zygnema cruciatum. Agardh.
Chætophora (*Tremella*) *meteorica.* Ehrenberg.
Saprolegnia ferax. Kützing.
Trichotraunia dermale. E. Germain of St. Pierre.
Confervæ of Gold-Fish. Bennett.
Algæ of the Stickleback. Manicus.
B. The Gills and the Cellular Tissue.
Psorospermia of the Pike. J. Müller.
P. of the *Synodontis Schal.* J. Müller.
P. of the Sandre. (*Lucioperca sandra.*) J. Müller.
P. of the Roach. (*Cyprinus rutilus.*) J. Müller.
P. of the *Labeo niloticus.* J. Müller.
P. of the *Pimelodus Blochii.* J. Müller.
P. of the *Pimelodus Sebæ*, and of *Platystoma fasciatum.* J. Müller.
P. of the *Catastomus tuberculatus.* J. Müller.
P. of the *Gadus callarias.* J. Müller.
P. of the *Acerina vulgaris* of Grenville. Creplin.
P. of the *Sciæna umbra.* Ch. Robin.
C. The Eggs. *Saprolegnia ferax.* Kützing.

VI. Insecta.
A. On the Elytra, and on the Articulations.
Botrytis Bassiana. Balsamo. Montagne.
Laboulbenia Rougelii. Ch. Robin. Montagne.
L. Guerinii. Ch. Robin.
Stilbum Buquetii. J. Müller and Ch. Robin.
B. On the Caterpillars and Chrysalises in the Tissues.
Botrytis Bassiana. Balsamo. Montagne.
Genus *Sphæria.* Haller.
Section *Cordyceps.* Fries.
Sphæria militaris. Ehrenberg.
S. sphærocephala. Klein.
S. entomorhiza. Dickson.
S. sobolifera. Hill.
S. Sinensis. Berkeley.
S. Robertsii. Hooker.
S. Taylori. Berkeley.
S. Gunnii. Berkeley.
Kentrosporium microcephalum. Wallroth.
K. mitratum. Wallroth.
Isaria eleuteratorum. Nees.
I. floccosa. Fries.
I. strigosa. Fries.
I. arachnophila. Dittmar.
I. leprosa. Fries.
I. Tartarica. Wallroth.
I. crassa. Persoon.
I. sphecophila. Dittmar.
I. exotela. Fries.
I. aranearum. Schweinitz.
I. sphyngum. Schweinitz.
I. gigantea. Montagne.
C. In the Intestines.
Mouliniea chrysomelæ. Ch. Robin.
M. cetoniæ. Ch. Robin.
M. gyrini. Ch. Robin.
Leptothrix insectorum. Ch. Robin.
Genus *Eccrina.* Leidy.
E. longa. Leidy.
E. moniliformia.
Cladophytum comatum. Leidy.
Anthromitus cristatus. Leidy.
A. nitidus. Leidy.

VII. The Myriapoda.
A. In the Intestines.
Enterobryus elegans. Leidy.
E. spiralis. Leidy.
E. attenuatus. Leidy.
E. Juli-terrestris. Ch. Robin.

VIII. The Mollusca.
A. On the Vesicle of Slugs. (Algue indéterminée, Lebert.)
B. The Eggs. *Saprolegnia ferax.* Kützing.

The most interesting of these species are undoubtedly those which attack man or the animals which he domesticates and employs. With the exception of the *Botrytis* of the silk-worm, the latter have not been much investigated. Those which attack man, and accompany diseased conditions of his body, are better known. They may be divided into those which are found on the skin, and those which are attached to or found in the secretions of the mucous membrane.

I. *Entophyta* of the Skin.—Ten species have been noted in this locality. We shall enumerate them in the order in which they are given by M. Robin.

1. *Trichophyton tonsurans* (Malmsten); *Trichomyces tonsurans; Mycoderma* of the *Plica Polonica;* fungus of the hairs in *Herpes tonsurans*, fungus of *Porrigo scutulata, Achorion Lebertii;* fungus of the *Teigne tondante*, Bazin; *Rhizophyte*, Gruby. This fungus was discovered and described in 1844 by Gruby in the disease called by the brothers Mahon *Teigne tondante*, by Cazenave *Herpes tonsurans*, by Erasmus Wilson *Trichoses furfuracea* (one of the diseases called Ringworm and *Porrigo scutulata* in this country). It exists also, as pointed out by Gunsberg, in the *Plica Polonica*, although the two plants were formerly described as different. The *Tricophyton* is formed by oval transparent spores, which give rise to articulated filaments. Its anatomical seat is in the interior of the roots of the hairs. The hairs and fungi simultaneously increase. The former seem larger than usual, are paler in colour, lose their elas-

ticity, soften, and break off when they have risen some one or two lines above the surface of the scalp. In the short cylinder then left the fungus grows still more rapidly, so that the normal structure of the small stump of hair soon becomes indistinguishable. Sometimes the hair breaks off before emerging from the skin, and the fungus, epidermis, and sebaceous matter, fill the ends of the piliferous conduits, and form the little prominences which can be seen by the naked eye in this disease, and give the skin a rough anserine appearance. The sporules and mycelium of the plants can sometimes be seen, in the form of a white powder, on the roots of the broken hairs. Sometimes the cutis becomes congested and thickened, and then the plant is mixed up with scales of epidermis, with fatty and albumenoid granules, with pus, &c., and crusts are formed of greater or less thickness in which the growth of the fungus can go on. Messrs. Robin and Bazin adopt unreservedly the opinion that the *Trichophyton* is the cause of the disease known under the various names above given, and each has given examples of the contagion of the disease by the transmission of the spores. Bazin has made the very important observation that the same disease will attack horses, and can be communicated from them to men. Both Robin and Bazin however admit that there is some condition of the hairs (dependent no doubt on constitutional causes) which is essential for the growth of the plant, as sometimes the disease disappears, that is, the fungus dies, without treatment. With respect to the name of the most common disease in which the *Trichophyton tonsurans* appears, the term used by Cazenave (*Herpes tondens*) is extremely unfortunate. No doubt vesicles are sometimes seen, and sometimes the cryptogamic disease succeeds to true *Herpes circinata* of the scalp, but in many cases there are no vesicles at all throughout the whole course of the disease. The term used in this country *Porrigo scutulata* is inconvenient as it is applied with greater justice to *Favus*. The old term of *Tinea* is after all by far the best, and the specific affix *tondens* expresses well one feature of the disease, the baldness arising from the brittleness of the hairs.

2. *Tricophyton (?) sporuloides* (Robin), (*Mycoderme* of the *Plica Polonica*). In addition to the former species, Walther describes in the *Plica Polonica* oval or circular flattened sporules, which have been too little studied at present to permit their exact characters to be stated.

3. *Trichophyton (?) ulcerum* (Robin). Lebert has described a fungus in the crusts covering an atonic ulcer of the leg.

4. *Microsporon Audouini* (Gruby). This plant has been studied by Gruby, and its existence, though denied by Cazenave, has been confirmed by Robin. It is present in the disease commonly called after Willan *Porrigo decalvans* or *Alopecia circumscripta*, or by Bazin, *Tinea achromatosa*. It differs from the *Trichophyton* of *Tinea tondens*, by its numerous waved filaments, and by the extremely small size of its sporules. It is not found, like the *Trichophyton*, in the interior of the root, but forms round each hair a little tube; the hair then becomes opaque, softens, and breaks off. The Alopecia is rapid, with or without vitiligo of the skin. The dermis is not congested, and the epidermis is thin and smooth. There is an affection which should probably be distinguished from the *Porrigo decalvans*, or *Alopecia circumscripta*, and which is characterised by a rapid disappearance of pigment from both skin and hair, with or without Alopecia. M. Bazin includes it in his *Tinea achromatosa*, but does not mention the fact that Alopecia is not constant. He states that a parasitic plant is present, but does not describe it. There must however be something more than a fungus to cause the total disappearance of pigment from a considerable portion of dermis. Besides, when the hairs return they are at first white, and only gradually regain colour; but if the vitiligo were owing to a plant, it is probable they would not grow at all. The disease appears to be allied to those obscure pigmentary changes which have a much deeper seat than the surface of the body.

5. *Microsporon mentagrophyta* (Robin), (*Mentagrophyte*, Gruby). This is a plant resembling the preceding, but possessing larger spores and filaments. It was discovered by Gruby in a case of mentagra, and has been since described by Bazin. Its seat differs from that of the preceding, and from that of the *Trichophyton*. It is between the bulb of the hair and the follicle in which the bulb is seated, and never extends beyond the surface of the skin.

6. *Microsporon furfur* (Robin). In 1846 Eichstedt discovered a cryptogamic plant in the disease called by Willan *Pityriasis versicolor*, and more lately *Chloasma*. Soon afterwards Sluyter described the same fungus, and lately Sprengler has described and figured it. It forms with the epidermic scales the yellowish-brown scurf seen in *Pityriasis*.

7. *Achorion Schœnleinii* (Remak), (*Oidium Schœnleinii*; *Mycoderma* of *Tinea favosa*; *Porrigophyte* (Gruby); Fungus of *Favus*. Schœnlein was the first to suggest that the honeycomb, or yellow favous crusts in the so-called *Porrigo lupinosa* (Willan) and *P. scutulata*, were constituted by a vegetable growth. This has been repeatedly confirmed, and many excellent descriptions have been given of the disease now called indifferently *Favus*, *Tinea favosa*, or *Porrigo scutulata*.

M. Robin believes he has discovered that the primary seat of the *Achorion* is in the depth of the hair follicle, against the hair, and, as well as we can understand the description, outside the layer of epithelium which covers the root of the hair, and which forms the 'inner root-sheath' of Kölliker. In this observation however he has been anticipated by Wedl, who has pointed out that by using a concentrated solution of liquor potassæ to make the parts transparent, the fungus is found in the follicle round the hair at the place where it passes through the epidermis. In addition to this, the plant is found in depressions on the surface of the skin, forming the yellow honeycomb-like masses which give the specific name *Favus* to the disease, and which from their frequent buckler-like shape suggested the term *scutulata*. The development of the *Achorion* in this situation is described by Robin after Remak and Lebert. A cuticular elevation is seen, beneath which is a small favus. When the cuticle is raised, a drop of pus sometimes issues: hence the error of those who have considered this disease always pustular. Generally however there is no pus or liquid of any kind. The plant grows, and the cuticle over it (supposing it has not been forcibly detached) finally separates, leaving the favus exposed to the air.

M. Bazin describes the *Favus* under three heads, which are fundamentally identical, and different only in respect of form:—

1. *Favus urceolaria dissemina*: this corresponds to the *Porrigo favosa*, *Favus dispersus*, and *Teigne alveolaire* of other authors.
2. *F. scutiformis*: this is the *Porrigo scutulata*, or *F. confertus*.
3. *F. squamosa*, a form usually called *scutulata*, but distinguished chiefly by the irregular distribution of the achorion, and by the furrowed masses formed by the fungus, the hairs, epidermis, and exudation.

8. *Puccinia Favi*. The achorion constitutes, with epithelium and a little exudation, the mass of the *Favus*; but it has been lately (1850) observed by Ardsten, of Christiania, that a different fungus, a species of *Puccinia*, is occasionally also present. Robin considers it to be only an epiphenomenon, and that it is certainly not present in all cases. The *Puccinia* is easily recognised. It has one extremity (the body) rounded, and composed of two cells of unequal size, a superior and an inferior. The other extremity is prolonged into a pointed stem or trunk.

There are still three other plants found upon the skin, which need merely be enumerated.

9. *Mucor*. In senile gangrene, an ill-described fungus, supposed to be the *Mucor mucedo* of Linnæus, has been seen on the sloughing mass.

10. *Aspergillus*. In the wax in the external meatus of the ear, Mayer many years ago described a fungus, and Paccini has lately made a similar observation—*Leptomitus*(?) of the epidermis. An *Alga* has been seen by M. Gubler in the epidermis of an arm which was irrigated for a long time to keep down inflammation after a gunshot wound. No one else has noticed it. Not only Messrs. Robin and Bazin, but Simon and others of the best dermatologists of Europe, have adopted the opinion that the plants are the actual causes of the diseases in which they are found. The contrary opinion is generally held in this country, on the grounds that fungi are generally the proofs and consequences of decay, but not its causes; that in the various forms of *Tinea* a special condition of the skin and hairs appears necessary for the growth of the plant; and that in *Tinea favosa* (*Favus*) in particular, a marked feature of the disease occasionally is an hyper-secretion of epithelium and exudation, owing to an hyperæmic cutis, before any trace of fungus can be found.

Nevertheless, these arguments, strong as they are, seem to be overborne by the two grand facts that *Tinea tondens* and

Tinea favosa can be communicated by transfer of the plant, and that the disease can be cured with the greatest readiness by the chemical agents which are most destructive to vegetable life. That a special nidus is necessary may very well be admitted by the partisans of this view, since even in the case of epidemic agents a predisposition is necessary; yet no one dreams of confounding the co-operating cause with the special and peculiar poison.

It may be desirable to recapitulate the diseases of the skin in which parasitic plants are found:—

1. *Tinea tondens*, in which the *Trichophyton tonsurans* is present.
2. *Tinea favosa*, in which are present the *Achorion Schœnleinii*, and the *Puccinia Favi* in some cases.
3. *Mentagra*, or *Tinea mentagra*, which exhibits the *Microsporon mentagrophyta*.
4. *Pityriasis versicolor* (*Chloasma*), in which the *Microsporon furfur* occurs.
5. *Porrigo decalvans* (*Tinea achromatosa*), in which the *Microsporon Audouini* is found.
6. *Plica Polonica*, in which the *Trichophyton tonsurans* and *Trichophyton sporuloides* are present.

II. *Entophyta* on the Mucous Membrane.—The plants forming on mucous membranes, or in the contents of cavities lined by mucous membrane, are of less interest than those which grow on the skin, as in most cases they are decidedly only secondary. We shall merely enumerate them:—

1. *Cryptococcus Cerevisiæ*, Kützing (*Torula Cerevisiæ*), the Yeast-Plant in the bladder, stomach, intestines, &c.
2. *Merismopœdia ventriculi*, Robin (*Sarcina*), in the stomach, intestines, &c.
3. *Leptothrix buccalis*, Robin (*Alga*), of the mouth.
4. *Oscillaria* of the intestines. (Farre.)
5. *Leptomitus urophilus*, Montague; an *Alga* described as forming in the urine. It has as yet been scarcely studied.
6. *Leptomitus* (?), Hannover, Robin; *Alga* found by Hannover in the pharynx and œsophagus.
7. *Leptomitus* of the uterus.
8. *Leptomitus* of the uterine mucus.
9. *Leptomitus* of the eye.
10. *Oidium albicans*, Robin (*Cryptogamiæ*) of diptheritis and aptha; Aptophyte. (Gruby.)
11. Fungus of the lungs. (Bennett.)
12. Fungus in the discharge of glanders.

To this list from M. Robin may be added the so-called Cholera Fungus of Brittan and Budd. It should however be added that no confirmation of the view originally taken by the discoverers, that the fungus discovered in the dejections of those affected with cholera was the cause of the disease, has been afforded. The only explanation that can be given of the occasional occurrence of the spores of fungi or spore-like bodies on the mucous membrane of the stomach and intestines, is their introduction with the food. It has been stated above that the spores of certain species of fungi are found naturally on grains of wheat, and only await favourable conditions for development. Such fungi may be constantly introduced into the stomach with the flour of wheat in the form of bread or other kinds of food.

"In the study of the vegetable parasites of animals, particularly those of the intestinal canals, it is necessary to be careful not to confound the tissues of certain well-known cryptogamic plants, which may serve as food or adhere to the ordinary food of such animals, with true *Entophyta*. Thus fragments of fungi, confervæ, lichens, and the spores of these, used as food, or adhering as foreign matter to food of an ordinary kind, are liable within the intestine to be mistaken for parasites.

"In mid-winter I found beneath an old fence-rail an individual of *Achela nigra*, or large black cricket, within the proventriculus of which were large quantities of what I supposed at the time to be a free floating Entophyte, resembling in general appearance the ordinary Yeast Fungus, *Torula*, but which I now suspect to be an ergot upon which the animal had fed. The plant consisted of oblong or oval vesicular bodies, apparently thickened at the poles, and filled with a colourless liquid; but this appearance more probably arose from the cells being distended with a single large, transparent, colourless, amorphous globule, which pressed a small existing amount of protoplasma to each end of the cavity. The cells were single, or in rows, to eighteen in number. Frequently a single cell of comparatively large size had an attached pair of cells, or rows of cells, at one or both ends. Occasionally they are met with containing one or two small round hyaline amorphous nuclei. The isolated cellules, measured from the $\frac{1}{2500}$th to the $\frac{1}{1666}$th of an inch in length by the $\frac{1}{5000}$th to $\frac{1}{6000}$th of an inch in breadth. The rows measured up to the $\frac{1}{500}$th of an inch in length." (Leidy.)

(Leidy, *A Flora and Fauna within Animals*; Robin, *Histoire Naturelle des Végétaux Parasites*; Bazin, *Recherches sur la Nature des Teignes, &c.*; Parkes, *Epiphytes and Entophytes*; *Brit. and For. Medico-Chirurgical Review*, 1853; *Journal of Microscopical Science*, vol. ii.)

ENTRE RIOS, one of the Riverine provinces of the Argentine Confederation, South America, owes its name to its situation between the rivers Paraná and Uruguay. It comprehends however only the southern part of the peninsula formed by those rivers, the northern portion forming the province of Corrientes. The boundary between the provinces is formed by the Rio Guayquirare, which falls into the Paraná, and the Mocoreta, which falls into the Uruguay, between 30° and 30° 30′ S. lat. The area is about 32,000 square miles. The population is about 25,000.

The surface is gently undulating; it is only broken by hills along the middle portion or interior of the country. This part is covered with forests of low stunted trees. The southern part of the province is low, and especially along the banks of the Paraná subject to inundations. The northern part is occupied by a low swampy tract, known as the Forest of Monteil. Besides the rivers Paraná and Uruguay, the province is abundantly watered by numerous small streams. The soil of Entre Rios is in general fertile, and covered with luxuriant herbage. The climate is mild and dry. Frost never occurs. Rain seldom falls more than fifty days in the year. The highest range of the thermometer at the town of Paraná during the year 1844-47 was 96° in January 1844; the lowest, 50°, occurred in the month of June in 1844 and 1846. (M'Cann.) Cultivation is limited to a comparatively few spots. The principal grain crops are wheat, barley, and maize. Tobacco and cotton of excellent quality are also raised, but the crops are precarious in consequence of frequent droughts. Great damage is also done to all kinds of crops by the immense swarms of locusts and ants, which sometimes devastate an entire district. The forest-trees are chiefly mimosas, nandubay, black and white espinello, guebracho, and guayiabo, but they are generally small, though in much request for carpenter's work and firewood. Vast herds of cattle are reared, but heavy losses frequently occur owing to the severe droughts to which the province is so often subject. In 1846 so great a drought occurred that the grass was everywhere burnt up; and Mr. M'Cann states that the whole of the cattle in the province went off from the feeding grounds in search of food and water: many estancias (cattle farms) lost from 5000 to 50,000 head of cattle, and one farm 150,000. Horses are bred in great numbers. Owing to the long-continued state of anarchy in the province there are, in the unsettled parts, numerous herds of wild cattle and horses. The rearing of cattle and horses is the chief occupation of the inhabitants. Mechanical employments are almost entirely neglected. The geographical position of the province admirably adapts it for commercial pursuits; but owing to the closure of the navigation of the two great rivers, and the disturbed state in which the country has so long been kept, comparatively little commercial progress has yet been made. Now however that the rivers are declared open to vessels of all nations, under the guarantee of the principal maritime powers, there seems to be required only internal peace for the development of the great capabilities of the country. The exports are principally of hides, horns, tallow, and jerked beef.

Like the other provinces of the Argentine Confederation, Entre Rios is a feudal state, owning but little dependence upon the central government. The government is almost entirely in the hands of a governor, elected for the term of two years. The Congress consists of deputies chosen from the several towns or districts. The revenue is derived chiefly from customs duties.

Except a few families of Guarini origin, the country is almost entirely inhabited by the descendants of Spaniards. In the towns however a few foreigners are settled, mostly Italians, who mainly conduct the river navigation, with some French and English traders. Some of the large estancias (cattle farms) and saladeros (tallow-melting establishments) are the property of and conducted by Englishmen.

Entre Rios took a leading part in the revolt against the supremacy of Buenos Ayres, joining with Corrientes in the engagements with foreign powers, which led to the fall of Rosas, and in all the subsequent proceedings which have had for their main object the opening of the rivers Paraná and Uruguay.

Paraná, or *Villa del Paraná*, the capital of the province, is about a mile from the left bank of the Paraná, in 31° 45′ S. lat., 60° 47′ W. long., and contains about 6000 inhabitants. It is built on the summit of a lofty cliff, which slopes gently towards Santa Fé, which stands on the opposite side of the river, and hence the town derived its original name, Bajada de Santa Fé, or the 'Descent to Santa Fé.' The only public building of any consequence in Paraná is the recently erected government house. A large church which was commenced some years back remains unfinished. The climate is mild and dry, but not healthy. The houses have no fire-places; and all classes live much in the open air. The supply of water is very bad; all that is consumed is brought to the town in carts drawn by oxen. The town at present has a quiet listless appearance. Only a few small vessels belong to it. The exports are hides, hair, tallow, and lime.

Concepcion de la China, formerly called Uruguay city, on the Uruguay, is a small but old town of about 1500 inhabitants. It once carried on some trade with Monte Video, but it is now decayed and ruinous. The houses are mostly built of wood and mud, with thatched roofs. In the centre of the Plaza is a pyramid now falling to pieces. In the vicinity is a large saladero. *Concordia*, on the Uruguay, opposite Salta, from a village of a few mud huts, appears to be growing into a place of some importance. It has about 1000 inhabitants, and carries on a good deal of trade. But the situation is bad, as vessels are unable to reach the town at low water, and are obliged to anchor about two miles below it. It contains a church and a large school-house, endowed by the government. *Gualeguay*, on the river of the same name (33° 10′ S. lat.), is a town of between 2000 and 3000 inhabitants, of whom nearly 300 are foreigners, chiefly Basques and Italians. It is a place of a good deal of trade, but vessels cannot approach nearer than about three leagues from the town. In the neighbourhood is the most extensive estancia in this part of the country, belonging to an English subject. It is the property of Mrs. Brittain of Sheffield, and occupies 200 square leagues of land. Several other estancias belonging to English subjects are in the vicinity. *Gualeguay-chu*, near the mouth of the Gualeguay-chu, about 60 miles E.N.E. from Gualeguay, population about 2500, including nearly 300 foreigners, contains a neat church and a good school-house, and is a place of some trade; but the situation is inconvenient, as vessels drawing more than 6 feet of water are sometimes obliged to wait two or three weeks to get across the bar at the mouth of the river. In the neighbourhood are some large tallow-melting establishments.

(Woodbine Parish, *Buenos Ayres*; M'Cann, *Ride through the Argentine Provinces*.)

EPERVA, a genus of Plants belonging to the natural order *Fabaceæ*. It has four thick and concave sepals connected together into a permanent urceolate tube at the base, with the sides incumbent, the upper one the broadest. It has but one petal, which is roundish, fringed, and inserted in the middle of the calyx. There are 10 stamens, which are long thickened filaments, rather villous at the base, and joined into a short monadelphous ring. The ovary is stipitate. The style long and filiform. The legume compressed, dry, coriaceous, falciform, 2-valved, 1- to 4-seeded. When young it is tomentose.

E. falcata is a tree with abruptly pinnate leaves, bearing 2 or 3 pairs of ovate acuminated shining leaflets. The panicle is pendulous on a long peduncle, constantly composed of numerous distant racemes. It is the Wallaba-Tree of Guyana according to Sir Robert Schomburgk, who informs us that its wood is deep red, frequently variegated with whitish streaks, hard, heavy, and shining, and impregnated with an oily resin which renders it very durable. The bark is bitter, and is used by the Arawaak Indians as an emetic.

EPSOMITE. [MINERALOGY, *S.* 1.]
EQUIDÆ. [HORSE.]

EQUITY. The proceedings of the Courts of Equity have been greatly simplified and cheapened by several recent statutes, founded on the first report, presented in 1852, of the Commissioners appointed to examine this subject in 1850. Instead of the writ of *subpœna*, which merely gave the defendant notice of a bill having been filed but afforded him no information of its contents, the bill itself, in a convenient printed form, is now served upon the defendant, either personally, or by being left at his house; or under special circumstances with some other person (as for instance, the solicitor or agent of the defendant) as his substitute. In default of appearance, the plaintiff may proceed against an *unprivileged* person, by having an attachment issued against him; against a privileged person, as a peer, or member of parliament, by a sequestration of his property; against a corporation, by a *distringas* and sequestration if necessary. Another course is, however, open to the plaintiff. Instead of proceeding by way of attachment and sequestration, he may *enter an appearance* for a defendant not appearing within eight days after the service, and thereupon proceed to judgment and execution.

Until the recent alterations, every bill in chancery contained what is called the *interrogating part* in which every statement and charge in the bill was converted into a series of questions, framed on the principle that the defendant might possibly be a dishonest defendant, disposed to answer evasively, and therefore suggesting modifications of the statement or charge. For example, if the statement were of a deed bearing a certain date, and made between and executed by certain parties in certain words, or to a certain effect, the questions would be, whether such a deed of that date, or of some other and what date, was not made between and executed by such parties, or some and which of them, or some other and what parties, in such words, or to such effect, or in some other and what words, or to some other and what effect. Originally these interrogatories were used much more sparingly, and were confined to those matters supposed to be within the knowledge of the defendant, as to which it was considered necessary or desirable to extract admissions from him. But in course of time the practice was altered, and the easier process was adopted of transmuting all the statements into questions of the nature above described. The length of the proceedings and the expense to all parties concerned were thereby greatly increased. There is now no interrogating part in any bill: but where the plaintiff requires an answer from any defendant or defendants to a bill, he may file interrogatories for their examination.

The demurrer, plea, or answer of the defendant to the bill, each remain very much as before;—except that the answer is no longer taken with the expensive formalities which used to accompany it. Formerly a *dedimus potestatem* or commission was issued to take the answer and oath of a defendant in the country, which was sealed up, and either brought by one of the commissioners to the court, or sent by a messenger, who swore he received it from one of the commissioners, and that the same had not been opened or altered since he received it. The answer is now however filed without further formality than in swearing and filing affidavits; and it may be sworn before any judge, court, notary public, consul, or vice-consul, lawfully authorised to administer oaths, the messenger's oath being dispensed with.

In many cases, indeed, when the facts in dispute between the parties are few and not of a complicated character, an answer is not now requisite. Affidavits may be filed by the plaintiff and defendant, upon which the Court will determine the case, unless it be thought proper, in addition thereto, to examine or cross-examine the parties orally.

The practice which formerly prevailed of examining witnesses on interrogatories, having been found in many respects very inefficient and objectionable, has also been abolished; the court retaining the power to order particular witnesses to be examined upon interrogatories, according to the old practice.

When therefore a suit commenced by bill is at issue, the plaintiff may give the defendant notice of the mode in which he desires the evidence to be adduced, namely, *orally* or upon *affidavit*; and if either party give no such notice, or if giving such notice, he expresses his desire that the evidence be adduced upon affidavit, then both plaintiff and defendant may verify their respective cases by affidavit, unless the defendant gives notice to the plaintiff that he desires the evidence to be taken orally. If evidence is to be thus taken, the witnesses are examined by or before one of the regular examiners of the court, or an examiner specially appointed if necessary. The principal defect in the old mode of examining witnesses was, that the examination being secret, and upon *written* interrogatories, the cross-examination being conducted in the same manner, the party cross-examining laboured under the disadvantage of not knowing what the witness had deposed to in his examination in chief; under the modern system, the *oral* examination of witnesses takes place in the presence of the parties, their counsel, solicitors, or agents;

and the witnesses are then and there subject to cross-examination and re-examination. Every deposition is taken down in writing by the examiner in the form of a narrative, and read over to the witness, and signed by him, in the presence of the parties. When concluded, the examiner transmits the original depositions to the Court, and the cause is then ripe for the hearing.

Another important change in equity procedure relates to the determination of questions of *law*, as distinguished from *equity*. Formerly, if a question of this nature arose in the course of a cause, it was the practice of the Court to refer it to the opinion of the judges of the Courts of Common Law, upon a case stated for that purpose; who certified their opinion to the chancellor, upon which certificate the decree was usually founded. The court must now itself determine any questions of law which require to be decided previously to the decision of the equitable question at issue between the parties; for which purpose any of the courts may obtain the assistance of the judges of the Courts of Common Law.

A shorter and simpler method of proceeding than that by Bill and Answer was introduced in the year 1850, namely, that of *Claims*. This plan was only intended to be used in certain definite cases of comparative simplicity; and subsequent legislative enactments have so much improved the mode of proceeding by *Bill*, that the advantage of having recourse to a *Claim* is not now so great as when that procedure was first introduced, and in many cases a Bill according to the new system is found to be far preferable. Claims are indeed nothing but short bills, without any interrogatories, the merits of which are to be decided upon affidavits on each side; every order made on the hearing of which has the same effect, and may be enforced as a decree in a suit commenced by *Bill*. Orders made on claims may also be discharged, varied, or set aside upon motion; and any order of the Master of the Rolls, or any of the Vice-Chancellors, may be discharged or varied by the Lord Chancellor or the Court of Appeal in Chancery.

A still more summary method of proceeding has been introduced, by the statute 15 & 16 Vict. c. 86, applicable to similar cases of administration. Any person claiming to be a creditor, legatee, or next of kin of a deceased person, may obtain a summons from the Master of the Rolls or any of the Vice-Chancellors, requiring the executor or administrator of the deceased person to attend and show cause why an order for the administration of the estate of the deceased should not be granted.

Upon proof of the due service of such summons, or on the appearance of such executor or administrator, and upon proof by affidavit of such other matters, if any, as the judge shall require, the judge may make an order for the administration of the estate of the deceased, with such variations, if any, as the circumstances of the case may require; and the order so made is to have the force and effect of a decree to the like effect made on the hearing of a cause or claim between the same parties.

A *special case* may also be filed, in order to obtain the opinion of the Court upon the decision of any question under Sir George Turner's Act, 13 & 14 Vict. c. 35; but as the Court can now make a merely declaratory decree, under 15 & 16 Vict. c. 86, the same end may be more conveniently obtained, in most cases, by a short Bill without interrogatories.

These are the principal alterations in the procedure of our Courts of Equity; some minor details of practice in which changes have been effected, it would be out of place to enlarge upon.

ERICSSON, JOHN, Engineer, a native of Sweden, but whose inventions have been brought before the scientific world in England and America, was born in the province of Vermeland in 1803. In 1814, by the friendship of Count Platen, who observed his mechanical tastes, he obtained a cadetship in a corps of Engineers. He subsequently entered the regular army as an ensign, and at length reached the rank of lieutenant. In 1826 he visited England in order to bring into notice a new kind of engine which he had invented, and which he proposed to work without steam, by the condensation of flame. The project failed from the impossibility of procuring suitable fuel for the engine. He competed for the prize which was offered by the Liverpool and Manchester Railway Company in 1829, for the production of the best locomotive, and presented an engine which went at the rate of fifty miles an hour. Ericsson's subsequent career lay chiefly in America. In the Great Industrial Exhibition of London in 1851, several instruments for the measurement of distances at sea, for measuring fluids under pressure, and other similar purposes, appeared in the American department under Mr. Ericsson's name, and were described by him in a small work which he issued at the time. His name is chiefly known in connection with a project for a caloric engine, which was to supersede steam, an object which, if accomplished would, by removing the necessity of carrying large cargoes of fuel, have effected a great commercial change in the intercourse between distant parts of the globe. As the principle did not obtain the sanction of the scientific men to whom the British government referred its consideration, Mr. Ericsson tried it in America, and obtained sufficient co-operation to enable him to launch a vessel named after himself, and measuring 2000 tons. This vessel made a trial trip, in which she sailed at the rate of twelve miles an hour, but on her return she was struck by a squall, filled, and foundered close to the city of Jersey. The Ericsson was subsequently raised, and the caloric engine was replaced by a steam engine, which possessed some improvements invented by Mr. Ericsson. Mr. Ericsson was a member of numerous scientific societies and a knight of the Swedish order of Vasa. He died on the 2nd of November, 1853.

ERINITE. [MINERALOGY, *S.* 1.]

ERLANITE. [MINERALOGY, *S.* 1.]

ERROL. [PERTHSHIRE.]

ERROR, IN LAW. The mode of appealing from the judgments of the Courts of Common Law to the appellate tribunals constituted to rectify their mistakes by bringing error, as it is technically termed, has been greatly simplified by the Common Law Procedure Acts of 1852 and 1854. These statutes have abolished writs of error in civil suits, and substituted for them a simple notice or memorandum of error, to the opposite party and to the Court, of the appeal having been made. The statutes have likewise extended and in so doing improved the jurisdiction of the Courts of Error. Formerly judgment could only be affirmed or reversed; but the Court of Error may now give the judgment which ought to have been given by the Court below, and award all necessary process for giving effect to it.

ERYTHACA, a genus of Birds belonging to the family *Sylviadæ*, the order *Insessores*, having the following characters:—Beak rather broad and depressed at the base, becoming narrower towards the point, and slightly compressed; upper mandible deflected and notched. Nostrils basal, lateral, oval, pierced in a membrane partly hid by feathers and hairs projecting from the base of the beak. Wings rounded; the three exterior quills graduated; the first only half as long as the second, which is shorter than the third; the fourth, fifth, and sixth longer than the third; the fifth the longest in the wing. The tarsus longer than the middle toe; the lateral toes nearly equal to each other in length; the outer toe united at its base to the middle toe; the claw of the hind toe longer and stronger than the others.

E. rubecula, *Sylvia rubecula*, *Motacilla rubecula*, the Robin Red-Breast, Robin-Redstart, Robinet, Ruddock, is so generally distributed over the British Islands, and so universal a favourite, that all are sufficiently interested in the bird to make themselves acquainted with its habits. These may be observed in any garden, field, or wood, for there is scarcely a hedge without its Robin inhabitant, and if Robins appear to be more numerous in winter than in summer, it is partly owing to the state of vegetation at the former season, which leaves them more exposed to observation, and partly because they resort to the habitations of men for food, when other means of supply fail. The song of the Robin is sweet and plaintive, but not very powerful. Mr. White of Selborne says, "The Robin sings all through the year. The reason that he is called an autumn songster is, because in the spring and summer his voice is lost in the general chorus, while in the autumn it becomes distinguishable."

The Robin is one of the latest birds to retire to rest, and the earliest to be seen moving in the morning, requiring apparently but little sleep."

This bird is very easily tamed, soon becomes familiar with those who feed it, and constantly builds its nest in places frequented by man.

Mr. Blackwall relates that a pair of Robins built their nest in a small saw-pit. Soon after the hen had begun to sit the sawing of timber was commenced at this pit, and though this noisy occupation was carried on every day close to the nest during the hatching of the eggs and rearing of the young birds, the old birds exhibited no signs of alarm or interruption. These birds exhibit great attachment to each other, and many instances have been related to prove that they pair for life. With all his interesting qualities the Robin is one of the most pugnacious of birds, and not only maintains his right against all intruders, but is said to kill those of his own family when they become troublesome to him. Robins breed early in the spring. The nest is composed of moss, dead leaves, and dried grass, lined with hair, and sometimes a few feathers; it is frequently placed on a bank sheltered by brushwood, or a short distance above the ground in a thick bush or lane hedge, sometimes in a hole of a wall partly covered with ivy. The eggs are from five to seven in number, white, spotted with pale reddish-brown; the length nine lines and a half, by seven lines and a half in breadth. The bird is found all over England, Ireland, and Wales; it is also an inhabitant of the most northern counties of Scotland. It also visits Denmark and Sweden in the breeding season; and so well does it bear cold weather, that among the summer visiters to the latter country, the Robin is one of the first to come and the last to go.

It is a constant resident throughout the year in all the temperate and warmer parts of Europe, abundant in Spain and Italy, Sicily and Malta.

In the adult bird the beak and irides are black, upper part of the head, neck, back, upper tail-coverts, and tail-feathers, a yellowish olive-brown; quill-feathers rather darker, the outer edges olive-brown; greater wing-coverts tipped with buff, over the base of the beak, round the eye, the chin, the throat, and the upper part of the breast, reddish-orange; encircling this red is a narrow band of bluish-gray, which is broadest near the shoulders; lower part of the breast and belly white; sides, flanks, and under tail-coverts, pale brown; under surface of wing and tail feathers dusky gray; legs, toes, and claws, purple brown. The whole length of the bird is $5\frac{3}{4}$ inches. The female is not quite so large as the male, and her colours are less bright. The young birds, after their first autumn moult, resemble adult females; but the red of the breast is tinged with orange, and the legs are dark brown. The Red-Breast is subject to variation in the colouring of the plumage. White and partly white varieties are not uncommon.

ETTY, WILLIAM, R.A., was born at York, March 10, 1787. His father rented a mill in the suburbs, and kept a baker's shop in the city; and the boy assisted in the shop till he was of age to be put to learn a trade. He had already shown a marked fondness for drawing, and his mother, as in after-life the great painter was fond of relating, had encouraged his propensity, while neighbours used to 'patronise' the incipient artist with halfpence and pennies to buy chalk and pencils. In his twelfth year he was apprenticed to a printer at Hull, in which situation, over-worked, without friends and distant from his family, and denied the privilege of drawing, he appears to have at first led a very uncomfortable life. But after awhile his master was persuaded to let the boy "at lawful hours" indulge his artistic tastes, and, though still without instruction, Etty soon began to acquire sufficient facility in drawing to make his companions in the printing-office desirous to possess, and some of them careful to preserve, his sketches and rude attempts at painting. At length, his seven years' apprenticeship having expired, he gladly obeyed the invitation of an uncle to come up to London. His uncle, himself a skilful draughtsman, saw promise in the youth's crude efforts, and generously afforded him the means of practically solving the question whether his inclination for the life of a painter was an impulse merely, or the result of a native aptitude.

At first, without any formal instruction, he drew, as he says in his 'Autobiographical Sketch,' "from prints, or from nature, or from anything he could; . . . his first academy being a plaster-cast shop, kept by Gianelli, near Smithfield." Having thus sufficiently mastered the difficulties of drawing "from the round," he obtained an introduction to Fuseli, then keeper of the Royal Academy, and was admitted by him to study there as a probationer. He entered as a student in January 1807, along with Collins, from whose companionship in study, with that of Hilton and Haydon, he derived considerable benefit. In the following July Etty became an in-door pupil for twelve months to Sir Thomas Lawrence, then in the height of his reputation—Etty's uncle kindly paying the hundred guineas required as a premium. From the great portrait painter Etty received little direct instruction; he however saw him paint, and though at first the extreme facility of the master's execution almost overwhelmed the pupil with despair, he gradually learnt this very important part of a painter's craft—"the great key to art," as he calls it; and he found, when he could copy Lawrence's pictures, that those of other painters, including the great painters of Italy, presented comparatively few difficulties. Etty laboured with untiring diligence in the school of the Royal Academy, and in copying at the British Institution and elsewhere, whilst preparing his earliest original works for the Academy Exhibition; but though his copies met with purchasers, and his original efforts with praise, it was long before he could find an opportunity to bring any of his works before the public. Year after year all the pictures he sent were returned from both the Royal Academy and the British Gallery. He applied in his despondency for advice to his old master. "Lawrence," he says, "told me the truth in no flattering terms; he said I had a very good eye for colour, but that I was lamentably deficient in all other respects almost." Etty took the reproof in good part, worked day and night, "and with such energy, to cure his radical defects, that at last a better state of things began to dawn." He had the delight to find one of his pictures, a 'Telemachus rescuing Antiope,' admitted to a place on the walls of the Royal Academy in 1811. But the place was a bad one, and the picture attracted no notice. However he went on, and at each succeeding exhibition of the Academy and the British Institution some of his paintings found a place. His subjects, with the exception of a few portraits, were mostly classical, though not of the kind by which he ultimately acquired fame and fortune; and the impression among his companions in the schools—where he was still one of the most regular attendants—as well as among artists and patrons, was, that he was a good-tempered plodding fellow, but would never become a successful painter. His friends suggested a visit to Italy, and for Italy accordingly—intending a year's stay in the land of Art—he set out in the autumn of 1816. But he soon became home-sick—moreover one of his oft-recurring love-fits—for "one of my prevailing weaknesses was a propensity to fall in love"—was strong upon him, and within three months he was back again and hard at work in London.

But his run into Italy, and still more a short stay among the painters of Paris, did him good service. He saw a new style of art, and new methods of execution, and had a fresh range of subjects suggested to his mind. It was not however till some three or four more years had passed away that he began to catch the eye of the artistic world. In 1820 he says, "I sent a small picture to the British Gallery, highly finished and carefully wrought; it made a considerable noise. I sent a larger the same year to the Royal Academy; it made a still greater noise." This last was the 'Coral Finders—Venus and her youthful Satellites arriving at the Isle of Paphos,' the first of his long series of representation of the undraped feminine form, for which Grecian and Roman poetry or legend suggested the subject or furnished the apology. This was followed the next year by his 'Cleopatra's arrival in Cilicia,' a work far more glowing in colour, skilful in composition, and brilliant in general effect; and its success was complete. The painter at once became famous. It was commissioned by Sir Francis Freeling, who, however, startled by the then unusual freedom with which the painter had depicted his bevy of fair forms—for Etty, reading as literally as possible the statement that Cleopatra appeared in the character of Venus, with her attendants as Nereides, Graces, Cupids, and Tritons, had rendered the voluptuous subject with infinite gusto—besought the painter to add a little drapery; and, though he never added too much, the hint was not lost, for while, during the rest of his life the nude female form continued to be the chief subject on which he exercised his pencil, he henceforth seldom suffered one to appear without some, however scant and unserviceable, clothing.

After this great success Etty resolved again to visit Italy, and though he this time also carried with him a new love sorrow, he did not suffer himself again to return without seeing Rome. There, and at Venice, where he stayed seven months, he laboured with a diligence and copied with a rapidity and decision of execution, which astonished the degenerate native painters; and the effect of his studies of the great Venetian colourists was displayed in every picture he subsequently executed. On his return he painted a 'Pandora crowned by the Seasons,' which at the exhibition of 1824 won for him new laurels, had the singular honour of being purchased by the President, and procured his election as Associate of the Royal Academy. "Strike while the iron is hot; you see what may be done by a little courage," was the advice now tendered by his old master, and Etty profited by the well-timed counsel. A succession of important works followed, some of large size and in the historical style, but mostly classic subjects of the order indicated above, and each succeeding one,—until he became careless or negligent under the pressure of competing patrons claiming ever new pictures from him,—contributing its share towards placing him in the position he ultimately obtained by general consent of the first English colourist of his day, and also by far the first English painter in his own peculiar walk of any day.

His life was a very quiet one. His days were almost entirely spent in London and in his painting-room—the only breaks being an occasional visit to a friend in the country, a run to Edinburgh or to the Netherlands, and a brief stay on account of illness at York. His evenings he passed, during the academic session, almost invariably in the Life School at the Royal Academy, where to the last he was one of the most regular and diligent among the students—it being his practice to paint studies in oil from the living model as shown there by gas-light—a practice which explains much that is evil as well as good in his painting of flesh: and so much attached was he to the Life Academy, that when it was formally suggested to him from the academicians, in prospect of his election as R.A. in 1828, that those gentlemen wished him to discontinue his attendance, as they deemed his taking his place among the students incompatible with the dignity of an academician, he replied that he would rather forego that honour, though the chief object of his ambition, than give up the Life Academy. Though always in love, Etty never married. A niece kept his house, and his quiet and blameless life passed on without adventure, in the steady practice of his calling, till 1848, when failing health and powers induced him to return to his native city; where in a pleasant little house his remaining days, with the exception of his visits to London, passed in almost unbroken tranquillity. He died there on the 13th of November 1849, and was buried in the churchyard of St. Olave Marygate; his funeral being attended by a large number of the citizens, headed by the mayor and other municipal authorities, with the Council of the Yorkshire Philosophical Society, the pupils of the York School of Design (in the establishment of which he took an active part), &c.

We have not attempted to record the appearance of more than a few of Etty's earlier pictures. To have mentioned in succession even the more attractive of the works of so prolific a painter during his career of nearly forty years would have been manifestly impossible here. The great event of his life was the collection of as many of his works as could be obtained, and their exhibition in 1849, in the rooms of the society of Arts, and on that occasion were exibited about 130 paintings, many of them of very large size. Few who saw that remarkable gathering will be likely to forget it, and the painter may well have felt proud as he gazed on so splendid a spectacle—and all the work of his own right hand.

Etty has himself, in the 'Autobiography' so often quoted, given a list of his principal paintings. And first he places of course his great historical pictures, his account of which will serve in some measure to illustrate the peculiar character of the man:—"My aim in all my great pictures has been to paint some great moral on the heart: 'The Combat,' the *Beauty of Mercy;* the three 'Judith' pictures—*Patriotism,* and self-devotion to her country, her people, and her God; 'Benaiah, David's chief Captain,' *Valour;* 'Ulysses and the Syrens,' the importance of resisting *Sensual Delights,* or an Homeric paraphrase on the 'Wages of Sin is Death;' the three pictures of 'Joan of Arc,' *Religion, Valour, Loyalty and Patriotism,* like the modern Judith; these in all make nine colossal pictures, as it was my desire to paint three times three." Of his other principal works the following may be mentioned as characteristic examples:—'The Judgment of Paris;' 'Venus attired by the Graces;' 'Hylas and the Nymph;' 'The Bevy of Fair Women;' 'The Rape of Proserpine;' 'La Fleur-de-Lis;' 'The Parting of Hero and Leander;' 'Diana and Endymion;' 'The Death of Hero and Leander;' 'The Graces;' 'A Bivouac of Cupid and his Company;' and numberless Cupids and Psyches, Venuses, Ledas, or as he more prudishly terms them 'Nymphs with Swans,' &c.; besides his 'Samson and Delilah;' 'Magdalen;' 'Captives by the Waters of Babylon;' 'Parable of the Ten Virgins;' and other scriptural subjects treated in a very unpuritanic style. The 'Judith' series, the 'Combat,' and 'Benaiah,' five colossal pictures magnificent in colour and execution, and in many respects admirable in conception and composition—even if they are not fairly to be classed in the highest style of historic art,—were purchased in a fine spirit by the Royal Scottish Academy; 'Ulysses and the Syrens' is the property of the Royal Manchester Institution. In the Vernon Gallery are eleven paintings by Etty, of which the chief is his 'Youth at the Prow and Pleasure at the Helm;' and in the Sheepshanks Collection are two others.

Etty is undoubtedly one of the greatest names in English art. He chose for himself a somewhat remarkable path, and in it he walked without a rival. His want of classical knowledge—his learning being pretty nearly confined to Lemprière's Dictionary—together with his deficiency in every kind of intellectual culture, except in the technics of painting, of course militated against his taking a first rank as a painter of classic themes. All his works evince his want of acquaintance with the history, the archæology, and even with the poetry of Greece and Rome. But, allowance being made for these deficiencies, or rather regarding his pictures as the mere vehicles for the exhibition of the undraped human form, his paintings must be allowed a very high place in comparison with those of any other modern painter.

To the highest order of female beauty either in face or form he never attained—hardly pretended; yet there is evidenced in all his female figures such a thorough sense of enjoyment, so much life and heartiness, and, looking at them as pictures, there is shown so remarkable a knowledge of the female form, and such facility in rendering it in free spontaneous action, as few if any modern artists of any country have equalled, and none even in olden times surpassed.

Etty towards the close of his life seems to have become especially disturbed by the strong remarks occasionally made on his choice of subjects, and still more on his mode of treatment. He seems to have thought (and his admirers have spoken as though they thought so too), that the objections raised to so free a display of the female form on the score of morality, was in fact an implication that the painter was immoral. But no such charge could have been intended by any one who knew anything of the painter. Few men in private life have given less occasion to the breath of scandal. He was scrupulously upright, sober, and pure. An enthusiast in his art, he was one of the most single-minded of men; but it was not to be wondered at that the painter of works so opposed to the current notions of propriety should have had to bear with some hard judgments on the tendency of his works. He sought to vindicate himself and his intentions with his pen as well as his tongue, but while personally he needed no vindication, the only vindication his pencil can receive must be that which the works themselves furnish.

EUCHROITE. [MINERALOGY, *S.* 1.]

EUGENINE. [CHEMISTRY, *S.* 2.]

EULIMELLA, a genus of *Mollusca* belonging to the family *Pyramellida,* founded by E. Forbes, to receive forms that had been previously referred to *Eulima* and *Odostomia.* The shell is elongated, and consists of many whorls, solid, smooth, and polished; the apex of the spine has a persistent embryonic sinistral shell; the aperture subquadrate; peristome incomplete; columella not plicated, straight or nearly so; operculum corneous, pyriform. There are four British species. *E. scillæ* (*Eulima crassula,* Jeffreys), *E. acicula* (*Melania acicula,* Philippi), *E. affinis* (*Eulima affinis,* Philippi), *E. clavula* (*Turbinella clavula,* Loven).

EUNICE, a genus of Dorsibranchiate *Annelida.* It is furnished with tuft-like gills; the trunk is armed with three pairs of horny jaws; each of the feet has two cirri and a bundle of bristles; two tentacles upon the head above the mouth, and two on the neck.

E. gigantea is the largest Annelide known. It attains a length of from one to four feet, and inhabits the sea around the Antilles.

EUPATORIA, previously named *Kozloff*, a sea-port town in the Russian government of Taurida, on the west coast of the Crimea, is situated on the north shore of the Bay of Kalamita, in about 45° 14′ N. lat., 33° 25′ E. long., 40 miles N.W. from Simpheropol the capital of the Crimea, and 45 miles N. by W. in a straight line from Sebastopol. The population according to the census of 1851 was 8200, chiefly Tartars and Karaitic Jews, with a few Greeks and Armenians. The port is shallow, admitting only vessels of about 8 feet draught, but tolerably safe and never frozen up. The bay forms an excellent road-stead, and ships may approach within cable's length of the shore, but it is exposed to the west and south winds which cause a heavy surf all along the coast. The town, which is surrounded by an old crumbling wall, is ill built; the streets are narrow, crooked, and dirty; the houses, low and built of bricks and clay, open upon courts or gardens in the Turkish fashion, but present to the street only low dead walls. The principal buildings are a Russo-Greek church, several mosques, an Armenian church, two pretty synagogues belonging to the Karaitic Jews, a bazaar, several khans, and the house in which the governor of the district resides. The principal industrial products are leather, felt stuffs, and wood-work. The town is famous for the preparation of the black lambskins, known in England as 'Astrakhans.' There are several shore-lakes to the south-east of the town on which a good deal of salt is gathered in summer. The water in the town and neighbourhood is bad. Before the Russian occupation of the Crimea, Eupatoria, it is said, had a population of 30,000, and was the centre of all the export trade of the country. In order to restore the prosperity of the place it was made a free port for a limited period from the year 1798, and its trade partially recovered, but subsequently dwindled away on the rise of Odessa. It still carries on some trade in salt, corn, flour, bar-iron, wool, hides, butter, wax, hairskins, &c. There is a quarantine station at Eupatoria.

Eupatoria is said to occupy the site of the ancient *Eupatoria*, or *Eupatorium*, founded by Mithridates Eupator, and named after him. The Russians call it Eupatoria, but this is no proof that the two places are identical. Some authors say that the site of the ancient Eupatoria is marked by the village of Inkerman on the north shore of the Bay of Sebastopol, where there are ancient ruins. Be this as it may, Eupatoria under the Tartars was one of the most important and populous towns in the Crimea. The Russians took it in 1736, 1771, and in 1783, when with the whole of the Crimea it came into the power of the Czars. In the Anglo-French invasion of the Crimea the town was occupied by the Allies Sept. 13, 1854, and they held it till the termination of the war, when it was restored to Russia.

EUXENITE. [MINERALOGY, *S.* 1.]

EVIDENCE. Great and important changes have been made during late years in the Law of Evidence. Not only have the means of obtaining and producing evidence been simplified, and facilities in doing so afforded to the suitor; but all the former disqualifications of the parties to and of the persons interested in the result of the proceedings have been entirely removed. The most important practical improvements have been in our Courts of Common Law, the want of a complete discovery by the oath of the parties having formed till recently one of the greatest and most prominent defects in the procedure of these tribunals. Each of the parties was indeed entitled to have such a discovery, by going through the expense and circuity of a Court of Equity, and therefore it was sometimes had by consent, even in the courts of law. But as it had long been established in our Courts of Equity, and as it seemed to be the height of judicial absurdity, that in the same cause between the same parties, in the examination of the same facts, a discovery by the oath of the parties should be permitted in some courts, and denied in others, the same power of compelling a discovery was at last conferred on the Superior Courts of Common Law as were possessed by the Court of Chancery. A second defect in the procedure of the Courts of Common Law was of a nature somewhat similar to the first; the want of a compulsive power for the production of books and papers belonging to the parties. In the hands of third persons they can generally be obtained by rule of court, or by adding a clause of requisition to the writ of *subpœna*, which is then called a *subpœna duces tecum*. But, in mercantile transactions especially, the sight of the party's own books is frequently decisive; as the day-book of a trader, where the transaction was recently entered, as really understood at the time; though subsequent events may tempt him to give it a different colour. As this evidence might be obtained, and produced on a trial at law, by the circuitous course of filing a bill in equity, an original power for the same purpose was also conferred on the courts of law, by the statute 14 & 15 Vict. c. 99.

This power to compel a party, on the application of his opponent, to produce documents, can only be exercised, however, where the applicant can satisfy the court or judge applied to, that the document, of which he seeks the production, is in the possession of his adversary. If he cannot do so, his application must fail. He must, in such a case, obtain a discovery from his opponent, if he has, in fact, the documents of which inspection is sought, which he is enabled to do by the Common Law Procedure Act, 1854. Upon an affidavit of his belief that any document, to the production of which he is entitled, is in the possession or power of the opposite party, the party against whom such application is made may be ordered to answer, on affidavit, what documents he has in his possession or power relating to the matters in dispute, or what he knows as to the custody of such documents, and whether he objects (and if so, on what grounds) to the production of such as are in his possession or power. Upon this answer being made, the court or judge may make such further order as is just; for the party may have the documents, and yet have good grounds on which to object to their production.

Until recently the Courts of Common Law possessed no power of compelling the discovery by one party of *facts* exclusively within the knowledge of his adversary. Each party may no doubt be called as a witness by his opponent; but this does not meet the difficulty, for a party ignorant of what his adversary will swear, will not, except in the most desperate emergency, put so interested a witness into the box. For the discovery, previous to the trial, of facts as well as of documents, the party desiring it had formerly no alternative but to resort to a Court of Equity. The Common Law Procedure Act, 1854, now, however, enables either party, by leave of the court or a judge, to *interrogate* his opponent upon any matter as to which discovery may be sought, and to require such party to answer the questions, within ten days, by affidavit, sworn and filed in court. By thus affording an opportunity for the examination of the parties upon matters relating to the question in dispute, prior to the trial, *facts* important for the applicant's case, but exclusively in the knowledge of the opposite party, may not only be discovered, but the trouble and expense of producing evidence of facts which he is prepared to admit may be entirely saved; while such an examination may in some cases tend to make manifest the matter really in contest, and thus prevent further litigation.

With regard to *parol* evidence, or *witnesses*, the process to bring them in by writ of *subpœna ad testificandum*, now runs (by statute 17 & 18 Vict. c. 34), into Scotland and Ireland; thus dispensing with the necessity of a commission to examine witnesses, which issues when a witness is abroad, or so ill as to be unable to attend and give evidence.

With regard to witnesses, the general proposition now holds that all witnesses, of whatever religion or country, that have the use of their reason, are to be received and examined, for all such are *competent* witnesses; though the jury from other circumstances will judge of their *credibility*. The law formerly excluded such persons as were *infamous*, or were *interested in the event of the cause*. Infamous persons are such as may be challenged as jurors; interested witnesses might however have been examined upon a *voir dire*, if suspected to be secretly concerned in the event, or their interest might be proved in court: which last was the only method of supporting an objection to the former class: for no man was to be examined to prove his own infamy. The law thus carefully excluded not only the parties to the cause, but any one who had the most minute interest in the result; for every person so circumstanced, however insignificant his interest, was presumed incapable of resisting the temptation to perjury; as every judge and juryman was presumed incapable of discerning perjury committed under circumstances especially calculated to excite suspicion. But as it is perfectly obvious that any witness who can throw any light upon the subject, should be allowed to state what he knows (subject, of course, to such observation as might be made, either as to his means of knowledge, or his disposition to state the truth), the stringent rules of our former law have been gradually relaxed by a series of modern statutes. The first inroad on the systematic exclusion of evidence, which was the result of the former state of the law, was made by the statute 3 & 4 Will. 4. c. 42, s. 96, which has been already mentioned, and is only again referred to for the sake of regularity. This statute enacted that, "in order to render the rejection of witnesses on the ground of interest less frequent, if any witness should be objected to as incompetent, on the ground that the verdict or judgment in the action would be admissible in evidence for or against him, he should nevertheless be examined; but in that case the verdict or judgment should not be admissible for or against him, or any one claiming under him." A much greater improvement was, however, effected by the 6 & 7 Vict. c. 85, which removed incompetency on the ground of *interest* in all persons, *except the parties to the suit*, or the persons whose rights were involved therein, or the husband or wife of such persons. The advantages found to flow from this alteration in the law led to the statute 14 & 15 Vict. c. 99, by the first section of which the proviso in the statute 6 & 7 Vict. c. 85 (which excluded all persons directly interested in the suit) was repealed. By the second section, the parties are made *competent* and *compellable* to give evidence on behalf of either or any of the parties to the suit in any court of justice. The third section of the statute provides that it shall not render any person charged with an offence competent or compellable to give evidence against himself, nor shall it render any person compellable to answer any question tending to criminate himself, nor shall it in any criminal proceeding render any husband competent or compellable to give evidence for or against his wife, or any wife competent or compellable to give evidence for or against her husband. The fourth section of the statute further provides that it shall not apply to any proceeding instituted in consequence of adultery, or to any action for breach of promise of marriage. It was decided, soon after it had become law, that the *second* section of the statute did not render a wife admissible as a witness for or against her husband, and accordingly the statute 16 & 17 Vict. c. 83, was passed, enacting that the husbands and wives of the parties to any suit, or of the persons on whose behalf any such proceeding is brought or defended, shall thereafter be competent and compellable to give evidence on behalf of either party or any of the parties. Neither husband nor wife is compellable, however, to disclose any communication made or received during marriage; and neither party is a competent witness in a criminal proceeding, or in any proceeding instituted in consequence of adultery. By these several statutes all rules tending to the exclusion of evidence have been abrogated, except in the particular instances above mentioned. (Blackst. 'Comm.' Mr. Kerr's ed., v. iii. p. 396.)

EXCELMANS, REMI-JOSEPH-ISIDORE, BARON, Marshal, was a native of Bar-le-Duc, where he was born November 13, 1775. He entered the army very young, and first drew attention to his services, in 1799, whilst under General Oudinot, during the campaign which terminated in the conquest of Naples. In 1800 he became aide-de-camp to General Broussier; but exchanged that for the same post under Murat. At the combat of Wertingen, on the Danube, October 8, 1805, he had three horses killed under him; and being commissioned to lay the numerous flags taken from the enemy at the feet of Napoleon I., he received from the hands of the emperor the decoration of officer of the Legion of Honour.

In 1806 he was made colonel of the first regiment of Chasseurs, and was mainly instrumental in the capture of Posen, in Poland. He was afterwards engaged at the doubtful battle of Eylau, and for his conduct in that action (1807) he was appointed to command a brigade, and placed on the staff of Prince Murat, whom he afterwards accompanied to Spain. It was General Excelmans who was commissioned to head the escort by which King Charles was attended to Bayonne, after he had been induced to abdicate in favour of his son. A few weeks after this special service, Excelmans was arrested, with other officers, and sent to England, where he remained a prisoner until 1811. On his release he again joined his former general, who had ascended the throne of Naples. Sent to Russia in 1812, in Junot's corps, as second in command, he was several times wounded, and was created a general of division, September 8, 1812. Savary, in his 'Memoirs,' ascribes entirely to Excelmans the merit of saving the remnant of their corps, which returned home after that arduous campaign.

In 1813 his division was placed under the orders of Marshal Macdonald; he took an active part in the operations in Saxony and Silesia, and was rewarded with the cordon of great officer of the Legion of Honour. In 1814 he commanded the cavalry of the Imperial Guard, and was present at most of the battles fought by Napoleon to defend the French territory. After the return from Elba, General Excelmans was called to the Chamber of Peers, June 2, 1815; and despatched to join the army of the north. He was not present at Waterloo, but he had the merit of bringing back his division to the walls of Paris, in time to defend the capital, and to check the advance of the Prussians, whom he defeated at Versailles in the last action of the war. Excelmans was included in the decree of July 24, 1815, and banished from France with many other generals, who had served the emperor during the hundred days. It was not until 1819 that he was permitted to return to France, during the ministry of Marshal Gouvion Saint-Cyr. In 1831 Louis Philippe restored to him his title and rank in the Chamber of Peers.

Louis Napoleon raised him to the dignity of Marshal of France in the early part of 1849, and nominated him Chancellor of the Legion of Honour in August of the same year. On the 2nd of December, 1851, Marshal Excelmans powerfully assisted in securing to the government of Napoleon the faithful adherence of the army. On the 21st of July 1852, the Marshal was on his way to the house of the Princesse Mathilde, in company with one of his sons, when he was suddenly jerked from his horse, and fell on the road, not far from the bridge of Sèvres. He never spoke afterwards, and expired at two o'clock the next morning.

(Rabbe; Savary, *Memoires; Biogr. des Contemp.; Dictionnaire de Conversation.*)

EXCHEQUER (Scotland). The Court of Exchequer in Scotland has been abolished by the statute 19 & 20 Vict. c. 56; and its jurisdiction, under an amended procedure, transferred to the Court of Session. This court was instituted with the object, carefully concealed however, of introducing into use in Scotland the Common Law process peculiar to England, by means of the writ of *quo minus*. Had this been effected, the legal procedure in both countries would probably by this time have become entirely assimilated. The first attempt of the Scottish Exchequer in this direction was, however, met by an assertion on the part of the Court of Session, of an authority to confine the jurisdiction of the former Court to matters of revenue, which being submitted to the writ of *quo minus* became useless for its intended object.

EXECUTION. [ATTACHMENT OF DEBTS, S. 2; DETINUE, S. 2; GOODS, S. 2.]

EXECUTOR. [PROBATE, S. 2.]

EXHIBITION OF 1851. The great Industrial Exhibition of 1851 was in itself an event of so much importance, one which excited such very general interest, and has been the parent of so many other exhibitions of a somewhat similar kind both in this and other countries, that—without entering upon the larger question of its immediate or remote influence upon manufacturing art and skill, or commercial enterprise—it may be useful to present in this work a brief summary of facts and figures illustrative of the history of the undertaking.

There had been industrial exhibitions in England and on the Continent, but they had been of a more or less local character, or at the utmost confined to the manufactures of the country in which they took place. In England there had been no general exhibition of the products of national industry resembling the well-known Paris exposition. The proposition for a great exhibition of national manufactures to be held at intervals of three or more years seems to have originated in 1845 with the Society of Arts, London, of which Prince Albert was president. On its first announcement the project was coldly received, and some three years were suffered to elapse before it was again brought distinctly before the public. Meantime the annual exhibitions of the society were rendered more attractive, and manufacturers and commercial men began to feel increased interest in the proposal. By the beginning of 1849 the council of the society had matured a plan, of which in March of that year they published an outline. The society now petitioned parliament for pecuniary aid. Prince Albert, who had all along warmly supported the proposal, conceived that the time had arrived for imparting to it a much more magnificent form, by throwing the exhibition open to the industry of the world. The council adopted his suggestion, and measures were taken for enlisting in behalf of the scheme the sympathies in the first place of the manufacturers of this country, and then those of every other nation. The idea of an International Exhibition of Industry at once seized the general mind. At the preliminary meeting held in the city under the presidency of the Lord Mayor for the purpose of publicly enunciating the scheme, it was received with the utmost favour, and the provinces speedily gave in their cordial adhesion. The Council of the Society of Arts, which in the first instance assumed the direction of the undertaking, entered into a contract with a private firm, Messrs. Munday, who covenanted to deposit a sum of 20,000*l.* on the 30th of August, 1849, and to provide whatever additional money might be required between that time and three months after the final closing of the exhibition on the 1st of October, 1851. The cost of the exhibition building was in the first instance estimated at 20,000*l.*, but Mr. Cubitt on being consulted by Prince Albert named 50,000*l.* as a far more probable sum—so entirely at sea were the projectors of the scheme as to its extent and the amount of money required to carry it into effect.

Upon the suggestion of Prince Albert, application was made to the government for the appointment of a Royal Commission for managing an Exhibition of the Works of Industry of all Nations; and a royal warrant was accordingly issued in January 1850 appointing such a Commission with Prince Albert as its president. At the first meeting of the Commission, the contract entered into with Messrs. Munday, against which the public opinion had been strongly expressed, was annulled, and eventually a sum of 5120*l.* was awarded to the contractors as compensation for their probable loss. The Commissioners now appointed (January 24) a Building Committee, to whom was entrusted the entire arrangements for providing a suitable edifice. On the 25th of January a great meeting was held at the Mansion House, at which the hearty adhesion of various influential merchants and manufacturers was announced, and a general subscription was inaugurated with a view to raising funds for meeting every kind of outlay connected with the undertaking. It was followed by corresponding meetings in every part of the country, and it was soon made evident that ample funds would be furnished. In fact a total of very nearly 80,000*l.* was ultimately reported to the Commissioners as subscribed, though only 67,896*l.* was paid into their bankers—upwards of 11,200*l.* having been somehow absorbed in the several localities as expenses. On the 21st of February, the Commissioners were able to make a public announcement of the general plan of the exhibition, and to communicate the Royal permission to hold it in Hyde Park.

The site granted for the building was on the south side of Hyde Park, between Kensington Drive and Rotten Row. The Commissioners announced that the building would cover an area of from 16 to 20 acres; that it must be ready for the reception of goods by the 1st of January, 1851; that from that day to the 1st of March following goods would be received, and that the Exhibition would be open to the public on the 1st of May, 1851. In March 1850 the Building Committee appealed to architects and engineers to assist them with sketches and suggestions as to the form and general arrangements of the building required for the Exhibition. This appeal was responded to by a large number of professional men, including several foreign architects. In the course of May the Committee announced that they had examined the 243 designs sent in, but though several were of sufficient excellence to obtain special commendations, they were unable to select any one design which fulfilled all the conditions prescribed by the nature of the undertaking. Of the designs sent in 18 were however singled out by the Commissioners for special commendation, and it was noticed as a curious circumstance that, though only 38 out of the competing architects were foreigners, of the 18 who were specially distinguished only three were natives of the United Kingdom. However, though unable to recommend any one of the designs for adoption, the Commissioners stated that they had derived much valuable suggestion from the plans to guide them in preparing a design of their own. In this design, which they laid before the Commissioners, a building was proposed which was to be 2300 feet long, 400 feet across, and to cover upwards of 20 acres. It was to be constructed of brick and lighted by skylights. The great feature of the building was to be a grand central hall, in shape a polygon of 16 sides, the main walls, which were to be of brick, being carried up to a height of 60 feet, and it was to be covered with an iron domical roof, much larger than any hitherto constructed, being 200 feet in diameter, or nearly twice the size of the dome of St. Paul's, and 48 feet larger than that of the Pantheon of Rome. The report of the Building Committee gave general dissatisfaction in various ways, but their design—so obviously unsuited for a temporary purpose—called forth a storm of disapprobation. For awhile the whole scheme seemed in peril, when Mr. (now Sir Joseph) Paxton came to the rescue by proposing an entirely new plan, that of a vast building of iron and glass resembling in its general principles the great conservatory he had constructed for the Duke of Devonshire at Chatsworth. Having powerful influence, he was enabled—though at this late hour when tenders had been publicly invited for the committee's design—to obtain permission to lay his design before the Commissioners and their president. Its singular adaptation to the purpose of the Exhibition, as well as the great comparative facility with which it could be erected and removed, at once commanded their approval. With the general public it from the first became popular, and as soon as the contractors, Messrs. Fox and Henderson, undertook its erection upon terms which removed all doubt of its economy as well as practicability, the Commissioners determined upon adopting it, and accepted Messrs. Fox and Henderson's tender. They were to receive 79,800*l.*, the materials of the building remaining their property.

From this time all proceeded rapidly and smoothly. The contract was signed on the 26th of July; on the 30th the contractors obtained possession of the site; on the 26th of September the first column of the building was erected, and on the 4th of December the first rib of the transept was raised; by the 31st of December the building was sufficiently advanced to allow of a lecture being delivered within it to the members of the Society of Arts, and on the 3rd of February, 1851, the completed building was formally handed over to the Executive Committee.

The form and character of the building are too well known to need any detailed description. It will be enough to say, that its entire length was 1851 feet—its breadth, 408 feet, with an additional projection on the north side, 936 feet long by 48 wide. The central portion was 120 feet wide by 64 high; on either side of this was another portion 72 feet wide by 44 high; and the north and south portions were 72 feet wide by 24 high. The portions or great avenues here described ran east and west through the building; very near the centre the transept crossed, with a width of 72 feet and a height of 108. The entire area was 772,784 square feet, or about 19 acres—nearly seven times as much as St. Paul's Cathedral. The entire ground area was divided off into a central nave, four side aisles, and several exhibitors' courts and avenues. There were 3 entrances, with 8 pay places to each, and 18 doors for exit. Four galleries ran lengthwise along the sides of the building, and others around the transept; and access was gained to these galleries by 10 double staircases. The iron columns in the building, which, with their connecting pieces, were about 20 and 24 feet high respectively, were about 3300 in number; and there were 1074 base pieces beneath the columns, on which the whole structure rested. There were nearly 3500 girders, of three different lengths, 24, 48, and 72 feet, and of five different weights, 12, 13, 35, 120, and 160 cwts. Altogether there were about 4000 tons of iron built into the structure.

In the woodwork for the glass roof, the Paxton gutters were arranged 8 feet apart, with a ridge between every two. The squares of glass were 49 inches by 10. Besides the 17 acres of glass for the roof (none being wanted for the open courts) there were about 1500 vertical glazed sashes. The ground floor and the galleries contained 1,000,000 square feet of flooring. Of sash bars there were 200 miles, and 20 miles of Paxton gutters. The total woodwork in the building was estimated at 600,000 cubic feet. The form of the columns and girders was the same throughout, so was that of the sash-bars, so likewise was the size of the panes of glass. The structure itself was built up of a series of bays or cubical compartments, each 24 feet square; each of these bays being formed by four columns, which supported girders very ingeniously put together. Thus the entire ground-plan may be regarded as a series of these squares, the parallelogram being 77 of them in length and 17 in width—columns being of course omitted and longer girders substituted to form the nave, courts, and transepts. The additional portion on the north side of the building was

39 of these squares long and 2 deep. The whole building, in fact, from the ground-plan to the ridges of the roof, was a repetition of certain regular forms; and, one portion having been first thoroughly modeled, was a matter of simple arithmetical calculation, and consequently from the hour when the contractors commenced their work, from the simplicity of the plan and the singularly small number of castings required, all the parts were prepared and adjusted to each other with almost mechanical regularity and precision. The colouring of the building was entrusted to Mr. Owen Jones, already well known by his works on the Alhambra, and on various points of decorative art; and he, with great skill and originality, executed his task by boldly covering the whole framework of the edifice with the three primitive colours, blue, red, and yellow, "in such relative proportions as to neutralise or destroy each other." Of course the announcement of his system was met with much deprecatory criticism, but the result amply justified his views, and it was generally admitted that the colour added much to the general effect of the building, while it harmonised well with the contents. How admirably the building answered its purpose, what new and elegant combinations of form, light, and shade and colour, both the exterior and interior offered to the eye, or what a magnificent and surprising appearance it presented as a whole, whether regarded externally, or when, looking down its unrivalled vista, with its rich and varied contents, from one of the end galleries, it belongs not to an article like the present to dwell upon or even to describe. As is well known, the building has been re-erected at Sydenham as a permanent structure, with great improvements on the original design.

As soon as provision had been made for the building, the Commissioners turned their chief attention to the means necessary for obtaining its contents. The outline of an elaborate system of classification, drawn up by Dr. Lyon Playfair, was issued, showing what a wide range of articles was sought to be brought together under the title of 'Objects of Industrial and Productive Art.' The whole was arranged under four great sections: Raw Materials, Machinery, Manufactures, and Fine Arts; and these were divided and subdivided into a vast number of classes and smaller divisions. To facilitate the collection of the objects, and to serve as ready means of intercourse between the producers and the commissioners, district committees were formed in all the principal towns and manufacturing localities, by whom all the arrangements respecting the allotment of space in the building and the transmission of the goods were conducted. Formal communications were made to the various foreign governments, as well as to the governors of British colonies, by most of whom commissioners were appointed to conduct the operations in those countries required for their adequate representation in the great undertaking. And so judicious were these several arrangements, that though from almost every country in Europe—from almost every state in the North American Union—from the republics of South America—from each of our own wide-spread colonies—from India, Egypt, Persia, and even from the Society Islands, specimens more or less bulky, valuable, and numerous were sent, the numbers were comparatively few that reached their destination materially later than the date at first fixed for their arrival. Considering the entire novelty of the whole proceeding, the immense difficulty there must have been in many instances experienced in getting the collections together, the little knowledge that a large proportion of the contributors could have had of the extreme importance of punctuality, as well as their comparative want of interest in the success of the scheme, and the various physical as well as conventional obstructions which had to be encountered, this must, we think, be regarded as by no means one of the least remarkable circumstances connected with the successful issue of the whole.

Of the actual number of objects exhibited no record was kept; and as often a large number of articles was included under a single entry, no close approximation was, perhaps, possible. The Jury Council, however, in their report to the Royal Commissioners, said that the duties of jurors had "involved the consideration and judgment of at least a million articles;" but this, though it tells much for the zeal and industry of the jurors, does not do anything towards explaining how the units of the million were determined. Of the value of the articles contained in the building, many wild guesses were hazarded during the continuance of the Exhibition; the Commissioners state in one of the appendixes of their Report that, taking in each case the owner's estimate of the value of his possession, the gross value of the articles exhibited—the famous Koh-i-noor being alone excluded from the reckoning—was under two millions (1,781,929*l.* 11*s.* 4*d.*) The total number of exhibitors was about 15,000.

The Exhibition was formally opened by her Majesty, on the 1st of May, 1851; it remained open 144 days, being finally closed on the 11th of October. The entire number of visits paid to the Exhibition was 6,063,986, being a daily average of 42,111. This average was not reached till June, but from that time till the close of the Exhibition there was comparatively little variation till the last week when the average was doubled. The number of visitors during this week was so extraordinary that we are tempted to set down the figures in detail. Monday, October 6th, 107,815, Tuesday, 109,915, Wednesday, 109,760, Thursday, 90,813, Friday, 46,913, Saturday, 53,061. The following are three pairs of contrasts presented by the daily returns: Highest five-shilling day, May 24th, 44,512; Lowest, July 19th, 9,327; Highest half-crown day, October 11th, 53,061; Lowest, September 6th, 12,672; Highest shilling day, October 7th, 109,915; Lowest, May 26th, 25,402.

The six million visits paid to the Exhibition plainly indicate but very roughly the actual number of visitors. Some persons went doubtless ten or even twenty times during the season, a very large proportion went twice. After weighing carefully the probabilities of the case, the authorities arrived at the conclusion that the probable average of visits would be about three, and that consequently about two millions of persons visited the Exhibition. Further, an attempt was made to arrive at the number of *foreign* visitors by an examination of the lists furnished to the Home Office by the captains of all steamers plying between the ports of England and the continent of Europe, and of returns furnished by the United States Legation, from which it appeared that the total number of aliens who arrived in England from all parts of the world, between the 1st of April and the 30th of September, 1851, was 58,427; a number very far below what the common imagination had supposed. During the same period in 1850 the number of aliens who landed in England was 15,514, so that 42,913 would seem to be the utmost number that can be supposed to have visited this country for the express purpose of seeing the Exhibition, though probably few of the remainder left these shores without visiting it. The largest number of visitors was from France, 27,200, then came Germany, 10,400, the United States, 5000, Belgium, 3,700, Holland, 2,900. But if the numbers be considered in relation to the population of the several countries, it will be seen that Holland sent most visitors, Belgium next, then France, Germany, and the United States. The respective proportions of town and country visitors was attempted to be arrived at by comparing the arrivals in London, from April to October, by steam-boats and railways—of course a very rude method, but the only available one—when it appeared that the arrivals in 1851 were 4,237,240, against 2,791,753 in 1850, a difference of 1,445,487. But as against this there had to be set off the regular yearly increase in the number of travellers by railway, and other allowances to be made; the inference was drawn that the number of persons who came from the provinces to view the Exhibition slightly exceeded a million: roughly, we may say that the Exhibition was visited by about a million of the inhabitants of London, the same number from the provinces, and about 50,000 foreigners.*

The details of the jury awards do not come within our present object; but the following are the general results, as affording materials for comparison.

There were 166 'Council Medals,' 2876 'Prize Medals,' and 2042 'Honourable Mentions,' making a total of 5084 honorary distinctions of all kinds. If we take the exhibitors at the estimated number of 15,000, about one-third were deemed worthy of some kind of recognition. Of the total number, 2039 were taken by exhibitors belonging to the United Kingdom, and 3045 by foreign exhibitors. Our foreign guests occupied about two-fifths of the space, and

* It may be interesting to compare these numbers with somewhat corresponding statistics of the Paris Universal Exhibition of 1855, given in the 'Third Report (1856) of the Commissioners for the Exhibition of 1851.' "The total number of visitors to the 'Palais de l'Industrie,' between the 15th of May, the date of its opening, and the 1st of December, when it was finally closed to the public, was 3,626,934, in addition to 906,530 visitors to the 'Palais des Beaux Arts;' of this number 40,000 were British subjects, including 2,768 furnished with workmen's passports free of charge. The total number of exhibitors was 20,839, about one-half of whom were French, while of the remainder 1,655 were from the United Kingdom, and about 1,070 from the British colonies."

took off three-fifths of the honours. The greatly-coveted 'Council Medals' were awarded in the ratio of 79 to British and 87 to foreign exhibitors; the 'Prize Medals,' 1244 British and 1632 foreign; the 'Honourable Mentions,' 716 British and 1326 foreign.

In relation to different classes of exhibited articles, there were a few striking and instructive facts. In machinery, in manufactures, in metal, and in glass and porcelain manufactures, the British exhibitors gained more prizes than all the foreigners combined. In textile fabrics, in fine arts, and in miscellaneous manufactures, the foreign exhibitors took off the honours in the ratio of about three-fifths to two-fifths British. But in the section of raw materials for food and manufactures, the foreign exhibitors gained nearly *four times* as many prizes as the British (988 to 262). It would be a hasty generalisation to infer from thence that Britain is a manufacturing and not a producing country; but the simple facts themselves are worthy of note, whether we theorise concerning them or not.

The great honours, the Council Medals, were very unequally distributed as regards the classes of exhibited articles; for out of the whole number of 166, no less than 88 (more than one-half) were awarded for machinery alone. This is a significant fact; showing that the Juries, or rather the Council of Chairmen, were not deterred by the gorgeous display around them from doing justice to the great working agencies by which modern wealth is produced.

We must devote a paragraph to the Financial results. The receipts at, and in relation to, the Exhibition, by which it was made a self-supporting concern, were truly remarkable. The admissions were by season tickets, and by payment at the doors. Of the season tickets, no less than 10,892 gentlemen's tickets at three guineas each, and 8615 ladies' tickets at two guineas each, were sold before the Exhibition commenced, making together 19,507, for which more than 52,000*l.* were paid. About 6000 more tickets were sold during the period of the Exhibition; and it is worthy of note that of these 6000, the ladies took off nearly a thousand more than the gentlemen. The smallest money receipt at the doors was on the second day after the opening: the largest was on the third day before the closing: these sums were 482*l.* and 5283*l.* respectively, the former in sovereigns and the latter in shillings. The average of the daily receipts at the doors was 2533*l.* There were two admission days at 1*l.*, twenty-eight at 5*s.*, thirty at 2*s.* 6*d.*, eighty at 1*s.*, one for season-tickets only, two for exhibitors and their friends, and one for exhibitors and the officials; making up the total of a hundred and forty-four.
