FOR THE

DIFFUSION OF USEFUL KNOWLEDGE.

VOLUME XII.

HADLEY, JOHN——INTESTINA.

LONDON:
CHARLES KNIGHT AND Co., 22, LUDGATE STREET.

MDCCCXXXVIII.

Price Seven Shillings and Sixpence, bound in cloth.

London: Printed by William Clowes and Sons, Stamford Street.

THE PENNY CYCLOPÆDIA

OF

THE SOCIETY FOR THE DIFFUSION OF USEFUL KNOWLEDGE.

HADLEY, JOHN, the reputed inventor of the sextant which bears his name, became a Fellow of the Royal Society in 1717, and died February 15, 1744. He was author of several useful papers, which appear in the Transactions of the Society, from vol. 32 to vol. 39. He was also upon intimate terms with Sir Isaac Newton, from whom it is supposed he borrowed, without acknowledgment, the idea of the sextant. It is now generally believed that Newton and Godfrey were the original and independent inventors of that instrument. [GODFREY.] Hadley gave an account of the instrument in the 'Philosophical Transactions' for 1731; but Newton, previous to his death in 1727, had given a description of the instrument to Dr. Halley, by whom it was, for some unknown reason, suppressed, though it was communicated to the Royal Society in the year 1742, after Halley's death, by his executor, Mr. Jones. (Hutton's *Dictionary*, 1815; Herschel's *Astronomy*, p. 102; and *Trans. of the American Society*, vol. i., p. 21, Appendix.)

HADRAMAUT. [ARABIA.]

HADRIA'NUS, ÆLIUS, son of Ælius Hadrianus Afer, a cousin of Trajan, and a native of Hatria Picena, but of Spanish descent, and of Domitia Paulina of Cadiz, was born at Rome, in January, A.D. 76. He was left an orphan at ten years of age, under the guardianship of Trajan and of Tatianus, a Roman knight. He made great progress in literature, especially in the study of Greek. In the reign of Domitian he served as commander of an auxiliary legion in Mœsia. Trajan gave him his niece Sabina in marriage, and he accompanied the emperor in his Dacian and Eastern campaigns. When Trajan died at Selinus, in Cilicia, in August, 117, Hadrian, whom he had left in charge of the army in Syria, was proclaimed emperor by the soldiers at Antioch, and he wrote to the senate, requesting their confirmation. Plautina, Trajan's widow, favoured his views by pretending that Trajan on his death-bed had appointed him his successor, and for this service Hadrian showed his gratitude to Plautina to the end of her life. The fact of Hadrian being adopted by Trajan a year before his death has been asserted by some writers and denied by others. His election being confirmed by the senate, Hadrian, after withdrawing the troops from the countries east of the Euphrates and making peace with the Parthians and the Armenians, set off for Rome, where he assumed the consulship in the following year (A.D. 118) with T. Fuscus Salinator. He refused to appropriate to himself the triumph which had been destined for Trajan, and he caused the image of the deceased emperor to be carried in the triumph: according to Spartianus he himself carried it. He remitted all the arrears due to the public treasury by individuals in Rome and the rest of Italy, and all that was due from the provinces for sixteen years past; and he burnt in the Forum of Trajan the schedules of the debts, which are said to have amounted to several millions sterling. Medals were struck on this occasion with the figure of Hadrian holding a torch and setting fire to the heap, and the legend 'He enriches the whole world.' In the following year Hadrian was consul again with Rusticus; and hearing that the Sarmatians and the Roxolani had made an irruption into Illyricum, he repaired to Mœsia, defeated the invaders, obliged them to recross the Danube, and to sue for peace. He appointed Marcius Turbo governor of Pannonia and Dacia. From his camp in the Illyricum he wrote to the senate, accusing of high treason four senators of consular families, who were ordered for immediate execution. Other persons were arrested and put to death as accomplices in the alleged conspiracy, and a general alarm spread at Rome, when Hadrian hurried back and affected to blame the precipitancy of the senate. He compelled Tatianus, his former guardian, whom he had made præfect of the Prætorian soldiers, and who had abused his power, and had advised the proscriptions, to resign his office. The year after, Titus Aurelius Fulvius, afterwards the Emperor Antoninus Pius, was made consul; and in the same year Hadrian began his travels through the various parts of the empire, which may be said to have occupied, with few interruptions, the remainder of his reign, a period of about eighteen years. We have memorials of his travels in numerous medals, struck in the various provinces on the occasion of his visit, which form an interesting series. An Italian medalist, Mezzabarba Birago, has put these medals in order and illustrated them. Hadrian began with Campania, where he distributed sums of money to the poor of the various towns which he visited. Indeed liberality in this respect was one of the most conspicuous qualities of this emperor. He next went to Gaul, where he visited all the principal towns and fortresses; from thence he proceeded to Germany, where the best legions of the empire were stationed, and he remained a considerable time among them for the purpose of restoring the discipline, which had become relaxed. He himself set the example by living as a soldier among the soldiers. Hadrian was not fond of pomp or show, and he went about with as little state as possible. He drew up a series of military constitutions or laws, which remained long in use after his time, and are quoted by Vegetius. He attached to every cohort a certain number of builders, masons, and other workmen.

In the following year, in the consulship of Annius Verus, grandfather of Marcus Aurelius, he left Germany, and returned to Gaul, from whence he passed into Britain, where he is said by Spartianus to have reformed many abuses. Although Hadrian did not live on very good terms with his wife Sabina, he punished those who presumed to fail in respect to the empress; among others Suetonius Tranquillus, the biographer, who was Hadrian's epistolographer, or secretary, whom he dismissed, as well as Clarus, the præfect of the Prætorium. While in Britain he constructed a rampart of earth, extending from the Solway Firth to the German Ocean near the mouth of the Tyne, a little to the south of the more substantial wall afterwards raised by Severus. On his return to Gaul, Hadrian built a magnificent palace at Nismes for Plautina, Trajan's widow. He thence proceeded into Spain, and spent some time at Tarraco (Tarragona), where he held a general assembly of the deputies of the various provinces of Spain, and settled several disputes and complaints. While walking in the palace garden at Tarraco a slave attempted to kill him. The emperor parried the blow, and consigned the assassin to his guards, but on hearing that the man was insane, he ordered him to be taken care of by his physicians. Hadrian returned to Rome in the consulship of Aulius Aviola and Cornelius Pansa, A.D. 122; but he left it again soon after, and the next year we find him at Athens, a city to which he was much attached. He ordered the embankment of the Cephisus, which had damaged the town of Eleusis, and the construction and reparation of various edifices. From thence he went to Syria, and had a conference with the king of the Parthians, when peace was confirmed between the two empires. In the year following he visited various parts of Asia Minor, and after building temples and other edifices at Nicomedia, Cyzicum, Nicæa, and other towns, he sailed to the islands of the Ægean Sea, and returned to spend the winter at Athens, where he was initiated in the Eleusinian mysteries, presided at the public games, and showed many marks of favour to the Athenians. He next went to Sicily, and ascended the summit of Ætna to see the sun rise. He returned to Rome under the consulship of Verus and Junius Bibulus, A.D. 126, and we know nothing of his movements for the two following years. He appears to have been at Rome in the year 129, under the consulship of Juventius Celsus and Julius Balbus, when a violent earthquake having destroyed the towns of Nicomedia and Nicæa in Bithynia, and others, he ordered them to be rebuilt at his own expense, for which he is styled on some medals the Restorer of Bithynia. In the same year he set off for Africa, where he distinguished himself, as he had done on his previous travels, by his munificence. Plautina having died meantime, Hadrian returned to Rome, and celebrated her funeral with great ceremony, and had her numbered among the gods. In the following year, 130, he raised a magnificent temple in honour of Venus and Rome, some remains of which are still seen near the arch of Titus. The plan of the building was made by Roman architects, and sent by the emperor to Apollodorus, a celebrated Grecian architect, for his opinion. Apollodorus observed that the building appeared too low for the size of the statues of Venus and Rome, which were intended to be placed therein, and which it would appear were represented seated, as Apollodorus remarked that those divinities, when once within, could not stand upright or walk out of the temple, if they should take a fancy to do so. Hadrian, stung at this sarcasm, sent Apollodorus into exile; and it is added by some writers that he afterwards ordered him to be put to death on some frivolous pretence. In that year Hadrian set off again for the East. He visited Cappadocia, where he held a conference with several kings or chiefs of the Caucasian tribes, the Abaxi, Zidretes, &c., whom he sent back loaded with presents. Even the Bactrians sent an embassy to propose an alliance with Rome. He next proceeded to Syria, Palestine, and Egypt, in which last country he remained two years. While he was in Egypt, and under the consulship of Lænas Pontianus and Antonius Rufinus, A.D. 131, the jurist Salvius Julianus completed, by his order, the Perpetual Edict, which may be considered as the first general code of Roman law published by authority.

There is a letter of Hadrian, written from Alexandria, to Servianus, his brother-in-law, in which he describes the state of the population of Egypt, and speaks of the various sects, Jews, Christians, Samaritans, &c., who were very numerous in that country; he says that they all adored but one god, namely, their own interest. He also notices as an extraordinary thing, that at Alexandria everybody, even the blind, followed some trade or occupation; a circumstance which probably struck him by contrast with the habitual idleness of the people of Rome. He restored the palace and museum of Alexandria, and held disputations with the learned men there. About this time his favourite Antinous died; some say he drowned himself in the Nile, and Hadrian disgraced himself by the apotheosis and other absurd honours which he paid to his memory. He next went to Cyrenaica, where he is said to have killed a large lion. Hadrian was an expert sportsman, and is said to have killed many wild beasts in his travels. Under the consulship of Hiberus and Sisenna, A.D. 133, Hadrian repaired to Syria, from whence he set off for Thrace and Macedonia, and lastly stopped at Athens. The insurrection of the Jews of Palestine under Barcochebas raged about this time. They took Jerusalem, and spread all over Syria, and Hadrian was obliged to send for his best general, Julius Severus, who was in Britain, to assume the direction of the war against them, which lasted about three years. [BARCOCHEBAS.] Hadrian raised a new city on the ruins of Jerusalem, which he called Ælia Capitolina, and he peopled it with a Roman colony, forbidding by an edict all Jews from setting their feet within it. The Christians, who were still confounded with the Jews by the Romans, were included in the prohibition. Hadrian meantime made another long residence at Athens, and in the festivals of Bacchus he appeared in the dress of an archon, and distributed money and corn to the people. He greatly embellished that city, a district of which was called by the name of Hadrianopolis. [ATHENS.] He also completed the temple of Jupiter Olympicus, which had been commenced a long time before. He returned to Rome under the consulship of Lupercus Pontianus and Rufus Aquilianus, A.D. 135, where he received the visit of Pharasmanes, king of Iberia, who came to answer several complaints laid against him by Vologesus, king of Armenia. An exchange of rich presents took place, and Hadrian took care that his should exceed in value those brought to him by his visitor. Soon after, falling ill, he thought of choosing a successor, and he fixed his choice upon Lælius Aurelius Ceionius Commodus Verus, whom he adopted and appointed Cæsar by the name of Ælius Verus. In the following year Hadrian retired to the neighbourhood of Tibur, where he built a magnificent villa, many remains of which are still existing, and which contained representations of the wonders of nature and of art which he had seen in his travels. Protracted illness seems to have soured his naturally suspicious temper, and he condemned several individuals to death, among others his brother-in-law Servianus, a man far advanced in age. Ælius Verus having died in the second year after his appointment as Cæsar, Hadrian now fixed his choice upon Titus Aurelius Antoninus, on condition that he should adopt Lucius Verus, son of Ælius Verus. After some deliberation Antoninus accepted the proposal, and the double adoption was solemnized with the usual ceremonies in February, 137. Sabina, Hadrian's consort, died about this time, and was numbered among the gods. Hadrian still finding his illness increasing, at last removed to Baiæ, where, in spite of the prescriptions of his physicians, he began to eat and drink according to his pleasure. Seeing his end approach, he composed some lines addressed to his soul, which show his doubts and fears concerning another existence:

> 'Animula vagula blandula,
> Hospes comesque corporis,' &c.

He died in July, A.D. 138, in his sixty-third year, and the twenty-first of his reign. (Spartianus, *Life of Hadrian;* Dion; Aurelius Victor; Eusebius.)

In his personal character Hadrian had many valuable qualities, tarnished by some vices. As emperor, his reign may upon the whole be considered a happy one for the empire, which enjoyed almost uninterrupted peace. Less warlike than Trajan, he made himself respected by foreign nations without having occasion to resort to arms. His extensive travels form an important epoch in the history of Roman civilization, which they must have tended to spread, while he corrected many abuses of provincial administration, and thus cemented the union between Rome and its vast dependencies. He used to say that an emperor ought to be like the sun, visiting by turns all the regions of the earth. He built numerous towns, embellished others, and peopled them with fresh colonies. Dion, who is in general not favourable to Hadrian's character, admits that he never appropriated to himself other people's property, and that he would not receive anything left him by will when the testator had children. Hadrian gave no power to his liberti, and punished those about him who boasted of their influence for the purpose of extorting money. He was attentive to business, and an enemy to pomp and parade. If he cannot be counted one of the best emperors, he certainly must not be reckoned among the bad. He had an extraordinary memory; was a good orator, grammarian, poet, and musician; was acquainted with mathematics and medicine and delighted in the company of learned men; he was also a great friend to the arts of sculpture and architecture. He was the first emperor who let his beard grow— in order, it is said, to conceal some blemish in his face.

The busts, statues, and medals of Hadrian are very numerous, and all bear a striking resemblance to each other in the character of the countenance. There is a full-length statue of him and two busts in the Townley Gallery, British Museum.

Coin of Hadrian.
British Museum. Actual Size. Copper. Weight, 360 grains.

Reverses of Coins of Hadrian.

HÆMATE'MESIS (from αἷμα, blood, and ἐμέω, to vomit), a bleeding from or into the stomach. [HÆMORRHAGE.]

HÆMATO'CELE (from αἷμα, blood, and κήλη, a tumour), an effusion of blood into the scrotum.

HÆ'MATOPS, a name given by Mr. Gould to a genus of birds inhabiting Van Diemen's Land and New South Wales, and thus characterized by him in 'Zool. Proc.' for 1836 (Dec. 27).

Bill shorter than the head, slightly curved, without any denticle at the apex, rather compressed. *Nostrils* longitudinal, and covered by an operculum; no bristles at the gape. *Wings* moderate, first quill short, third and fourth nearly equal and longest. *Tail* moderate, equal or slightly forked. *Tarsi* moderate, the rather strong *hallux* and claw equalling the middle *toe* and claw; external *toes* equal in length. Ensanguined spots or marks (*nævi sanguinolenti*) above the eyes.

Mr. Gould recorded two species, *Hæmatops valdirostris*, 6¾ inches in length (Van Diemen's Land), and *H. gularis*, 6 inches long (New South Wales).

These were among the specimens from which drawings had been taken for the first part of Mr. Gould's new work on the Birds of Australia. The name, in sound, comes rather near to *Hæmatopus*.

HÆMA'TOPUS. [OYSTER-CATCHER.]

HÆMATORNIS. [FALCONIDÆ, vol. x., p. 174.]

HÆMATO'XYLON CAMPECHIA'NUM (Logwood), a tree native of Campeachy, but cultivated also in Jamaica. The finest wood is the produce of the former place. The bark and alburnum being removed, there is within a dark red coarse-fibred duramen, having a violet-like odour, and a taste at first sweetish, afterwards astringent. It dyes the saliva violet-coloured, and produces a similar change on many of the other secretions. Specific gravity 1·057. Ten pounds of wood yield 16-18 ounces of extract. Its chief constituents are volatile oil, resinous or fatty matter, and a principle termed *hæmatoxyline*, which is occasionally found in the wood in the form of crystals.

Logwood acts as a mild astringent in hæmorrhages or increased secretions; and in some forms of diarrhœa it often effects a cure where more powerful astringents fail. (See Abercrombie on 'Diseases of the Stomach, &c.') It may be exhibited in the form of infusion or of extract: the former is preferable. Logwood is also used extensively in the arts, especially for dyeing. It gives the peculiar colour to the paper in which sugar-loaves are always wrapped.

HÆMATU'RIA (from αἷμα, blood, and οὖρον, urine), voiding of bloody urine. [HÆMORRHAGE; KIDNEYS, DISEASES OF.]

HÆMO'CHARIS. [LEECHES.]

HÆMODORA'CEÆ. Under this name Dr. Robert Brown proposed, in the year 1810, to separate from the natural order Iridaceæ, the genera Hæmodorum, Conostylis, Anigozanthos, Phlebocarya, Dilatris, Lanaria, Heritiera, and Wachendorfia. He remarked that they are abundantly different, especially in being hexandrous, or in having the stamens, if only three in number, stationed opposite the petals, and in having the anthers opening on the side next the stigma; the habit was moreover different. This distinguished botanist mentioned in connection with his new order, without actually adding it, Xiphidium. The latter genus has more recently been introduced along with Hagenbachia as an undoubted member, notwithstanding its having a superior ovary. All the species have equitant leaves, and perennial fascicled fibrous roots or bulb-like cormi; there is also a general appearance of wool upon their flowers, in some cases to such an extent as to bury all the outer surface. The order may be considered a connecting link between Iridaceæ and Liliaceæ. One species, Dilatris Heritieri, yields a dyeing matter in its rhizoma.

Hæmodoraceæ. Wachendorfia Thyrsoidea.

1, a flower spread open to show the position of the three stamens; 2, a ripe capsule; 3, a seed.

HÆMO'PIS. [LEECHES.]

HÆMO'PTYSIS (from αἷμα, blood, and πτύω, to spit), a spitting or coughing of blood. [HÆMORRHAGE; LUNGS, DISEASES OF; PHTHISIS PULMONALIS.]

HÆMORRHAGE (from αἷμα, blood, and ῥήγνυμι, to break). The most common cause of hæmorrhage is external violence, by which the vessels of a part are divided, and the blood escapes from their cavities. When an artery of some calibre is wounded, a bright scarlet stream of blood is propelled to a distance proportioned to the size of the vessel, in a current continuous, yet increased in force at intervals corresponding with the pulsations of the heart. This is called a jetting stream. If a vein of some size be divided, a stream of dark crimson blood is projected in a perfectly continuous and equable current, and with less force than from an artery of the same calibre, in consequence of the loss of power which the blood sustains in its passage through the minute capillary vessels. In wounds in which no vessel of more than a line in diameter has been divided, the blood flows in a constant more or less rapid oozing, but is not projected to any distance from the body; and when it issues from both kinds of vessels at once, and in equal quantities, its colour is intermediate between those peculiar to each of them. The same mixture of the two kinds of blood may sometimes, when a number of small vessels of both kinds, and a large one of either kind, are simultaneously divided, make it doubtful, from the colour alone, to which kind it belongs; and the distinction becomes still more difficult if the arterial blood be long detained in the tissues, for then it assumes a venous colour.

When a large artery, as one of the main trunks of the limbs or head, is divided, the blood rushes forth with such impetuosity that life is often destroyed almost instantaneously. The quantity of blood lost however, and the rapidity with which death ensues, will depend in some measure on the freedom of exit which the blood finds after issuing from the wounded vessel, as well as on the mode in which it is wounded. If there be a free external aperture, no obstacle is presented to its flow, and death speedily follows: if, on the contrary, the aperture be small, as in a punctured wound, the blood can escape but slowly, and is liable to coagulate in the passage, so as partially to block it up and render it still more narrow. If again the artery be completely divided, its extremities will retract into the tissues around, and be thus partly covered, so that the hæmorrhage will be retarded. If it be cut longitudinally, the blood will flow much less rapidly than if the wound be transverse, because the aperture will gape much less widely. If, lastly, the wound be not cleanly made, if the edges be rough and torn, as by a gun-shot, no blood at all will flow, at least for some time. None of these circumstances however is likely to do more than retard the fatal consequence of a wound of a large artery, unless immediate assistance be given.

When an arterial branch of the second magnitude, as one of the primary divisions of the main trunks in the leg or fore-arm, is wounded, the flow of blood is at first profuse, and a large quantity is soon lost; but after a time the patient faints from extreme exhaustion, and then the heart ceasing to act the blood no longer flows, but begins to coagulate both within and around the vessel, whose extremities contract, and further loss may thus be prevented. More frequently, however, as soon as the patient recovers from his exhaustion, and the heart regains some of its power, the slight obstacles formed during the fainting are forced away, and the hæmorrhage recommences and continues till the patient is again exhausted. Thus by a succession of hæmorrhages and of temporary staunchings, he may at last be destroyed by extreme debility. From arteries of smaller size, as those about the fingers, &c., the blood flows at first in a rapid little stream, but after a few minutes, if they are exposed to the cold air, they retract; their orifices contract and close, and the bleeding altogether ceases, without much danger of returning.

Hæmorrhage from wounded veins is of less importance. It is much more slow, for the blood is prevented by the valves from flowing from that part of the vein which is between the heart and the orifice, and in the part which is beyond the orifice it has only the force of that in the smaller arteries. Hence it is seldom immediately fatal, and when the patient becomes faint the edges of the vessel fall together, instead of remaining open as those of arteries. Thus a coagulum forms within and round them, and, except from the largest trunks, prevents any further flow. Other cases in which bleeding takes place from large vessels are those in which they are burst by sudden efforts, as sometimes happens in the aorta, especially when it or the heart is diseased; those in which the walls of an aneurism or otherwise diseased artery or vein burst or ulcerate; those in which ulceration, whether in internal or external organs, spreads from surrounding parts, and at last (though they always resist for a long time) invades the walls of arteries and veins. The bleeding so common from ulcerated surfaces, and from various vascular morbid growths, probably depends on rupture of the very delicate vessels which they contain; and the same delicacy of the walls of its vessels, with their great liability to disease in advanced life, may be assigned for many cases of hæmorrhage in the more vascular parts of the brain producing apoplexy.

But bleeding to a great extent may take place without visible rupture of any vessel. This form of hæmorrhage, which may take place in various parts of the body, is that popularly supposed to arise from the 'bursting of a blood-vessel;' but in the large majority of cases where blood is poured forth in the interior of the body, the most careful examination can discover no aperture through which it had flowed. It is therefore called hæmorrhage by exhalation, from the idea that the vessels which in health are traversed only by the fluids of the exhalations or secretions, now permit the passage of the blood. The only instances in which the blood has been seen flowing in those cases are those extremely rare ones of hæmorrhage from the skin of the face, hands, feet, &c. In these the surface is covered by a dew of blood; if this be wiped away no unnatural appearance is perceptible, but the blood soon exudes again. From this the process would appear to be very similar to that of menstruation. When internal organs from which hæmorrhage has taken place are examined after death, they are sometimes found loaded with blood, but at others quite pale, their vessels having been completely emptied; when pressed, small clots of blood like grains of sand sometimes ooze out on the surface, as if proceeding from the orifices of secreting ducts. From these and other circumstances it is probable that the blood does pass through the vessels which naturally are permeated by the secretions, though the minute details of neither process are yet wholly explicable. It cannot however be certainly affirmed that the minute blood-vessels are not ruptured, for neither the apertures nor the cicatrices in them could be in any way visible.

The circumstances under which these hæmorrhages take place are various. In some cases they arise from distension of the vessels in consequence of some local excitement, either with or without increased activity of the circulation generally, and in these the flow of blood is preceded by a sensation of fullness and throbbing in the part, which, if visible, appears red and swollen. Such are those which take place in bronchitis, producing some rare cases of hæmoptysis; in dysentery and acute inflammation of the intestines; from the membrane of the nose, producing the epistaxis so common in young persons in robust health; in the brain, producing some forms of apoplexy, especially those connected with hypertrophy of the heart; and occasionally in the acute inflammations of nearly all the tissues. In other cases the main cause of the hæmorrhage is the existence of some obstacle to the free passage of the blood through the vessels. Such are those very frequent cases in which hæmoptysis, or spitting of blood, takes place in consumption, where the blood is obstructed in its passage through the pulmonary arteries by the masses of tuberculous matter deposited around them; those of hæmatemesis, or vomiting of blood, which arise from obstruction of the splenic or portal vein, by coagula, or by disease of the liver or other adjacent organs, and the consequent congestion of the vessels of the stomach; many of those which occur from the stomach, uterus, and other organs, in the early stages of various structural diseases; those which depend on disease of the heart, producing obstruction in the large vessels, and which may take place in the brain, lungs, and various other organs; and those arising from obstacles in the veins, as in hanging, or even from the influence of gravitation.

But a simply mechanical distension of the vessels, whether from an increased afflux of blood into them, or a retarded removal of it from them, cannot explain all the phænomena of these spontaneous hæmorrhages. In many cases a peculiar condition of the vessels, or of the blood itself, must be assumed, and is indeed nearly proved. To these must be referred many cases of what is called idiopathic hæmorrhage, as in some instances of hæmatemesis, hæmaturia, &c. In some persons indeed there appears to be a peculiar disposition to bleeding, a hæmorrhagic diathesis. Mr. Abernethy (*Surgical Lectures*) used to speak of a bleeding family, in all of whom it was extremely difficult to staunch the blood from even the slightest wound; and among other similar cases are not a few in which fatal hæmorrhage has followed the extraction of a tooth, or, in children, the application of leeches. Every surgeon also must have observed that in the same operations in different persons the number of vessels requiring to be tied varies greatly; in some amputations, for example, it is not necessary to secure more than the main artery, while in others eight or more must be tied, and this not admitting of any explanation from local differences. Many other circumstances might be adduced to show that there are conditions of the smaller vessels in which they may not only more easily permit hæmorrhages, but are less capable of effecting those changes which are necessary for arresting them, and on these conditions the majority of the hæmorrhages termed passive must be supposed to depend. Such are especially those from the nose, rectum, and other organs, which occur in persons of weak lax habit, and which may be distinguished from the first class we have noticed rather by the general appearance of the patient than by any local circumstances.

Lastly, there are cases in which the hæmorrhages that take place, often coincidently from several organs, may be presumed to depend on alterations of the blood itself. Such are those that occur in scurvy, in which the blood, when drawn from a vein, does not separate, as in health, into a firm coagulum and a clear serum, but settles into a loose, livid, or dark jelly-like mass, and rapidly putrefies. Such too are probably the petechial and other effusions of blood in fever.

Hæmorrhages by exhalation may take place habitually or constitutionally, without injuring the health; most commonly the blood flows from the nose or rectum, more rarely from the lungs or stomach, or even from the skin. They are sometimes periodical; and when occurring in men, have seemed to favour the idea of a periodic action of the system in the male sex as in the female, and the more so as the menstrual evacuation, when suppressed in the latter, is not unfrequently compensated for by hæmorrhage from some other organ. Most of the cases of spontaneous bleeding from the skin are of this class, and in other instances the blood has flowed at regular periods from the gums, the breasts, umbilicus, axillæ, or kidneys, but most frequently from the stomach or lungs. Similar vicarious hæmorrhages occur in men when an habitual discharge from any organ has been suppressed, or when an old ulcer has been suddenly healed.

Of the means of arresting Hæmorrhages.—When an artery is wounded, unless death rapidly follow, a natural process takes place by which further bleeding may be prevented. If completely divided, both extremities retract into the sheath of cellular tissue in which they lie, so that a considerable interval is produced between them, bounded by loose and irregular walls, into which the blood as it flows infiltrates, and coagulating, tends to fill it up and obstruct the vessel. The open mouths of the artery also contract, and gradually, but at last completely close, either at or just above their extremities. As the stream of blood is thus checked by the narrowing and closure of its canal, at the same time that by the faintness induced by the previous loss the action of the heart is weakened and the whole circulation retarded, it begins to coagulate within the vessel itself, till its tube is nearly filled by a clot adhering loosely to its walls. Further changes then ensue; the divided vessel and the parts around become inflamed; coagulating lymph is effused from the edges of the wound into the artery itself and over its extremities, forming a firmer plug than the blood alone had: in process of time this lymph becomes organized, vessels enter it from the parts around, and it becomes firmly and permanently united to them and the vessel, till at length its tube is rendered impervious from the point of division up to the first branch given off from it, and is at last converted into a solid cord, closely connected with the substance of the cicatrix around it. If the artery be only partially divided, the same effects follow; though, if the cut be extensive transversely, with less certainty, because retraction cannot take place, and the internal coagulum, if formed, is washed away by the stream which still partly passes along the vessel. The natural cessation of hæmorrhages from veins is effected in the same manner, but far more easily, for the valves prevent any bleeding from the part nearest to the heart, and both orifices, instead of gaping open, fall together, and soon become adherent.

But in the human subject it is only in the very small arteries that the hæmorrhage can be confidently expected to terminate thus naturally, and hence various artificial means of checking bleeding from the larger ones have been invented. The simplest of these is pressure: if the finger be placed with moderate firmness over the mouth of a small bleeding vessel for a minute or two, on removing it the orifice will be found closed and no more blood will flow. Pressure is also especially useful when a number of small arteries are bleeding together, with a constant oozing rather than a rapid flow of blood. in such cases, when the edges of the wound are brought together, a compress should be laid on, and bandaged firmly and steadily over them. The same means, or a tourniquet applied a short distance above the wound, so as to compress the trunk of the artery, may be useful by lessening the force and volume of the current, and thus permitting the natural processes to take place undisturbed. But if these means be insufficient, the artery must be tied; if it be completely divided, ligatures must be placed on both extremities; and if only partially cut, then on both sides of the opening, for, from the numerous communications of the arteries, when the main current is checked, another in a retrograde direction is always established into the part beyond the ligature. The operation of the ligature is not merely to prevent mechanically the flow of blood from the opened vessel. When a fine cord is drawn tightly round an artery, something is felt to give way under it, and, on removing it and opening the artery, its inner and middle membranous coats are found cleanly cut through as with a knife, while the outer coat remains entire. When the ligature is left on, it embraces this outer coat closely, and thus rendering the canal impervious, completely prevents further bleeding. The blood thus becoming stagnant coagulates in the lower part of the vessel and adheres to its walls; these at the same time inflame, coagulating lymph is effused from their cut edges, and becoming organized, at last, as in the natural process, completely fills up the canal of the vessel, while the part constricted by the ligature ulcerates and gives way, permitting the cord to be safely drawn away at the end of from six to sixteen days.

Previous to the general use of the ligature, introduced by Ambrose Paré in the sixteenth century, numberless means for checking hæmorrhages, then so frequently fatal, were resorted to by surgeons, under the names of styptics, astringents, &c. They were in the habit of applying hot irons to the stumps of amputated limbs to stop the bleeding, which it is probable the eschar thus formed would generally effect. At present however the use of the actual cautery is nearly abolished in this country; it can only be justifiable in the few cases where, from peculiarity of situation, the vessel can neither be tied nor compressed, and for such cases it is certainly the most effectual styptic known. Cold air or ice is nearly as useful, and far oftener applicable: it is quite sufficient in all common cases where only small vessels are divided. In the very few cases where any astringents are required, as in some of external bleeding from diseased surfaces or from tumours, the best are solutions of sulphate of copper and of alum. Another class of remedies that may be usefully employed are those which act mechanically —as sponge, agaric, lint, and other light very porous bodies, which placed over a small bleeding orifice will soon completely obstruct it by favouring the coagulation of the blood.

Such are the principal modes of treatment applicable in cases of external or surgical hæmorrhage in which vessels are divided by external injury, and are within reach of the eye or fingers. In internal hæmorrhages however it is obvious that mechanical means can rarely be employed. From the varied nature of the cases from which they arise it is evident that different means may be required in the several kinds of cases. In those so closely related to inflammation, in which there is accumulation of blood from local or general excitement, the hæmorrhage is itself a naturally curative means of its cause, and need not be checked unless it implicates some important organ, as the brain, and then the most advisable means of arresting it is to bleed from the arm. So, too, in cases of habitual or vicarious hæmorrhages, if not dangerous or very inconvenient from locality, it will seldom be advisable to check them, for they are generally outlets by which a plethoric condition that would else be highly injurious is cured; at any rate they should be arrested gradually and cautiously. Where external means are applicable none are so useful as cold, or, as a last resourse, pressure; as by plugs put in the nostrils, &c. Where a mechanical obstacle to the passage of the blood exists, medicine can often do nothing for the permanent cure of the hæmorrhage that it produces. For the time, the most effectual means are cool air, cold water or ice applied as near as convenient to the seat of bleeding, iced drinks, perfect quietude, and the avoidance of all stimuli; the body should be placed in that position in which blood may gravitate from the affected part, and if there be any indication of plethora or accelerated circulation blood should be drawn from the arm to an amount to be determined by the circumstances of the case. In many cases great benefit results from exciting the vessels, of and near the part, to a copious secretion of the usual fluids, as in some cases of hæmatemesis by administering purgatives. If astringent remedies be deemed advisable, and in many cases they are highly useful, the acetate of lead will generally be preferable, and next to it the different vegetable compounds of gallic acid. [ASTRINGENTS.] The treatment of the peculiar class of hæmorrhages from alteration of the blood is considered under FEVER, &c. (J. F. D. Jones, *On Hæmorrhage and the Ligature;* T. Watson, *Cyclopædia of Medicine*, art. ' Hæmorrhage.')

HÆMORRHOIDS (from αἷμα, blood, and ῥέω, to flow), varicose tumours of the veins of the rectum. [VEINS, DISEASES OF.]

HÆ'MULON, a genus of fishes of the section Acanthopterygii and family Sciænidæ. Generic characters:—a single dorsal fin; seven branchiostegous rays; lower jaw compressed, a small oval opening and two small pores under its symphysis; the vertical fins partially covered with scales.

These fishes generally approach to an elongate oval form; the body is moderately compressed; the tail is forked; the dorsal fin, which occupies the greater portion of the distance between the back of the head and the tail, although continuous, has a considerable indentation at that part where the spinous rays join the flexible. The portion of the under-jaw which is covered by the upper when the mouth is closed, is invariably of a bright red colour. The species of Hæmulon chiefly inhabit the Caribbean Sea, and are eaten by the inhabitants of the West Indian islands. They are of moderate size, varying from six inches to one foot in length, and generally adorned with longitudinal or oblique dark markings on a pale ground colour.

HÆMUS. [BALKAN.]

HÂFIZ, MOHAMMED SHEMS EDDÎN, a celebrated Persian poet, was born at Shiras, at the beginning of the fourteenth century of the Christian æra. From his earliest years he received a lettered education; and paid great attention to the study of religion and Mussulman jurisprudence. He afterwards cultivated poetry, and became so celebrated that the Sultan of Bagdad invited him to his court. Hâfiz however appears to have remained in his native town the greater part of his life. His Persian biographers relate an interview he had with the celebrated Timur (Tamerlane), who conquered Shiras, A.D. 1387. The date of his death is uncertain; it is placed by Daulet Shâh, A.D. 1389. A splendid monument was erected over his grave, which is described by Kaempfer (*Amœnitates Exoticæ*, p. 301); and Franklin (*Observations on a Tour from Bengal to Persia*, pp. 90-7) gives us an account of another monument erected to his memory in more modern times.

The poems of Hâfiz, like those of Anacreon, celebrate the pleasures of love and wine. They have always been greatly admired in Persia; though many Mohammedans have condemned them for their irreligious and licentious tendency. The admirers of Hâfiz, on the other hand, contend that his poems are not to be understood in a literal, but in a figurative or allegorical sense; and that they express in emblematical language the love of the creature to the Creator. The sect of the Sûfis, who interpret the poems of Hâfiz in this manner, possess many similar poems. They maintain that by wine he meant devotion, by perfume the hope of divine favour, and some have gone so far as to compose a dictionary of words in the language of the Sûfis (see Sir W. Jones, ' On the Mystical Poetry of the Persians and Hindus,' *Asiatic Researches*, v. 3). But we are not sure that any of the poems of Hâfiz ought to be interpreted in this manner. Sir W. Jones, who was a great advocate for such a mode of interpretation, remarks, in the essay referred to above, ' It has been made a question whether the poems of Hâfiz must be taken in a literal or figurative sense; but the question does not admit of a general and direct answer; for even the most enthusiastic of his commentators allow that some of them are to be taken literally, and his editors ought to have distinguished them, instead of mixing the profane with the divine, by a childish arrangement according to the alphabetical order of the rhymes' (p. 172-3). We are aware that many Europeans justify the allegorical mode of interpreting the poems of Hâfiz, by a reference to Solomon's Song and the Sanscrit poem ' Gita Govinda' by Jayadêva. It is however very doubtful whether these poems ought to be interpreted in an allegorical manner. [SOLOMON; JAYADEVA.] The poems of Hâfiz have had a great number of Sûfi commentators, such as Shuri, Seid Ali, Lamei, Sururi, and Shemei; but the most celebrated are the Turkish commentators Feridun and Sudi.

The poems of Hâfiz were arranged after his death, by Seid Kâsem Anvâri, and were entitled the ' Divân.' The ' Divân' contains, according to the best MSS., 571 odes, called ghazels. They were published in the original Persian, at Calcutta, 1 vol. fol., 1791; this edition contains only 557 ghazels, and 7 cassidehs, or elegies. Rewuski published a few of the odes with a Latin translation and the commentary of Sudi, under the title of ' Specimen Poeseos Asiaticæ, sive Haphyzi Ghazelæ, sive odæ sexdecim,' Vienna, 1771. Several of the odes are inserted in Sir W. Jones's ' Commentarii Poeseos Asiaticæ;' Wahl's ' Neu Arabische Anthologie,' 8vo., Leip., 1791; Ousley's ' Persian Miscellanies,' 4to, Lond., 1791; ' Asiatic Miscellany,' 2 vols., Calc., 1785-6. The whole ' Divân' was translated into German by Von Hammer, Tübing., 1812; and several of the odes have been translated into English by Richardson, ' Specimen of Persian Poetry, or the odes of Hâfiz, with an English translation and paraphrase, chiefly from the *Specimen Poeseos Asiaticæ* of Baron Rewuski,' Lond., 1774; Nott, ' Select Odes of Hâfiz translated into English verse,' 4to., Lond., 1787; Hindley, ' Persian Lyrics, or scattered poems from the Diwan-i-Hâfiz,' 4to., Lond., 1800.

Further particulars concerning the life and writings of Hâfiz are given in the life prefixed to the Calcutta edition of his poems; in the biography of Daulet Shâh, in Wilken's *Chrestomathia Persica*, Leip., 1805; and in the 4th vol. of the *Notices et Extraits des MSS. de la Bibliothèque du Roi;* in the article ' Hâfiz' in the *Biographie Universelle*, by Langlès: and the same article in Ersch and Gruber's *Encyclopädie*, by Kosegarten.

HAGGAI (חַגַּי, Ἀγγαῖος), one of the twelve minor Hebrew prophets. We know nothing concerning the place or time of his birth. The pseudo-Epiphanius, in his Lives of the Prophets, states that he was born at Babylon; and according to the Rabbis he was a member of the Great Synagogue. The date of Haggai's prophecy is fixed by himself (i. 1), and by Ezra (v. 1), in the second year of the reign of Darius Hystaspis (B.C. 519). We learn from Ezra that the Jews, who returned to their native country in the first year of the reign of Cyrus, commenced rebuilding the Temple, but were interrupted in their undertaking by the neighbouring satraps, till the second year of the reign of Darius Hystaspis, when the building was again continued in consequence of the exhortations of Haggai and Zechariah.

The prophecy of Haggai may be divided into four parts: in the first, the prophet urges the people to continue building the temple, by the promise that God would bless them in their undertaking, and that their previous neglect had been the cause of the drought and bad seasons which they had experienced (i.); in the second, he encourages them by the promise that this second temple should surpass the first in glory; this prophecy is supposed by many to have been fulfilled by Christ entering the temple (ii. 1—9); in the third, he promises the people an abundant harvest, since they had begun to build the temple (ii. 10—19); and in the fourth, he fortels the prosperity of Zerubbabel, governor of Judah (ii. 20—23). Zerubbabel is considered by many commentators to be a type of the Messiah; and the prophecy is supposed to relate to the glory of the Messiah's kingdom.

The canonical authority of this book has never been disputed. It is quoted by the author of the Epistle to the Hebrews, xii. 26; compare Hag. ii. 7, 8, 22.

The prophecy of Habakkuk is written in a dull and prosaic style, and bears traces of having been composed in a late period of Hebrew literature. It possesses none of that vigour and sublimity which distinguish the works of most of the Hebrew prophets who lived before the Babylonish captivity.

The Septuagint, Vulgate, and Syriac versions of the Old Testament attribute the 111th, 126th, 127th, 146th, 147th, and 148th Psalms to Haggai and Zechariah.

(Eichhorn, *Einleitung in das Alte Testament*, iv. 422—427; Augusti, *Einleitung in das Alte Testament*, p. 344—348; Rosenmüller, *Scholia;* and the list of commentators in Watt's *Bibliotheca Britannica*.)

HAGGARD. [FALCONIDÆ, vol. x., p. 181.]

HAGUE, THE (*'s Gravenhaag*), a large and beautiful town, the capital of the province of South Holland, in the kingdom of the Netherlands. It is not fortified, but is surrounded with a moat with drawbridges over it. Though from being thus open it has been generally designated as a village, it may be ranked among the handsomest cities of Europe for its stately buildings, its broad and regular streets traversed by canals, and for its pleasant situation on a dry soil, which is rather more elevated than the surrounding country, so that the air is tolerably pure and healthy. Many of the streets are planted with rows of trees and paved with coloured bricks. The finest parts of the town are the Voorhout and the Vyverberg, of which the latter, with a fine avenue of trees and a walk on one side, and on the other a spacious basin of water with magnificent buildings, is peculiarly agreeable. Among the most remarkable public buildings may be reckoned the royal palace, the exterior of which is by no means beautiful, with a large garden; the former residence of the Stadtholder, beautified by Louis Bonaparte, in which the two chambers of the States-General now hold their sittings, and in which there are many public offices; the palaces of the Prince of Orange and Prince Frederick; the Buitenhof, which contains a gallery of pictures; the town-hall, with very fine paintings; the cannon-foundry, erected in 1668; the theatres, and the state-prison. Among the churches are three Dutch Reformed, and the French church, formerly Reformed, now Roman Catholic. The Portuguese and German Jews have large synagogues, and the Lutherans, Presbyterians, Remonstrants, and Jansenists have chapels. There are likewise numerous charitable and scientific institutions, and fine private collections. On one side of the town there is a canal constantly covered with vessels, and on the other a fine wood of oaks called the Bosch, in which is the country-palace of the royal family, resembling a gentleman's country-seat, but with a fine collection of pictures, and extensive gardens laid out in a less stiff and formal manner than the usual Dutch style. There are numerous elegant villas in the environs, and on the west of the town is Scheveling, or Scheveningen, a neat fishing-village, containing about 700 houses, and which has become, especially of late years, much frequented for its sea-bathing. Between that and the Hague is a fine avenue of oaks, beeches, and limes.

The Hague seems to have owed its origin to a hunting-seat of the counts of Holland in the wood (Haag), which however so early as 1250 became a palace, round which many other houses were soon erected. In the sixteenth century the Hague became the residence of the States-General of the States of Holland, the Stadtholder, and the foreign ambassadors. In the course of the seventeenth century it was gradually enlarged, and at the commencement of the eighteenth was the centre of the most important diplomatic negotiations. [Anne, Queen of England; George I.] The prosperity of the Hague was very materially injured by the Revolution in 1795, and afterwards by the government of Louis Bonaparte, who removed the great public offices, &c., to Utrecht and Amsterdam: the return of the Prince of Orange in 1813, who was most enthusiastically welcomed by the inhabitants, restored it to its former splendour. The population, which had greatly decreased, has since gradually recovered. In 1817 there were 42,000 inhabitants, and in 1837, 54,000. The Hague never having been either a commercial or a manufacturing town, the inhabitants have not the mercantile habits of the generality of their countrymen. (N. G. Van Kampen, *Staat-en aardrijkskundige Beschrijving van het Koningrijk der Nederlanden*; Stein, *Handbuch*.)

HAILES, LORD. [Dalrymple.]

HAINAN, an island situated in the Chinese Sea, opposite the southern extremity of the province of Quan-tong, or Canton, to which it is annexed, and from which it is divided by the channel of the Junks, a straight only 15 or 16 miles wide. It lies between 18° 10′ and 20° 24′ N. lat., and 108° 50′ and 111° E. long., and encloses the gulf of Tonquin on the east. Its length from south-west to north-east may be about 200 miles, and its average breadth perhaps not less than 100 miles; its surface may cover an area of 20,000 square miles, or nearly the double of Sicily.

The interior of the island is occupied by an extensive mountain-mass, called Ta Utshi Shan, or the Great Utshi range: from this there issue a great number of offsets, which towards the south-west and north-east advance close to the sea, but are separated from the south-eastern and north-western shore by a level tract of considerable width. These plains, which are of great fertility and well cultivated, yield annually two or three crops of rice and other grains. the small rivers which descend from the mountain-region are used for irrigating this tract. Sweet potatoes form the principal food of the people, though they cultivate fruits, sugar-cane, tobacco, indigo, and cotton on a large scale. But the extensive forests which cover the sides of the mountains form the principal wealth of the island. Besides different kinds of timber-trees, these forests produce sandal-wood, brasiletto, ebony, rosewood, and many other kinds, which are used as dye-woods, or for furniture. Wax is gathered in large quantities. An insect called Pelatshhung produces a white wax, from which candles are made at Khiung-tsheou, and exported to other parts of China. The climate of the island is not very hot, being exposed to the wind which blows over a large expanse of sea: fogs and heavy dews are frequent, and maintain a vigorous vegetation. The coast is frequently laid waste by hurricanes, which are peculiar to the ocean that surrounds the island.

According to the census of 1823 Hainan was inhabited by 987,725 persons, subject to the Chinese government; but the higher parts of the mountains are possessed by aboriginal tribes, which are still independent, and called Li. Those which are subject to China resemble the Chinese in figure, and have adopted their usages, but they speak a different language, though they use the Chinese characters. They are very industrious husbandmen. There are some very populous towns in this island. Khiung-tsheou, the capital, situated at its northern extremity on the channel of the Junks, is said to have 200,000 inhabitants; and Kai Kheou-so, where the governor resides, is said to contain as many. Some others have 80,000 or 90,000 inhabitants each. (Du Halde, *History of China*; Klaproth's *Description de l'Isle de Hainan*, in 'Nouv. Ann. des Voy.,' vol. vi.; and Captain Purefoy's *Diary of a Journey to the Coast of Hainan*, in 'Asiat. Journ.,' vol. xx.)

HAINAULT (in Flemish, Henegouwen), a province of Belgium, bounded on the north by East Flanders and South Brabant; on the east by Namur, on the south by France, and on the west by West Flanders. Hainault lies between 49° 58′ and 50° 48′ N. lat., and between 3° 17′ and 4° 33′ E. long.; its greatest length from south-east to north-west is about 55 miles, and its breadth 30 miles. Its area is 372,193 bonniers, equal to 1438 square miles (English), thus divided:—

Cultivated	295,178	bonniers.
Uncultivated	2,071	„
Woods	61,832	„
Towns and Buildings	3,659	„
Rivers and Canals	1,165	„
Roads and Paths	8,288	„
Total	372,193	bonniers.

The province does not contain any mountains, but is hilly towards the south and east. It is watered by the Schelde, the Sambre, the Dender, the Haine, from which the province derives its name, the Trouille, and the Senne. The Schelde enters the province from France, near to its confluence with the Scarpe at Condé, and flows to the north-north-west to Tournay; then changing its course to north-north-east, it forms the boundary-line between Hainault and West Flanders, and quits the province at Escancffles, its north-western extremity. The Sambre also enters the province from France, near Maubeuge, flows north-west to Charleroy, and soon after enters Namur. The Dender rises within the province at Herchies, flows north-east to Ath, and then north-north-west, quitting Hainault at Grammont. The Haine is formed by three brooks which rise in the commune of Anderlues, a little to the west of Charleroy; it flows from east to west, near to Mons, and falls into the Schelde at Condé. The Trouille rises at Grandreng, near the frontier, and flows from east to west; it enters France, but leaves it again almost immediately, flows then north-north-west to Mons, and falls into the Haine near Jemappes.

The soil of the province is for the most part fertile. The arrondissement of Tournay is the most productive, and that of Charleroy the least so. The chief agricultural productions are wheat, rye, oats, winter barley, potatoes, beans, rape, flax, and hops: tobacco and chiccory are cultivated in some parts. Much of the land near the rivers, where irrigation can be practised, is natural meadow. In othor places trefoil, lucern, and sainfoin are cultivated.

Hainault is divided into three arrondissemens, Mons, Tournay, and Charleroy; and contains 21 towns and 424 communes. The towns are Antoing, Ath, Beaumont, Binch, Braine-le-Compte, Charleroy, Châtelet, Chièvres, Chimay, Enghien, Fontaine l'Evêque, Gosselies, Lessines, Leuze, Mons, the capital of the province, Péruwelz, Rœulx, St. Ghislain, Soignies, Thuin, and Tournay. [Ath; Beau-

MONT; BINCH; CHARLEROY; MONS; TOURNAY.] Antoing is a small town, with 1922 inhabitants, on the right bank of the Schelde, and on the high road from Mons to Tournay, about 4 miles south-east from Tournay. Some limestone quarries and some large breweries are situated there. Braine-le-Compte, about 4 miles north-east from Soignies, contains 4218 inhabitants; it stands on the high road from Brussels to Mons. This town contains some cotton-mills, breweries, dye-houses, tanneries, and oil-mills. Châtelet is a small town, about 4 miles east from Charleroy, with 2555 inhabitants. Cotton and woollen manufactures, pottery, salt-refining, brewing, and tanning are carried on in this town. Chièvres, a small town with 3055 inhabitants, stands 2½ miles north-north-west from Ath. Flax-spinning and linen-weaving occupy a great number of hands, and there are in the town several breweries and oil-mills. Chimay has 3300 inhabitants: it stands 28 miles south of Charleroy, and 32 miles south-south-east from Mons; it contains a college and four schools. A great part of the working-class in this town are employed either in the iron-works or in procuring fuel for their use: the proximity of the place to the French frontier causes a brisk contraband trade to be carried on. Enghien, 12 miles east-north-east from Ath, and 8 miles north from Soignies, contains 3739 inhabitants. The town is built on the side of a hill; it is regularly laid out and well built: it contains a college, four schools, and a hospital. The castle and park of Enghien were built and formed in 1712, by Duke Leopold of Aremberg. The cattle was destroyed at the close of last century: the park, which was laid out with much taste and embellished with groups of statuary, is said to have served as the model for the gardens at Versailles. Fontaine l'Evêque, 6 miles east from Charleroy and 16 miles east from Mons, contains 2825 inhabitants. Nail-making is the chief branch of industry carried on in this town. Gosselies, a town with 4240 inhabitants, is about 3 miles north from Charleroy: great part of the malo inhabitants are employed in the coal-mines; nail-making, salt-refining, and glass-blowing are also carried on. Lessines, a small town with 4592 inhabitants, is 7½ miles north of Ath; it is so surrounded by the Dender as almost to form an island. This is a place of much trade. The quarries furnish large quantities of paving-stones, and likewise some stone for building. The other chief branches of traffic are coal, wood, and vegetable oil. Leuze has 5386 inhabitants, many of whom are employed in the cotton and woollen manufactures. A considerable number of persons are also employed in preparing mercery and small wares. The town is 10 miles east from Tournay; the high road from Brussels to Lille passes through it. Péruwelz, on the road between Valenciennes and Ghent, about 11 miles south-east from Tournay, is a town of 6958 inhabitants, who are principally occupied in manufacturing hosiery goods, cotton and woollen cloths, and leather. A considerable trade was formerly carried on in the article of alum, prepared from aluminous schistus found on the spot; but since the discovery of the method of chemically composing this salt from its components by a cheap and easy process, this branch of industry has ceased at Péruwelz. Rœulx is a small town containing 2450 inhabitants, situated 8 miles north-east from Mons. The castle of Rœulx is a very antient building, the principal façade of which was rebuilt in 1760 in a very handsome style; the gardens and grounds are extensive, and laid out in the English style. There are not any manufactures and but little trade is carried on in this town. Saint Ghislain, 7 miles west from Mons, is a small town built on the river Haino, and containing 1573 inhabitants. Standing in the middle of the coal district, various manufactures which depend for their prosecution upon an abundauce of cheap fuel have been established; among these may be mentioned salt-refining, soap-boiling, and brewing. The town stands on the high road from Mons to Tournay. Soignies, a well-built town on the Senne, is situated 10 miles north-north-east from Mons, and contains 6313 inhabitants. Many of the houses are largo and handsome. The town is surrounded by ramparts, which were formed in 1150, and are now crumbling through age. The church of St. Vincent is said to be the oldest building in the province. There is a college within the town, which in 1827 contained above 280 students. There are many religious and charitable establishments in Soignies, and it is said that 2200 of the inhabitants are regular pensioners; altogether two-thirds of the population are in an indigent condition. The chief means of employment is afforded by some limestone quarries, whence considerable supplies of building-stone are procured. Thuin, on the Sambre, is 10 miles south-west from Charleroy, and contains 3686 inhabitants. An iron-work established at this place produces 1100 tons per annum: there is but little other trade. Boussu, 7 miles west from Mons, stands on the Haine. This is a considerable village, containing a church, a chapel, two schools, and 500 houses. The population in 1829 was 2887, many of whom are employed in raising coal or burning lime. Courcilles, 5 miles north-west from Charleroy, contains 3226 inhabitants, whose principal employments are nail-making and weaving napkins and tablecloths. Dour, a large bourg, 8 miles south-west from Mons, has a population of 5484 inhabitants, many of whom find employment in the productive coal-mines of the district. there are also ropewalks, tan-yards, lime-kilns, and a manufactory of safety-lamps. Fontenoy, an inconsiderable village, containing 678 inhabitants, is 4 miles south-east of Tournay, on the high road from that town to Mons. A battle was fought near Fonteuoy in May, 1745, between the French under Marshal Saxe and the allies under the duke of Cumberland, in which the latter were defeated with the loss of 15,000 men. Hornu, a village 5 miles west from Mons, is the seat of considerable coal-mines, giving employment to from 1500 to 1800 men. The village is chiefly composed of the cottages of the miners, which are built on a regular plan, and so arranged that the steam-engine which discharges water from the mines is also employed to distribute both warm and cold water to each habitation. There are likewise warm and cold baths, two large squares for promenading and public games, and a dancing-room for the use of the workmen, all established by the proprietor of the mines, who likewise supports a school for 400 children and a library. There are employed in these works 12 steam-engines, whose united power is equal to that of 320 horses. The village of Jemappes, on the high road from Mons to Valenciennes, about 3 miles from Mons, with a population of 4667, is also the site of considerable coal-mines. This place is celebrated for the victory gained on 5th November, 1792, by the French over the Austrians, and which led the way to the conquest of Belgium. Jumetz, to the left of the high road from Charleroy to Brussels, contains 6528 inhabitants, many of whom are engaged in prosecuting various manufactures, among which glass-blowing, brewing, distilling, and tanning are the most considerable; severa. are also employed in coal-mining.

The number of persons accused and convicted before the courts of assize and the correctional tribunals in this province, during each of the four years from 1831 to 1834, was, according to official returns, as follows:—

	Courts of Assize.		Correctional Tribunals.	
	Accused.	Convicted.	Accused.	Convicted.
1831 . .	95	48	1,936	1,366
1832 . .	35	13	2,488	1,876
1833 . .	21	19	2,526	1,851
1834 . .	116	12	3,031	2,211

The great difference in the number accused before the courts of assize in these years arose from 48 persons in 1831 and 77 persons in 1834 having been concerned in riots, the greater part of whom were acquitted. The only capital conviction occurred in 1834, when one man was found guilty of murder. In proportion to its population, Hainault presented in the above years fewer delinquents than any other province of the kingdom; and it is deserving of remark, that, with the exception of Luxembourg and Namur, the proportion of students is greater also. In 1831 there were 888 schools, giving instruction to 35,671 boys and 29,048 girls, being very nearly 1 in 9 of the whole population. [BELGIUM.]

HAINAULT SCYTHE AND HOOK. [FLANDERS AGRICULTURE.]

HAIR. The hairy coverings of mammalia are composed of long delicate processes of a horny substance, which grow from bulbs situated in or beneath the skin. Each hair is contained at its lower part in a delicate sheath, or follicle, which passes obliquely from the surface of the skin on which it opens to a greater or less depth, and at its base dilates into a pouch containing the bulb of the hair. The bulb of the hair consists of a small cone-shaped body, the pulp. soft and delicate, and apparently made up of blood-vessels and nerves, and covered by a reflection of the smooth lining of the sheath of the hair, which is continued from the cuticle covering the surrounding skin. On the whole surface of this bulb the substance of the hair is secreted, and as each layer which is deposited pushes that previously formed onwards, the whole gradually advances along the sheath till it projects beyond the skin, and thence continues to grow free. In the early embryo the sheath or follicle in which the hair is afterwards formed is alone seen, then a delicate vessel may be traced to its base, where a little black spot is soon formed, and this, as all the other parts increase, is gradually developed into a hair. Into each hair-follicle, as Gurlt has shown, there open the ducts of one or two little glands, by which the oily matter is secreted to lubricate the hair and keep it supple and firm, and where these are deficient the same purpose seems to be performed by the follicle itself. The annexed cut will explain the general mode of formation of hairs, which, it may be observed, is effected in the same manner as that of horn, nail, and many other extra-vascular appendages of animal bodies, viz. by the deposition of successive layers of organic matter on the surface of an abundantly vascular tissue. *Fig.* 1 represents an oblique section of the pulp and lower part of the whisker of a lion, in the Hunterian Museum, in which *a* is the body of the hair, *b* the conical pulp, and *c* a blood-vessel passing into and ramifying in it. *Fig.* 2 is a section of the skin of the upper lip of a lion, with part of a whisker completely formed, and another in progress of growth, from the same collection; *a* is the outer part of the hair-follicle, formed by a deep depression in the skin; *b* is its internal cuticular lining; *c* the contained hair; *d* the sheath containing the vessels and nerves, passing to the base of the follicle and bulb of the hair. *Fig.* 3 is a section of the skin, containing a hair from the human scalp, from the figure by Gurlt, in Müller's 'Archiv für 1835:' here *a* is the thin cuticle, *b* the cutis, *c* the subjacent fat, *d* the cellular tissue, in which the base of the hair follicle *e* is seen; *f* is the hair itself, enlarged at its base, and *g g* are the two sebaceous glands opening into the sheath. These views are of course all much magnified; indeed in man the component structures are so minute that part of the description is of necessity taken from the analogous structures in other animals.

Fig. 1.

Fig. 3.

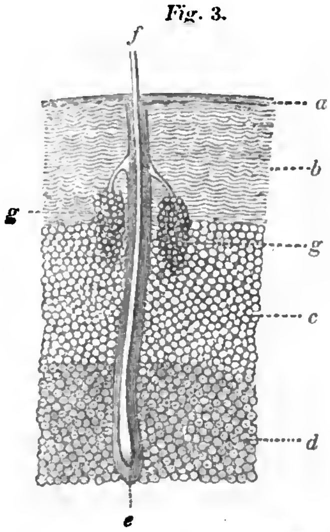

Fig. 2.

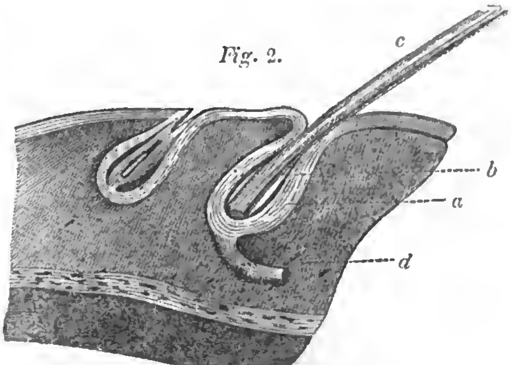


In man the hairs are not, as has been generally supposed, perfectly cylindrical. Weber has shown that they are all more or less flattened, so that a transverse section presents an elliptical form, or sometimes, from one side being grooved, has the shape of a bean. The hair of the whiskers, beard, and mustachios, and in general all short curly hair, is most flattened. In most instances flatness and curliness are directly proportionate, and both attain their maximum in the crisp woolly hairs of the negro, which are sometimes as much as two-thirds broader in one direction than in the other. The hair of the negro however, though called woolly, differs considerably from the wool, properly so named, of sheep and other animals: the latter is not spirally curled, but wavy, all its curves being nearly in the same plane; it is much more delicate, and perfectly round, and hence, from its being equally fitted to curl in any direction, is peculiarly adapted for spinning, while the flattened hairs of men have always a tendency to turn their broadest surfaces towards the middle of the curl.

Except at their base, into which the conical pulp enters to a variable distance, the hairs are perfectly solid, and in most animals their substance is similar throughout. Weber has shown that the appearance of a central canal running along them, and of a softer internal than external material, has resulted from microscopic errors, occasioned by the unequal refraction of light passing through their rounded or grooved surfaces. Only in the lion, zebra, and llama did Weber find that the internal part seemed rather paler than the outer; in the roebuck and a few other animals he found the cellular structure which has been sometimes erroneously supposed to exist in all hair. The cells are all hexagonal, much like those in the cellular tissue of plants. The average diameters of hairs from the human head are respectively about $\frac{1}{300}$th and $\frac{1}{500}$th of an inch, and hairs often attain a length of 6 or 7 feet in women. Instances are recorded also of the hair of the beard growing to a length of nine feet. They are generally of the same thickness throughout their whole length in man, but in the finer kinds of wool they are of unequal size at different parts. This seems to indicate an occasional alteration in the size or activity of the pulp, a supposition which is further supported by the varieties of colour which the same hair sometimes presents, as in those animals which seem to have grey furs, but in which each hair is made up of alternate bands of black and white. In man however nothing of this kind occurs; the colour of each hair is uniform, the appearance of greyness being produced by a mixture of completely white with dark hairs. The colour of the human hair generally varies with the colour of the iris and the general dark or light hue of the skin. Commonly the darker the hair, the more robust the body, and the coarser the skin and other tissues; and this holds still more with animals than in man, for not only are white or grey horses less healthy and vigorous than dark ones, but if one or two of a dark horse's legs be white, they are always most liable to injury and to disease.

Hairs are very elastic; they admit of being stretched nearly one-third of their length, and regain their original length almost completely: in proportion to their size, they are very tough and firm. In masses they are impenetrable, except to very great violence, and hence one of their uses in the thick coverings of animals: they are also adopted in armour, as for the coverings of helmets. They are extremely bad conductors of heat, and they are generally found most thick and abundant in animals subject to long exposure to cold, in whom moreover an additionally thick coat is provided at each winter after the annual shedding. They are non-conductors of electricity, and when rubbed with almost any other substance so large a quantity of negative electricity is developed, that in the dark even sparks may be seen, and the peculiar crepitating sound of rapid little electrical discharges may be heard. This is especially the case with the drier hairs of cats, dogs, &c., but weaker electrical phenomena may be observed by rubbing the human scalp. Hair is also remarkably hygrometric, attracting and retaining in its tissue a large quantity of moisture, in consequence of which it becomes flaccid and lengthens, and hence it is used in the construction of the more common hygrometers. It assists also to shield the skin from moisture by its oily surface, and when thick presents almost an impenetrable barrier to water. Thus serving to isolate the animal from the three most powerful external agents, heat, electricity, and moisture, it is scarcely possible to imagine any structure better adapted for the external covering of the wholo body, whose motions it is too light to impede, and to whose beauty it so remarkably contributes.

In chemical properties hair resembles horn, nails, &c. It is soluble in water at a very high temperature, as in a Papin's digester, leaving a large quantity of oil mixed with sulphuret of iron, and some sulphuretted hydrogen. It is this oil, with the sulphuret of iron, which gives the colour to the hair, and by whose absorption greyness is produced. The iron is most abundant in the darkest hair, and the sulphur is the ingredient on which the action of the various black dyes for red or grey hair depends. These are all composed of some salt of silver or lead, which, mixed with some oily or fatty substance in the form of pomatum, insinuates itself into tho hair, where it is decomposed and a black sulphuret of silver or lead is formed. Hair is soluble in alkalis and alkaline earths, and for this reason the depilatories in common use are chiefly composed of quiok-lime, which however is materially injurious to the skin at the samo time that it removes the hair. Hair contains a vory small quantity of water, and when burnt leaves a large proportion of ashes, containing iron, manganese, and various salts of lime; it is owing to these properties that hair is peculiarly indestructible, and has been found unaltered on mummies more than twenty centuries old. It has even been supposed to grow after death, but it is probable that, in the few authentic cases in which this is stated, it was owing to the lengthening of the hair by the attraction of moisture from the body or surrounding atmosphere, and to the more rapid drying and contraction of the adjacent tissues.

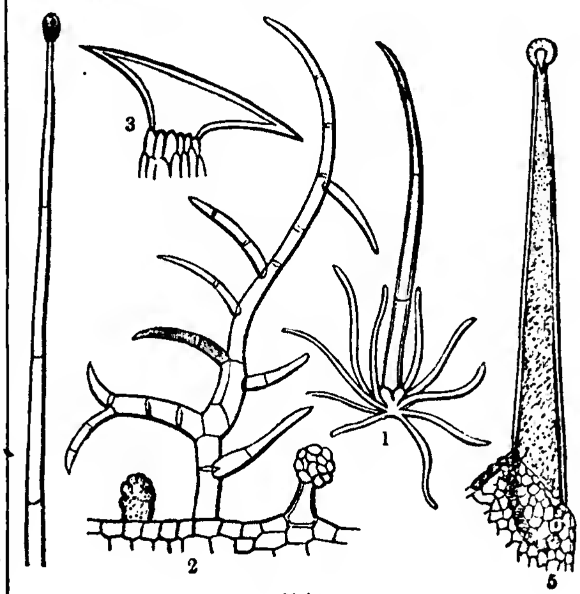
Little need be said of the diseases of hairs. Possessing neither vessels nor nerves, except at their base, they are rarely altered except by the diseases of the skin itself. Their fall, as it is called, is in most animals annual, but in man seems not to occur except by accident, or after particular diseases. The process by which it takes place is unknown, but is probably similar to that of the shooting of the quills of the porcupine, by the gradual approximation of tho base of the follicle to the surface. Their loss of colour, which is sometimes exceedingly rapid, is owing to deficient secretion of the colouring oil, and can only very rarely be remedied. When sufficient moisture is not supplied, they sometimes split at their points like bristles; at others they break at the middle of the shaft, snapping off, and leaving a little fringed extremity to the stump. The most singular alteration however to which they are subject is that called the plica polonica, from its occurring almost exclusively in some towns in Poland, in which, with so much general disease as sometimes proves fatal, the hair of the head becomes sticky and matted together, when touched gives extreme pain, and is sometimes said even to bleed when cut. This fact cannot however be regarded as evidence of the hair naturally containing vessels, though it indicates an elongation of the pulp to some distance beyond the skin, just as is the case in dogs, whose whiskers will sometimes bleed if cut very close to the surface.

(Weber, in Hildebrandt's *Anatomie*, vol. 1; Gurlt, in Müller's *Archiv für Anatomie und Physiologie*, 1835.)

HAIRS. In plants these are long expansions of the cuticle, chiefly intended to answer the double purpose of collecting moisture from the atmosphere and of protecting the surface of a plant from the too powerful influence of the sun's rays. It is supposed that they are also destined to assist in the conveyance of certain kinds of seeds through the air, and in other cases, as in that of cotton, they are specially adapted for the use of man. That the two first purposes are those for which hairs growing on the surface of plants are intended, seems sufficiently indicated by tho following facts. Hairs are seldom found on water-plants, which have no occasion for absorbing organs, and when water-plants are accidentally obliged to grow in dry places they acquire them; while on the other hand species naturally found in hot dry places or in arid climates are as usually provided with them, unless in those cases where the cuticle becomes excessively thickened. If a hairy-leaved plant is observed in dry weather it will be found that all its hairs are weak and flaccid; but no sooner does a shower of rain fall, or the atmosphere become humid, than the hairs acquire a rigid consistence.

In all cases hairs are composed of lengthened cells of cellular tissue, extending from one or more of the cells of the cuticle. Most commonly they are quite simple, and are merely formed of several cells of equally diminishing size, placed end to end, or of a single cell. Of the latter kind are the long entangled hairs that clothe the surface of the cotton-seed, and which are manufactured into thread and linen. Sometimes several such hairs spring from a common point as in Malvaceous and Euphorbiaceous plants, and Marrubium creticum (*fig.* 1); these are technically called *stellate*. Others branch in various ways, as in Nicandra anomala (*fig.* 2), and from such the woolly appearance of the surface of plants often takes its origin. It somotimes happons that the cell, out of which a hair is formed, instead of growing perpendicular to the surface, lengthens in a parallel direction, growing at two opposite sides; cases of this sort are found commonly in Malpighiaceous plants, and in the common hop (*fig.* 3). Finally, in those instances where the the terminal cell enlarges and is furnished with an aperture, hairs becomo glands, and consequently secreting organs (*figs.* 4 and 5).

In consequence of the hairs of plants being an extension of cellular tissue, which is naturally thin-sided, all hairs are much weaker than the tough thick-sided tubes of which woody tissue is composed. This accounts for the well known fact that all goods manufactured from cotton, which is vegetable, are far less tough and durable than those which, like linen, are prepared from the tissue of bark or wood. When the two forms of matter are submitted to microscopical examination, the thin sides and transverse partitions of the former will usually distinguish it from the thick-sided tubes of the latter, in which no partitions are discoverable.



Hairs.

HAJE, a name of a venomous serpent, *Coluber Haje* of Linnæus. [NAIA.]

HAKE, a fish allied to the cod. [MERLUCIUS.]

HAKLUYT, RICHARD, born in 1553, studied at Christ Church, Oxford, and applied himself particularly to the study of geography, or cosmography, as it was then called, and he was made a lecturer on that subject at Oxford. In order to promoto the study of his favourite scienco he published narratives of several voyages and travels, both English and foreign, which ho afterwards brought together in his great collection. About 1584 he went to Paris with Sir Edward Stafford, ambassador of Queen Elizabeth to the French court, where he remained five years. On his return to England he was made by Sir Walter Raleigh a member of the company of gentlemen adventurers and merchants of London, for the inhabiting and planting 'of our people in Virginia,' as appears from his 'Collection of Travels,' edition of 1589, p. 815, which he published in one vol. fol., and which he afterwards enlarged and published in 3 vols. fol., 1599—1600, under the title, 'The Principal Navigations and Discoveries of the English Nation, by Sea or over Land, to the remote and farthest distant quarters of the Earth, at any time within the compass of these 1500 years.' Tho first volume embraces the discoveries by tho English in the north and north-east by sea, towards Lapland, the Straits of Waigatz, Nova Zembla, and towards the mouth of the river Oby, and also travels through the empire of Russia, Georgia, Armenia, Bactria, Tartary, &c. The second volume contains accounts of the discoveries of the English by sea and land in the southern and south-eastern parts of the globe; and the third, their discoveries in the new world of America. Hakluyt has inserted many curious documents, such as letters of various sovereigns; charters and privileges granted by the Czars of Russia, the Sultan, and others, to English merchants; tables of weights, coins, and distances of different countries, &c. Most of the voyages and discoveries contained in this collection were effected in the sixteenth century, although a few are of a prior date. A new and improved edition, in 5 vols. 4to., was published in London 1809-12. Hakluyt published also or edited translations of several foreign narratives of travellers, of which a selection has been since made: 'A Selection of curious, rare, and early voyages and histories of interesting discoveries, chiefly published by Hakluyt, or at his suggestion, but not included in his celebrated compilation,' 4to., London, 1812. It contains among others La Brocquière's 'French Narrative of a Visit to Palestine,' in 1442-3; the 'Travels of Louis Vertomanus of Romo to Arabia, Persia, and the East Indies in 1502;' and 'Virginia richly valued by the description of the mainland of Florida, her next neighbour,' from the Spanish of Fernando de Soto. Hakluyt died in 1616 and was buried in Westminster Abbey.

HALBERSTADT, an antient bishopric, founded in the year 804, was secularised by the treaty of Westphalia in 1648, and assigned, under the name of a principality, to Frederick, the great elector of Brandenburg, as a compensation for hither Pomerania, which he was obliged to cede to Sweden. It has ever since belonged to Prussia, except that after the treaty of Tilsit it formed part of the ephemeral kingdom of Westphalia. The principality had a superficial extent of about 600 square miles, with 13 large and small towns, 431 villages, and about 135,000 inhabitants, chiefly Lutherans. It is a level and fertile country. The four circles of the principality now form part of the government of Magdeburg, in the province of Saxony, and the name of Halberstadt is confined to one of those circles, about 50 square miles in extent, with 20,000 inhabitants.

HALBERSTADT, the chief town of the circle, is pleasantly situated on the river Holzemme. It is an antient city, said to have been founded by the Cherusci; though the actual date of its foundation is unknown. It became a bishop's see in 804. The most antient part is the Dom Platz (Cathedral Square), formerly a castle. In 1179 the greater part of the town was burnt by Henry the Lion; it was rebuilt in 1203 and surrounded with ramparts. In the Thirty Years' War it made a brave resistance; in the Seven Years' War the French destroyed the gates and a large portion of the ramparts. In 1809 Duke William of Brunswick-Oels stormed the city and made prisoners of the whole Westphalian garrison under Count Wellingerode. In 1813 the Westphalian General Ochs, who was posted here with 20,000 men and 14 pieces of cannon, was suddenly attacked by the Russian General Czernitscheff, who took 1000 of his men and many officers prisoners. The streets of Halberstadt are for the most part long, broad, and tolerably straight. It has many good manufactures of various kinds, and a considerable trade. It is the seat of a high court of justice, and has many public institutions worthy of notice, such as tho cathedral school, with a library of 8000 volumes, a cabinet of natural history, and a collection of instruments; a gymnasium, a seminary for schoolmasters, a literary society, several charitable foundations, &c. There are 7 Lutheran churches, 2 Reformed, or Calvinist, 3 Roman Catholic churches, and a Jewish synagogue which is perhaps the handsomest in Germany. The most remarkablo of the churches are St. Mary's Church, which was completed in 1003, and the cathedral dedicated to St. Stephen, built in the noblest style of the fifteenth century—it is 412 feet long, 72 wide, and 94 high inside, and has 32 altars. The cathedral contains several valuable pictures as well as interesting antiquities and some paintings on glass. The number of the inhabitants is now about 17,000, of whom 1300 or 1400 are Roman Catholics, 450 Calvinists, and as many Jews. About half a mile from the city is the Spiegelsberg, formerly a barren hill, which Baron von Spiegel, dean of the chapter, converted into a public promenade, or what the Germans call an English garden, and left a fund to keep it in order. Halberstadt is in 51° 53′ 55″ N. lat., and 11° 3′ 53″ E. long. (*Top. Stat. Handbuch*, Von Furst; Stein, *Handbuch*; Huber, *Lexicon*.)

HALCYO'NIDÆ. [KINGFISHERS.]

HALDE, DU, born at Paris in 1674, entered the society of the Jesuits, and being distinguished for his information and laboriousness, he was entrusted by his superiors with the care of collecting and arranging the numerous letters written by the missionaries of the society from various parts of the world. This employment furnished him with materials for the collection styled 'Lettres Edifiantes et Curieuses,' which he edited, and which contain much interesting and valuable matter. He also compiled from the reports of the Jesuit missionaries and their translations of Chinese works, a full and well digested description of that empire, which was the first published in Europe: 'Description Historique, Géographique et Physique, de l'Empire de la Chine et de la Tartarie Chinoise,' 4 vols. fol., with an atlas, Paris, 1735, reprinted soon after at the Hague, in 4 vols. 4to., and translated into English by R. Brookes, 4 vols. 8vo., London, 1736. Du Halde made a conscientious use of the best materials which he could get at the time from his brethren of the Chineso missions, and his authorities must answer for the charge brought by some against his work, that it is too favourable to the Chinese and their social system, and that he is too credulous as to the accounts of the Chinese concerning the prodigious amount of their population, the size of their towns, &c. Subsequent writers, chiefly Jesuits, have increased and improved our stock of information concerning China. [AMIOT, LE PERE.] A clever, though sarcastical and somewhat desultory notice of Du Halde's work appeared in England not long after its publication, under the title, 'An Irregular Dissertation occasioned by reading Father Du Halde's Description of China,' London, 1740.

Du Halde was at one time secretary to Father le Tellier, confessor of Louis XIV. He died at Paris in 1743.

HALE, SIR MATTHEW, was born on the 1st of November, 1609, at Alderley, in the county of Gloucester His father had been educated for the bar, but he abandoned the practice of the law because he could not understand the reason of giving color in pleading, which, as he thought, was to tell a lie. Both his parents having died while he was yet an infant, Matthew Hale was educated, under the directions of a near relation on his mother's side, by a clergyman professing puritanical principles. At the age of seventeen he was removed to Magdalen Hall, Oxford, where he speedily got rid of his puritanical notions, and plunged into dissipation with a looseness proportioned to his former austerity. At this period he was upon the point of becoming a soldier in the army of the Prince of Orange, then engaged in the Low Countries. Accidental circumstances however introduced him to the notice of Serjeant Glanvil, who, perceiving the valuable qualities which the young man possessed, persuaded him to apply himself to the study of the law. Acting under this advice he was admitted a student of Lincoln's Inn on the 8th of November, 1629, and immediately commenced a course of arduous study. One of his companions in a debauch having been taken suddenly and dangerously ill, Hale was so struck with remorse that he gave up his intemperate habits. After having studied with great diligence the laws of England and the civil law, and also several other branches of learning, he was called to the bar some time previous to the commencement of the civil war. He resolved not to take any part in the political dissensions and contests which then agitated the country, and he steadily kept his resolution. This part of his conduct is mentioned by some of his biographers with commendation, whereas in reality it arose from a weakness in his character which showed itself on several subsequent occasions. Indeed he seems to have been aware at a later period of his life that it is not the part of a good citizen during times of political agitation, when the liberties of his country are at stake, to prefer his own individual ease and quiet to the general good. His neutrality was highly favourable to his interest as an advocate; he was engaged as counsel for the court party in a number of the most important stato trials, and was notwithstanding held in such esteem by the parliamentary party, that he was constituted counsel to the commissioners deputed by parliament to treat with the royal commissioners as to the reduction of Oxford. After the execution of Charles I., Hale took tho engagement to be true and faithful to the Commonwealth, and accepted the appointment of one of the commissioners for reforming the law. In 1653, after having shown some hesitation as to accepting the dignity, he was made one of the judges of the Common Bench; resolving, after discussing his doubts with lawyers and divines, 'that as it was absolutely necessary to have justice and property kept up at all times, it was no sin to accept a commission from usurpers.' To this his biographer Burnet goes on to add, 'if he made no declaration acknowledging their authority, which he never did.' This addition has given rise to much of tho odium which has attached to Hale's memory in consequence of this apparent insincerity; but credit can hardly be given to the statement, for it is impossible to suppose that Hale, who was unquestionably an honest and sincere man, though perhaps weak in matters of conscience, could have been guilty of the pitiful and shallow attempt to evade the evident conclusion, that acting as a judge under his commission was the most effectual and formal declaration he could make of his submission to Cromwell's authority. Some colour however is given to Burnet's imputation by Hale's subsequent conduct. After having discharged the duties of his office with consummate skill and strict impartiality, he suddenly, and without any apparent cause, affected to feel scruples of conscience at acting as judge in criminal cases, and refused to preside in the crown courts, though he still continued to administer the law in civil cases. This conduct was directly contrary to his reason for accepting the office of judge, and appears to be founded on no just view. On the death of Cromwell, Hale refused to act under a commission from tho Protector Richard, alleging that he could no longer sit under such authority. He was a member of the parliament which recalled Charles II., and was made chief baron of the exchequer in 1660, and knighted. In 1671 he was raised to the chief-justiceship of the King's Bench, where he presided with honour to himself and advantage to the public till 1675, when, from the state of his health, he resigned his office. He suffered considerably from repeated attacks of asthma, and died from dropsy on Christmas-day, 1676.

As a lawyer Hale's reputation is high, and his integrity is unimpeached: indeed his punctilious feelings were carried to a fantastical excess, as many anecdotes related by his different biographers show.

The only spot upon his memory as a criminal judge is the notorious fact of his having condemned two wretched women for witchcraft, at the assizes at Bury St. Edmunds, in the year 1665. Hale in the course of the trial avowed himself a believer in witchcraft, and the jury found the prisoners guilty, notwithstanding many impartial bystanders declared that they disbelieved the charge. No reprieve was granted, and tho prisoners were executed. An anecdote is mentioned by his biographers of having hastened the execution of a soldier found guilty of murder, for fear he should be reprieved; but in so doing he certainly overstepped the bounds of his duty as a judge.

Sir Mathew Hale was a voluminous writer, though none of his productions were printed during his life. His 'Pleas of the Crown,' 'History of the Common Law,' and some other treatises connected with the law, have been published since his death, and also several others upon scientific and religious subjects. His manuscripts, which he had collected at a very considerable expense, he bequeathed to the Society of Lincoln's Inn, and he directed that they should not be lent out or printed, saying, 'As they are a treasure not fit for every man's view, nor is every man capable of making use of them, I would have nothing of these books printed;' and he also directed that any of his posterity, members of that society, might, on giving security, have ono book at a time lent out to them by the society.

A catalogue of the manuscripts was contained in his will, and a full account and catalogue of all his works is printed in Dr. Williams's 'Life of Hale'—recently published. His life has also been written by Burnet and Roscoe, and many anecdotes relating to him are detailed by that amusing gossip Roger North, in his 'Life of Lord-Keeper Guilford,' though it should be observed that the author does not write in a very friendly spirit towards Hale. Notices of his life will also be found in the 4th vol. of tho *Biog. Brit.*

Sir Matthew Hale was twice married: first to Ann, daughter of Sir Henry Moore, by whom he had ten children; and secondly, late in life, to one of his own domestic servants.

HALEB (commonly but erroneously called ALEPPO), the capital of a pashalik of Asiatic Turkey of the same name, is situated in tho north part of Syria, in 36° 11′ 32″ N. lat. (according to Niebuhr), and 37° 9′ E. long. It is one of the largest and most important towns in Western Asia. Tavernier, in 1670, estimated the population at 258,000; D'Arvieux, in 1683, at about 258,000; Russell, in the last century, at 235,000, of which 200,000 were Mohammedans, 30,000 Christians, and 5,000 Jews; Volney reduces the number to 100,000; but Rousseau, who lived for some time at Haleb as French consul, estimates it at 200,000. Rousseau also informs us that the town is built on four hills, called Djeleb beni el-Kaka, on one of which there is a fortified castle; that it is surrounded by a stone wall, and has seven gates*; that it contains 5 serais, or governor's palaces, 100 mosques, of which the most celebrated is that of Zacharias; 50 mesjeds, or oratories, of which the most beautiful, called Helawie, is supposed by Pococke to have been formerly a Christian church built by Helena, mother of Constantine; 10 or 12 public schools, 2 public libraries, 5 mehkems, or courts of justice, 60 baths, 100 coffee-houses, 40 or 45 great bazaars, 31 khans, occupied principally by Franks or other strangers, 200 fountains, about 15 wakfs, or religious institutions, 1 mewla-khâné, or college of dervishes, 5 Christian churches, and 40,000 houses. But the state of the city has been greatly changed by an earthquake which happened in August, 1822, and which destroyed almost two-thirds of the buildings. The population is a mixture of Turks, Arabs, Christians, and Jews. The Christians principally belong to the Greek, Syrian, and Armenian churches: of these the Greeks are the most numerous and the richest. The small river Koik runs along the west side of the town.

Before the earthquake of 1822 Haleb was supposed to possess 12,000 artisans, and was celebrated for its gold and silver lace, its manufactures of silk and cotton goods, shawls, &c.; but its prosperity was chiefly owing to its situation, which rendered it one of the great commercial marts between Europe and Asia. It carries on a great caravan trade with Bagdad, Persia, and the eastern parts of Asia. The goods destined for the European market are shipped from the port of Latakia. Consuls from all the commercial states of Europe reside at Haleb.

The antient name of the town was Chaleb, or Chalybon, which was changed by Seleucus Nicator into Berœa. It continued to be called by that name until its conquest by the Arabs under Abu Obeidah in 638, when its original name of Chaleb or Haleb was restored. It afterwards became the capital of an independent monarchy under the sultans of the race of Hamadan, under whose rule it appears to have enjoyed great prosperity. In the latter part of the tenth century Haleb was again united to the Greek empire by the conquests of Zimisces, emperor of Constantinople. During the crusades Haleb was subject to the Seljuke princes. In 1260 it was plundered by the Moguls, and again in 1401 by Timur. It was afterwards annexed to the dominions of the Mameluk sultans of Egypt, but was conquered by Selim I., the Turkish sultan, and has since that time been subject to the sultans of Constantinople. It is at present however in the possession of the pasha of Egypt.

The pashalik of Aleppo is bounded on the west by the Mediterranean, on the east by the Euphrates, on the north by an imaginary line drawn from Scanderoon (the antient Alexandria) on the coast to El Bir on the Euphrates, and on the south by another line drawn from Billis to the Mediterranean, passing by Murrah and the bridge of Shogher. The northern part is occupied by high mountains, known to the antients under the name of Amanus, which is only a branch of Mount Taurus. The southern part is sterile and sandy; but the plains at the foot of the mountains are fertile, and afford good pasturage for the numerous flocks of the Arabs and Kurds, which graze upon them during the greater part of the year. The inhabitants only cultivate the land in the mountainous districts, which produce wheat and other sorts of corn, melons, olives, cotton, tobacco, figs, &c.: the level parts of the country are abandoned to the Kurds and Arabs. The heat of the climate is seldom oppressive, in consequence of the west winds which blow from the Mediterranean. Tho country is reckoned healthy; but the inhabitants of Haleb are very subject to a disease, which first appears under the form of an eruption on the skin, and afterwards forms into a sort of boil: it dies away in about eight months from its appearance. Volney and many other travellers

* In Niebuhr's plan, 1766, there are nine gates.

attribute the disease to the badness of the water which the inhabitants drink.

The pashalik of Haleb is watered by the Euphrates, the Orontes, and the Koik. The Koik rises near Amtab in the north, and passing by Haleb, loses itself in a morass about 16 miles south of the city.

The pashalik contains no other towns of any importance, with the exception of Haleb. Alexandria (Scanderoon) and Antioch, which were once so celebrated, are now of little importance.

(Russell's *Natural History of Aleppo*, 2nd edition, 2 vols. 4to., 1794; Rousseau's *Description du Pachalik de Haleb*, in 'Fundgruben des Orients,' vol. iv., pp. 1-25, 93-97; Volney's *Voyage en Syrie et en Egypte*; Olivier's *Voyage dans l'Empire Othoman, l'Egypte, et la Perse*; the third vol. of C. Niebuhr's 'Reisebeschreibung,' published at Hamburg in 1837, contains a ground-plan of Haleb, as it existed in 1766.)

HALES, STEPHEN, D.D., was born at Beckesbourn, in Kent, September 7, 1767, entered of Benet College, Cambridge, in 1696, was elected Fellow in 1702; and having taken holy orders, was presented about 1710 to the perpetual curacy of Teddington, near Twickenham, where, though he obtained other church preferment, he resided to the end of his life. He was elected F.R.S. in 1717, and in 1753 was admitted a foreign associate of the Académie des Sciences, in place of Sir Hans Sloane. He died in 1761.

During his residence at Cambridge he applied himself diligently to physical researches, which continued to be his favourite pursuit through life. His first important publication was 'Vegetable Statics, or an Account of some Statical Experiments on the Sap in Vegetables, &c.;' and he has the honour of having made the first essays towards the modern discoveries in vegetable physiology. This work, which is still referred to for excellent evidence concerning many facts in vegetable physiology, obtained for him a foreign reputation, being translated into French, Italian, Dutch, and German. 'Hæmastatics,' a similar treatise on the circulation of the blood, followed in 1733. Dr. Hales's genius was of a very practical turn: most of his numerous inventions and writings refer to some direct application of science to daily use. They comprehend anatomical and surgical treatises, analyses of medicines, experiments on the preservation of provisions during long voyages, the distillation of salt water, and the like; with several sermons. Of all these labours the most brilliantly successful was his plan of ventilating prisons, the holds of ships, and other close and unhealthy places. Having bestowed great pains on this object, he procured, in 1749, the erection of one of his machines in the Savoy prison; and the benefit obtained is stated by Mr. Collinson to have been so great, 'that though 50 or 100 in a year often died of the gaol distemper before, yet from 1749 to 1752 inclusive no more than four persons died, though in 1750 the number of prisoners was 240.' By the introduction of his system into the old gaol of Newgate the mortality was reduced in the proportion of 7 to 16. In France it was extensively adopted with similar beneficial result in prisons, hospitals, ships of war, the preservation of corn in granaries, &c. Numerous papers of Dr. Hales are printed in the 'Phil. Transact.' A list of his works will be found in Watt's 'Bibl. Britann.' (CHEMISTRY, p. 34; Memoir, by Peter Collinson, in the *Ann. Reg.*, 1764.)

HALIÆ'ETUS. [FALCONIDÆ, vol. x., p. 170.]

HALICARNASSUS. [ANATOLIA; HERODOTUS.]

HALICHŒ'RUS. Professor Nilsson's name for a genus of seals. [PHOCIDÆ.]

HALI'CORE, or HALI'CORA, a name for the Dugongs. [WHALES.]

HALI'DRACON, Wagler's name for the genus *Plesiosaurus*. [PLESIOSAURUS.]

HA'LIEUS, a name for the Cormorants. [PELECANIDÆ.]

HALIFAX, a market-town and parish in the West Riding of the county of York, in the wapentake of Morley, was created a parliamentary borough by the Reform Act, and now sends two members to parliament. The borough includes the town and townships of Halifax, Owram, and Ovenden. It is about two miles long and one mile broad, and includes 31,317 inhabitants, of whom 1300 occupy houses of 10*l.* and upwards. The population of the town was, in 1831, 15,382. Halifax is 194 miles north-north-west from London, 17 miles west-south-west of Leeds, 22 miles north-east of Manchester, and 7 miles south-west of Bradford.

The parish is one of the largest in England, and includes the following 23 townships:—Barkisland, Elland-cum-Greetland, Erringden, Fixby, Halifax, Heptonstall, Hipperholme-cum-Brighouse, Langfield, Midgley, Norland, Ovenden, Northowram, Southowram, Rastrick, Rishworth, Shelf, Skircoat, Sowerby, Soyland, Stainland, Stansfield, Wadsworth, and Warley. These townships are divided into three parochial chapelries for ecclesiastical purposes. They comprise 75,740 acres, a population (in 1831) of 109,899 persons, and 23,139 houses. The united annual value of their lands and buildings, as assessed for the property-tax in 1815, amounted to 140,272*l.*, and their yearly moduses, in lieu of vicarial tithes, amount to 1406*l.* 15*s.* 6*d.*, with the exception of Elland-cum-Greetland and Stainland, which townships were not parties to the Act of 1829 for the commutation of the vicarial tithes. In addition to the parish-church and two other churches in Halifax, and the two parochial chapels-of-ease of Elland and Heptonstall, there are in this parish fourteen chapels-of-ease, supported chiefly by the inhabitants of the respective townships or the united chapelries.

Halifax ranks next to Leeds and Bradford as a seat of the woollen and worsted manufactures. The town seems, on approaching it, to stand in a low valley, which is owing to the ranges of hills by which it is almost wholly surrounded; but it is in reality situated on the south-eastern declivity of an eminence which rises to a considerable height above the river Hebble. The Hebble flows through the eastern parts of the town, and falls into the Calder. The scenery in the immediate vicinity of the town is of a highly interesting and beautiful character. The soil, which in a merely agricultural district would have remained uncultivated, has been brought from its original barrenness to a state of luxuriance by its proximity to the town. The situation of Halifax is well adapted for the purposes of manufactures and commerce. The descent from the neighbouring hills of numerous brooks, so important as agents of power before the introduction of the steam-engine, gave to Halifax those facilities in manufacturing which were early a source of wealth. Its situation with reference to Manchester and Leeds, its abundant supply of coal and water, its inland navigation by means of the Rochdale Canal and the rivers Calder and Hebble, have severally tended to increase its importance as a seat of manufactures. The commencement of its woollen trade is traced to the time when the manufacturing Flemings sought refuge in England, in the reign of Henry VII., from persecution in their own country. Many of these foreigners are supposed to have settled here, though Halifax had manufactures long before this time. In an early period of the history of the woollen manufacture there was a peculiar local law designed to afford protection to clothiers from the depredations to which their goods were exposed during the progress of manufacture. It was then, as now, customary to stretch the cloth on wooden frames, or tenters, in the fields to dry; and it was therefore liable to be stolen from being thus left during the night. The magistrates were invested with power to inflict capital punishment on all persons who stole property of the value of *thirteen-pence-halfpenny* within the liberties or precincts of the forest of Hardwick. The felon was however to be deliberately and publicly tried by a jury consisting of the frith-burgers within the liberty; and they could only convict on three grounds, namely, if he were taken in the act of thieving, if the stolen goods were found on him, or on his own confession. On the first market-day following the conviction he was taken to the scaffold or gibbet, the stone platform of which may still be seen on Gibbet Hill, and the execution was performed by means of an instrument in some respects similar to the guillotine. [GUILLOTINE.] The 'Halifax Gibbet Law' was not alone exercised for the protection of the clothiers, but it was also used for the punishment of other felonies. The original axe of this instrument is preserved at the gaol in Halifax.

The chief articles at present manufactured at Halifax are worsted stuffs, including shalloons, tammies, calamancoes, duroys, everlastings, moreens, shags, serges, merinoes; also baizes, narrow and broad cloths, and kerseymeres. Bombasins, crapes, and other fabrics, composed of silk and worsted, are also manufactured here, and the cotton-trade is carried on to a considerable extent. The Vale of Ripponden is celebrated for its blue cloth: it is said that the whole of the British navy is clothed from this small district. Of the twenty-three townships of which Halifax is composed, nineteen are said to be manufacturing, and contain 141 mills in operation, which have an aggregate power of 2319 horses; 57 of them are cotton-mills, 35 woollen, 45 worsted, and 4 silk mills. They employ together 18,377 persons, of whom 8,978 are females. A considerable portion of the population is employed in making mill-machinery and wool-cards. The manufacture of these cards gives occupation to numerous wire-workers and curriers. The wire teeth of the cards are fixed in leather, and nearly 20,000 people are employed, at a very low rate of wages, in fixing the wires in the leather.

A weekly market is held on Saturday, chiefly for the sale of woollen cloth. The Piece Hall, which was erected in 1779 by the shalloon and other worsted manufacturers, is a large quadrangular structure of stone, which cost 12,000*l.*, and which occupies an area of 10,000 square yards of land, which were given for this purpose by Mrs. Caygill. It is 100 yards long and 91 yards broad; the centre is occupied by a grass-plot. It contains 315 apartments for the reception of goods, the quantity of which exposed for sale at one time is often of the value of 50,000*l.* The east side has three stories, being on a descent; the other sides only two. Each story is fronted by a colonnade, with spacious walks round the whole square, having columns in the front opposite to the partitions of the rooms, each of which has a door, and sash-window to the galleries. The simplicity and elegance of the design accord with the magnitude of the building. It was erected from a design by Mr. Thomas Bradley, and is said to be fire-proof in every part except the roof. The appearance of the town of Halifax is generally handsome; it contains many edifices entirely of stone; it is well lighted with gas, and amply supplied with soft water from reservoirs about a mile north-west of the town, which were opened about 1827. Under the act of 1823 for paving, cleansing, and otherwise improving the town, many great improvements have been effected by the widening of streets, the formation of drains, and the removal of unsightly buildings. The modern streets are spacious, and lined with good houses.

The parish-church of Halifax is a handsome and spacious edifice of pointed Gothic architecture, erected at different dates. It is said that the chancel is an addition to the original fabric, and that the tower was built by the munificence of the Lacys and Saviles. There are several monumental inscriptions worthy of notice in the chancel, one of which is to Archbishop Tillotson. Trinity Church is a handsome Grecian building, with Ionic pilasters, and an elegant tower surmounted by a dome: it was built in 1795. St. James's Church, built in 1831, is in the Pseudo-Gothic style, with turrets at the west end. The other places of public worship in Halifax are the Catholic chapel, which was built in 1836, three chapels belonging to the Independents, two belonging to the Baptists, two of the Wesleyan Methodists, two of the new Connection Methodists, one of the Primitive Methodists, a Friends' meeting-house, and a Unitarian chapel. A general cemetery was formed in 1837 by a company of shareholders. To the above-named places of worship Sunday-schools are attached, and the religious and charitable institutions of the town and county are liberally supported. The free grammar-school at Skircoat was established in 1585 by letters-patent of Queen Elizabeth: it is under the direction of twelve governors, chosen from the discreet and honest men of Halifax. Its property yields 187*l.* per annum, exclusive of the school-house, garden, and offices, which are occupied by the master. The school is free for classical instruction to all the sons of parishioners. The national school will accommodate 400 pupils; it generally contains about 200. The British school contains about 300 children of both sexes. There are also some smaller school charities. Waterhouse's Charity, established in 1636, provides almshouses for twelve poor widows, a stipend for the lecturer at the parish church, small yearly stipends to the curates of certain chapels-of-ease within the district, and various sums for other local purposes. The property of this trust has of late years greatly increased in value. The infirmary is a very noble building, which is just opened to the public: the first stone was laid in September, 1836. It affords medical and surgical assistance both to in and out patients. A subscription of 5000*l.* was raised, to which an addition of 2500*l.* was made by the trustees of the dispensary, which institution is now consolidated with it. The public baths are delightfully situated in a valley on the road to Huddersfield. They afford all the various accommodations of the most superior bathing establishments: attached to them is a large garden and a bowling-green. The literary institutions of Halifax are the Literary and Philosophical Society, which has an elegant hall and a museum; the Mechanics' Institution, with a library of upwards of 1000 volumes; and the news-rooms, which also comprise a subscription library. There are also assembly-rooms and a theatre. Daniel De Foe resided here when he wrote 'Robinson Crusoe;' and Sir William Herschel was for some time organist at the parish church. In January, 1837, the parish of Halifax was formed into two unions for the administration of the poor-laws. The Halifax Union comprises nineteen townships, and the Hebden Bridge Union the five townships of the Heptonstall parochial chapelry, and the town and chapelry of Todmorden. For other interesting particulars respecting Halifax reference may be made to White's 'Gazetteer and Directory of the West Riding,' a laborious and useful work, whose accuracy we have had the opportunity to test and confirm. (*Communication from Yorkshire.*)

HALIFAX. [NOVA SCOTIA.]

HALILIMNOSAURUS. [GEOSAURUS, vol. xi., p. 180.]

HALIME'DA, a portion of the genus Corallina, Linn., for which Lamarck had used the name Flabellaria, is thus styled by Lamouroux. (*Exposition Méthodique des Genres.*) The articulations are flat or compressed, rarely cylindrical, almost always flabelliform; the axis fibrous, surrounded by a thin cretaceous substance.

HA'LIMUS. [MAIADÆ.]

HALIO'TIDÆ, HALIOTIS TRIBE, or FAMILY. The species belonging to this section of Gastropods, commonly called 'Ear-shells,' or 'Sea-ears,' are more numerous than is generally supposed. Mr. Swainson, in his first series of 'Zoological Illustrations,' observes, when writing on the 'Small-holed Californian Ear-shell' (*Haliotis Californiensis*) (1820-21), that the definitions given by conchologists up to that time were so imperfect that they had left our knowledge of these shells nearly the same as in the time of Linnæus. Seventeen species only are enumerated in Mr. Dillwyn's work;* although thirty-four have fallen within my own observation during the last few months.'

Linnæus, who records the seven species known to him under the generic appellation of *Haliotis* (Sea-ear), describes the *animal* as a slug (*Limax*) and the *shell* as ear-shaped and open (*patens*) with a lateral hidden spire, and the disk longitudinally pierced with holes (*poris*). He places the genus between *Nerita* and *Patella*.

Cuvier, in the first edition of his 'Règne Animal' (1817), makes the *Ormiers* (Haliotis of Linnæus) the first genus of his sixth order of Gastropods, *Scutibranchiata*. [GASTEROPODA, vol. xi., p. 93.] He observes that it is the only genus of the order which has its shell turbinated, and that among these sort of shells that of the *Ormiers* is remarkable for the excessive amplitude of its aperture, its flatness and the smallness of the spire, which is seen from within. This form, he adds, has caused it to be compared to the ear of a quadruped. Cuvier divides the genus into the following subgenera:—1. The *Haliotids, properly so called* (Haliotis of Lamarck). 2. The *Padolli* of De Montfort. 3. The *Stomatiæ* of Lamarck. The *Ormiers* are immediately followed by the *Cabochons* (Capulus of De Montfort—*Patella Hungarica*).

Lamarck ('Animaux sans Vertèbres,' 1817) arranges the genus *Haliotis*, which is immediately preceded by *Stomatia*, as the last genus of his *Macrostomes*. The following is his definition of *Haliotis*:—

'Shell ear-shaped, most frequently flattened; with a very short spire, sometimes depressed, nearly lateral. Aperture very ample, longer than it is wide, entire in its perfect state. Disk pierced with holes disposed on a parallel line near the left-hand border, the last commencing with a notch.'

The same zoologist makes the following observations on the genus as restricted by him:—'The *Haliotids* constitute a very beautiful genus, rather numerous in species and remarkable for the singular form and the brilliant nacre of their shell. They have received the name of *Sea-ears*, because they in fact represent sufficiently well the form of the cartilage of the ear in man. Their shell is an oval-oblong, flattened in general, slightly spiral near one of its extremities, and furnished with a row of holes disposed on

* 'A Descriptive Catalogue of recent Shells,' arranged according to the Linnean method, by Lewis Weston Dillwyn, F.R.S. and L.S., &c. &c., 2 vols. 8vo., London, J. and A. Arch, 1817.

a curved line near the left-hand border and parallel to it. As the animal increases in growth, it forms for itself a new hole on the edge of the anterior part of the shell; this hole commences with a notch which serves to give a passage to the siphon of the animal, and is afterwards completed; when another is formed posteriorly. In its natural situation and when the animal crawls, this shell may be considered as a reversed basin with its convexity upwards. Its circumference is then considerably exceeded by the very large foot of the animal, and the spire is found on the posterior part of its body. Following the description of the *Ormier* (the animal of the Haliotis) given by Adanson, I had supposed that the branchiæ of this animal were exterior, like those of tho *Phyllidians:* but M. Cuvier has undeceived me by showing me that they are hidden in a particular cavity. *Haliotis* therefore belongs to the family of *Macrostomes*. With regard to the tentacula, it has not perhaps really more than two. But as it is not uncommon (assez fréquent) among the marine trachelipods to find tho eyes carried each upon a tubercle which springs at the external or posterior base of the tentacula, theso tubercles are apparently more elongated here than elsewhere: in this case the two larger tentacles are the anterior ones.' Lamarck records fifteen species, including *Haliotis dubia*.

Mr. Swainson ('Zool. Illustr.' 1st series) remarks that 'the genus *Padollus* of Montford' (De Montfort?) 'resting entirely on the unevenness of the outer lip, without any knowledge of the animal,' appears to him an unnecessary distinction, for such, he observes, is the character of all young shells, and also of mature ones, whose outer surface is rugged or uneven.

De Montfort (1810) gives the following generic characters for *Padollus*:—Shell free, univalve, in the form of an ear, pierced with one or two holes; summit spiral, flattened, dorsal; aperture oval, wide open (évasée), entire, perpendicular; left lip reflected and trenchant; back covered with an epidermis, having a gutter in the middle and in the direction of the spire. He gives as the type of the genus *Padollus rubicundus*, and proceeds nearly as follows:—'In arranging this shell as intermediate between the *Sigareti*, the *Stomatiæ* and the *Haliotides*, we consider that we have been able to establish upon it a new genus. Sufficiently similar to the *Haliotides* by its general contour (l'ensemble de ses formes), it is in some manner nevertheless approximated to the *Stomatiæ*, inasmuch as it has very few holes; but it presents, more than almost any of these shells, a spiral gutter, hollow in the interior, elevated on the back, placed in the middle and curved in tho direction of the spire. This hollow, or gutter, is independent of the curved and serial line of holes, which are nearly all obliterated. The right lip is also more opened out (s'épanouit aussi d'avantage), it juts out and festoons (festonne) over the left lip towards the summit, and to the height of the spire: the interior offers an iridescent and undulated nacre. Externally it is of a brick-red, and the summit, in consequence of losing its exterior calcareous and coloured coat, is nacreous. The back is finely striated and reticulated, and the successive periods of growth are very strongly marked there. There is no doubt that the obliteration of the holes of the *Padolli* are a consequence of the absence of some organs, with which the *Haliotides* must be eminently provided, and it is even probable that the singlo hole which notches their border serves during the life of these mollusks to lodge a fold of the border of the mantle, rolled into a tube and serving for respiration; a tube which we shall find among many of the spirivalve mollusks.'

Considering the time at which De Montfort wrote, there is much good reasoning in this passage; it must be recollected that he evidently gavo his description from a young shell; for he says in the course of it that the shell sometimes reaches more than an inch in its greatest diameter.

Dr. Leach (1814) adopted De Montfort's distinction and name. The Doctor says that this genus is readily distinguished from *Haliotis* (*Ear-shell*) by the irregular form of the outer edge or lip; the disk, he adds, has fewer perforations and the spire is placed farther on the back. He states, in conclusion, that the animal is unknown, but is probably not very unlike that of tho ear-shell.

Mr. G. B. Sowerby (*Genera of Recent and Fossil Shells*, No. xiv.) observes, that with the exception of a few that are commonly known by collectors and Linneans as *Imperforate Ear-shells*,the genus Haliotis has not suffered any dismemberments. 'An attempt,' continues Mr. Sowerby, 'has indeed been made by Montfort to separate from the genuine *Haliotides* two or three species under the name of *Padollus*, in which he has been followed by Leach, but as far as respects general adoption this attempt appears to have been as unsuccessful as it was unnecessary. Not so the separation of the *imperforate Haliotides*, which are easily distinguished by wanting the row of perforations so very characteristic of the true Haliotis.'

The *Otidea* form the first family of *Scutibranchiata*, tho the third order of *Paracephalophora Hermaphrodita* in M. De Blainville's arrangement (*Manuel de Malacologie*, 1825). The first genus of this family is *Haliotis*, divided into four sections, and including the genera *Padollus* and *Stomatia*.

M. Rang (*Manuel*, 1829) continues the *Ormiers* (*Macrostomes* of Lamarck, *Otidea* of De Blainville, *Auriformes* of Latreille) as the first family of *Scutibranchiata*, Cuvier: but he makes it consist but of one genus, *Haliotis*, Linn The genus *Stomatia* of Lamarck he places under the *Sigarets* of Do Férussac, as well as the genus *Stomatella* of Lamarck, which he seems to consider as including the *Padollus* of De Montfort. Tho *Sigarets*, in this arrangement, are made to form the 9th family of the *Pectinibranchiata* of Cuvier.

In Cuvier's last edition of the 'Règne Animal' (1830), the position and arrangement of the *Ormiers* remains as in the first edition, with the exception that in the last edition the Scutibranchiata form the eighth order of his Gastropods.

In the present state of our information, it will perhaps be as well to select the arrangement proposed by Cuvier, and in great measure adopted by M. Do Blainville. M. Rang, in his description both of *Stomatella* (including *Padollus*), and *Stomatia*, says 'Animal unknown.'

Haliotis (properly so called; *Haliotis*, Lam.).

Animal.—One of the most ornamented of Gastropods. All round its *foot* to its mouth there is, at least in the more common species, a double membrane cut out into leaflets (feuillages) and furnished with a double row of filaments. On the outside of its long *tentacles* are two cylindrical pedicles for carrying the eyes. The *mantle* is deeply divided on the right side, and the water, which passes by means of the holes in the shell, can, through this slit, penetrate into the branchial cavity; along its edges again are also threo or four filaments, which the animal can also cause to come out through these holes. The mouth is a short proboscis. (Cuvier's description for all Gmelin's Haliotides, except *H. imperforata* and *perversa*.)

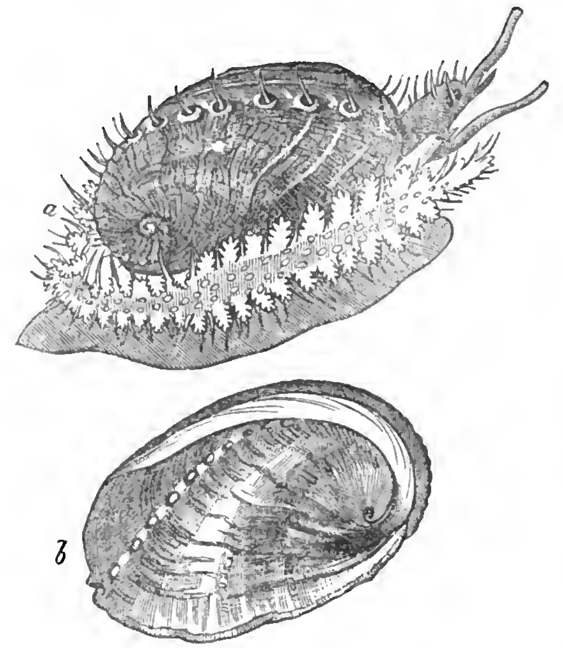
Body oval, very much depressed, hardly spiral behind, provided with a large foot doubly fringed on its circumference. *Head* depressed; *tentacles* a little flattened, joined (connés) at the base; *eyes* carried on the summit of prismatic peduncles, situated on the external sido of the tentacles. *Mantle* very delicate, deeply divided on tho left side; the two lobes pointed, forming by their junction a sort of canal for conducting the water into the branchial cavity situated on the left, and inclosing two very long, unequal, pectinated *branchiæ* (peignes branchiaux).—(De Blainville.)

Animal oblong, depressed, furnished with a large *head* and a short proboscis, at the extremity of which is the *mouth*, containing a *tongue* armed with points (aiguillons); tentacles two, long and cylindrical; *eyes* on pedicles, implanted at their external base, a little backwards. *Mantle* short, delicate; *foot* very large, oblong, furnished all round with a double row of festoons agreeably cut out or pinked (decoupés). *Organs of respiration* composed of two unequal pectinated *branchiæ*, in a cavity open to tho left, tho *muscle of attachment* occupying the middle of tho animal; vent (anus) opening into this cavity opposite the slit which forms its aperture. (Rang.)

In addition to the general account of the organization given by Cuvier, we refer the reader to No. 489 (Gallery) of the Physiological Series of preparations in the Museum of the Royal College of Surgeons. A small specimen is there prepared to show the stomach. The floor of the branchial cavity, the gills, and anus, are turned back, and the integument is removed from above the œsophagus and first stomach. A bristle is passed through the mouth into the œsophagus, and another from the first to the second stomach. The latter cavity is imbedded in the liver, and receives the secretion of that gland by such wide orifices, that portions of the alimentary substances have entered the biliary ducts, which thus appear to be ramifications of the alimentary canal. (Catalogue. Gallery. Vol. 1.)

Shell nacreous, very much depressed, more or less oval, with a very small spire, very low, nearly posterior, and lateral; aperture as large as the shell, with continuous borders, the right border delicate and trenchant, the left flattened, enlarged and trenchant; a series of complete or incomplete holes, parallel to the left side, serving for the passage of the two pointed lobes of the mantle; a single large muscular impression, median, and oval. (De Blainville.)

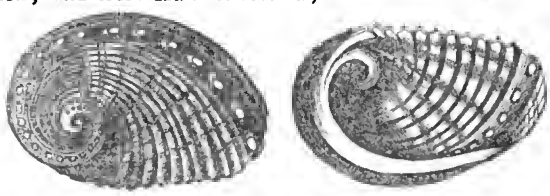
These, the true Haliotides, forming M. De Blainville's section A, consisting of species whose disk is rounded forwards and pierced with a series of holes, vary much in size and shape. The general form may be imagined from that of *Haliotis tuberculata*, the most common species, the size,



Haliotis tuberculata.

a, animal and shell; *b*, interior of shell.

shape, &c., of which is too well known to require description; and from *Haliotis costata*; but there are some of



Haliotis costata.

the species from the warmer climates that are as large as or larger than the crown of a hat, and are absolutely dazzling from the splendid iridescence of their nacre. The shape too varies considerably. Thus we have among the comparatively small species a form very nearly round (*Haliotis excavata*), whilst *Haliotis Asinina* is very much elongated.

The effect of treating the shell of *Haliotis* with acid, so as to deprive it more or less of its earthy material, and to exhibit the shape still retained after the removal of that earthy matter, will be seen in the specimens numbered 98, 98 A, 98 B, in the gallery of the same museum.

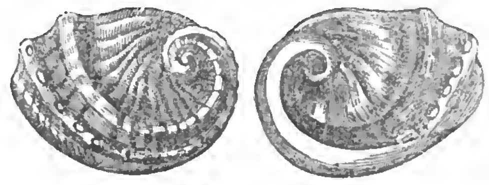
Geographical Distribution.—Both M. de Blainville and M. Rang state that species of Haliotis exist in all the seas; the latter uses the expression 'elles sont très répandues dans toutes les mers,' but their limits seem not to go far beyond temperate climates. None appear to have been seen by our northern voyagers; and though *Haliotis tuberculata* (which there can be little doubt is the ἀγρία λεπάς, ἥν τινες καλοῦσι θαλάττιον οὖς—'the wild *lepas*, which some call the Sea-Ear'—of Aristotle, *Hist. An.*, lib. iv., c. 4) is common at Guernsey and Jersey, and has been found—that is, the shell—on the south coast of Devonshire, we agree with Mr. Sowerby in thinking that, on the present evidence, this species cannot with propriety be considered a native of our own coasts though the dead shells are sometimes thrown up on our southern shores after violent storms.

Habits.—The *Haliotides*, which are all marine and littoral, being without opercula, adhere, like the *Patellæ*, by applying their under parts to the surface of the rocks. They are generally found near the water's edge, and, according to Lamarck, go during the fine summer nights to feed on the herbage which grows near the shore.

Utility to Man.—As an article of food this genus is by no means to be despised. We have eaten *Haliotis tuberculata*, and when served by a good cook it is tender and sapid. The large fleshy foot, if not properly managed, is apt to be tough. The people of Guernsey and Jersey ornament their houses with the shells of this species, disposing them frequently in quincunx order, and placing them so that their bright interior may catch the rays of the sun. We have often thought that some of the large and splendid intertropical species, whose exterior, after removing the outer coat, take a polish almost equalling the natural brilliancy of the inside, might be converted into dishes for holding fruit: if mounted with good taste, their indescribable iridescence would materially add to the richness of an elegant table.

B. Species whose disk, besides the series of holes, is raised by a large parallel rib, hollowed interiorly, and whose anterior border is more or less irregular.

Padollus. (De Montfort.)



Padollus rubicundus?

M. De Blainville refers to *Haliotis canaliculata*, Lam. as the example. The figure in Knorr, referred to by Lamarck, is red externally, and has the elevated rib; but the shape of the shell is longer than that of *Padollus scalaris*, Leach, and of other *Padolli* which we have seen. The specimen recorded by Mr. Gray in the appendix to the 'Narrative of a Survey of the Intertropical and Western Coasts of Australia, performed between the years 1818 and 1822, by Captain Phillip Parker King, R.N., F.R.S., &c.,' vol. ii., and which Mr. Gray notices as the largest he ever saw, measured three inches and a half by two and a half. We have seen the shell, and never saw so large a specimen. Mr. Gray records it as *Padollus rubicundus* of De Montfort, with the synonyms of *Padollus scalaris*, Leach, and *Haliotis tricostalis*, Lamarck.

Locality.—Lamarck, on the authority of M. Leschenault, says that his *Haliotis tricostalis* inhabits the seas of Java. The fine specimen brought to England by Captain King was found upon Rottnest Island, on the west coast of New Holland, and is now in his cabinet. It has only three holes, the anterior ones, open. All, both those which are closed and those which are open, are very highly elevated, and so is the curved longitudinal rib. The left border externally is very much raised and nodulous, looking at first sight as if it had another row of holes which had been closed; but it was evidently always imperforate.

C. Species whose disk is not pierced, but hollowed longitudinally by a decurrent canal.

M. De Blainville gives as an example of his section C. *Haliotis dubia* of Lamarck. It will be clear to the observer that the animal protected by such shells as the two next, must exhibit some differences from that of a true *Haliotis*.

D. Species whose disk is not pierced, and which offer the two gutters together, but approximated, so as to leave externally a decurrent rib between them.

Stomatia. (Lamarck.)

Cuvier, who says that the animal of Stomatia is much less ornamented than that of *Haliotis*, is of opinion that this form connects the *Haliotides* with certain Turbines.

Mr. G. Sowerby (*Genera of Recent and Fossil Shells*, No. xix.) observes that Lamarck, in his observations upon *Stomatella*, tells us that in respect to their general form those shells appear to be nearly related to the *Stomatiæ*; and that they are principally distinguished by the transverse ridge and the elevated outer lip of the *Stomatiæ*.

Upon a careful examination however of ten species, Mr. Sowerby was unable to discover any difference in the outer lip; and he remarks that Lamarck places among his *Stomatellæ* one species, *S. rubra*, which has a nodular *keel* placed exactly in the same position as the transverse ridge, by which the latter characterizes *Stomatia;* so that Mr. Sowerby does not find any generic difference whatever, and has therefore united the two Lamarckian genera under the appellation *Stomatia*. He thus characterizes the genus thus reformed:—Shell pearly within, mostly coloured externally; suborbicular or long, generally ear-shaped and depressed. The spire, in most species, prominent, but not produced nor elongated; sometimes very small, marginal and inconspicuous. Aperture mostly longitudinal, in some species nearly orbicular, in others much elongated, always very largo; its edges entire, united at the upper part, and scarcely modified or altered in form by any portion of the last volution. Volutions from two to four. Muscular impressions two, seldom distinct, nearly marginal, and in the open part of the shell.

Mr. Sowerby goes on to state that Stomatia appears to be related to *Haliotis*, and is therefore rightly placed by Lamarck among his *Macrostomes*. One of its species is arranged by Linnæus, he adds, as a Haliotis, under the name of *Haliotis imperforata* (Gmel.). Mr. Sowerby does not pretend to discuss the question of their resemblance to Lamarck's *Turbinacées;* but only observes that in general form, some of them approach very nearly to some of Lamarck's *Monodontes*. The *Stomatiæ*, he states in conclusion, are marine, and he says that all the species he has seen were brought from the East Indies and New Holland.

Locality.—Stomatia has been found at a depth of seven fathoms, adhering to *Meleagrinæ* and corals.

Fossil Haliotidæ.

Mr. G. B. Sowerby, speaking of the true *Haliotides*, says that the existence of fossil species is very doubtful; the only approach to it that he had ever seen, were, he adds, some incrustations taken up from the sea near the Cape of Good Hope. He states that he never saw a fossil species of *Stomatia*, as modified by him. M. de Blainville remarks, at the end of his arrangement, that it would appear that no fossil species are known. Cuvier, speaking of tho true *Haliotides*, observes that the genus *Haliotis* certainly has, though the fact has been disputed, its analogue among the fossils; and he refers to the 'Ann. des Sc. Nat.,' t. xii., p. 45, f. A, for a species (*Hal. Philberti*) found in tho *calcaire* of Montpellier, described by M. Marcel Serres. M. Rang, speaking of the same genus, says, 'Nous en possédons une ou deux à l'état fossile.' M. Deshayes, in his tables, records one species, *H. tuberculata*, as both living and fossil (tertiary), from Sicily. (Pliocene Period of Lyell.) Of *Stomatia* M. Deshayes mentions no fossil species, but of *Stomatella* he records one fossil (tertiary) with an unknown locality.

HALISPO'NGIA. According to the structure and composition of the numerous species of sponges, they may be divided into genera. If, in accordance with the observations of Dr. R. Grant, we consider sponges in three groups, one having a horny tubular structure, another containing calcareous spiculæ, a third containing siliceous spiculæ, we may adopt the three generic types, Spongia, Calcispongia, and Halispongia, of Blainville.

Halispongia is thus characterized:—Mass more or less rigid or friable, of irregular figure, porous, traversed by winding canals, which end in openings scattered over the surface; substance subcartilaginous, supported by simple siliceous spiculæ.

Tho species exhibit various external forms, encrusting, branching, or foliaceous. Dr. Fleming includos them under the title Halichondria.

HALITHE'A, a genus of marino dorsibranchiate annelids belonging to the family *Aphroditidæ*. [Dorsibranchiata; Sea-Mouse.]

HALL, or HALLE, EDWARD, an English lawyer and historian, was the son of John Halle of Northall in Shropshire, and was descended from Sir Francis Van Halle, K.G., in the time of Edward III., who was the son of Frederic de Halle of the Tyrol, natural son of Albert king of the Romans and archduke of Austria. He was born, at the close of the fifteenth century, in the parish of St. Mildred, London, and received the first part of his education at Eton school. In 1514 he became scholar of King's College, Cambridge, and continued there till he became a junior fellow; afterwards, about 1518, when Cardinal Wolsey founded various lectures at Oxford, he removed to that university. Having entered at Gray's Inn, he was called to the bar, and became first one of the common serjeants, and subsequently under-sheriff of the city of London. In 1533 he was appointed summer-reader of Gray's Inn, and in 1540 double reader in Lent, and one of the judges of the Sheriff's Court. He died in 1547, and was buried in the church of St. Benet Sherehog, London.

Hall's Chronicle, entitled 'The Union of the two noble and illustrate Families of Lancaster and Yorke,' was first printed by Berthelette, in small fo o, in 1542. This edition is so very rare as to have been seen by scarcely any of our bibliographers. It was dedicated to King Henry VIII., and ended with his twenty-fourth year, 1532. Grafton, who reprinted it in 1548, continued the work from Hall's papers to the end of Henry VIII.'s reign. He again printed it in 1550. 'The boke commonly called Halle's Cronycles' is one of those which were forbidden by proclamation, 13th June, 1555, 1 and 2 Phil. and Mary. A fourth edition, but without any additions or improvements, was printed in 4to., London, 1809, by the booksellers, among the 'English Chronicles.' (Herbert's *Ames*, p. 527; Bliss's edit. of Wood's *Athenæ*, vol. i., p. 164; Warton, *Hist. Eng. Poet.*, 4to., vol. iii., p. 214; Nicolson's *Hist. Lib.*, edit. 1776, p. 58.)

HALL, JOSEPH, an eminent divine and prelate, was born July 1st, 1574, at Ashby-de-la-Zouch, in Leicestershire, and received his academical education at Emmanuel College, Cambridge, of which in due time he was elected Fellow. Having taken orders and received some minor benefices in succession, he was made dean of Worcester in 1617; sent as one of the English deputies to the synod of Dort in 1618, appointed bishop of Exeter in 1627, and translated to Norwich in 1641. His professional zeal and earnest piety involved him in those jealous timos in the charge of puritanism; and being harassed by frequent and vexatious attacks, he plainly told, to use his own words, archbishop Laud—'Under how dark a cloud I was hereupon I was so sensible, that I plainly told the lord archbishop of Canterbury (Laud) that rather than I would be obnoxious to those slanderous tongues of his misinformers I would cast up my rochet. I knew I went right ways, and would not endure to live under undeserved suspicions.' In truth he was well attached to the church of which he was a member, and wrote strongly in defence of episcopacy when the danger of the times became imminent. In November, 1641, having joined others of the bishops in a protest against all laws made during their forced absence from parliament, he was sent to the Tower, and only released in the following June on giving bail for 5000*l*. In the next year the revenues of his bishopric were sequestrated, and during the rest of his life he suffered much from poverty and harsh treatment, of which he has given an account in a piece called 'Hard Measure.' He removed in 1647 to Higham, near Norwich, and died there in 1656.

His numerous works fill several volumes in the old folio editions, and ten in the modern 8vo. They are chiefly controversial, as will appear from the catalogue in Watt, and therefore of ephemeral popularity. His 'Contemplations' are of more personal and lasting interest, and esteemed for their language, criticism, and piety; as also his 'Enochismus, or Treatise on the Mode of Walking with God,' a beautiful tract, translated into English in 1769. To tho student of English manners his Satires entitled 'Virgidemiarum,' in 6 books, are peculiarly valuable. They have been analyzed by Warton, in an unpublished portion of his 'Hist. of Poetry,' first printed in Chalmers's 'British Poets.' He says of them, 'The characters are delineated in strong and lively colouring, and their discriminations are touched with tho mastorly traces of genuine humour. The versification is equally energetic and elegant. His chief fault is obscurity, arising from a remote phraseology, constrained combinations, unfamiliar allusions, elliptical apostrophes, and abruptness of expression.'

HALL, a town in tho Innthal, in Tyrol, with 4500 inhabitants, having a mint and other public establishments, and salt-works which produce about 300,000 cwt. of salt annually; the rock-salt is brought from the Salzberg, 5088 feet high, which is ten miles distant.

Swabian Hall, in the circle of the Iaxt, and the kingdom of Würtemberg, has 6500 inhabitants, six churches, including the antient Gothic church of St. Michael, a handsome town-hall, and salt-works yielding 80,000 cwt. annually.

It was formerly a free Imperial city, and annexed to Würtemberg in 1802.

HALLE, in Saxony, on the Saale, a town in the district of Merseberg, and the province of Saxony, in Prussia, the chief town of the circle of the Saale. It is celebrated chiefly for its salt-works, for the Orphan Asylum founded by A. H. Francke [FRANCKE], and as the seat of the Frederick's university. It consists of three towns, viz. Halle itself with five suburbs, and Glaucha, and Neumarkt, which have magistrates of their own. The university was founded in 1694, and by a decree of the king of Prussia was united in 1817 with that of Wittenberg. It has always maintained a very high character, and has a number of scientific institutions connected with it, such as the botanic garden, the museum, theological and philological seminaries, a medical, chirurgical, and clinical institution for surgery, midwifery, &c., the anatomical theatre, the physical and chemical institution, the observatory, the mining institution, with a cabinet of minerals, &c. The university library consists of above 50,000 volumes. The first professors having been divines of what the Germans call the Pietist party, the theological faculty had from its origin a very local character, and Halle has been the chief seat of that party, which, notwithstanding its prejudices and peculiarities, has had a salutary influence on practical Christianity. A great change was however effected by Christian Von Wolff, who inspired the students with a love of mathematics and philosophy; and though by the influence of the Pietist divines he was for a time exiled from the Prussian states, he, with his whole school, triumphed in the end. The university had attained its highest lustre at the beginning of the nineteenth century, when Napoleon dissolved it after the battle of Jena. The Westphalian government indeed re-established it, but it had only from 300 to 400 students, and in 1813 Napoleon again decreed its dissolution. His overthrow restored it to Prussia, and after its union with that of Wittenberg it had in 1829 1300 students, of whom 944 studied divinity. The competition with the new university of Berlin however affected it, and the number of students now fluctuates between 800 and 900. There are above 40 professors and teachers, among whom are some highly eminent names. There are several remarkable buildings, such as St. Mary's church, built in the Gothic style in the sixteenth century; St. Ulrich's church, built in 1339; that of St. Maurice, of the middle of the twelfth century; the cathedral, built in 1520-23; and the town-hall. The antient castle, called the Moritzberg, formerly the residence of the archbishops of Magdeburg, was reduced to a ruinous condition in the Thirty Years' War, and only a wing now remains. Halle possesses many charitable institutions. There are numerous manufactories, but the most important are the salt-works, producing 462,000 bushels of salt annually. The workmen are called Halloren, and are a peculiar race, distinguished by their physiognomy, costume, and customs: they are supposed to be descended from the aboriginal inhabitants, and enjoy many privileges and immunities.

The 'Allgemeine Litteraturzeitung,' one of the very best in Germany, originally published at Leipzig, has appeared at Halle ever since 1804. The population of Halle itself is about 17,000, and with Glaucha, &c., 24,000.

HALLE, or HALLEIN, in the circle of Salzburg, in Austria, with 5000 inhabitants, has extensive salt-works, which produce annually 450,000 cwt. of salt.

HALLER, ALBERT VON, was born at Berne, October 16, 1708, of an antient and respectable family. His father, Nicholas Emmanuel von Haller, who was an advocate and had the reputation of being an able lawyer, died in 1721, but even at that time could foresee the distinction which his son would attain, from the superiority which he evinced over his fellow-pupils. In early life Haller was feeble and delicate, being affected with rickets, a circumstance which, as his friend and biographer Zimmermann observes, not unfrequently tends to foster and develop the talents of a youth. He is said, at the age of nine, to have been in the habit of writing down each day all the unusual words he met with. He composed also short lives of nearly two thousand distinguished persons, after the manner of Bayle's dictionary, and formed a Chaldee grammar. A satire in Latin verse upon his master was known to have been written by him when only ten years old, and two years later he first began to compose verses in his native language.

His father had intended him for the church, but his own inclinations leading him to the study of physic, he went in 1723 to the university of Tübingen, where he lived with Duvernoy, afterwards professor of anatomy at St. Petersburg. Being but little satisfied with his progress here, he resorted in 1725 to Leyden, where the zeal and talent of the professors afforded him an opportunity of pursuing his studies in a manner more accordant with his wishes. At this university Boerhaave was then in the height of his fame, attended by 120 pupils, whose instruction was his greatest delight; and Albinus was delivering the lectures on anatomy and surgery. Having enjoyed such advantages as these, it is not extraordinary that Haller should ever after speak with the greatest satisfaction of his residence at Leyden. About this time he visited Ruysch at Amsterdam, then in his eighty-ninth year, and saw a portion of his celebrated collection of anatomical preparations, the superiority of which, he tells us, depended rather upon skill in manipulation than on any secret process. At the end of the year 1726 he offered himself for his doctor's degree, and delivered his Thesis 'De ductu salivali Coschwiziano,' which he showed to be merely a blood-vessel. In 1727 he visited London, where he became acquainted with Sir Hans Sloane and Cheselden; thence he went to Oxford, and thence to Paris, whence having pursued his anatomical and surgical studies for some time under Winslow and Le Dran, he went to Basle to study mathematics under Bernouilli, and then returned to his native country and began to practice as a physician. In 1735 he was appointed physician to the hospital at Berne, and soon after principal librarian to the large public collection of books and medals; but these offices he did not hold long, for in the following year he was offered the professorship of medicine, anatomy, botany, and surgery, at Göttingen, by George II., which after some hesitation he accepted. Having declined practising, he devoted himself to the duties of his office with the greatest zeal, and especially exerted himself to increase the facilities for the study of anatomy. During eighteen years that he retained this appointment, while fully discharging all its laborious duties, he was a constant contributor to the different scientific Transactions. In 1747 he published the first edition of his 'Primæ Lineæ Physiologiæ,' which he had that year used as the ground-work of his lectures, having previously employed the 'Institutions' of Boerhaave. In 1751 the Royal Society of Göttingen was established, and Haller, at whose house the first meeting took place, was appointed perpetual president. To their Transactions, of which the first volume appeared shortly after under the title of 'Commentarii Societatis Regiæ Scientiarum Gottingensis,' he was a constant contributor, even after 1753, when, in consequence of the delicate state of his health, being obliged to leave Göttingen, he retired to Berne. Here he resided during the rest of life, constantly occupied in the publication of his most important and voluminous works, in the cultivation of the science of his profession and of general literature, and in the active and honourable discharge of various duties in the service of the republic, in which he at all times strenuously advocated the cause of the aristocracy. He died in October, 1777, in the enjoyment of the highest reputation, both as a citizen, a scholar, and a philosopher, his literary labours ceasing only with his life.

It would be difficult to determine how large a portion of the facts of medical science now most familiarly known we owe to the extraordinary labours of Haller. Some idea of the extent of his works may be formed from the fact that the titles of nearly two hundred treatises published by him from 1727 to 1777 are given by Senebier in his Eloge of Haller, and that this list does not profess to be complete. He is unanimously received as the father of modern physiology, whose history commences with his writings. He was the first to investigate independently the laws of the animal economy, which had before been studied only in connection with the prevailing mechanical and chemical or metaphysical theories of the day. Commencing with a sound knowledge of anatomy and of the structure of the organs in the dead body, he sought experimentally and systematically to discover the laws which governed their actions during life, proceeding from the most simple to the most complex phenomena. Excluding all the metaphysical explanations which Van Helmont and Stahl had invented, and all those deduced from mechanics and chemistry which were not clearly sufficient for the phenomena ascribed to them, he sought for powers peculiar to the living body, which he believed must govern the actions which he found occurring only in it. These he thought might be restricted to two—sensibility and irritability; the former seated in the brain and nerves, the latter in muscular fibre. In this he had indeed been partially anticipated by Glisson [GLISSON], who perceived the necessity of admitting an inherent property in muscular fibre, by which its contractions take place under the influence of certain stimuli, but the laws of this property, and the distinction between it and elasticity, had never been at all clearly determined. Haller thus illustrated these properties: the intestine removed from the abdomen, or a muscle separated from the body, is irritable, for when pricked or otherwise stimulated, it contracts—yet it is not sensible; the nerves on the other hand are sensible but not irritable, for when stimulated, though the muscles to which they are distributed are thrown into action, they themselves do not exhibit the slightest motion. Henco irritability, he said, cannot be derived from the nerves, for it is impossible they should communicate what they do not possess themselves; but he attributed a *nervous power* to some of the muscles as a necessary condition of their irritability, and supposed it to be convoyed to them during life from the brain through the nerves, and to govern their actions under the influence of certain undetermined laws. Proceeding to investigate further the laws of irritability, he found that it differed in intensity and permanency in different parts of the body. He found that it continued longest in the left ventricle of the heart, next in tho intestines and the diaphragm, and that it ceased soonest of all in the voluntary muscles, and by reforence to this superior degree of irritability he explained the constant action of tho heart and diaphragm even during sleep. He denied all irritability to tho iris, and believed that the action of light upon it takes place through the medium of the retina, a view since proved to be perfectly correct. He supposed the arteries to be supplied with muscular fibres, but that the cellular tissue around them prevented any motion from taking place in them, and he explained the accumulation of blood in an inflamed part, partly by the contraction of the veins and partly by the diminished contractility of the arteries. He endeavoured to prove by experiments that the tendons, the capsules of joints, the periosteum, and tho dura mater are entirely insensible, and that the pain which occurs in diseases of these parts ought to be referred to the affection of the nerves distributed to and around them; and in these and some other tissues which he held to be destitute of irritability he admitted a force analogous to elasticity, by which they contracted slowly and in a mannor altogether different from muscular tissue when divided or exposed to cold, &c.

Such is a sketch of the great doctrine of irritability and sensibility on which Haller based all the phenomena of lifo, and around which he arranged all the facts of physiology kuown at his time in his 'Elementa Physiologiæ.' It gave the first impulse to the study of the laws of life as a separate and exclusive science, and though in some parts erroneous, and in many insufficient, it still contained enough of truth to form a firm basis for the observations collected during many successive years. His doctrines were strongly opposed by Whytt and others, and in the controvorsies that followed numerous new facts were advanced and the most important additions to physiological knowledge rapidly made. It was soon shown that the restriction of the vital powers to the two, as defined by Haller, was much too exclusive, for that there were many parts which, though they gave no evidence of possessing either of them, were not the less alive, while others to which Haller refused these properties gave sufficient demonstration of possessing them when excited by othor and appropriato stimuli. Hence first originated the discovery of the fact that for the action of each organ a peculiar stimulus is required, and that each tissue has what Bichat, who illustrated it most completely, called a *vie propre*.

But even if Haller had not attempted to establish any such great generalization of vital phenomena as this, his learning and his admirable mode of studying physiology might have been sufficient to obtain for him a reputation nearly as high as that which he has always enjoyed. Possessed of a competent knowledgo of all the sciences which could throw any light on the actions occurring in the living body, he pointed out in numberless instances what part of them was to be attributed to the laws of inorganic matter and what to those peculiar to the state of life, whilo he carefully avoided admitting any of the former as sufficient by themselves to explain the whole of the latter, which had been the chief error of nearly all his predecessors. He rarely drew any conclusion respecting the mode of action of any organ or part in the human body, without previously investigating the analogous function in the bodies of animals by dissection or experiment; and he tells us that he often found that questions to which no sufficient answers could be obtained by observations on the human body, were at once solved by his examinations in the various classes of animals. Deeply read in all the works of those who preceded him and in all those of his cotemporaries in every nation, he did not attempt to decide anything till he had considered all their statements and compared them with his own investigations, and hence each of his works contains so perfect an epitome of the labours of all former writers on the same subject, and a mass of evidence so extensive, that whatever errors the conclusions he sometimes arrived at may contain, they can never fail to be records of the highest value. At the same time the elegant and lucid style in which they are written, the result of the combination, almost unique, of the poet with the anatomist, has rendered them attractive, notwithstanding their great extent, to his successors in every country.

Haller was fortunate in receiving the high honours which he deserved during his life-time. In 1739 he was appointed physician to the king of England. In 1743 he was elected a fellow of the Royal Society of London, and at different times subsequently of all the scientific societies of Europe. When George II. visited Göttingen in 1748 he was ennobled by the omperor: he was invited by Frederick the Great to settle in Berlin, with a handsome salary, to which no duties were attached, and was offered a professorship at Oxford and at Utrecht. He enjoyed throughout his life the friendship and esteem of the most eminent of his contemporaries throughout Europe; and, varied as his pursuits wore, he acquitted himself in all with the highest honour and success. It would be impossible here to give a complote list of his original writings and compilations; few writers have ever been so voluminous· and it is extraordinary that, amidst all his personal and laborious investigations, he should have had opportunity for the composition of so extensive a library as they alone would form. A large portion were probably formed from the accumulation of notes which he had made in following out his system of invariably recording everything which appeared to him worthy of notice; a plan which, commenced, as we have seen, in childhood, he continued without intermission to the last years of his life. The following are his principal works:—

His chief poetical production, 'Versuch Schweizerischer Gedichte,' was published anonymously at Berne; afterwards two more editions of it were printed there, and four at Göttingen. Three editions of a French translation were also published. From 1750 to 1760 he was engaged in publishing, in 19 vols. 4to., a number of the most select disputations and theses in anatomy, surgery, and medicine, and from 1757 to 1766 his 'Elementa Physiologiæ Corporis Humani,' undoubtedly the greatest work on medical science which the eighteenth century produced. It contains every fact and every doctrine of physiology at that time known, and is written in such a style of elegance and classical beauty that it is still a model for writers on the same subject. It appeared in eight 4to. volumes from 1757 to 1766, and a posthumous 'Auctarium' was published in 1782 in four 4to. fasciculi. From 1774 to the time of his death he was engaged in publishing part of his 'Bibliothecæ Anatomiæ, Chirurgiæ, Medicinæ Practicæ, Botanicæ, et Historiæ Naturalis,' which form together ten 4to. volumes, of which the publication was completed posthumously. They aro composed principally of abstracts of the writings of all the most esteemed authors on each subject, so as to form a complete history of the doctrines of each science. His 'Icones Anatomicæ,' which were published from 1743 to 1756, contain most accurate and well-engraved representations of the principal organs of the body, especially of the arteries. The greater part of his contributions to the various scientific transactions, and of his shorter works, were collected in his 'Opera Minora,' in 3 vols. 4to., from 1762 to 1768. The most valuablo of the papers contained in them are those on the Development of the Chick, on tho Formation of the Heart and the Bones, on the Circulation, and on the Eye. (*Das Leben des Herrn von Haller*, von J. G. Zimmermann, 1 vol. 8vo., 1755; Senebier, *Eloge de Haller*, Geneva, 1778; *Histoire de la Medicine*, par K. Sprengel.)

HALLEY, EDMUND. The materials for the personal life of Halley are principally in the Biographia Britannica, which makes considerable use of a manuscript furnished by Mr. Price, Halley's son-in-law Some years ago a manuscript belonging to the Bodleian library, purporting to be the life of Halley by some one acquainted with him, was read to the Royal Astronomical Society (see their Monthly Notice, December, 1834). We find some extracts from this manuscript agreeing almost word for word with passages in the Biog. Brit., and conclude that the document in the Bodleian library is the original, or perhaps an abridged copy, of that cited in the printed work. The éloge of Halley in the Memoirs of the Academy of Sciences is by Mairan, and is reprinted in the small collection of éloges by that writer, Paris, 1747.

Edmund Halley was born October 29th, 1656, at Haggerston, near London, at a country-house belonging to his father, who was a soap-boiler in Winchester Street, London. He was educated at St. Paul's school, under the care of Dr. Gale, and was placed at Queen's College, Oxford, in 1673, being then possessed of much erudition for his age, and a strong turn for observation, as appears by his having discovered for himself before he left school the alteration in the variation of the magnetic needle. At the university, being well supplied with instruments by his father, he began to apply himself to astronomy, and before he reached the age of twenty he had given (in the Phil. Trans.) a memoir on the problem of Kepler, had invented a method of constructing the phases of a solar eclipse, and had made many observations, particularly of Jupiter and Saturn, the results of which we shall presently see. Finding however that nothing could be done in planetary astronomy without more correct tables of the stars, and relying upon Flamsteed and Hevelius for the amelioration of the northern catalogues, he determined, with his father's consent and assistance, to appropriate to himself the task of forming a catalogue of the southern hemisphere. Furnished with a recommendation from Charles II. to the East India Company, he set sail for St. Helena in November, 1676, and remained there two years. His 'Catalogus Stellarum Australium,' published in 1679, was the result of this voyage, and contains, besides the positions of 350 stars, some other points of interest, particularly an observation of the transit of Mercury over the sun's disc, and a hint that such observations might be employed to determine the sun's parallax (afterwards so successfully carried into effect with the planet Venus). He also notices the increased curvature of the moon's orbit when in quadratures, which was afterwards explained by Newton. In his voyage out he had observed the fact that the oscillations of a pendulum increase in duration as the instrument approaches the equator.

At his return from St. Helena the king granted him a mandamus to the university of Oxford for the degree of Master of Arts, and he was elected a Fellow of the Royal Society. This body sent him to Danzig in 1679 to judge of the observations of Hevelius, who maintained the superior accuracy of instruments with simple sights, in opposition to Hook, who advocated the use of the telescope. Halley was a man of rapid movements: in November, 1678, he returned from St. Helena; in May, 1679, he set out for Danzig, having in the interval published his catalogue, and procured his Oxford degree, and admission to the Royal Society. He returned from Danzig in July, and remained at home till the end of 1680, at which time he set out on a continental tour, accompanied by his schoolfellow Mr. Nelson, since well known as the author of a work on the Feasts and Fasts. In December, being on the road to Paris, he saw the celebrated comet of 1680 in its return from perihelion, being the first who perceived it since it was lost in the preceding month. This body he observed with Cassini at Paris, and the observations thus made are remarkable as forming part of the foundation upon which Newton, in the Principia, verified his deduction of a comet's orbit from the theory of gravitation. He returned to England at the end of 1681, and in 1682 married the daughter of Mr. Tooke, auditor of the Exchequer, with whom he lived fifty-five years. He resided at Islington till 1696, and in 1683 published his theory of the variation of the magnet, followed by other papers in subsequent years, containing ingenious speculations, now forgotten. His astronomical occupations during this period consisted chiefly of lunar observations and comparisons. He was strongly of opinion that the moon would, when sufficiently known, furnish the means of finding the longitude, and at this period it seems that he had formed the idea of observing that body through a whole revolution of the nodes. His observations (1682-1684) are published in Street's 'Astronomia Carolina.' He was interrupted however by the state of his father's affairs, which had suffered by the great fire.

Among other objects of speculation he had considered the law of attraction, which he imagined must be as the inverse square of the distance. Having applied in vain to Hook and Wren for assistance in the mathematical part of the problem (himself being more of a mathematician than either), he heard of Newton, and paid him a visit at Cambridge. Finding all he wanted among the papers of his now friend, he never rested until he had persuaded Newton to publish the Principia, of which he superintended the printing, and supplied the well-known copy of Latin verses which stand at the beginning. In 1691 he was a candidate for the Savilian professorship, which he lost, according to Whiston, on account of his avowed unbelief of the Bible. This rests on the authority of Whiston, and of an anecdote to be found in Sir David Brewster's Life of Newton, and yet it is certain that he afterwards was appointed to the same professorship, and as he then obtained the degree of doctor of laws, which required no subscription to articles, it may be presumed his opinions, if known, were not considered to be a disqualification. Flamsteed, if we remember rightly, speaks of his opinions on this matter as things of common notoriety. In 1696 he was appointed comptroller of the mint at Chester, where he resided two years.

In 1698 king William, who had heard of his magnetic theory, gave him the commission of captain in the navy, with the command of a small vessel, and instructions to observe the variation of the magnet, and the longitude and latitude of places in the American settlements, and to attempt the discovery of land south of the Western Ocean. He set out in November, but was compelled to return by the insubordination of his first lieutenant. Having tried this officer by a court-martial, he set out again in September, with the same ship and another, observed in many parts of the Atlantic as far as the ice would permit, touched at the Canaries, Madeira, Cape de Verd Islands, St. Helena, Brazil, Barbadoes, and returned September, 1700, having not lost a man by sickness during the whole voyage. He published in 1701 a chart of the variation of the magnet in all seas of the known world, and immediately afterwards sailed to survey the coasts of the Channel, of which he also published a chart. He was then twice successively ordered to the coast of the Adriatic, to assist in the formation and repairs of harbours in the emperor's dominions, and returned to England in November, 1703, just in time to succeed Dr. Wallis, who had died a few weeks before, in the Savilian chair of geometry at Oxford.

If Halley was active and energetic, he was no less universal. The captain-professor found an unfinished translation by Dr. Bernard of a tract of Apollonius, and, though he did not understand Arabic, undertook to complete the work. [Apollonius Pergæus.] The Oxford MS. says, 'This he did with such success, through his being so great a master of the subject, that I remember the learned Dr. Sykes (our Hebrew professor at Cambridge, and the greatest naturalist of his time when I was at that university) told me that Mr. Halley, talking with him upon the subject, showed him two or three passages which wanted emendation, telling him what the author said, and what he should have said, and which Dr. Sykes found he might with great ease be made to say, by small corrections he was by this means enabled to make in the text. Thus, I remember Dr. Sykes expressed himself, Mr. Halley made emendations to the text of an author he could not so much as read the language of.' It is not necessary (after the article last cited) to say more of the splendid edition of the whole of Apollonius, published in 1710.

The Miscellanea Curiosa, a collection of pieces, mostly from the Philosophical Transactions, many of them by himself, was superintended by him, and published in 1708.

Halley resided at Oxford for some years after his appointment to the Savilian chair, nor do we know when he again became a permanent resident in London: it was however not later than 1713, for in that year he became secretary to the Royal Society. He had been assistant-secretary before, as far back as 1685, and the Transactions from 1686 to 1692 were superintended by him. From the manner in which his name is mixed up with the affair of Flamsteed, he must have resided in town for some years previous to 1713. [FLAMSTEED.] In the article cited we have called Flamsteed's work the Principia of practical astronomy; and it were to be wished the connexion of Halley with the printing of this one had been as creditable as that which links his name with the Principia of Newton. It is difficult to say to what extent Halley was involved in originating any of the unworthy proceedings to which we allude; and we must protest against his being made a scapegoat for Newton, in which position even Flamsteed seemed inclined to place him, as well as several more recent writers on the controversy. Neither the position nor the character of Halley renders it likely that he would prefer making a tool of Newton to any direct mode of aggression. The committee appointed by Prince George of Denmark must bear the blame of all the formal proceedings; and in that committee the name of Halley is not found, though it is on the list of those who published the Commercium Epistolicum, a position which we cannot defend. [COMMERCIUM EPISTOLICUM; FLUXIONS.]

At the beginning of 1720, after the death of Flamsteed, Halley was appointed astronomer-royal. In the previous years he had been employed in completing his lunar and planetary tables, which were then ready to be published. But upon his appointment to Greenwich he revived his old idea of observing the moon through a revolution of her nodes. It was doubtful that at the age of sixty-four he should live to complete an undertaking which required nineteen years of health; but he did undertake it, and did live to finish it. The result is the comparison of nearly 2000 observed lunar places with his previously formed tables. [GREENWICH OBSERVATORY.] He died January 14, 1741-42, in the 86th year of his age.

The remarks on the personal character of Halley which appear in the éloge of Mairan were furnished (it is asserted) by his friend Mr. Folkes, and their justice must be allowed so far as they speak of his prodigious information and activity. His disinterestedness in money matters is supposed to be attested by his request to Queen Caroline not to increase the salary of the astronomer-royal on his appointment to that office, lest it should afterwards become an object of ambition to incompetent persons; but, though allowing that Halley was not greedy of gain, we see but little to commend in this act of a man of independent fortune. The social qualifications of Halley were such as endeared him to his friends; and he could, when no partiality stood in the way, be fair and just to others. Thus Mairan remarks on his not having treated either Des Cartes or Vieta with the injustice which their memory received from several English writers. It were to be wished that he had been as free from personal as from national prepossessions, and that Leibnitz and Flamsteed had received their due from the friend of Newton. In his edition of the observations of the latter [FLAMSTEED] he inserted a preface containing culpable misrepresentations, an account of which is to be found in Mr. Baily's work. We shall also cite the following suppression, which is a parallel to that of Newton mentioned in the article FLUXIONS, since any presumption which can be afforded of the frequency of the practice may be some palliation for the particular cases. In all the editions of the Synopsis Cometica published during Halley's life a numerical deduction from observations is given, to which the following is appended: 'At the *moment* of the first example the comet was observed at London to be close to the second star of Aries, of which it was nine minutes north, and three minutes east; the observer being *Robert Hook*.' But in the augmented edition left by Halley to be published with his tables, the comet, at the same *hour* as in the preceding, is nine or ten minutes north of the star of Aries, and nearly in the same longitude; the observer being no longer Robert Hook, but Auzout and another. Doubtless Halley had quarrelled with Hook (as almost everybody was obliged to do) in the interval; and though the example was evidently worked for comparison with Hook's observation, at the same *moment*, we find it struck out in favour of one by Auzout in the same *hour*.

But though the scientific fame of a philosopher be no excuse for that suppression of his faults to which biographers are prone, still less should the latter be allowed to colour our views of the former. Among the Englishmen of his day Halley stands second only to Newton, and probably for many years after the publication of the Principia he was the only one who both could and would rightly appreciate the character and coming utility of that memorable work. His own attention was too much divided to permit of his being the mathematician which he might have been; but nevertheless his papers on pure mathematics show a genius of the same order of power, though of much less fertility, than that of John Bernoulli. We shall close this article with a brief account of his printed writings, and of the most remarkable points in them.

The separate works of Halley consist of the 'Catalogus Stellarum Australium,' &c., London, 1679, translated into French by M. Royer in the same year; the work of Apollonius 'De Sectione Rationis,' Oxford, 1706; the Conic Sections of Apollonius, Oxford, 1710; the unfortunate edition of Flamsteed's 'Historia Cœlestis,' London, 1712; and the planetary tables published in 1749, though printed for the most part in 1717-19. The superintendence of this work is attributed to Bradley, though it is evident that he did not write the preface. Besides the preceding there are from eighty to a hundred memoirs, including many of small importance, in the Philosophical Transactions.

In astronomy we owe to Halley, 1. The discovery and the detection of the amount of what is called the *long inequality* of Jupiter and Saturn, which he confidently expected would be shown to be a consequence of the law of gravitation, as was afterwards done. 2. The detection, by comparison of antient and modern observations of eclipses, of the slow acceleration of the moon's mean motion. 3. The first prediction of the return of a comet. [HALLEY'S COMET.] 4. The explanation of the appearance of Venus in the daytime at particular seasons, arising out of the now well-known method of estimating the brilliancy of the planet. 5. The recommendation to observe the transit of Venus for the determination of the sun's parallax.

The following list of the most remarkable labours of Halley out of astronomy, arranged in the order of publication, will instruct the reader to what articles to look for further information:—1. On the variation of the compass. 2. The law according to which the mercury falls in the barometer while the instrument ascends, being the first application of this instrument to the measurement of heights. 3. Theory of the trade-winds. 4. Construction of equations of the third and fourth degree. 5. Estimation of the quantity of vapour raised from the sea. 6. Inquiry into the point at which Julius Cæsar made his entry into Britain. 7. Tables of mortality, from observations made at Breslau, the first of the kind constructed. 8. Application of algebra to the problem of lenses. 9. Method of constructing logarithms, a celebrated paper, reprinted in Sherwin's 'Logarithms.' 10. Improvements in the diving-bell. Those papers only have been cited which refer to points on which Halley's name is inseparably connected with the history of the progress of science.

HALLEY'S COMET, the first of the comets which was proved to be a constituent part of the solar system, and to revolve regularly round the sun, deriving its name from HALLEY, the astronomer who first discovered that it had made several revolutions within the æra of correct astronomical observation, and predicted the year of its return. For the other periodic comets now known, see COMET OF BIELA, and ENCKE'S COMET. See also the general article COMET.

We cannot here attempt to give an account of this body in detail proportioned to the interest which its recent appearance excited; but such detail is rendered unnecessary by the number of publications which then appeared. Exclusively of articles scattered through the 'Astronomische Nachrichten,' the notices of the Astronomical Society, and other astronomical periodicals, and also of communications to the daily papers, the editors of which, as might be supposed, were not always able to detect the difference between sound and superficial knowledge, we may refer the reader to the following articles: 'Some account of Halley's Astronomiæ Cometicæ Synopsis,' Oxford, 1835, by Professor Rigaud: 'Des Comètes en Général,' by M. Arago, Paris, 3rd edition, 1834; 'Notice sur la Comète de Halley,' by M. Pontécoulant, Paris, 1835; and for the general history, to an article in the 'Companion to the Almanac' for 1835; and for the history of mathematical methods, to the address of the Astronomer-royal to the Astronomical Society, on delivering their medal to M. Rosenberger, in their 'Monthly Notices,' vol. iv., p. 50.

The 'Astronomiæ Cometicæ Synopsis' o Halley was published in the Philosophical Transactions for 1705, and again at the University press in Oxford, and also in an English translation published in London in 1705, which was reprinted in 1706, in the Miscellanea Curiosa. It was again reprinted in the second edition of Gregory's Astronomy, in an English edition of the same work, 1715, in Lemonnier's Theory of Comets, and was finally left for publication, in an augmented form, hy Halley himself, and was published with his tables in 1749. This work was a consequenee of the Principia of Newton, in which the method of applying Kepler's laws to the computation of the parabolic orbit of comets, the idea of the possibility of a periodic comet, and even an implied assertion that sueh things would be discovered, is to be found in book iii., prop. xli., first edition, 1687) · 'I leave their axes and times of revolution to be determined from the comparison of comets which return in the same orbits after long periods.' Halley, acting upon this hint, collected the observations of all such comets as had been observed with any degree of accuraey, up to the year 1700. These were 24 in number, and had appeared in the following years:—

1337	1580	1652	1680
1472	1585	1661	1682
1531	1590	1664	1683
1532	1596	1665	1684
1556	1607	1672	1686
1577	1618	1677	1698

On looking over the list, it needed only a glanee to see that three of these comets exhibited very nearly the same orbit, and that the intervals of the appearances were very nearly the same. The following extract from Halley's table will show this:—

In the years	1531	1607	1682
Comets appeared having	° ′	° ′	° ′
Long. of asc. node	49 25	50 21	51 16
Incl. of orbit	17 56	17 2	17 56
Long. of perih.	301 39	302 16	302 52
Perih. distanee, that of earth being 1.	56700	58680	58328
Perih. passage	Aug. 24.	Oet. 16.	Sept. 4.
Distanee from perih. to asc. nodo	° ′ 107 46	° ′ 108 5	° ′ 108 23
Motion	Retrog.	Retrog.	Retrog.

The interval hetween the perihelion passages of the first and second comet is fifteen months longer than that between the second and third, which might have puzzled a person not acquainted with the Principia. But the disturbing action of the planets, wbich has since heen so successfully computed that the motion of this hody is now much better known than was that of the moon in the time of Halley, immediately suggested itself. He announced accordingly the return of the comet about the year 1758.

It may seem perhaps that we have lessened the éclat of Halley's announeement by attributing the hint to Newton, and making his part of the work seem to be mere calculation. But it must he remembered that though at this time an expert computer in the Nautical Almanae Office would perform the same work in half a year, yet Halley had all the difficulties of a less advaneed state of pure mathematics. He had his method to organize, if not to invent; and so rare were those who had a competent understanding of the Principia, that, after a little hesitation, we agree perfectly with the astronomer-royal in saying that Halley was in all probability the only man in Europe who was competent to perform this labour.

In the latest edition of the Synopsis Halley examined the elements of the eomet's orbit further, and repeated his predietion still more eonfidently, desiring that all would remember that its author was an Englishman, 'Quoeirca si secundum prædicta nostra redierit iterum circa annum 1758, hoc primum ab homine Anglo inventum fuisse non inficiabitur æqua posteritas.' Among the years preceding 1531, in which the same eomet probably did become visible, 399, 1305, and 1456 are years of well attested eomets. But there is less evidence for the years A.C. 130, and A.D. 323, 550, 930, 1005, 1230, and 1380, all of which are described as years in which comets appeared in the collection of Lubienietski, upon various authorities.

The prediction of Halley caused various astronomers to eompute orbits of the coming comet, but none of these took into account the perturbations eaused by the planets. In 1757 Clairaut and Lalando (see these names) undertook the enormous labour of computing the effect of the perturbations of the principal planets through a period of 150 years. Assisted by Madame Lepaute, wife of a well-known watchmaker of that name, Lalande performed the drudgery of the process, while Clairaut, the first who extended Newton's application of his theory, applied the results. The consequence was, that in November, 1758, when the comet was already expected, the announcement was made that it would arrive at its perihelion within a month, one way or the other, of April 13, 1759. The announcement of Clairaut was just in time, for on December 25, 1758, George Palitzch, a farmer and amateur astrouomer in the neighbourhood of Dresden, detected the comet. It was afterwards repeatedly observed in various parts of Europe, bnt it is not on record that any one saw it with the naked eye, nor was its position at all favourable for that purpose. Various orbits were computed, but no one seemed inclined to undertake the task of applying the corrections for perturbation, so as to prediet the perihelion place for 1835. The comet slept in peace therefore until the improvement of methods of computing the perturbations, and the approaeh of a new appearanee, induced first the Academy of Turin, and next that of Paris, to offer prizes on the subject. The first was gained by M. Damoiseau, the second by M. de Pontécoulant (1817 and 1833). And M. Rosenberger at various times (*Astron. Nachr.*, Nos. 196, 180, 250, 276, 288), computed the elements of the orbit for 1682 and 1759, and the whole of the perturbations from 1682 to 1835. This enormous labour has been duly appreciated, and has placed M. Rosenberger in a very honourable position among living astronomers.

The following list of elements (extraeted from the Nautical Almanac for 1835) were given, the first by M. Pontécoulant from his own computation of perturbations, the second hy M. Damoiseau, the third by Mr. Lubhock, who applied the perturhations of M. Pontécoulant to elements for the year 1759, computed by himself. The fourth column contains the elements approximately corrected, during the reappearanee of the comet, by the superintendant of the Nautieal Almanac, from 56 roughly reduced right ascensions and deelinations.

Perih. passage 1835.	November. 7·2 Paris Mean time from noon.	November. 4·32 Paris Mean time from midn.	October.* 20·2 Paris Mean time from midn.	November. 15·93546 Greenwich mean astron. time,

The comet was first seen at Rome, on the fifth of August, by M. Dumouchel, director of the observatory of the Roman college. From that time it continued to be observed till the end of the year in Europe, and through a great part of the ensning spring in the southern hemisphere. During a part of the time it was distinctly visible to the naked eye. The number of good observations which were procured greatly exceeded, as might be supposed, those made on any previous occasion. And in full proportion to the increase of observers and instruments has been the means afforded to the astronomieal public of turning their ohservations to useful aecount. We allude to the Appendix to the Nautical Almanae for 1839, in whieh will he found the result of the most eomplete preparation for the treatment of observations which has ever been furnished for any heavenly body. Taking the elements above given as a basis, it contains the perturbations of the comet by all the planets from the beginning of August, 1835, to the end of March, 1836, the deduction of the variations of the elements during every four days, the computation of an ephemeris for the whole period, and finally the equations of eondition by the help of which an observer may deduee the corrections of the elements of the orbit which his own observations should indieate. These last are given as often as eight times a-day, for the period of the comet's most rapid motion. Every thing therefore which could be done previous to the observation being made, is effected: and the praise due to Lieut. Stratford and his assistants for this voluntary addition to their already arduous labours has heen awarded hy judges more competent than ourselves.

The history of the last appearance of Halley's comet is not yet completed, nor ean it be until the reduction and comparison of all the observations are made to produce a new

* From mean Equinox of November 15, 1835.

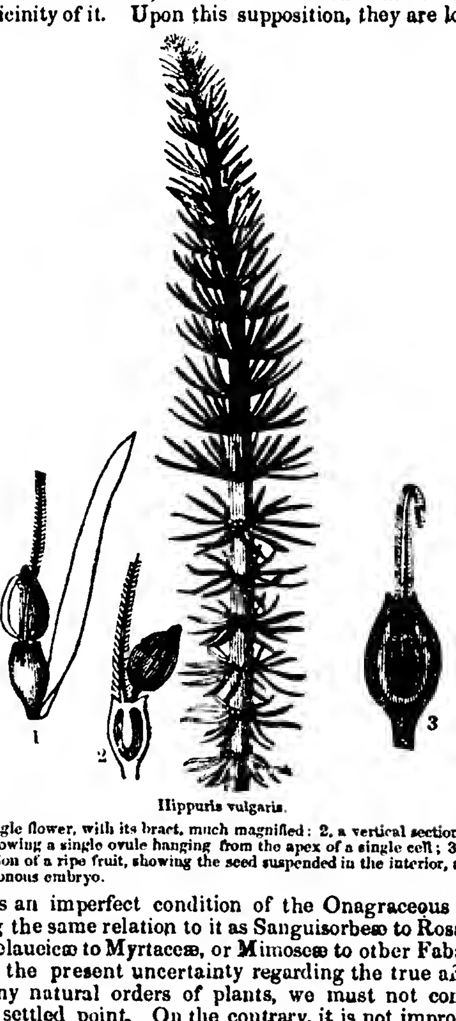
determination of the elements of 1835. Those who have collected the materials, both theoretical and practical to which we have alluded, have been working for posterity; and it is the year 1911 which must show the progress of astronomy between 1759 and 1835, just as the year 1835 was evidence of the change which took place between 1682 and 1759.

HALLI'RHOA, the name proposed by Lamouroux for a group of fossil Polyparia, referred by many writers to Alcyonia. The spheroidal figure, contracted base, deep central pit, and pores on the surface, appear the characters most relied on by Lamouroux. Goldfuss gives characters for the genus Siphonia of Parkinson, which may include the two species mentioned by Lamouroux from the vicinity of Caen and the Vaches Noires. Hallirhoa costata of Lamouroux is found in the greensand of Normandy and England.

HALMATU'RUS. [KANGAROOS.]

HALO'DROMA. Illiger's name for a genus of sea-birds allied to the Petrels and Albatrosses. [LARIDÆ.]

HALORA'GEÆ, a small group of Exogenous plants, many of which inhabit watery places, and all of which have minute inconspicuous flowers. In consequence of the calyx being superior, the embryo without much albumen, and some of them having four petals, they are often considered to form a peculiar section of Onagraceæ, or if separated from that order, are at least stationed in the immediate vicinity of it. Upon this supposition, they are looked



Hippuris vulgaris.

1, a single flower, with its bract, much magnified: 2, a vertical section of the ovary, showing a single ovule hanging from the apex of a single cell; 3, a vertical section of a ripe fruit, showing the seed suspended in the interior, and the dicotyledonous embryo.

upon as an imperfect condition of the Onagraceous type, bearing the same relation to it as Sanguisorbeæ to Rosaceæ, Chamælaucieæ to Myrtaceæ, or Mimoseæ to other Fabaceæ. But in the present uncertainty regarding the true affinity of many natural orders of plants, we must not consider this a settled point. On the contrary, it is not improbable that Halorageæ constitute an imperfect form of the great Epigynous group of Exogens, of which Onagraceæ are only one of the members. What renders it peculiarly difficult to determine the real affinity of this little group is, that as it is now constituted, it offers striking modifications of development both in the organs of vegetation and those of fructification. While Haloragis has a stem with a complete vascular organization, and regularly constructed leaves, Myriophyllum has its vascular system reduced to a rudimentary condition, and in some of the species the leaves themselves appear only in the form of filiform ramifications; and in Hippuris, the development of the vascular system of both stem and leaves is still further reduced. In like manner in the flowers, Haloragis has four petals, eight stamens, four stigmas, and four cells to the ovary; Proserpinaca has no petals, three stamens, three stigmas, and three cells to the ovary; and Hippuris has no petals, one stamen, one stigma, and but one cell to the ovary. This latter genus is a common plant in the marshes and meadows of this country, where it is vulgarly called Mare's-tail.

HALS, FRANCIS, an eminent portrait-painter, born at Mechlin, 1584, died in 1666. No artist of that time was superior to him except Vandyck, and very few could be compared with him. With the first merit of a portrait, that of strong resemblance, his pictures were executed with remarkable freedom and boldness: his colouring was extremely good, and the effect very striking.

HALSTED. [ESSEX.]

HALYATTES. [ALYATTES.]

HALYMENITES. Under this generic name Sternberg (*Flora der Vorwelt*) and Bronn (*Lethæa Geognostica*) include several species of fossil fucoid plants, found in the slaty oolitic rocks of Stonesfield and Solenhofen.

HALYS. [KIZIL ERMAK.] We have referred to this head, because some further information on this river may be soon expected.

HALYSITES, the name given by Fischer to a genus of fossil corals, synonymous with Catenipora of Goldfuss. As having priority, it is adopted by Bronn in his 'Lethæa Geognostica.'

HAM, EAST and WEST. [ESSEX.]

HAMADAN. [ECBATANA.]

HAMAMELA'CEÆ, or HAMAMELI'DEÆ, a very small group of woody Exogenous plants, characterized by having a superior calyx, a definite number of stamens, half of which are usually sterile, a two-celled ovary, and an embryo in the midst of horny albumen. There are only three genera in the gardens of this country, Hamamelis, Trichocladus, and Fothergilla. It is at present uncertain to what order Hamamelaceæ are most nearly allied, and until some further discoveries shall have been made, the question is not likely to be settled. Some of the species are large forest trees, affording good timber, but nothing is known of any other useful property in the order.

HAMBURG, the largest city in Germany after Vienna and Berlin, and by far the most important emporium of commerce, is situated in 53° 33′ N. lat., 9° 58′ 35″ E. long. The origin of this city is attributed to Charlemagne. The founder chose for its site the most elevated spot on the north bank of the Elbe and the east bank of the Alster, about 75 miles from the German Ocean. Though at first merely the resort of fishermen, its advantageous position could not fail to make it in time a place of trade. It was several times destroyed by the neighbouring barbarians, yet it always recovered, and had attained considerable commercial importance at the beginning of the twelfth century. In the thirteenth century it concurred in the formation of the Hanseatic League. [HANSE TOWNS.] Till 1500 it was confined to the space between the Elbe and the east bank of the Alster; but the west bank was gradually built upon, especially by refugees from the Netherlands, who fled from the tyranny of the Duke of Alba. Hence arose the new town, which increased so rapidly that it was thought advisable to extend the walls so as to enclose it within the city. The actual fortifications of the city were not further enlarged after this time, though some outworks were made and a fortified line was formed enclosing the suburb of St. George. Its rights as an estate of the empire were contested by the Danes, and though it was recognised as such in 1618, it did not obtain a seat or vote in the Diet. The kings of Denmark claiming the sovereignty as counts of Holstein, Hamburg was obliged at different times to avert a threatened attack by the payment of large sums, till a convention with the house of Holstein in 1768 removed all difficulties; and in 1770 it was confirmed by the emperor in its rights as a free city of the empire. The possession of the cathedral had been always claimed by the archbishops of Bremen, but it was assigned by the treaty of Westphalia in 1648 to Sweden, and afterwards passed to Hanover with the duchy of Bremen. The general effect of the repeated wars in Germany to the close of the eighteenth century was favourable to Hamburg, by causing a great addition to its population and its wealth, and extending its commerce. In

1802 the cathedral and all the property hitherto belonging to Hanover in the city and territory were finally assigned to Hamburg, and its independence still further secured. Thus Hamburg at the commencement of the nineteenth century was one of the most flourishing, happy, and opulent cities of the Continent. Its misfortunes commenced with the occupation of Hanover, in 1803, by the French, who seized Ritzebüttel, at the mouth of the Elbe, to prevent English ships from entering the river. Upon this the English instituted a most rigorous blockade, so that the commerce of Hamburg was paralyzed, and its direct maritime trade interrupted. It was compelled by French threats to advance two millions and a half of Banco marks (about 200,000*l.* sterling) to the estates of Hanover. After the pillage of Lübeck in 1806 Marshal Mortier with his corps occupied Hamburg, and made the city pay sixteen millions of francs as a ransom for the English goods in the warehouses. Though the French troops were withdrawn after the treaty of Tilsit, and the city had for a short time a shadow of independence, it was still subject to numerous extortions from the French generals. The decrees of Berlin and Milan ruined the little remaining trade of Hamburg, and the English goods which it had been forced to ransom were now confiscated and consigned to the flames. At the end of 1810 it was incorporated with the French empire as the capital of the department of the Mouths of the Elbe. In 1813 the citizens hailed with rapture the entrance of a Russian corps, at the approach of which the French had evacuated the city. The old constitution was restored; a burgher guard of 7000 men was formed, and two thousand of the inhabitants volunteered to join the allies, and the Russians repaired the fortifications, which had been partly razed. But the French soon returned and attacked the city on the Elbe side. The Russians, being too weak, withdrew, and Marshal Davoust and General Vandamme entered Hamburg, which they treated with a degree of wanton severity that excited in the highest degree the sympathy and indignation of Europe. They imposed a contribution of two millions sterling; and being afterwards besieged, drove out 40,000 inhabitants in the depth of winter, and even seized the treasure deposited in the bank, amounting to about 700,000*l.* sterling. An unhappy combination of circumstances enabled them to retain possession of it till May, 1814. On the 26th of that month the old constitution was restored, and on the 8th of June, 1815, Hamburg joined the German Confederation as a free Hanseatic city. For all its severe sufferings, including the robbery of the bank, a very inadequate indemnity was obtained from France at the peace. But the public spirit of the inhabitants, its internal resources, and its favourable situation, have gradually restored its former prosperity.

The territory of Hamburg, including the area of the city (which is nearly an oval four English miles in circumference), is about 150 square miles, bounded on the south by the Elbe, and on the other sides by the Danish territories. It has likewise some islands in the Elbe, some parcels of land on the Hanoverian side of the river, and the bailiwick of Ritzebüttel at the mouth of the Elbe, in which is the harbour of Cuxhaven. Conjointly with Lübeck it has the bailiwick of Bergedorff, and the districts called the Vierländen, 16 miles from Hamburg, with 10,000 inhabitants. The population of Hamburg and its suburbs is 100,000; and that of the territory, including Bergedorff, between 25,000 and 30,000. The great majority are Lutherans. The Roman Catholics may be from 5000 to 6000, the Calvinists 1500 to 2000, and the English may fluctuate between 1000 and 1500; the number of Jews is stated in some late works at 14,000, which we believe to be more than double the real number. In 1824 it appeared from the bills of mortality that they could not exceed 4000.

The constitution is a mixture of aristocracy and democracy. The senate, consisting of four burgomasters and twenty-four senators, with four syndics and four secretaries, has the executive power, and the sole right of proposing laws; but no laws can be made and no taxes imposed without the consent of the citizens in common hall. The citizens are divided into five parishes, each of which chooses 36 members to the council of 180, consisting—1, of 15 elders, who are the guardians of the laws, and have the affairs of the churches and the poor under them; 2, of 45 deacons, 9 from each parish, who with the elders form the council of 60; and 3, of 24 subdeacons from each parish: all these are obliged to appear in the common hall, where at least 200 citizens must be present. From this council is chosen the board of 60, and out of that the 15 elders or aldermen. Only the senators and the elders receive salaries. For the administration of justice there are various tribunals. In the last resort the decision is with the High Court of Appeal for all the free cities, sitting at Lübeck. In the German Diet Hamburg has one vote in the deliberations, but in the select council it has a vote only in common with Lübeck, Bremen, and Frankfort. Its contingent to the army of the Confederation is 1298 men, and its contribution to the general fund 500 florins per annum. It has also an admirably organized burgher guard of 9000 infantry, cavalry, and artillery.

The interior of the city by no means corresponds with its commercial importance and its wealth. As in most of the old fortified towns of Germany, the streets are in general narrow, irregular, and dark; the houses old-fashioned and awkward, and yet not interesting to the lovers of antiquity. In modern times handsome houses have certainly been erected in some streets, but they are exceptions. Some streets in the New Town are indeed broader and more regular, but that is all. Nor can Hamburg boast of its public buildings, either ecclesiastical or civil. The number of churches has been reduced of late years: the antient cathedral was pulled down almost as soon as it was ceded to Hamburg, and since the peace four smaller churches have been demolished. There are now five principal and six smaller churches or chapels: the former, having been shamefully profaned by the French, who used them as stables for their horses, and committed the most wanton mischief, have been much beautified inside since 1814. The most worthy of notice is the great church of St. Michael, which was saved from French desecration. It was begun in 1751, and completed in 1762, except the spire, which was not erected till 1778. This church, built by Sonnin, is the pride of Hamburg; it is capable of accommodating 2000 persons: the height of the steeple is said to be 456 feet. These churches are all Lutheran. The Roman Catholics had formerly no places of worship, except the chapels of the ambassadors of that religion; but the French seized for their use the small church of St. Michael, which has since been granted them by the city. Of the public edifices, the most distinguished for their style of architecture are the new bank, the new observatory, and the new theatre, built after a design of the celebrated Schinkel of Berlin. But if the public edifices have so little to recommend them, Hamburg may well be proud of the number and variety of its charitable institutions, the bare enumeration of which would exceed our limits, but of which it may be affirmed that they are on the most liberal plan, and managed in the most exemplary manner. There are only two learned institutions supported by the state—the Johanneum, designed to qualify young men for the university, and the gymnasium. Hamburg has been the birth-place of many learned men and the chosen residence of many others. Its numerous literary institutions, its private collections of paintings, the general taste for music, the fondness for the study of foreign languages, prove that the whole attention of the inhabitants is not absorbed by thirst of gain. The principal public library, called the City Library, contains nearly 200,000 volumes, besides 3000 volumes of MSS.

The arm of the Elbe, next the town, is narrow, but the two harbours are capable of receiving a considerable number of ships. The old town is so intersected with canals as to resemble a Dutch city: the canals are filled chiefly by the Elbe, but partly by the Alster, and almost all the warehouses are close to them. The Alster forms on the north side of the town a fine basin, chiefly used for parties of pleasure. On the south side of this basin is the finest line of houses in the city, with a spacious walk planted with trees, and called the Jungfernsteig, or Ladies' Walk. Since the peace, this favourite promenade has been continued along the west side of the basin, so as to join the ramparts, the whole of which are beautifully laid as a public garden and promenade (the carriage-way is broad enough for three carriages), all round the city, affording a most agreeable place of recreation to the inhabitants. North of this Inner Alster is the Outer Alster, a very large basin, on the banks of which are numerous fine country-seats, which however are not equal to those possessed by some of the wealthy merchants in the Danish territory, at Blankenese, on the banks of the Elbe, six miles west of Hamburg.

To give an account of the vast commerce of Hamburg would fill a volume. Every thing that can be bought and sold, however costly or however mean, is an object of trade, which is as free as can be desired. The import duties are extremely low, and no transit duties are levied. This city is consequently the great receptacle for English goods imported into Germany, and of the ships (about 2000 in number) which annually enter the port, at least one-third are English. Within these few years there has been a regular communication by steam-boats with London, Hull, Leith, Amsterdam, and Hâvre. (J. L. v. Hess, *Hamburg, Topog. Polit. Histor.;* K. J. H. Hutte, *Ansichten der Stadt Hamburg;* H. E. Lloyd, *Hamburg*, &c.)

HAMEL, JEAN BAPTISTE DU, was born in 1624, and died August 6, 1706. In 1632 he published a very perspicuous treatise on the Sphærics of Theodosius, which was followed by several other works on natural philosophy and astronomy. Upon the foundation of the Royal Academy of Sciences by Louis XIV. in 1666, Du Hamel was appointed secretary, which office he continued to hold till 1697, when he was succeeded by Fontenelle. His philosophical and astronomical works were collected and published at Nürnberg, 1681, in 4 vols. 4to., and in 1698 appeared his history of the Royal Academy and its transactions, from its foundation to the year 1700. This latter work, entitled 'Regiæ Scientiarum Academiæ Historia,' is the only one which possesses any value at the present day.

HAMELN, a considerable town in the Hanoverian principality of Calenberg, at the confluence of the Hamel with the Weser, over which there is a bridge of boats. It has above 5000 inhabitants.

HAMILCAR, BARCAS, the leader of the popular party at Carthage, was appointed in the eighteenth year of the first Punic war (B.C. 247) to the command of the Carthaginian forces. We possess no particulars respecting his early life or the time of his birth; but we learn from Nepos (*Hamil.*, c. 1) that he was very young when he obtained the command. He ravaged with his fleet the coasts of the Bruttii and the Epizephyrian Locrians, and afterwards seized upon a strong fortress in Sicily, which was situated between Eryx and Panormus. In this place he continued for some years, with very little support from the Carthaginian government; and although the Romans were masters of almost the whole of the island, they were unable to dislodge him. He frequently ravaged the southern coasts of Italy as far as Cumæ, and defeated the Roman troops in Sicily. On one occasion he took Eryx, which he held till the conclusion of the war. The Romans at length fitted out a fleet to cut off all communication between Hamilcar and Carthage; the Carthaginian fleet sent to his assistance was defeated by the Roman consul Lutatius Catulus (B.C. 241), and the Carthaginians were obliged to sue for peace. This was granted by the Romans; and Hamilcar led his troops from Eryx to Lilybœum, whence they were conveyed to Africa. But a new danger awaited Carthage. The Carthaginian treasury was exhausted; and it was proposed to the troops that they should relinquish a part of the pay which was due to them. The soldiers rejected the proposal, appointed two of their number, Spendius and Matho, commanders, and proceeded to enforce their demands. Being joined by many of the native tribes of Africa, they defeated Hanno, the Carthaginian general sent against them, and brought Carthage to the brink of ruin. In these desperate circumstances Hamilcar was appointed to the command, and at length succeeded in subduing them after the war had lasted three years and four months.

After the end of this war Hamilcar was sent into Spain (B.C. 238). He remained in Spain nearly nine years, during which time he extended the dominion of Carthage over the southern and eastern parts of that country. He fell in a battle against the natives, B.C. 229.

The abilities of Hamilcar were of the highest order; and he directed all the energies of his mind to diminish the power of Rome. Polybius states his belief (b. iii., p. 165-6, *Casaubon*), that his administration would soon have produced another war with the Romans, if he had not been prevented by the disorders in which his country was involved through the war of the mercenaries.

Hamilcar was succeeded in his command in Spain by his son-in-law Hasdrubal, who must not be confounded with Hasdrubal the brother of Hannibal. He carried on the conquests of Hamilcar, and reduced almost the whole of the country south of the Iberus (Ebro), which river was fixed by a treaty between the Carthaginians and the Romans, B.C. 226, as the frontier of the Carthaginian dominions. Hasdrubal was murdered in his tent by a Gaul, B.C. 221, after holding the command eight years. (Polybius, b. i. ii.; Appian; Nepos.)

HAMILTON [LANARKSHIRE.]

HAMILTON, A. [GRAMMONT.]

HAMILTON, GAVIN, descended from a noble family of Scotland, spent the greater part of his life at Rome. Though not perhaps gifted with eminent genius for invention as an artist, yet a liberal education and refined taste enabled him at least to equal his most distinguished contemporaries. This is manifest in several subjects which he painted from the 'Iliad.' It is probable that he would have attained greater eminence had he devoted more time to the practice of his profession; but a considerable part of the latter period of his life was dedicated, perhaps more advantageously for the cause of the arts, to the discovery of antient monuments. He opened scavos in many parts of the Roman territory, especially at Tivoli, in Hadrian's villa. In the Museo Clementino, the statues, busts, and bas-reliefs contributed by him form the most important portion, next to the treasures of the Belvedere; and many great collections in Russia, Germany, and England are indebted to him for their chief ornaments. The 'Townley Gallery,' published under the superintendence of the Society for the Diffusion of Useful Knowledge, contains a list of the marbles procured by him for the collection of Mr. Townley. Neither the date of his birth nor death is certainly known; he died however between 1790 and 1800. However eminent his talents, they were excelled, says Fuseli, by the liberality, benevolence, and humanity of his character.

HAMILTON, WILLIAM, of Scotch descent, but probably born in London, studied at a very early age under Zucchi, the painter of ornaments, at Rome. After his return he soon obtained general employment. He was engaged in all the public works, such as the Shakspeare Gallery, Macklin's Bible, &c. He excelled in ornament, to which he gave propriety, richness, and a classic appearance. He died in 1801, at the age of fifty.

HAMILTON, SIR WILLIAM, a well-known diplomatist and lover of art, was born in Scotland in 1730. He began life, he says, 'with an antient name and 1000*l*.;' but removed the discrepance between his name and his fortunes by marrying in 1755 a lady of very large property, as well as amiable and agreeable character. It is said in the French biographies that he was foster-brother to George III., which may account for his appointment in 1764 to be English ambassador at Naples, whence he was not recalled till 1800. His connexion with the stirring events born of the French revolution, more especially with the brilliant exploits of Nelson in the Mediterranean, belong to the history of the period. The master-spirit in that troubled time was his second wife (married to him in 1791), the fascinating, mischievous, and wretched Lady Hamilton. [NELSON.] Sir William appears however to have maintained an unblemished character, except in his weak indulgence of his licentious wife. He was made a Knight of the Bath in 1771, and a privy-councillor in 1791. He died, much impoverished, in England, April 6, 1803.

Immediately after his arrival at Naples he applied himself diligently to observe and record the volcanic phenomena of the neighbourhood; and the continued activity of Vesuvius from 1766 to 1771 gave him excellent opportunity for these researches, of which his great work, the 'Campi Phlegræi,' Naples, 1776-7, 2 vols. fol., is a noble monument. It consists of a series of coloured plates, exhibiting the most remarkable volcanic phenomena and the scenery of the most remarkable spots with great vividness, accompanied by explanations in French and English. Sir W. Hamilton published a Supplement to it in 1779, containing similar representations of the great eruption of Vesuvius in August of that year.

His collection of Greek and Etruscan vases (now in the British Museum) was very valuable; the foundation of them was laid by the purchase of the Porcinari collection at Naples in 1765. They gave rise to that splendid work 'Antiquités Etrusques, Grecques, et Romaines, tirées du Cabinet de M. Hamilton,' 4 vols fol., published at Naples, the two first vols. in 1766, the others at a later date. The profit of the work was assigned to the editor D'Hancarville. Many of the marbles now in the Townley Gallery of the British Museum came from the collection of Sir W. Hamilton. (See *Library of Entertaining Knowledge, Townley Gallery*, vol. ii., index.)

Mr. Hamilton took a lively interest in all subjects connected with art or with antiquity, especially in the progress of the excavations at Herculaneum and Pompeii, and the formation of the museum of Portici. He was earnest in recommending to the Neapolitan government the great work of unrolling the Herculaneum manuscripts, but produced little effect on that most supine court. He himself bestowed a part of his income upon this object. Ten papers of his composition, upon matters observed during his abode in Italy, are printed in the 'Phil. Trans.' for the years 1767 to 1795 inclusive. His other works are, 'Observations on Mount Vesuvius, Mount Etna,' &c., Lond. 1772; and 'Lettera sul Monte Volture,' Naples, 1780. (Chalmers' *Biog. Dict.*; *Biog. Univ.*; Watt, *Bibl. Br.*)

HAMILTON, ELIZABETH, born at Belfast in Ireland, but probably of Scottish parentage, is deservedly remembered as an early advocate of an enlarged and intellectual system of female education, and as one of the leaders of that useful class of novelists who have placed the interest of their fictions, not in rare adventure and glowing description, but in the accurate portraiture of the daily workings of domestic life. We find little to tell of her personal history. It appears that she filled the office of governess to the daughters of a Scottish nobleman, for the eldest of whom her 'Letters on the Formation of the Religious and Moral Principle' were written. She died July 25, 1816, regretted and beloved. Her warm and sincere piety was untinctured by severity, and her natural cheerfulness and lively talents rendered her delightful in society, and, in old age, a universal favourite with the young.

The following are her chief works:—'Letters of a Hindoo Rajah,' 1796; 'Modern Philosophers,' 1800, a clever, popular, and effective satire, intended to throw discredit on the sceptical and republican doctrines taught by some disciples of the French Revolution; 'Letters on the Elementary Principles of Education,' 1801-2; 'Life of Agrippina,' 1804, an attempt to make history interesting, by expanding it into something bearing the resemblance of a novel; 'Letters on the Formation of the Religious and Moral Principle,' 1806; 'Cottagers of Glenburnie,' 1808; 'Exercises in Religious Knowledge,' 1809; 'Popular Essays,' 1813. Of these the 'Letters on Education' is the most sterling and important. She has here applied the principles of metaphysics to the subject of education, and shown (we quote words ascribed to a female writer of still higher note) 'how the doctrine of the association of ideas may be applied in early education to the formation of the habits, of temper, and to the principles of taste and morals; she has considered how all that metaphysicians know of secretion, abstraction, &c., can be applied to the cultivation of the judgment and the imaginations of children. No matter how little is actually ascertained on these subjects; she has done much in wakening the attention of parents, and of mothers especially, to future inquiry; she has done much by directing their inquiries rightly; much by exciting them to reflect upon their own minds, and to observe what passes in the minds of their children.' As a novelist, she will be best recollected by the 'Cottagers of Glenburnie,' 'a lively and humorous picture of the slovenly habits, the indolent temper, the baneful content, which prevail among some of the lower class of people in Scotland.' This piece, though only the picture of humble life in a remote and obscure district, can never lose its interest, for the characters are true to nature, essentially, not locally true; and the pathos, the humour, the admirable moral lessons, are of all time, and independent of the national peculiarities under which they are conveyed. (Notice ascribed to Miss Edgeworth, in the *Monthly Mag.* for September, 1816.)

HAMITES, a genus of Cephalopodous Mollusca proposed by Mr. James Sowerby. (*Min. Conchology of Great Britain.*) It includes only fossil species, and is yet incompletely understood. According to the original views of Mr. Sowerby, only those chambered shells belong to hamites which have the form of a hook or siphon bent in one plane with parallel but unequal limbs, and sinuous septa. But the specimens having these characters appear always imperfect; and when Professor Phillips found in Yorkshire many fossils, in other respects perfectly resembling hamites described by Mr. Sowerby, rolled in a plane spiral, the volutions in some species touching, in others free, and in a few terminating in a straight elongation (like spirula), he extended the use of the term. Dr. Buckland has adopted this view in his 'Bridgewater Treatise.'

In the 'Transactions of the Geographical Society of France,' June 11, 1837, M. Leveillé gives descriptions and figures of species of fossil Cephalopoda, which might be considered as the spiral part of hamites (Phillips), and names them *Crioceratites*. Bronn adopts this genus. Mr. Sowerby has recently been led to very similar results, and has proposed to call the same group *Tropæum*. Now as certain forms of ammonites in the lias and oolitic rocks (A. fimbriatus) have no very obvious difference from Tropæum, Crioceratites, or the spiral parts of Scaphites (*e.g.* Scaphites Yoannii in the British Museum), it is evident that the whole question of the true relations of these remarkable fossil genera to ammonites remains to be further examined. We shall therefore reserve till the article TROPÆUM a general view of these relations.

Hamites of the typical forms occur at Folkstone, Hamsey, and other situations in the gault, greensand, and other cretaceous beds. Crioceratites and Tropæum belong chiefly to the same groups of rocks in England, France, Switzerland, &c. [TROPÆUM.]

HAMMERFEST. [NORWAY.]

HAMMERSMITH. [MIDDLESEX.]

HAMMOND, HENRY, a learned and excellent divine of the church of England, was born at Chertsey, August 18, 1605. Having been educated at Eton, and Magdalen College, Oxford, of which he became Fellow, he was presented to the rectory of Penshurst in Kent, in 1633, ten years after which he was appointed archdeacon of Chichester. By birth and education a confirmed royalist, he retired to Oxford soon after the civil war broke out, continued to reside there while that city was held by the king, and attended the king's commissioners to Uxbridge, where he disputed with Vines, a Presbyterian minister. He was appointed canon of Christchurch and public orator in 1645, and attended Charles I. as his chaplain from the time when he fell into the hands of the army until the end of 1647, when the king's attendants were parted from him. Hammond then returned to Oxford, and was chosen sub-dean of Christchurch, from which situation he was expelled in March, 1648, by the parliamentary visitors, and placed for some time in confinement. On his release he repaired to Westwood in Worcestershire, the seat of Sir John Packwood, where the remainder of his life was spent in literary labour, 'doing much good to the day of his death, in which time he had the disposal of great charities reposed in his hands, as being the most zealous promoter of almsgiving that lived in England since the change of religion. . . . Great were his natural abilities, greater his acquired; and in the whole circle of the arts ho was most accurate. He was also eloquent in the tongues, exact in antient and modern writers, well versed in philosophy, and better in philology, most learned in school divinity, and a great master in church antiquity.' He died after long suffering from a complication of disorders, April 25, 1660. It is said that Charles II. intended for him the bishopric of Worcester. Of his numerous works, chiefly controversial, the following are some of the most remarkable: 'Practical Catechism,' 1644; 'Humble Address to the Right Hon. the Lord Fairfax and his Council of War,' 1649, concerning the impending trial of Charles I.; 'Paraphrase and Annotations on the New Testament,' 1653, best edition 1702. He began a similar paraphrase of the Old Testament; but advanced no farther than the Psalms, 1659, and one chapter of Proverbs. His works, in 4 vols. folio, were collected by his amanuensis Fulman, 4 vols. folio, 1674-84. (*Life*, by Bishop Fell; Wood, *Athen. Oxon.*)

HAMMOND, JAMES, was the second son of Anthony Hammond, Esq., of Somersham Place, in Huntingdonshire. He was born in 1710, and educated at Westminster; he sat in parliament for Truro, on the interest of the Prince of Wales, whose equerry he was. He died in 1742.

His verses are mostly elegiac, and addressed in the vapid style of pastoral sentiment, then in fashion, to a fictitious object, whom he names Delia. He is said to have been in love with a Miss Dashwood, who refused him—if she read his poems it is hard to say how she could do otherwise—and to have lost his intellects in consequence of her cruelty.

An attempt has been made to defend his poetry, but we think there will be few in this age to differ from Dr. Johnson in his somowhat oracular opinion that 'these elegies have neither passion, nature, nor manners.' (Johnson's *Lives*; Chalmers' *Biog. Dict.*; Aikin's *Brit. Poets*.)

HAMOAZE. [PLYMOUTH.]

HAMPDEN, JOHN, the eldest son of William Hampden, of Hampden, in Buckinghamshire, and his wife Elizabeth, second daughter of Sir Henry Cromwell, of Hinchinbrooke, in Huntingdonshire, and aunt of the Protector, was born in London in 1594, and succeeded in his infancy to the estates of his antient and respectable family. He was educated first at a grammar-school at Thame, afterwards at Magdalen College, Oxford, and in 1613 was admitted a student in the Inner Temple, where he made considerable progress in the common law. In 1619 he married at Pyrton, in Oxfordshire, Elizabeth, only daughter of Edmund Symeon, and for some years continued to lead a country life, entering freely into field sports and other amusements of his age. His attention however was not thus wholly occupied, but was likewise attracted by the political struggles of the day; so that when the king was by necessity compelled to summon a parliament, Hampden became anxious for a seat in the lower house. The borough of Grampound first returned him to parliament; the borough of Wendover next elected him three successive times. He was then chosen by the county of Buckingham, and being doubly returned to the Long Parliament by the constituencies of Wendover and Buckinghamshire, he made his election for the county. In 1634 his wife, to whom he was tenderly attached, died, leaving nine children,—three sons and six daughters: Elizabeth, the eldest, married Richard Knightley, of Fawsley, in Northamptonshire; the second, Anne, became the wife of Sir Robert Pye, of Faringdon. Mrs. Knightley, Hampden's favourite daughter, died during the first year of the civil war. He married, for his second wife, Lætitia, daughter of Mr. Vachell, of Coley, near Reading: by this lady, who survived him, it does not appear that he had issue.

In the first short parliament to which he was elected Hampden took no very forward part in the business of the house; but his opinions coincided with those of Pym, Selden, and others of the popular party, who were determined to resist the unwarrantable encroachments of the crown upon the privileges of the parliament and the rights of the people. Gradually his influence increased both in and out of parliament, and especially in his native county of Buckingham. At length his reputation became general. At the close of Charles I.'s second parliament, the king, in pursuance of his threat to resort to new modes of raising supplies, required a general loan; to this loan Hampden resolutely refused to contribute, denying the king's right to demand it. In consequence of this refusal he was imprisoned in the Gate-house, removed thence in custody to Hampshire, but was afterwards, with seventy-six others, unconditionally liberated by an order of council. He now became one of the most industrious members in the house, both in its general business and the superintendence and conduct of committees. His resistance to the arbitrary imposition of ship-money (1636) induced many other residents in Buckinghamshire to follow his example. Proceedings were instituted against him on the part of the crown. The case was argued in the Exchequer Chamber (1637) during twelve days before all the twelve judges, who, two excepted, gave a decision in favour of the crown. It is remarkable that there is no appearance of an assessment of ship-money having been made upon the county of Buckingham after Hampden's trial. The judgment however which was then given strengthened the claim which the king had made to the power of taxing in any manner and to any extent, and the fear of oppression began to operate as an inducement to emigration. Many, especially among the puritans, had already left the kingdom, and more were preparing to do so, when an order from the king, dated April, 1638, prohibited all ships from sailing with passengers unless with a special licence. Eight ships were then lying in the Thames for the reception of emigrants; in one of which had engaged their passage across the Atlantic two no less considerable persons, it is said, than Oliver Cromwell and his kinsman Hampden: to this ship a licence was refused. (Lord Nugent's *Memorials of Hampden*, vol. i., p. 254.)

For an account of Hampden's conduct generally in the Long Parliament we must refer to Lord Nugent's 'Memorials of Hampden,' to Clarendon, Whitelock, and the general histories. His resistance to the undue influence of the king so irritated Charles I., that the king accused him, with three other members of the Commons and one of the Lords, of having traitorously endeavoured to subvert the fundamental laws and government of the kingdom, and even made an attempt in person to seize them in the House. The House protected them from seizure, but violent debates and tumults arose, which were shortly after followed by the civil war. Hampden now raised and commanded a troop, with which he joined the parliamentary army, acting chiefly in Berkshire and the counties of Oxford, Northampton, Warwick, Middlesex, and Buckingham. Being a member of the Committee of Public Safety, as well as a military leader, he was incessantly and variously occupied in all the affairs of the war. His counsel was for vigorous and resolute attack; he considered that Essex, the parliamentary general, should have acted more on the offensive. In an engagement with Prince Rupert upon Chalgrove Field, June 18, 1643, Hampden placed himself at the head of the attack, but in the first charge received his death-wound. Two carabine balls struck him in the shoulder, and, breaking the bone, entered his body: he left the field, and obtained surgical aid at Thame, but the wound was incurable, and after six days' severe suffering he expired.

Historians of the most opposite parties unite in unanimous praise of this great man: all bear testimony to his affability in conversation; his temper, art, and eloquence in debate; his penetration in counsel; his industry, vigilance, and enterprise in action; and his courage in war. His last words were a touching and beautiful prayer for the welfare of his country. (Lord Nugent's *Memorials of Hampden*; Clarendon, *Hist. Rebel.*; Hume, *Hist of England*.)

HAMPSHIRE, a southern maritime county of England, lying between 50° 34′ and 51° 22′ N. lat., and 0° 43′ and 1° 54′ W. long. It is principally on the mainland of England, but includes the Isle of Wight. [WIGHT, ISLE OF.] The portion on the mainland approximates in form to a parallelogram, except at the south-west corner, where a portion juts out to the westward: the sides of the parallelogram face the four cardinal points. Hampshire is bounded on the north by Berkshire, on the east by Surrey and Sussex, on the south by the English Channel, and on the west by Wiltshire and Dorsetshire. The length of the county (mainland part) from north to south varies from 37 to 46 miles; the breadth varies from 28 to 41 miles. The Isle of Wight is in the form of a lozenge, having its longer diagonal from east to west 23 miles, and its shorter diagonal from north to south 14 miles. It is separated from the main part of the county by an arm of the sea averaging about 3 miles over; but in the narrowest part not more than one mile. There is a small detached part of the county 9 miles long, and for the most part less than half a mile wide, extending from near Haslemere in Surrey to Midhurst in Sussex. The area of the county, including the Isle, is 1625 square miles; in size it is the eighth of the English counties, being a little smaller than Somerset and a little larger than Kent. The population in 1831 was 314,280, or 193 to a square mile. In absolute population it is the fifteenth, in relative population the twenty-fourth of the English counties. Winchester, the county town, is on the Itchin, 62 or 63 miles in a direct line south-west of St. Paul's, London; 65 miles from Hyde Park Corner by the road through Staines, Farnham, and Alton, or 62½ miles by Basingstoke: but Southampton, from which the county derives its name, is 71 miles south-west of St. Paul's, London, in a direct line, or 77 miles from Hyde Park Corner by the road through Alton and Winchester.

Coast-line, Surface, Hydrography, Communications.—The coast of Hampshire (not including the Isle of Wight) is low towards the east side of the county, where there is a wide but not very deep bay or inlet, divided by Hayling Island and Portsea Island into three parts; Chichester harbour on the east, Langston harbour in the middle, and Portsmouth harbour on the west. These harbours, when the tide is up, present broad sheets of water; and Portsmouth harbour especially, with its shipping, has, when viewed from the top of Portsdown, a striking appearance; but when the tide is out, little is seen but an assemblage of sand or mud banks, with channels of deeper water running between them. Hayling Island is about 4 miles long from north to south, and nearly as much broad at the widest part, which is next the open sea. It contains the two villages of North and South Hayling, with a population of 882. Portsea Island, 4 miles long from north to south, and about 3 broad, contains the antient borough of Portsmouth and the town of Portsea, with their extensive suburbs. The principal naval dockyard in England, or indeed in the world, is at Portsea. The two towns have a population of 50,389. [PORTSMOUTH.] There are salt-works on both these islands.

From the entrance of Portsmouth harbour the coast runs north-west to the entrance of the inlet or æstuary called Southampton Water. In this part are some low cliffs. Southampton Water penetrates about 7 miles inland to the town of Southampton, at the junction of the Test and the Itchin: its breadth, when the tide is up, is from 1½ to 2 miles; at low water, about half a mile. From the entrance of Southampton Water a low coast runs south-west until opposite to the western extremity of the Isle of Wight. Along this low coast are extensive salt-works, and at its extremity, upon the point of a long sandy neck, stands Hurst Castle. From Hurst Castle the coast runs west, forming the shallow bay of Christchurch, terminated at its western point by Hengistbury Head, from which the coast still runs west to the border of Dorsetshire. From the neighbourhood of Hurst Castle the coast is generally high and abrupt.

The surface of this county is rather irregular. The South Downs enter the county from Sussex on the south-east, near Petersfield, and cross it in a north-west direction into Wiltshire: Butser hill, between Petersfield and Horndean, on the Portsmouth road, one of the highest points in this range, is 917 feet high. The North Downs enter the county from Surrey near Farnham, and extend across the county, by Odiham, Basingstoke, and Kingsclere, into Wiltshire. Highclere Beacon, one of the points of this range, in the north-western part of the county, near the border of Wilts and Berks, is 900 feet high. The Alton hills form a connection on the east side of the county between the South and North Downs, and run from Petersfield northwards past Alton. Portsdown is an isolated eminence extending east and west just above Portsmouth and Langston harbours; its height is about 447 feet; its length 7 miles, and its breadth one. All these hills are in the chalk formation.

A large part of Hampshire is within the basin of the Southampton Water; a small portion on the north and north-east sides of the county is in the basin of the Thames; a small portion on the south-east side is in the basin of the Arun, and a small portion of the west side is in the Wiltshire and Dorsetshire basin.

The principal streams which drain the Southampton basin are the Anton or Test, the Itchin, and the Hamble. One branch of the Test rises near Hurstbourne Tarrant (between Newbury, Berks, and Andover), and another near Whitchurch; their united stream flows by Stockbridge and Romsey to Southampton. The Itchin rises in the hills around Alresford and flows past Winchester to Southampton. The Hamble rises near Bishop's Waltham, and joins the Southampton river some miles below Southampton. A stream, to which the maps assign no name, flows by the village of Titchfield into the sea, near the mouth of the Southampton Water. The length of these rivers is as follows:—the Anton or Test to Southampton, 35 miles; the Itchin 25 miles (of which 13, viz. up to Winchester, are navigable); the Hamble 10, and the Titchfield river 20 miles; the length of the Southampton Water has been already given. The Itchin navigation does not coincide with the natural bed of the river.

The New Forest occupies nearly all that part of the county which has been represented as projecting at the south-west corner. It is drained by two small streams, the Ex or Beaulieu river and the Boldro Water, besides some smaller streams. The Ex and the Boldre flow south-east into the sea, the first at Exbury, the second at Lymington: the length of the Ex is about 13 miles, that of the Boldre Water about 15 miles.

The basin of the Thames is separated from the rest of the county by the North Downs, and drained by the Wey, the source of which is in Hampshire and by the Auborne and the Loddon, which have their course along the border.

The basin of the Arun is separated from the rest of the county by the Alton and Petersfield hills and the South Downs. It is drained by the Rother, which rises in this county and flows past Midhurst into the Arun.

The Wiltshire and Dorsetshire basin comprehends a narrow strip of the county to the west of the New Forest. It is drained by the Avon, which, entering the county just below Downton, Wilts, about six miles from Salisbury, runs south past Fordingbridge, Ringwood, and Christchurch, into the sea. That part of the river which is in the county is about 20 to 22 miles long. A small portion of the Dorsetshire Stour, and of the Great Leonards Water, a tributary of the Stour, are in the county or upon its boundary; the Stour joins the Avon below Christchurch: their æstuary forms Christchurch haven.

The county has two principal canals. The Andover Canal commences at Andover, and is carried along the valley of a small feeder of the Anton or Test, till the junction of this feeder with the main stream. The canal then crosses the Anton and follows the valley of that river on the eastern side of the stream to Redbridge, three or four miles above Southampton, where it enters the Anton. Its whole length is 22½ miles: its total fall is above 176 feet. It has a branch to Salisbury. It is chiefly used for the import of coal and other fuel, and of general goods from the coast, and for the export of agricultural produce. The Basingstoke Canal commences at Basingstoke, and is carried in a very winding course 22 miles east on one level to the Loddon, which it crosses into the county of Surrey, its farther course through which to the navigable part of the river Wey (near its junction with the Thames) is 15 miles, with a considerable fall. That part of the canal which is in Hampshire is the summit level, and is 38 feet wide and 5½ feet deep. About four miles east of Basingstoke the canal is carried by a tunnel above a mile long through a chalk hill; from this chalk, which yields a great quantity of water, the chief supply is obtained for lockage at that part of the canal which is in Surrey. Not far from the border of the county this canal is carried by an aqueduct across a valley three quarters of a mile broad. This canal serves for the conveyance of coal, deals, groceries, bale goods, &c., from London, and for the export of timber, flour, malt, bark, and earthenware. Part of the canal from Arundel by Chichester to Portsmouth is in this county.

Three principal mail-roads cross the county, viz. the road from London to Portsmouth, that to Southampton and Poole, and the great western road through Salisbury. The Portsmouth road enters the county between Godalming and Petersfield, but again quits it to pass through a projecting corner of the county of Sussex: it re-enters Hampshire not far from Petersfield, and runs through that town and through the villages of Horndean and Cosham to Portsmouth. The Poole and Southampton road first enters the county and crosses a portion of it between Bagshot and Farnham, both in Surrey; beyond Farnham it again enters it and runs by Alton, Alresford, and Winchester to Southampton. From Southampton it runs by Ringwood into Dorsetshire. The great western road, travelled by the Penzance, Falmouth, and Exeter mail, and by the Exeter mail, enters the county between Bagshot (just beyond which it branches off from the Southampton road) and Basingstoke, and passes through Basingstoke, Whitchurch, and Andover to Salisbury in Wiltshire. At Andover a road, travelled by the Falmouth, Devonport, and Exeter mail, branches off from this to Amesbury, in Wiltshire. Beside these principal roads there are many other roads of less importance. A road parallel to the coast coming from Chichester passes through Havant, Cosham, near Portsmouth, and Fareham to Southampton; a road from Southampton leads by Lymington and Christchurch to Poole; a road from Newbury (Berks) runs by Andover, Stockbridge, and Romsey to Southampton; a road from Salisbury leads by Fordingbridge and Ringwood to Christchurch; and several roads from Winchester communicate with different parts of the county.

Geological Character.—That vast district of chalk which overspreads so large a portion of Wiltshire, and of which Salisbury Plain forms a part, extends into Hampshire and occupies a considerable part of it. It is bounded on the north by a line drawn from Inkpen Beacon, near Great Bedwin, Wiltshire (the highest point in all the chalk formation of England), by Kingsclere and Basingstoke to Odiham; on the east by a line drawn from Odiham by Alton, and along the Farnham road to the neighbourhood of Bishop's Waltham; and on the south by a line drawn from the neighbourhood of Bishop's Waltham and north of Bishopstoke into Wiltshire. The extent of this chalk district from north to south is about 20 or 22 miles; from east to west its Hampshire extent varies from 22 to 32 miles, but its whole extent through Hampshire and Wiltshire together is much greater. The breadth of the North Down range is about two or threo miles, that of the South Downs about four miles. Portsdown hill is an outlying mass of chalk.

The country to the north of the great chalk district and of the North Downs belongs to the London basin; the country to the south of the great chalk district and of the South Downs belongs to the Isle of Wight basin; and theso are almost entirely occupied by the strata above the chalk.

The country to the east of the great chalk district and embraced between the North and South Downs is occupied by the strata which underlie the chalk, and which extend into Surrey and Sussex, and form the district of the Weald of the south-east of England. In the London basin the Bagshot sand, belonging to the upper marine formation, is found at Frimley Heath, on the border of Surrey, and is surrounded by a belt of the London clay; but these two formations are found only in the north-east of the county, and are of small extent: the rest of this basin in Hampshire is occupied by tho plastic clay, except near Kingsclere, where, for a short distance the chalk marl, and greensand crop out from beneath the chalk. In the Isle of Wight basin that part of tho New Forest which extends from the Boldre Water to the Southampton Water is for the most part occupied by a sand probably agreeing in its principal characteristics with the Bagshot sand; this district is peculiarly adapted to the growth of oak. The remaining part of the New Forest, the country around the Southampton Water, and the whole line of tho coast eastward from the Avon, and including Portsea and Hayling Islands, aro occupied by the London clay; the country west of the Avon and a belt varying from three to seven miles south of the chalk, are occupied by tho plastic clay. The Weald district east of the chalk is occupied by the chalk marl and greensand; and the small detached part of the county included in Sussex, partly by these formations and partly by the Weald clay.

No minerals are procured from this county to any extent, except near Petersfield, where grey chalk is quarried and sent to Portsmouth dockyard to be burnt for limo.

Forests.—There are several forests in this county, namely, the New Forest in the south-west, Alice Holt and Woolmer Forest in the east, and the forest of Bere in the south-east. The New Forest, the most important of these, appears to have heen, at tho time of the Conquest, a wooded tract thinly peopled. William the Conqueror or his immediate successors afforested the tract extending from Godshill, near Fordingbridge, to the sea, and from Ringwood to Hardley, near Southampton Water, and comprehending 92,365 acres. The bounds were so far enlarged between the commencement of Henry II.'s reign and the reign of Edward I., that they comprehended all tho country hetween the Southampton Water and the Avon for several miles inland. These additions were disafforested in the reign of Edward I., in pursuanco of the Charta de Foresta, and the original hounds retained till the perambulation in tho time of Charles II. The forest at present comprehends nearly 64,000 acres, and is the property of tho crown, subject to rights of common and other antient claims. The crown has also manorial rights over some, and the absolute property of other plots of ground included in the former, but not in the present bounds of the forest. For local purposes the forest is divided into nine bailiwicks, which are subdivided into fifteen walks. The forest is under a purveyor for the navy attached to the dockyard at Portsmouth, and under the surveyor-general of woods and forests. The chief value of the New Forest is for the raising of oak and beech timber for the use of the navy; but for many years this was much neglected, and the management of the forest was very bad. Within the present century many reforms have been made, from which considerable benefit may be expected. There aro many deer kept in the forest: rabbits, which formerly abounded, are now scarce: a diminutive breed of horses, and a peculiar breed of swine, bearing considerable resemblance to the wild boar, are found in a half-wild state in the forest. The oaks seldom riso into lofty stems; their branches aro commonly twisted into the most picturesque forms; and tho scenery of the forest is vory beautiful. Many of the trees are antient and of great bulk. Various encroachments have been made on the forest, and many rudo cottages crected by the poor who live round the borders of tho forest, and who are in general an indolent race, poor and wretched in the extreme, and depending for a subsistence on casual pilfering from the forest.

Tho forest of Bere extends northward from Portsdown-hill, and its bounds, according to a perambulation made in 1688, and still observed, comprehend about 16,000 acres, of which one-third is enclosed. It is divided into two larger divisions, the East and West Walks, with some smaller portions dependent on these, and is under the control of a warden and other officers. The quantity of timber grown in this forest is trifling compared with what it once yielded. Some deer are kept.

Alice Holt and Woolmer Forest lies between the Portsmouth and Southampton roads. It is divided into two parts by intervening private property, namely, Alice Holt, near the Southampton road, a little beyond Farnham, and Woolmer, nearer the Portsmouth road, between Liphook and Petersfield. It contains altogether nearly 15,500 acres, more than half of which belongs to the crown. Tho growing timber in Alice Holt is of considerable value. Like tho other forests of tho county it had during the last century been much neglected. In the marshy bottoms of Woolmer Forest many trees have been found and dug up with the peat, and many hundreds of Roman coins, several of them those of Marcus Aurelius and the Empress Faustina, were dug up in the bed of Woolmer pond, when dried up in 1741 by the heat.

Waltham Chace, a waste of 2000 acres, belonging to the bishop of Winchester, is on the north-west side of the forest of Bere, near Bishop's Waltham. It is connected in our criminal annals with the atrocities of the deer-stealers, called the 'Waltham Blacks;' and the statute known as 'the Black Act,' passed for their suppression.

Agriculture.—The climate of Hampshire is generally mild and favourablo to vegetation. The southern part of the Isle of Wight is considered to have the mildest climate in Great Britain, and is resorted to on that account by invalids during tho winter. But a great part of Hampshire consists of poor sands and gravelly soils or chalky hills, having between them low bottoms, with no ready outlet for the water, which has produced marshes and peat-bogs. In such places the nature of the soil has a greater effect on the climate than the difference of several degrees of latitude would have under other circumstances.

The northern part of the county, where it borders on Berkshire and Surrey, consists chiefly of the poor, dark sand, mixed with an ochery loam, which is well known as the Bagshot-heath soil. This extends to Basingstoke. The whole of this part of the county is naturally very unproductive, and till within a few years was almost entirely covered with a brown heath, on which some hardy forest sheep and a few miserable cattle were reared, and contrived to pick up a scanty living. There were however some spots between the hills which contained a few farm buildings and somo green fields, forming a striking contrast with the surrounding waste. Within the last thirty years much of this hoath, which lay in common, has been enclosed and divided. Some of it has been brought into cultivation at a great expense, and a considerable portion has been planted with fir-trees, which have thriven wherever the proprietor was at tho expense of trenching and draining the land before planting.

The great roads which traverse this part of the county, and the numerous places in which horses are kept for posting, stage-coaches, and waggons, have caused a supply of manure, by which the poor soils immediately around them have been much improved. The very poverty of the soil has set ingenuity to work to produce the most improved practices and implements. Most of the drilling-machines which are used within a certain distance in the counties of Surrey and Berks, as well as in Hampshire, are manufactured in the neighbourhood of Basingstoke.

South of this district, as far as Winchester and a few miles beyond it, the chalk prevails. The soil which lies over this chalk varies in depth, and, where it is sufficiently deep, produces good crops of barley, wheat, and oats. In many places it lies very near the chalk, and is intermixed with flints and pebbles. Although the appearance of it is not very promising, it is tolerably productive in good seasons; the pebbles and flints reflect the sun's beams, while the young plant is sheltered by them from the cold easterly winds which, in spring, sweep over the hills, where few trees break their force.

Where tho soil is thin and very near the chalk, it is scarcely fitted for the plough, but remains in the state of down; and the natural grasses which grow there, when kept closely cropped by sheep, aro sweet, and make the best sheep-pastures. If these downs are not sufficiently stocked, or if they are reserved for cows, the furze and brambles are apt to overrun them, and the coarse grasses get the upper hand.

In the valleys and along the lower slopes of the chalk-hills the soil is of a tough, tenacious nature, being a mixture of chalk washed down the hills by the rains and stiff clay. This is a soil very difficult to cultivate. In spring it is extremely heavy, and retains moisture a long time, and when dried it becomes so hard, that unless it has been worked at the exact moment when it is dry on the surface, and the clods are still friable, there are no means of reducing it to a proper tilth. But when it is carefully managed and well manured, it produces very good crops of beans, wheat, and oats. This land can scarcely be cultivated and kept clean without occasional fallows, and the most profitable rotation is wheat, beans, oats, fallow. It is much too heavy for turnips. In some spots which are not quite so heavy the Suffolk rotation of barley, after a long fallow, clover, wheat, beans, and oats, might be introduced with advantage. It is not at all adapted to the Scotch convertible system; for although grass-seeds might grow well, the land could seldom be depastured with cattle, either in spring or autumn, and after a dry summer it would be almost impossible to plough it up in good time to sow it with wheat. On the eastern side of the county, bordering on Surrey and Sussex, is a small tract of land, which is provincially called malmy land, forming the vale of Petersfield. It has a groy, tender, sandy soil of some depth, lying on a soft sandstone, which is almost impervious to water. This circumstance counteracts the advantages of a light soil, unless the water be artificially carried off. On the higher grounds the poor sandy soil is only fit for plantations of firs.

The land in the New Forest, and on the opposite side of the river, or æstuary, below Southampton, is mostly of a light nature, intermixed here and there with heavier loams and clays. Where it is sound and free from springs it is of a good quality; and that which is not so may be materially improved by judicious under-draining. Some spots in the New Forest were effectually drained many years ago by Mr. Elkington, and have amply repaid the expense incurred, both by the improvement of the land and the greater salubrity of the neighbourhood; for where the land has not been drained, low bogs and marshy places are formed, which are the cause of frequent fevers and agues.

Various kinds of marl are found in many places; some of these are very useful on poor gravelly soils, which they greatly improve when a sufficient quantity is carried on. The value of marl depends on the union of carbonate of lime and clay, and is readily discovered by its effervescing strongly when any acid is poured upon it. When the quantity of carbonate of lime is small, very good white or red bricks are made of it. The white colour is caused by the calcareous matter, the red by the presence of the oxide of iron.

The Isle of Wight consists principally of chalk, over which are found various soils, such as gravel, sand, and very stiff clay. The mildness of the climate is favourable to vegetation, and there are some neat farms, in which the land is well cultivated.

In traversing the whole country it will be observed that the poorer soils predominate, and a great part of the land will scarcely repay the expense of cultivation. There are a few fertile spots, and some very valuable water-meadows along the principal rivers, especially the Avon, which runs through the western part of the county bordering on Dorsetshire. Where a farm has a portion of water-meadow and a run for sheep on the downs, the occupier generally thrives; but the greatest agricultural skill is displayed in the cultivation of the poorer soils, where manure must be made on the spot, and the cattle and sheep kept on the produce of the arable land.

Hampshire, although it cannot be compared with some eastern and northern counties for agricultural improvements, is not far behind them; and there are some farms as well managed as any in England. The great fault lies in the want of economy of labour; too many horses are used; the threshing-machine is not sufficiently common; the stock is not fed so economically as it might be; the manure is not so carefully collected, nor so well prepared, before it is put on the land; and there is a great waste of the liquid part of it on the best managed farms.

The old clumsy plough, once in general use, is now replaced by a lighter and more durable plough, of which the parts that wear out most are made of cast-iron. Two horses now plough land which formerly was thought to require four. The seed is put in by a drilling-machine instead of being scattered by the hand. The corn is put into neat stacks, raised on stone pillars, and well thatched, instead of being exposed to the depredation of rats in a huge barn. The farm buildings, as well as the house of the farmer, are more commodiously arranged, and there is a general spirit of improvement. The correction of the abuses of the old poor-laws, and the commutation of the tithes for a fixed annual payment, will much encourage the improvement of poor lands; and in half a century the general face of the county will be very different from what it is at present.

There are no breeds of cattle, horses, or sheep, peculiar to Hampshire, unless we consider the small New Forest ponies in that light. The cows are of various breeds. The oxen are chiefly Sussex and Devon. The horses used in husbandry are mostly bred in other counties. The sheep are—the common small forest breed, or heath-sheep, which, when tolerably fat, give the high-flavoured mutton formerly known by the name of Bagshot mutton; the Dorset and Leicester sheep, in the richer meadows; and the South Down, on the chalky hills. The last are most numerous, and preferred for folding on the land.

Hampshire has long been famous for the curing of bacon; and a Hampshire hog is a very common sign for a public-house; yet the native breed of pigs in this county is by no means remarkable for its qualities. The native hogs, which live on the acorns and beech-mast of the New Forest, although the flavour of their flesh may be good, are coarse, raw-boned, flat-sided animals, and are now seldom met with. The improved breeds produced by crosses of the Berkshire, the Suffolk, Essex, and Chinese pigs, are so much better and more profitable, that the only difference to be noticed in the pigs bred on different farms is that which arises from the predominant character of any one of the above-mentioned breeds.

The reputation of the Hampshire bacon is owing entirely to the care with which it is cured. The hogs being fatted on peas and barleymeal, are kept fasting for twenty-four hours, at least, before they are killed; they are used as gently as possible in the act of killing, which is done by inserting a long pointed knife into the main artery which comes from the heart. The hair is burnt off with lighted straw, and the cuticle of the skin scraped off. The carcass is hung up after the entrails have been removed, and the next day, when it is quite cold, it is cut up into flitches. The spare ribs are taken out, and the bloody veins carefully removed: the whole is then covered with salt with a small quantity of saltpetre mixed with it. Sometimes a little brown sugar is added, which gives a pleasant sweetness to the bacon.

The flitches are laid on a low wooden table, which has a small raised border all round it. The table slants a little so as to let the brine run off into a vessel placed under it, by a small opening in the border at the lower end. The flitches are turned and re-salted every day; those which were uppermost are put under, and in three weeks they are ready to be hung up to dry. Smoking the bacon is no longer so common as it used to be, as simply drying it is found sufficient to make it keep. Those who, from early association, like the flavour given by the smoke of wood, burn sawdust and shavings in a smothered fire for some time under the flitches. When they are quite dry, they are either placed on a bacon-rack for the use of the family, or are packed with wheat-chaff into chests till they are sold.

The practice of cutting the hogs into pieces and pickling them in a vat, being attended with less trouble, is very generally preferred when there is only a sufficient number of hogs killed to serve the farmer's family; but flitches of bacon, well cured, are more profitable for sale.

The fatting of hogs is profitable when a pound of green bacon, when it is first dried, is worth more than the tenth part of the price of a bushel of barley, for a bushel of barley is supposed, with good management and a good breed of hogs, to produce 10 lb. of bacon. The risk and attendance are fully compensated by the value of the dung made by the hogs, which is of the richest nature. Hogs may be made fat with less expensive food, such as boiled roots mixed with meal; but in this case the bacon is much less valuable, and is not superior to the Irish bacon, which is mostly fatted on potatoes.

The following are the principal fairs in Hampshire:—Alresford, last Thursday in July, October 17; Alton, Saturday before May 1, September 29; Andover, May 13, November 17 and 18; Basingstoke, Easter Tuesday, September 23, October 11; Botley, July 23, August 20, November 13; Christchurch, June 13, October 17; Hambleton, February 13, October 2; Kingsclere, April 2, October 15; Lymington, May 12, October 2; Magdalen Hill, near Winchester, August 2; Newport, Isle of Wight, Whit-Monday, Tuesday, and Wednesday; Overton, May 4, July 18, October 22; Petersfield, March 5, July 10, December 11; Portsmouth, July 10, lasts 14 days; Rumsey, Easter Monday, August 26, November 8; Southampton, February 17, May 6, December 15; Stockbridge, Holy Thursday, July 10, October 7; Weyhill, October 11, 12, 13, 14, 15, 16 (this is one of the greatest fairs in England, for cattle, sheep, wool, and hops); Whitchurch, April 23, June 17, July 7, October 19; Wickham, May 20; Winchester, first Monday in Lent, October 24.

Divisions, Towns, &c.—The most antient division of the county is into hundreds, of which there were fifty at the time of the Domesday survey. There are now thirty-nine hundreds, beside the city of Winchester with the liberty of Soke, the borough of Portsmouth with the district of Portsea and Portsea Guildable, the town and county of Southampton, and eleven liberties, including the liberties of East and West Medina in the Isle of Wight. From the great number of the hundreds and liberties they have been arranged in 'divisions' for administrative purposes. At the time of the census in 1831, these divisions, with their situation in the county, included subdivisions, area, and population, were as follows:—

Division.	Situation.	Hundreds.	Area.	Population in 1831.
I. Alton, North Division.	East.	Alton, Bishop's Sutton, and Selborne, and the liberty of Alresford.	74,320 acres.	14,968
II. Alton, South Division.	South-east.	East Meon and Finchdean.	44,160 „	7,483
III. Andover Division.	West.	Andover, Barton Stacey, King's Sombourn, Thorngate, and Wherwell.	130,210 „	27,465
IV. Basingstoke Division.	North-east.	Basingstoke, Bermondspit, Crondall, Holdshott, Mitcheldever, and Odiham, and the liberty of Bentley.	144,800 „	29,592
V. Fawley Division.	Central.	Bountisborough, Buddlesgate, Fawley, Mainsborough, and Mansbridge.	129,690 „	24,020
VI. Kingclere Division.	North.	Chutely, Evingar, Kingsclere, Overton, and Pastrow.	102,500 „	18,070
VII. New Forest, East Division.	South.	New Forest (East), New Forest (North), Redbridge, Bishop's Waltham (part of), Ringwood (part of), and the liberties of Beaulieu, Dibdin, and Lymington.	62,360 „	18,346
VIII. New Forest, West Division.	South-west.	Christchurch, Fordingbridge, and Ringwood (the greater part of), with the liberties of Breamore and Westover, and that part of the New Forest which is not included in any parish.	133,870 „	19,127
IX. Portsdown Division.	South-east.	Bishop's Waltham (the greater part of), Bosmere, Fareham, Hambledon, Meon-Stoke, Portsdown, and Titchfield, and the liberties of Alverstoke and Gosport, and Havant	100,520 „	41,298
X. Isle of Wight Division.	South.	Liberties of East and West Medina.	86,810 „	35,431
Separate Jurisdictions		City of Winchester and liberty of Soke.	2,250 „	8,767
		Borough of Portsmouth, with Portsea and Portsea Guidable.*	5,090 „	50,389
		Town and county of Southampton.	1,970 „	19,324
			1,018,550	314,280

By a subsequent arrangement made under the direction of the magistrates of the county, the divisions of the county have been increased to thirteen, not including the Isle of Wight. They are as follows:—Alton, Andover, Basingstoke, Droxford, Fareham, Kingsclere, Lymington, Odiham, Petersfield, Ringwood, Romsey, Southampton, and Winchester. Hampshire, not including the Isle of Wight, contains one city, Winchester; six parliamentary boroughs, Andover, Christchurch, Lymington, Petersfield, Portsmouth, and Southampton; and thirteen other market-towns, Alresford, Alton, Basingstoke, Bishop's Waltham, Fareham, Fordingbridge, Gosport, Havant, Kingsclere, Odiham, Romsey, Stockbridge, and Whitchurch, which last two were disfranchised by the Reform Act. Of these some are described elsewhere. [ALRESFORD; ALTON; ANDOVER; BASINGSTOKE; BISHOP'S WALTHAM; CHRISTCHURCH; LYMINGTON; PETERSFIELD; PORTSMOUTH; SOUTHAMPTON; WINCHESTER.] Of the others an account is subjoined.

Fareham is in the hundred of Fareham, at the head of the north-west branch of Portsmouth harbour, 73 miles from London, at the intersection of the road from London to Gosport and that from Chichester to Southampton. The parish is extensive, containing 6670 acres: it constitutes the whole of the hundred, and had in 1831 a population of 4402. Fareham was in Leland's time a fishing village: it is now a tolerably thriving town, depending for its prosperity chiefly on its neighbourhood to Portsmouth. Several persons connected with the naval establishments at Portsmouth reside here. Some small vessels are built at Fareham; and cordage, sacking, and coarse pottery are made. Vessels of 300 tons can get up to the port; and considerable trade in corn and coal is carried on. The market is on Wednesday, and there is one yearly fair. Petty sessions are held here. The architecture of the church is of various dates and styles; the chancel is early English. The living is a rectory in the peculiar jurisdiction of the bishop of Winchester, in whose gift it is; the annual value is 671*l.* There were in 1833 twenty-two day and four boarding-schools, with nearly 700 children: of these schools, one with 27 boys was an endowed free-school, another with 130 children, a national school, and a third with 62 children, a subscription infant school. There were also three Sunday-schools, containing above 400 children. There are congregations of Independents and Methodists.

Fordingbridge is in the hundred of Fordingbridge, on the right or west bank of the Avon, 92 miles from London on the road to Christchurch. The parish is large, containing 5720 acres, and had in 1831 a population of 2822, more than half agricultural. Fordingbridge was formerly a place of greater extent than now, and has suffered several times from fire. There is a stone bridge of seven arches over the river. There are some manufactures of sail-cloth and bed-ticking. The market is on Saturday, and there is one yearly fair. The living is a vicarage, united with the parochial chapelry of Ibsby, or Ibsley, in the diocese and archdeaconry of Winchester, and in the gift of King's College, Cambridge: the annual value is 601*l.*, with a glebe-house. There is an Independent congregation. There were in the parish in 1833 one infant-school with

* Portsea Guildable is a part of the parish of Portsea, not within the jurisdiction of the borough of Portsmouth, but comprehended in the hundred of Portsdown.

45 children, eight day and boarding-schools with 153 children, one day and Sunday-school with 231 children daily and 113 on Sundays, partly supported by endowment, and one Sunday-school with 292 children.

Two miles from the town, on a hill called Godshill, overgrown with oaks, are the remains of an antient camp, perhaps of Saxon origin, secured on one side by a double trench, and on the other by the steep slope of the hill.

Havant is in the liberty of Havant (which comprehends only this parish), near the head of Langston harbour, 66½ miles from London by Petersfield and Horndean. The parish comprehends 2560 acres, and had in 1831 a population of 2083, about one-fourth agricultural. The church is in the centre of the town, in the form of a cross, with a tower rising from the intersection: some parts of it are of Norman architecture. The living is a rectory, in the peculiar jurisdiction of the bishop of Winchester, who has the presentation: it is of the yearly value of 489*l.*, with a glebe-house. There is an Independent congregation. Havant has little trade: some parchment is made, and some of the inhabitants are engaged in fishing and fowling. The market is on Saturday, and there are two yearly fairs. There were in the parish in 1833 two national-schools with about 200 children, one boarding and day-school and four day-schools with 115 children, and one Sunday-school with 130 children.

Kingsclere is in Kingsclere hundred, 55 miles from London through Basingstoke. The parish is large, containing 17,240 acres, and had in 1831 a population of 3151, three-fourths agricultural: the parish extends into the hundred of Evingar. Kingsclere is a small town of mean appearance. There is some trade in malt carried on: the market is on Tuesday, and there are two fairs in the year. The living is a vicarage, with the chapelries of Ecchinwell and Sidmonton annexed, in the diocese and archdeaconry of Winchester; of the yearly value of 400*l.* There were in the parish in 1833 seven day-schools with 124 children, one of which (with 27 boys) is endowed; and one day and Sunday-school with 50 children daily and 60 on Sundays. At Kingsclere was antiently a residence of the West Saxon kings, and there was a royal residence in the neighbourhood as late as the time of King John.

Odiham is in Odiham hundred, a little to the left of the great western (Salisbury and Exeter) road, 40 miles from London. The parish is large, comprehending 7550 acres, and had in 1831 a population of 2647, about half agricultural. The market is on Friday, and there are two yearly fairs. Odiham was formerly a free borough, belonging to the bishop of Winchester: it had a royal residence and park: the remains of the residence have been converted into a farm-house, still called Palace Gate, or Place Gate. There is an old almshouse near the church, which latter is a large, antient brick building. The living is a vicarage, with the parochial chapelry of Grewell annexed, in the diocese and archdeaconry of Winchester; of the yearly value of 537*l.*, with a glebe-house. There is an Independent congregation at Odiham. There were in the parish in 1833 ten day or boarding and day-schools with about 250 children: one of these schools, with 41 children, was partially supported by endowment: there was also one Sunday-school with 187 children.

Near Odiham are the remains of an old castle, which, in the civil wars at the close of King John's reign, was bravely but unsuccessfully defended by a garrison of thirteen against the Dauphin, Louis of France. In this castle David Bruce, king of Scotland, was confined for eleven years after his capture at Neville's Cross.

Romsey is a corporate town, locally situated in the hundred of King's Sombourn, upon the left bank of the Anton or Test, over which is a bridge, and close to the Andover Canal. It is 73 miles from London, on a road leading by Winchester to Ringwood and Poole. The whole parish is very extensive, comprehending 9310 acres, with a population of 5432, about one-fourth agricultural; but the borough comprehends only that part of the parish known as 'Romsey Infra,' having an extent of 380 acres, and a population of 2046. The church formerly belonged to an abbey founded in the reign of Edward the Elder, and occupied by Benedictine nuns: the abbey was valued at the dissolution at 528*l.* 8*s.* 10*d.* per annum gross, or 393*l.* 10*s.* 10*d.* clear. The church is a cross church, having its exterior for the most part of Norman architecture, much enriched in some portions with zigzag and other ornaments: the central portion of the interior, the transepts, and the sides of the chancel, are also Norman: the west end of the church is in the early English style, very plain outside, but rich within. There are various windows of later date inserted, especially some fine ones at the east end. On the roof of the church grows an apple-tree, which for many years has borne fruit. There are dissenting meeting-houses, a town-hall, an 'audit-house,' supported on piers, with an open space below for the market people, a small borough gaol, and some almshouses. There were formerly considerable manufactures carried on at Romsey of sacking and shalloon, but these have much declined: there are in or about the town several paper and flour-mills and tan-yards. The market is on Thursday, formerly on Saturday, and there are three yearly fairs. By the Municipal Reform Act, the council of the borough consists of a mayor, four aldermen and twelve councillors. The living is a vicarage, in the diocese and archdeaconry of Winchester, of the yearly value of 365*l.* There were in the parish in 1835 twelve infant or dame-schools with 136 children, twenty day-schools with about 650 children, and seven Sunday-schools with about 700 children. Of the day-schools one is a free-school, another is a national-school, united with an old endowed free-school, and a third is wholly supported by Lord Palmerston and family. Sir William Petty was a native of Romsey, and lies buried in the church.

Stockbridge is a borough in the hundred of King's Sombourn, on the left bank of the Anton or Test, and near the Andover canal; it is 66½ miles from London on a road leading from Basingstoke to Salisbury. The parish and borough limits coincide and comprehend 1220 acres; the population in 1831 was 851, about one-third agricultural. The town consists of one street, in which are seven bridges: it has little trade, but is chiefly supported by being a considerable thoroughfare. There are races in the neighbourhood. The market is on Thursday, and there is a yearly fair (there were formerly three fairs), one of the largest in the county for lambs. Stockbridge returned two members to parliament up to the passing of the Reform Act, by which it was disfranchised: it is a borough by prescription; the town-hall is a neat building. The living is a chapelry, in the diocese and archdeaconry of Winchester, annexed to the vicarage of King's Sombourn, to which the chapelry of Little Sombourn is also annexed; their joint yearly value is 696*l.* with a glebe-house. There were in Stockbridge in 1833 five day-schools with 99 children, and two Sunday-schools with 60 children.

Whitchurch is a borough in the hundred of Evingar, 56½ miles from London on the great Western road, between Basingstoke and Andover, near the head of the river Anton. The parish comprehends 7330 acres, with a population in 1831 of 1673, about half agricultural. Shalloons and serges are manufactured; also paper for the exclusive use of the Bank of England. The market, held on Friday, is said in some of our authorities to be now disused. Whitchurch is a borough by prescription, and returned two members to parliament until disfranchised by the Reform Act. The living is a rectory, in the peculiar jurisdiction of the bishop of Winchester; of the yearly value of 140*l.* There were in 1833 seven day or boarding and day-schools, with about 230 children, and three Sunday-schools with above 300 children.

Emsworth, a hamlet of the parish of Warblington, at the head of a channel which forms a branch of Chichester harbour, is a place of some trade as a port; ship-building and rope-making are carried on. Hayling Island is becoming a place of considerable resort for bathers, and numerous new buildings have been recently erected. Titchfield, about two miles from Fareham, on the road to Southampton, is a place of some trade: it is on a small river, by which small vessels get up to the town. A customary market is held.

Divisions for Ecclesiastical and Legal purposes.—Hampshire is included in the diocese of Winchester and the ecclesiastical province of Canterbury, and constitutes (inclusive of the Isle of Wight), the archdeaconry of Winchester. This archdeaconry is subdivided into ten deaneries, viz., Alresford, Alton, Andover, Basingstoke, Dorkinsford, or Droxford, Fordingbridge, Sombourn, Southampton, Winchester, and the Isle of Wight. The number of churches and chapels is given in Warner's 'Collections for the History of Hampshire' at 277. In Lewis's 'Topographical Dictionary' the number of benefices is given at 305, viz. 154 rectories, 72 vicarages, and the rest perpetual curacies.

This county is in the Western circuit: the assizes and quarter-sessions are held at Winchester. For the election of members of parliament, the county was by the Reform Act divided into two parts. The Northern division comprebends Alton, Andover, Basingstoke, Droxford, Kingsclere. Odiham, Petersfield, and Winchester divisions; the chief place of election is Winchester, and the polling stations are Winchester, Alton, Andover, Basingstoke, Kingsclere, Odiham, Petersfield, and Bishop's Waltham. The Southern division comprebends Fareham, Lymington, Ringwood, Romsey, and Soutbampton divisions; the chief place of election is Southampton, and the polling stations are Southampton, Fareham, Lymington, Portsmouth, Ringwood and Romsey. Tbe 'divisions' are those made by the county magistrates, subsequently to the census of 1831. Tbo Isle of Wight was by tbe same act severed from tbe county for parliamentary purposes, and allowed to return one member: tho chief place of election is Newport, and the polling stations are Newport and West Cowes. Formerly, two members each were returned from the city of Winchester, the boroughs of Christchurch, Lymington, Portsmouth, Southampton, Andover, Petersfield, Stockbridge, and Whitchurch, and for the boroughs of Newport, Newtown, and Yarmouth, in the Isle of Wight. By tbe Reform Act, Stockbridge, Wbitcburch, Newtown, and Yarmouth were disfranchised, and Christchurch and Petersfield reduced to one member each. The act, by regulating the franchise, opeued the city of Winchester, and the boroughs of Portsmouth, Christchurch, Lymington, Petersfield, Andover, and Newport, wbich were all previously very close.

History, Antiquities, &c.—Before the Roman invasion, this county was iuhabited by three tribes: the Regni (Ῥηγνοι, Ptol.), wbo occupied the coast, as well as tbe counties of Sussex and Surrey; tbe Belgæ (Βελγαι, Ptol.), who inhabited tbe middle portion, and extended into Wiltshire; and the Atrebates, or Atrebatii (Ατρεβατιοι, Ptol.), who occupied, it is likely, the northern part on the confines of Berkshire. Winchester appears to bave been a British town antecedently to its being occupied as a Roman station, and Silchester also, if it may be identified with Calleva Atrebatum. This part of tbe island was reduced by the Romans, probably under Vespasian, who is distinctly recorded by Suetonius (*Vespas.*, c. iv.) as having subjugated the Isle of Wigbt, called by the Romans Vectis (Οὐηκτις, Ptolemy). It was comprehended in Britannia Prima, and was crossed by several Roman roads, and contained several Roman stations. It was Camden's opinion that the Trisanton river mentioned by Ptolemy (Τρισάντωνος ποτάμου ἐκβολαί) was the Anton or Test; perhaps it was the Southampton Water, with all the streams that flow into it. Others however identify the Trisanton with the Arun of Sussex. If Trisanton be a representation of tbe British Traeth Anton, 'tbe æstuary or frith of Anton,' it is a designation peculiarly suitable to Southampton Water. The Roman station Clausentum, mentioned in the Iter VII. of Antoninus, is generally admitted to have been near Southampton. At Bittern Farm abundance of Roman remains are found, and modern antiquaries seem to agree in fixing the station at tbis spot, which is on the east side of the Itchin, by a bend in which it is nearly surrounded. There are remains of the Roman works, a ditch and part of a rampart on the land side, composed of earth, flints, and large flat bricks, and faced roughly with small square stones. A quantity of Roman coins and of fine red pottery, a glass urn, and sculptured and other stones have been dug up. The area of the station is about half a mile in circumference; Southampton probably arose from its ruins. In tbe latter part of the name Claus-entum we probably discern the same root which may be traced in Tris-anton, South-hampton, and Hampton- (now shertened into Hamp-) shire. Another station mentioned by Antoninus is Venta (a Roman modification of the more antient British name Caer Gwent, 'the white city'), distinguished from some other places of the same name, as 'Venta Belgarum.' Ptolemy mentions Venta, or as he writes it Οὐέντα, as one of the towns of the Belgæ. It is the modern Winchester, the first part of which name is a corruption of the British Gwent, or the Roman Venta. This was an important station: the walls with which the Romans enclosed it yet form the cbief part, though frequently repaired and much altered, of the town walls. Roman tombs containing human bones, sepulchral urns, and some other antiquities, have been discovered just outside the town walls. An entrenchment on St. Catherine's Hill, south of the city, is perhaps tbe Roman castra æstiva, or summer camp.

P. C., No. 728.

But the most remarkable remains of a Roman station are at Silchester, a village on the border of the county, due north from Basingstoke. It was certainly a station of importance, though it is difficult to determine whether it was the Calleva Atrebatum or the Vindomis of the Itinerary. Camden identifies it with the latter, and assigns to it the British name of Caer Segont, which is said to have been destroyed in the invasion by Ella, who founded the kingdom of the South Saxons. The remains of this station are among the most entire in the kingdom. The walls form an irregular octagon and are about a mile and a half in compass; they enclose a space of about 100 acres, divided into seven fields, together with the parish cburch and church-yard, a farm-house and its offices. The enclosure contains several springs, and slopes to the south: the foundations of the streets may yet be traced running across it in parallel lines, and in the centre is an open space supposed to have been the forum, where tbe foundations of a large building and other remains have been dug up. The walls are generally from fifteen to eighteen feet high; on the south side, where they are most perfect, they are twenty feet. There are four gates, facing the four cardinal points: some other openings have been made since tbe ruin of the town. The walls are formed by layers of flat stones of variable dimensions, and of rubble-stone consolidated by cement: the whole is surrounded by a ditch wbioh has in many parts been filled up by tbe ruins of the wall. Coins, inscribed stones, and other antiquities have been dug up. At a short distance north-east of the walls are the remains of an amphitbeatre.

The remains of a Roman station, supposed to have been the Brige of Antoninus, were observed by Mr. Gale at Broughton, not far from Stockbridge. The walls of Porchester Castle contain some portions of Roman architecture, and are probably on the site of one of the stations denominated Portus, either Portus Magnus, or more probably Portus Adurni, mentioned in the Notitia Imperii. Roman roads may be traced leadiug from Venta to Sorbiodunum (Old Sarum); to Silchester and to Porchester; and from Silchester in various directions.

This county appears to have been the scene of contest in the Saxon invasion. The invasion of Ella has been noticed. Cerdic, who founded the kingdom of Wessex, is said to have defeated and slain in tbe New Forest a British chieftain who bore the name of Natanleod: and Porta, an ally of Cerdic, is said to have landed at Portsmoutb. Portsmouth obviously derives its name from its situation; and the landing of Porta may have been fixed here by the ignorance of some who sought to give to the name an historical rather tban a topographical origin. Hampshire was included in the kingdom of Wessex, and Venta, called by the Saxons Wintanceaster, became the seat of government. Here Cerdio was buried, and here, on tbe conversion of the West Saxons to Christianity, a bishop's see was established. In the contests of the Saxon princes the Isle of Wight was taken by Wulfhere, king of Mercia, and annexed by him to the kingdom of Sussex: it was however soon after reconquered by Ceadwalla, king of Wessex. Upon the predominance of the West Saxon kings over the other Saxon potentates being permanently established by Egbert, Winchester became the metropolis of England.

When the Northmen attacked the island, Hampshire was exposed to their ravages. In tbe reign of Ethelbert, grandson of Egbert (A.D. 860—866), a body of them landed at Soutbampton, and advanced to Winchester, which they partially laid waste: they were routed however as they returned to their ships and much of the booty recovered. At Basing, near Basingstoke, Ethelred I., king of Wessex, and his brother Alfred, were defeated by the Danes, A.D. 870. A year or two after, viz. in 871 or 873, in the reign of Alfred, tbe invaders made another attack on Winchester, damaged the cathedral and murdered the ecclesiatics belonging to it. From the timo of Alfred's restoration the county experienced scarcely any hostility till the time of Ethelred II., in whose reign, about the close of the tenth century, the Danes ravaged the Isle of Wight. In the civil dissensions of the reign of Edward the Confessor, the same island was infested by Godwin, earl of Kent, and his son Harold, then in rebellion: and in the subsequent reign, of Harold II., it was laid under contribution by Tostig, the king's rebellious brother. Winchester continued to be the principal seat of royalty in the reign of William tbe Conqueror.

The extension or formation of the New Forest by William has been already noticed; it became the scene of several disasters which befel his family, and which were regarded as judgments on him for his arbitrary and cruel behaviour in the transaction, which however has been much exaggerated. His son Richard lost his life here by what Camden describes as 'a pestilential blast:' his grandson Henry, son of Robert, was entangled among the branches and killed while hunting; and his successor William Rufus was shot by a random arrow by Walter Tyrrel, A.D. 1100. Upon Rufus's death, Henry, his brother, hastened to Winchester, where he possessed himself of the royal treasure, and afterwards succeeded to the crown. Robert, his elder brother, to whom the succession rightfully belonged, landed at Portsmouth with an army the next year (A.D. 1101) to enforce his claim; but finding his rival too strong, came to an accommodation with him, and retired.

In the civil war between the supporters of King Stephen (then a prisoner) and the Empress Maud, Winchester was the scene of conflict. The cathedral and Wolvesey Castle, the residence of Henry of Blois, bishop of Winchester and brother of Stephen, were in the hands of the king's party, and Winchester Castle and other parts of the city in the hands of the empress. The empress's friends were gradually dispossessed of all they held, except the castle; and, when this was hard pressed, it is said that the empress escaped by being carried through the opposing army, wrapped in a sheet of lead, like a corpse for interment. Her natural brother and chief supporter, the earl of Gloucester, was taken soon after at Stockbridge and exchanged for the captive king. In the civil war which marked the close of the reign of John, Odiham Castle was gallantly but vainly defended for that prince against the revolted barons and the Dauphin, Louis of France.

At the commencement of the French war of Edward III., A.D. 1338, the town of Southampton was attacked by the French with their allies the Genoese and Spaniards. Their fleet was of fifty galleys. They took the town, burned the greater part of it, and slaughtered many of the inhabitants. About the close of the reign of Edward III., or the commencement of that of Richard II., another attack was made on this town, but failed. About the same period the Isle of Wight was attacked by the French, and Newtown and Yarmouth burned, and Carisbrook Castle vainly besieged. In A.D. 1415, when Henry V. was about to embark at Southampton for France, a conspiracy against his life was detected; for which the Earl of Cambridge and others were executed in that town. In the reign of the same monarch the Isle of Wight was once attacked and a second time threatened by the French. About the close of the reign of Henry VIII. another attack was made by the same people, but repulsed. It was at Winchester that Mary I. was married to Philip of Spain, A.D. 1554.

Of these early times the county contains several relics. [BISHOP'S WALTHAM; CHRISTCHURCH; SOUTHAMPTON.] Porchester Castle, at the head of Portsmouth harbour, is of great antiquity and doubtful origin. It is probable that the site has been occupied by a fortress from a period anterior to the Roman conquest; and the present structure exhibits traces of Roman, Saxon, and Norman architecture. It is a quadrangle enclosing an area of four or five acres, and is still in sufficient preservation to be used occasionally as a place of confinement for prisoners of war. The walls are from eight to twelve feet thick and eighteen feet high, having in many places a passage round them, defended by a parapet. It is enclosed by a ditch (double on the east side), and has eighteen towers including those of the keep, which are four. The keep forms the north-west angle of the castle, and encloses a quadrangle of one hundred and fifteen feet by sixty-five. The remains of Roman workmanship are chiefly observable in the outer walls. Many Roman coins and medals have been dug up at different times. The parish church of Porchester is within the outer court of the castle: it is a large Norman cross church, of which the south transept has been destroyed. All the doors and windows of the more antient part have semicircular arches. Calshot and Hurst castles are of the time of Henry VIII., and though still occupied as garrisons are of little strength. Both are on small headlands jutting into the sea: Calshot, at the entrance of Southampton Water; and Hurst, near Lymington. Netley Castle, near Netley Abbey, built about the same time, is now a ruin.

The chief monastic remains beside those mentioned elsewhere [CHRISTCHURCH; WINCHESTER] are Netley and Beaulieu abbeys, and the Priory of St. Dionysius, near Southampton, beside the church of Romsey, mentioned above as having formerly been conventual. Netley Abbey is a short distance from the bank of the Southampton Water, about three miles east of the town of Southampton. It appears to have been founded in the thirteenth century, though probably not by Henry III., to whom its origin is commonly attributed. It was of the Cistertian order. At the time of the dissolution its possessions were valued at 160*l.* 2*s.* 9*d.* gross, or 100*l.* 1*s.* 8*d.* clear yearly value. The ruins stand on the declivity of a hill gently rising from the water, and are so environed by wood as to be scarcely observable, except on a near approach. The principal remains are the chapel, a crypt popularly called 'the Abbot's Kitchen,' the chapter-house, and the refectory. The chapel was in the form of a cross; the southern transept and the choir are the most perfect portions; the northern transept has been destroyed, and many parts are much mutilated. The roof of the whole has fallen in, and most of the windows have lost their tracery. Many parts of the ruins are finely mantled with ivy. The length of the chapel when entire was about 200 feet: the breadth 60 feet, and at the transepts 120 feet. The crypt is a curious vaulted apartment, 48 feet long by 18 broad. Beaulieu Abbey, also Cistertian, was founded, A.D. 1204, by King John: its yearly revenue at the dissolution was 428*l.* 6*s.* 8*d.* gross, or 326*l.* 13*s.* 2*d.* clear. The stone wall which surrounded the precincts of the abbey is in several places nearly entire and is finely mantled with ivy. The abbot's apartments, converted after the dissolution into a family seat, having a well-proportioned vaulted hall; a long building, supposed, from the extent and height of the apartments, to have been the dormitory; the antient kitchen and the refectory are still standing. There are some traces of the cloisters; a gateway leading to the area enclosed by them is standing; the church is entirely destroyed. The refectory, a plain stone building, with strong buttresses, and a curiously raftered oak roof, forms the parish church of the village of Beaulieu. This abbey possessed the privilege of sanctuary, and as such afforded shelter to Margaret of Anjou and her son Prince Edward, on their landing in England at the time of the battle of Barnet, and to Perkin Warbeck, after the failure of his attempts in the West of England. St. Dionysius's (commonly called St. Denis's) Priory, is on the bank of the Itchin above Southampton. It was founded by Henry I. for Augustinian or Black Canons. It yearly revenues at the dissolution were valued at 91*l.* 9*s.* gross, or 80*l.* 11*s.* 6*d.* clear. The ruins are of small extent, and appear to have formed the west end of the Priory church.

In the beginning of the reign of Charles I. the duke of Buckingham was stabbed at Portsmouth, and in the civil war of that reign this county was the scene of partial hostilities. The strong posts of the Isle of Wight were early in the contest secured for the parliament, and the island was thus preserved from subsequent disturbance. In December, 1643, the Royalists were defeated at Alton by Sir William Waller. But the most remarkable event in the contest that occurred in this county was the defence of Basing House, near Basingstoke, by its possessor, John Paulet, marquis of Winchester. The marquis was a Royalist, and fortified his mansion for the king with works, which inclosed a space of above fourteen acres. The outline of the works was irregular, but the ditches were deep (in some parts thirty-six feet perpendicular), and the ramparts, of which there are yet some remains, very high and strong. The investment commenced in August, 1643, and Sir William Waller, who made the first serious assaults, after being repelled in three attempts to storm the place in nine days, was obliged to retreat to Farnham. The investment continued, probably at intervals, for two years. In 1644 the garrison, when much pressed by hunger, was twice relieved by a detachment from the Royalist quarters at Oxford, under Colonel Gage. The final investment was by Cromwell, who, in Oct., 1645, took the house by storm, and burned it to the ground. The plunder in cash, jewels, and rich furniture, is said to have been immense. In A.D. 1647, Charles I., after his escape from Hampton Court, remained concealed at Titchfield House till he gave himself up to Colonel Hammond, governor of the Isle of Wight. He was imprisoned for some time at Carisbrook, and afterwards at Hurst Castle.

Statistics.

Population.—Hampshire is an agricultural county, few of its inhabitants being engaged in manufactures. Of 74,711 males twenty years of age and upwards living in the county in 1831 there were 28,683 employed in agricultural pursuits, and only 292 in manufactures or in manufacturing machinery; 10,348 were employed as labourers not agricultural.

Hampshire ranks the 22nd in the list of agricultural counties.

The population of this county at each of the four enumeratious made in the present century was—

	Males.	Females.	Total.	Increase per cent.
1801	105,667	113,989	219,656	..
1811	118,855	126,225	245,080	11·57
1821	138,373	144,925	283,298	15·59
1831	152,082	162,198	314,280	10·94

showing an increase between the first and last periods of 94,624, or rather more than 43 per cent., which is 14 per cent. below the whole rate of increase throughout England.

The following table contains a summary of the population, &c., of every division, as taken in 1831:—

Summary of the County of Southampton (otherwise Hampshire, or Hants).

DIVISIONS, BOROUGH, CITY, TOWNS, &c.	HOUSES.				OCCUPATIONS.			PERSONS.			
	Inhabited.	Families.	Building.	Uninhabited.	Families chiefly employed in Agriculture.	Families chiefly employed in trade, manufactures, and handicraft.	All other Families not comprised in the two preceding classes.	Males.	Females.	Total of Persons.	Males, twenty years of age.
Alton, North Division	2,401	2,883	11	52	1,523	742	618	7,553	7,415	14,968	3,763
Alton, South Division	1,238	1,455	8	25	847	319	289	3,739	3,744	7,483	1,854

County Expenses, Crime, &c.—The sums expended for the relief of the poor at the four dates of—

		£.		s.	d.	
1801	were	124,019,	being	11	3	for each inhabitant.
1811	„	225,601	„	18	4	„
1821	„	193,294	„	13	7	„
1831	„	215,229	„	13	8	„

The sum expended for the same purpose for the year ending March, 1837, was 123,840*l.*; and assuming that the population had increased at the same rate of progression as in the ten preceding years, the above sum gives an average of 7*s.* 6*d.* for each inhabitant. These averages are all above those for the whole of England and Wales.

The sum raised in Hampshire for poor-rate, county-rate, and other local purposes, in the year ending the 25th of March, 1833, was 248,176*l.* 3*s.*, and was levied upon the various descriptions of property as follows:—

On land	£180,534	4
Dwelling-houses	58,680	3
Mill, factories, &c.	4,112	7
Manorial profits, navigation, &c.	4,849	9

The amount expended was—

For the relief of the poor	£211,075	18
In suits of law, removal of paupers, &c.	5,467	2
For other purposes	35,980	7
	252,523	7

In the returns made up for subsequent years, the descriptions of property assessed are not specified. In the years 1834, 1835, 1836, and 1837, there were raised 243,525*l.* 15*s.*, 211,826*l.* 17*s.*, 177,547*l.* 2*s.*, and 151,240*l.* respectively; and the expenditure of each year was as follows:—

	1834. £.	s.	1835. £.	s.	1836. £.	s.	1837. £.
For the relief of the poor	203,466	4	174.418	2	141,933	11	123,840
In suits of law, removals, &c.	6,545	11	4,324	12	3,504	9	2,105
Payment towards the county-rate	33,934	17	5,799	2	14,061	12	15,507
For all other purposes			22,251	5	18,485	7	13.297
Total money expended	£243,946	12	216,793	1	177,984	19	154,839

The saving effected on the whole sum expended in 1837, as compared with that expended in 1834, was therefore about 36½ per cent.; and the saving effected on the sum expended for the relief of the poor was rather more than 39 per cent. in 1837, as compared with the expenditure in 1834.

The number of turnpike trusts in Hampshire, as ascertained in 1835, is 36; the number of miles of road under their charge is 810; the annual income in 1835, arising from the tolls and parish composition, was 30,321*l.* 13*s.* 6*d.*; and the annual expenditure, 29,894*l.* 11*s.* 7*d.*

The county expenditure in 1834, exclusive of that for the relief of the poor, was 19,618*l.* 3*s.* 5*d.*, disbursed as follows:—

	£.	s.	d.
Bridges, building, and repairs, &c.	1,247	3	5
Gaols, houses of correction, &c., and maintaining prisoners, &c.	3,909	18	3
Shire-halls and courts of justice, building, repairing, &c.	898	19	8
Prosecutions	2,999	8	5
Clerk of the peace	732	2	8
Conveyance of prisoners before trial	791	15	5
„ transports	91	0	0
Constables, high and special	71	1	0
Coroner	298	12	0
Debt, payment of, principal and interest	6,165	10	0
Miscellaneous	2,412	12	7

The number of persons charged with criminal offences in the three septennial periods ending with 1820, 1827, and 1834, were 2085, 2190, and 3187 respectively; making an average of 298 annually in the first period, of 313 in the second period, and of 455 in the third period. The number of persons tried at quarter-sessions, in each of the years 1831, 1832, and 1833, in respect to which any costs were paid out of the county rates, were 109, 156, and 202 respectively. Among the persons charged with offences, there were committed for—

	1831.	1832.	1833.
Felonies	82	129	144
Misdemeanors	9	6	16

The total number of committals in each of the same years was 151, 227, 249 respectively.

	1831.	1832.	1833.
The number convicted was .	98	167	163
„ acquitted .	18	23	43
Discharged by proclamation .	35	37	43

In 1837, at the assizes and sessions, 622 persons were charged with crime in Hampshire. Of these, 42 were charged with offences against the person, 15 of which were for common assaults; there were 24 offences against property, committed with violence; 512 offences against property, committed without violence; 2 for setting fire to crops, &c.; 4 for maiming cattle; 13 for forging and coining; 16 for poaching; 5 for riot; 4 for other misdemeanors. Of the whole number of offenders, 437 were convicted, 138 were acquitted, no bill was found against 36, and 11 others were not prosecuted. Of those convicted, 8 were condemned to death, none of whom were executed, but the sentence of 6 was commuted to transportation for life; and of 2 to imprisonment for six months or under. Besides the above six, 19 were transported for life, 3 for 14 years, and 45 for 7 years; 3 were sentenced to imprisonment for 2 years and above one, 49 for one year and above 6 months, and 308 for 6 months and under; 2 were fined. Of the whole number of offenders, 509 were males, and 113 were females; 225 could neither read nor write; 344 could read and write imperfectly; 47 could read and write well; 2 had a superior instruction, and the degree of instruction of 4 could not be ascertained.

The number of persons qualified to vote for the county members of Hampshire is 8983, being about 1 in 35 of the whole population, and above 1 in 8 of the male population twenty years and upwards, as taken in 1831. The expenses of the last election of county members to parliament were to the inhabitants of the county 233*l.* 17*s.* 2*d.*, and were paid out of the general county-rate.

There are 11 savings' banks in this county. The number of depositors and amount of deposits on the 26th of November in each of the following years were—

	1832.	1833.	1834.	1835.	1836.
Number of depositors	7,700	8,581	9,237	9,898	10,408
Amount of deposits	£279,299	£301,906	£322,493	£341,155	£356,456

The various sums placed in the savings' banks in 1835 and 1836 were distributed as under:—

	1835.		1836.	
	Depositors.	Deposits.	Depositors.	Deposits.
Not exceeding £20	4,805	£35,629	5,018	£36,067
„ 50	2,885	89,323	3,056	95,660
„ 100	1,381	92,851	1,473	95,838
„ 150	487	58,629	501	60,758
„ 200	260	43,922	282	47,298
Above 200	80	20,801	78	20,835
	9898	341,155	10,408	356,456

Education.—The following summary is taken from the Parliamentary Returns on Education, made in the session of 1835:—

	Schools.	Scholars.	Total.
Infant schools	99		
Number of infants at such schools; ages from 2 to 7 years:—			
Males		627	
Females . . .		634	
Sex not specified .		805	
			2,066
Daily schools	1197		
Number of children at such schools; ages from 4 to 14 years:—			
Males . . .		15,911	
Females . . .		13,577	
Sex not specified .		7,179	
			36,667
Schools .	1,296		
Total of children under daily instruction			38,733
Sunday-schools	440		
Number of children at such schools; ages from 4 to 15 years:—			
Males		12,088	
Females . . .		12,714	
Sex not specified .		7,610	
			32,412

Assuming that the population between the ages of 2 and 15 has increased in the same proportion with the whole population since 1821, when the relative population at different ages was last taken, and likewise assuming that the whole population has increased since 1831 in the same ratio as it did the ten years preceding that date, we find by approximation that there were 108,217 children between the ages of two and fifteen in the county of Hampshire in 1834, the time the educational inquiry was made. Sixteen Sunday-schools are returned from places where no other school exists, and the children, 441 in number, who are instructed therein, cannot be supposed to attend any other school; at all other places Sunday-school children have opportunity of resorting to other schools also; but in what number or in what proportion duplicate entry of the same children is thus produced must remain uncertain. Ninety schools, containing 6215 children, which are both daily and Sunday-schools, are returned from various places, and duplicate entry is therefore known to have been thus far created. Making allowance from this cause for a number of children having been entered twice as under instruction, we may perhaps fairly conclude that not two-thirds of the children between the ages of 2 and 15 are receiving instruction in this county.

Maintenance of Schools.

Description of Schools.	By endowment.		By subscription.		By payments from scholars.		Subscrip. and payment from scholars.	
	Schls.	Scholars.	Schls.	Scholars.	Schls.	Scholars.	Schls.	Scholars.
Infant Schools	2	125	7	139	77	1103	13	699
Daily Schools	93	2143	128	8,362	865	19,438	111	6454

Total...	110	3271	527	37,573	942	20,541	157	9760

The schools established by dissenters, included in the above statement, are:—

	Schools.		Scholars.
Infant school . .	1,	containing	69
Daily schools . .	29,	„	1,499
Sunday-schools .	125,	„	12,888

The schools established since 1818 are:—

			Scholars.
Infant and other daily schools	794,	containing	22,399
Sunday-schools	334	„	23,706

One hundred boarding-schools are included in the number of daily schools given above. No school in this county appears to be confined to the children of the Established Church, or of any other religious denomination, such exclusion being disclaimed in almost every instance, especially in schools established by Dissenters, with whom are here included Wesleyan Methodists and Roman Catholics. Lending-libraries of books are attached to 92 schools in this county.

HAMPSHIRE, NEW. [New Hampshire.]

HAMPSTEAD. [Middlesex.]

HAMPTON. [Polybius.]

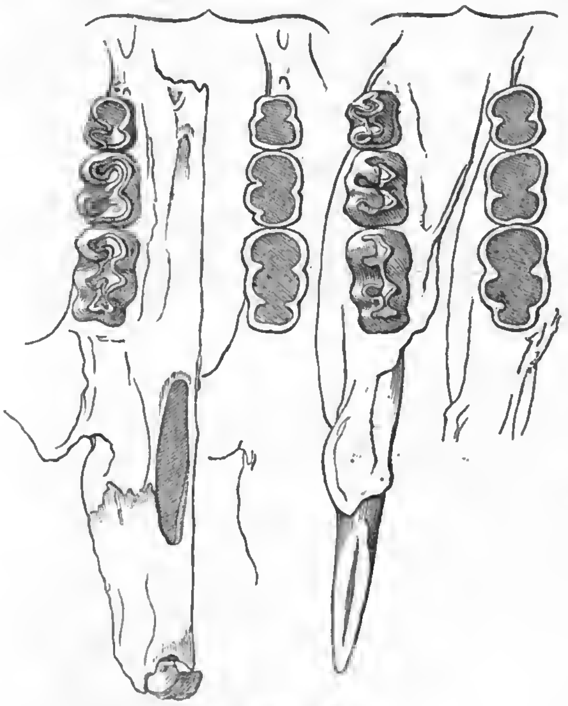
HAMSTER, *Cricetus*, the name of a genus of Rodents, whose economy makes them one of the most interesting of the great Linnæan genus *Mus*, or the family of *Muridæ* in its most extensive sense.

Generic Character—Molar *teeth* simple; their crown furnished with blunt tubercles. Four *toes* and the vestige of a thumb on the fore-feet; five toes on the hind feet; nails robust. *Tail* short and hairy.

Dental Formula.—Incisors $\frac{2}{2}$; molars $\frac{3-3}{3-3} = 16$.

Geographical Distribution of the Genus.—All the north of Europe and of Asia, the temperate countries of Persia, and the deserts of Astrakan. If the *Canada pouched* rat (*Hamster du Canada—Cricetus bursarius* of Desmarest, *Mus bursarius* of Shaw) is to be considered a hamster, Canada and the borders of Lake Superior must be added; and it must be remembered that the *Tucan* of Hernandez, an inhabitant of New Spain, is considered by some to be identical with this 'Canada Rat' (Dr. Richardson thinks on insufficient grounds). But the last-mentioned zoologist places Desmarest's *Canada Hamster* under the genus *Geomys*, with a note of interrogation; and Say has given it a generic distinction under the name of *Pseudostoma*.

There are five or six species of the genus; but we shall select as our example the *Common Hamster, Cricetus vulgaris, Mus Cricetus* of Pallas, Le *Hamster* of Buffon and the French authors.



Teeth of Hamster. (F. Cuvier.)

Description.—Reddish brown above; black below, with three great whitish spots on the sides. Feet white; a white spot on the throat, and another on the breast. Length about 9 inches; tail 3. Males bigger than females. Weight of some males from 12 to 16 ounces; weight of females seldom exceeding from 4 to 6.

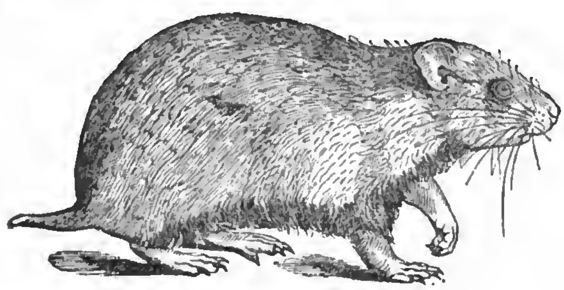
Varieties.—Variations in colour are not uncommon. There is one variety entirely black. Pennant figures one which is entirely black, with the exception of the edge of the ear, the muzzle, the under-jaw and feet.

Localities.—All the north of Europe and Asia (Lesson), Austria, Silesia, and many parts of Germany, Poland, and the Ukraine; all the southern and temperate parts of Russia and Siberia; and even about the river Yenesei, but not farther to the east. In the Tartarian deserts, in sandy soil: they dislike moist places. Swarming in Gotha (Pennant).

Food, Habits, Reproduction.—The *Common Hamsters* are ill friends to the farmer. The quantity of grain which they consume is very great, nor does the destruction stop with mere satiety of appetite; the animal never forgets its hoard, and fills its two cheek-pouches till they seem bursting with the booty. They are also said to be very fond of the seeds of liquorice. Their dwellings are under the earth; their mode of forming them, and the purposes to which they apply them, have been thus described:—They first form an entrance, burrowing down obliquely. At the end of this passage one perpendicular hole is sunk by the male; the female sinks several. At the end of these they excavate various vaults, some as lodges for themselves and young, some as storehouses for their food. Every young one is said to have its separate apartment; each sort of grain its different vault. The 'living apartments,' as they may be called, are lined with straw or grass. The vaults are said to be of different depths, according to the age of the constructor: a young hamster, it is stated, makes them scarcely a foot deep, an old one sinks to the depth of four or five; and the whole 'curtilage,' so to speak, is sometimes eight or ten feet in diameter. From the mode of proceeding in their work, the reader will be prepared for the statement that the male and female live in separate apartments; and indeed it appears that, excepting at the short season of courtship, they have very little or no intercourse. Pennant gives them a very unamiable character. 'The whole race,' writes that zoologist, 'is so malevolent as to constantly reject all society with one another. They will fight, kill, and devour their own species, as well as other lesser animals; so may be said to be carnivorous as well as granivorous. If it happens that two males meet in search of a female, a battle ensues; the female makes a short attachment to the conqueror, after which the connection ceases. She brings forth two or three times in a year, and brings from sixteen to eighteen at a birth: their growth is very quick, and at about the age of three weeks the old one forces them out of the burrows to take care of themselves; she shows little affection for them; for if any one digs into the hole, she attempts to save herself by burrowing deeper into the earth, and totally neglects the safety of her brood; on the contrary, if she is attacked in the season of courtship, she defends the male with the utmost fury.'

The harvest of these animals commences in August. Grains of corn, ears of corn, peas and beans in the pods, all find their way into their cheek-pouches, which will hold a quarter of a pint English. This forage is carefully cleaned in their burrows, and the husks and chaff carried out. When all is in order, they stop up the entrance and prepare for their hybernation, which lasts during the whole of the severe season; the provision they have made having been collected for the purpose of their support before their torpidity actually commences, and also in the spring and summer before the season has produced a supply for them in the fields. If all tales be true, they are a bold generation, and will jump at a horse if he tread near them, and hang by its nose so as to be disengaged with difficulty. Their voice is said to be like the barking of a dog. Fierce as they are, they quail before their deadly enemy the polecat, which, chasing them into their holes, destroys them unrelentingly. Notwithstanding this check, they are said to be so numerous in some seasons as to occasion a dearth of corn.

Utility to Man.—The fur of the animal is said to be valuable; and the peasant, when he 'goes a *Hamster-nesting*' in the winter, not only possesses himself of the skin of the plunderer, but of the plunder, which is said commonly to amount to two bushels of good grain in each magazine. Buffon, quoting Sulzer, says that in Gotha, where these animals were proscribed on account of their vast devastations among the corn, 11,564 of their skins were delivered at the Hôtel de Ville of the capital in one year; 54,429 in another, and 80,139 in a third.



Hamster; Cricetus vulgaris. (F. Cuvier.)

FOSSIL HAMSTER.

Professor Kaup records *Cricetus vulgaris fossilis*, from the Epplesheim sand.

HANAPER OFFICE, one of the offices belonging to the Court of Chancery. Writs relating to the business of the subject, and their returns, were, according to the simplicity of antient times, originally kept in a hamper, *in hanaperio;* and the others, relating to matters wherein the Crown was immediately or mediately concerned, were preserved in a little sack or bag, *in parvâ bagâ;* whence the distinction of the Hanaper Office and Petty Bag Office, both belonging to the Common-Law Court in Chancery.

The business of the clerk of the Hanaper is to receive all money due to the king for the seals of charters, patents, commissions, and writs, as well as all fees due to the officers for enrolling and examining them.

HANAU-MÜNZENBERG is a county in the electorate of Hesse Cassel, on the north bank of the Main, a very fertile and well-cultivated district, containing about 490 square miles, with a population of above 90,000 inhabitants. The county had formerly its own count, but the family was subsequently divided into two branches, that of Münzenberg and that of Lichtenberg. Both branches becoming extinct in the male line, Hanau-Münzenberg came, in 1736, to the electorate of Hesse Cassel, with which it has ever since been united (except from 1806, when the French took possession of it, to 1814, when the elector recovered it). It is contains some mountainous tracts, extensive forests, and rich mines of copper, silver, cobalt, and salt. The inhabitants are Protestants, with the exception of between 400 and 500 Roman Catholics and 800 Jews. In 1818 the Lutherans and Calvinists agreed to unite together as an evangelical church. There are some manufactures, chiefly in Hanau, the capital.

Hanau-Lichtenberg was formerly nearly equal in extent to Hanau-Münzenberg, but the larger portion, lying in Alsace, is now part of France; and the remainder, which occupies about 100 square miles, with 20,000 inhabitants, belongs to Baden.

HANAU, the capital of Hanau-Münzenberg, situated in an extensive plain on the river Kinzig, near its junction with the Main, consists of the old and the new town. In the former is the magnificent castle, the gymnasium, the theatre, the hospital, and the synagogue. The new town has straight broad streets, and in the middle of it a large market-place, forming an oblong parallelogram, with handsome fountains in the four corners, and the large town-hall at one end. The cathedral has a leaning tower, like that at Pisa. The inhabitants are 13,000, among whom are some descendants of the Walloons and Flemings who fled from the tyranny of Philip II.; likewise some of the French Calvinists expelled by the revocation of the edict of Nantes. Hanau is the most manufacturing place in Hesse Cassel, and has a considerable trade. In the vicinity are the electoral palace of Philipsruhe and the baths of Wilhelmsbad. On October 30, 1813, a dreadful battle was fought near Hanau, when an army of Bavarians and Austrians, commanded by Prince Wrede, endeavoured to stop Napoleon on his retreat to France. The loss was very great on both sides, especially on that of the French, who were stated to have had 15,000 killed and wounded and 10,000 prisoners, but Napoleon made good his passage.

HAND. [MAN.]

HANDEL, GEORGE FREDERICK, who, from having passed nearly the whole of his life in this country, and produced in it all his great works, the English feel some right to claim as their own, was born at Halle, in Saxony, on the 24th of February, 1684. He was the issue of a second marriage, which his father, an eminent physician and surgeon, contracted after he had reached his grand climacteric. This son of his rather advanced age he destined for the profession of the civil law, but the child's passion for music, his sacrifice of play-hours, often of his meals, to its pursuit, and the determined manner in which he evaded or resisted all attempts to divert him from a purpose nature seems to have prompted, at length softened the obduracy of his father, who, by the earnest advice of the duke of Saxe-Weissenfels, placed him under Friedrich Zachau, organist of the cathedral of Halle, an excellent musician. This professor soon made so willing a pupil acquainted with the principles of the science and the laws of harmony; he then placed in his hands the best works of the greatest composers, without directing his attention to any one in particular, thus leaving him to form a style of his own out of an acquaintance with numerous models of acknowledged superiority. So successful was this plan of education, that the youthful student composed a set of sonatas when only ten years of age, which was in the possession of George III., and most probably still forms a part of the Queen's library.

Handel continued his attendance on the same master till he attained his fourteenth year, when he was taken to Berlin, where the Italian opera was flourishing under the direction of Bononcini and Ariosti, afterwards his rivals in London. He there attracted the notice of the elector, who proposed to send him to Italy, which offer, for some reason unknown, was declined by his father, who shortly after died; and from this period we lose all trace of the young Handel till the year 1703, when he reached Hamburg, in which city he may be said to have commenced his professional life. He there found Reinhard Keiser in the office of director of the opera, a composer of the highest celebrity, but whose expensive and somewhat dissipated habits led him frequently to absent himself from his post, on which occasions Handel was appointed to fill his situation, a preference so irritating to Mattheson, an able musician and a voluminous writer on the art, that he violently assailed his favoured rival. A duel ensued, and nothing but a *score*, buttoned under Handel's coat, on which his antagonist's weapon broke, saved a life that soon proved of such inestimable value. Shortly after this he was employed to set a drama entitled *Almeria*, the success of which was remarkable; it ran thirty nights uninterruptedly. Next year he produced *Florinda*, and *Nerone* in the year following, both of which were as favourably received as his former work. He now found himself possessed of the means of visiting Italy, then the land of song. At Florence he was welcomed in the most flattering manner by the grand-duke, and there, in 1709, produced the opera of *Rodrigo*, for which he was rewarded with a hundred sequins (50*l.*), and a service of plate, presents which now seem quite disproportioned to each other. He then proceeded to Venice, and brought out his *Agrippina*, which was performed twenty-seven nights successively. In this, we are told, horns and other wind instruments were first used in Italy, as accompaniments to the voice. 'Here the charms of his music made an impression on the famous beauty and singer, Signora Vittoria, a lady particularly distinguished by the grand-duke; but in this, as in every instance of a similar kind, Handel showed no disposition to avail himself of any partialities exhibited in his favour. His thoughts were nearly all absorbed by his art; and it is but just to conclude that he was also influenced by those sentiments of moral propriety which so distinctly marked his conduct through life. (*Gallery of Portraits*, vol. ii., p. 41.)

Quitting Venice, Handel went to Rome, where he was hospitably entertained by the Cardinal Ottoboni, who had in his service a band of excellent performers, under the direction of the famous Corelli [CORELLI], with whom, as well as with Domenico Scarlatti, the young Saxon speedily formed an acquaintance. There he produced *Il Trionfo del Tempo*, the text written for him by the Cardinal Pamphilii, and a sacred opera, a kind of mystery, *La Resurrezione*. The former altered and enlarged, with English words by Dr. Morell, he afterwards brought out in London, as an oratorio, under the name of *The Triumph of Time and Truth*. From Rome he advanced to Naples; but being anxious to return to Germany he declined many proffered engagements, and in 1710 reached Hanover, finding there a generous patron in the Elector, afterwards George I., who soon appointed him his *Maestro di Capella*, with a salary of 1500 crowns, on condition that he would, on the termination of his travels, return to perform the duties of his office.

In 1710 this great musician first arrived in London, and was soon honoured by the notice of Queen Anne. Aaron Hill, then manager of the opera, having formed a drama from Tasso's *Gerusalemme Liberata*, which Rolli worked into an opera under the title of *Rinaldo*, Handel set music to it, and it was produced in March, 1711. He then returned to Hanover; but the attractions of London brought him back the following year to this metropolis, which thenceforward became his home. At the peace of Utrecht he, by the queen's command, composed a *Te Deum* and *Jubilate*, for the rejoicings on that event. A pension of two hundred pounds was the reward of this service. His promise to return to Hanover was now either forgotten or its fulfilment delayed; when, in 1741, the demise of Queen Anne placed the elector of Hanover on the British throne. Handel, taken by surprise, and conscious of having offended his patron, did not dare present himself at court; but his friend Baron Kilmansegge having contrived that he should meet the king, during a royal excursion on the Thames, with a band of wind-instruments, playing the charming *Water-Music*, written for the occasion, the composer was again received into favour, and never after lost the royal protection. His pension was immediately doubled; and many years after, when appointed to teach the princesses, Queen Caroline, consort of George II., added another 200*l.* to the former grants; making altogether 600*l.* per annum, no small income a century ago. From 1715 to 1718 Handel was an inmate in the house of the Earl of Burlington, where he constantly met Pope, whose regard for the German composer is manifest from all he said and wrote concerning him. During the same period he produced three operas, *Amadis*, *Tesco*, and *Il Pastor Fido*, besides several detached pieces. In 1718 he undertook the direction of the Duke of Chandos's chapel at Cannons, for which he composed many fine anthems. He there also produced most of his concertos, sonatas, lessons, and organ fugues, his *Acis and Galatea*, for which Gay furnished him with the poetry, and the oratorio of *Esther*.

The busiest, but not the most fortunate, period of Handel's life now arrived. The English nobility formed a project for converting the Italian theatre into an Academy of Music, a title borrowed from the French, and engaged the subject of this biographical notice as manager, with a condition that he should supply a certain number of operas. In consequence, he went to Dresden to engage singers, among whom was Senesino. His first opera was *Radamisto*, the success of which was unparalleled. But Bononcini and Ariosti, before alluded to, had been attached in some measure to the theatre, and having powerful friends, opposed themselves to the German intruder, as they very insolently called the great composer. Hence those feuds, among the weak people of fashion, the remembrance whereof is propetuated by Swift's well-known epigram. To calm these it was proposed that an opera in three acts should be produced, and that each of the contending composers should set one act. The drama chosen was *Muzio Scevola*. Handel's portion was declared the best; 'but, strange to say, though each, no doubt, strained his ability to the utmost in this struggle, not a single piece in the whole opera is known in the present day!' Handel now, master of the field, produced about fifteen new operas; 'but the genius of discord,' says the work from which we have before quoted, 'must always have a seat in the temple of harmony,' and that spirit of cabal often caused and always encouraged by the weak, that is the larger, part of the ranks of fashion, compelled the great composer and able manager to retire from the theatre in 1726, with the loss of 10,000*l*., and a constitution much damaged by incessant labour and constant turmoil. A slight paralytic affection was the consequence, which however the baths of Aix-la-Chapelle removed. He then made an attempt to give operas at Covent Garden Theatre, but this proved equally mortifying and unprofitable. But the vexations and losses he encountered at the Italian Theatre ultimately led to the advancement of his fame and the repair of his fortune. He now announced performances during the Lent season, in imitation of the *Concerto Spirituale*, which he called oratorios, and at Covent Garden gave several, most of them composed for the occasion. But the receipts at these did not indemnify him for the expenses he incurred: even his sublimest work, *The Messiah*, was as ill-attended as received in the capital of the empire, when first produced in 1741.

These failures were imputed, and justly, to the hostility of the nobility, who, notwithstanding the unvaried patronage of the Royal Family, still pursued him with unabated rigour. From such persecution he determined to seek refuge in Ireland, then noted for the gaiety and splendour of its court. Pope alludes to this circumstance in the well-known appeal to the Goddess of Dullness:—

> 'But soon, ah! soon rebellion will commence,
> If music meanly borrows aid from sense.
> Strong in new arms, lo! giant Handel stands,
> Like bold Briareus, with a hundred hands:
> To stir, to rouse, to shake the world he comes,
> And Jove's own thunders follow Mars's drums.
> Arrest him, empress, or you sleep no more—
> She heard,—and drove him to th' Hibernian shore.'

'On his arrival in Dublin,' says Dr. Burney, in his *Commemoration of Handel*, 'he, with equal judgment and humanity, began by performing *The Messiah* for the benefit of the city prison.' He remained in Ireland about nine months, and had every reason to be satisfied with his visit. Returning to London in 1742, he renewed his oratorios at Covent Garden Theatre, beginning with *Samson*. From this time success attended all his undertakings. His last work drew crowds to the house, and *The Messiah* was equally attractive. The latter was, during a long period, performed annually at the Foundling Hospital, and alone added 10,300*l*. to the funds of that institution. It is next to impossible to calculate what it has produced to other charities; the amount must be prodigious. He continued his oratorios to nearly the last day of his life, deriving considerable pecuniary advantage from them; for though still opposed by most of the nobility, the king (George II.) and the people actively supported him.

Late in life Handel was afflicted with blindness; he nevertheless continued to conduct his oratorios, and, as usual, performed concertos and other organ pieces between the acts. He even composed, employing as his amanuensis Mr. John Christian Smith, and assisted at one of his oratorios a week only before his decease, which took place on a Good Friday (according to his wish, it is said), April 13th, 1759. He was buried in Poet's Corner, Westminster Abbey, where a monument by Roubilliac—a work which never fails to arrest attention and excite admiration—is erected to his memory. 'But,' says the biographer before quoted, 'a still more honourable tribute to his memory was paid in the year 1784, by the performances which took place under the roof which covers his dust. A century having elapsed from the time of his birth, it was resolved that a *Commemoration of Handel* should take place.' The management was entrusted to the directors of the Antient Concerts, and eight of the most distinguished members of the musical profession. The king, George III., zealously patronized the undertaking, and nearly all the upper classes of the kingdom seconded the royal views. The receipts at five performances amounted to the sum of 12,736*l*., the disbursements to rather more than 6000*l*.; of the profits 1000*l*. was given to the Westminster Hospital, and the remainder to the Society for Decayed Musicians.

Handel was great in every style. In sacred music, especially of the choral kind, he not only throws at an immeasurable distance all who preceded and followed him, but reaches that sublimity which, it is now almost universally admitted, the art is so capable of attaining. Till within the last few years his works were unknown out of the British Isles; now they are heard with admiration in every part of Germany—the true land of harmony, in France and in Russia. The United States we should also name, but that we consider them as morally a part of the country from which they were peopled. But Italy, who now scarcely knows her own Dante, is shocked by the energetic strains of a Handel.

It is worthy of remark, and encouraging to those who are unwilling to believe that the intellectual powers decay in proportion to the diminution of bodily activity, to know that most of Handel's greatest works were composed when he was between fifty-four and sixty-seven years of age. *Jephthah* was produced at the latest moment of that period. And here we may, in passing, observe that the finest offsprings of Haydn's genius had their birth after he had become a sexagenarian.

In the Queen's library are the original MSS. of nearly all Handel's works, filling eighty-two large folio volumes. These include 32 Italian operas, 23 oratorios, 8 volumes of anthems, 4 of cantatas, 3 of Te Deums and a Jubilate, together with concertos, sonatas, &c. Not in the royal collection are 11 operas, harpsichord lessons, fugues, organ concertos, water-music, &c. &c. Of the oratorios *Deborah* was first performed in 1733; *Israel in Egypt* in 1738; *Saul* in 1740; *Messiah* in 1741; *Samson* in 1742; *Judas Maccabæus* in 1746; *Joshua* in 1747; *Solomon* in 1749 and *Jephthah* in 1751.

HAND-FASTING. [BETROTHMENT.]

HANDGLASS is a name given by gardeners to a portable glazed cover which they place over certain plants for one of two purposes; either to screen them from the effects of cold and wet without depriving them of much light, or to maintain around them an atmosphere of uniform humidity. Bell-glasses differ from handglasses in no respect with regard to the purpose they are intended to serve, but are blown from a single piece of glass instead of being composed of many pieces fastened together. Glasses of this description are principally used to assist cuttings of plants in the process of striking root, or newly-planted individuals in establishing themselves in the soil. The rationale of the action of handglasses seems to be this:—when cuttings or newly-planted individuals are exposed freely to the atmosphere, they part readily with the moisture they contain, in consequence of the specific power possessed by light, especially direct solar light, of causing perspiration. Under ordinary circumstances the moisture they part with is lost in space, so that it cannot be re-absorbed; and as the atmosphere of the plants or cuttings remains dry, perspiration will go on till the plant is exhausted or dead. The effect of a handglass is to invert this state of things: the moisture raised from the soil by evaporation, or produced by vegetable perspiration, necessarily accumulates beneath the handglass, the air enclosed by which gradually becomes more and more moist, and at last is saturated; this circumambient humidity is re-absorbed by the leaves, or branches, or soil, and thus restored to the plant which had lost it; in addition to which, perspiration itself necessarily goes on the more slowly in proportion as the air itself is charged with humidity. It may also be presumed that a handglass, or any such transparent cover, keeps the temperature in which the plant breathes higher than the external air, and thus stimulates the languid powers of vegetation.

HA'NNIBAL, the son of Hamilcar Barcas, was born B.C. 247. At the age of nine he accompanied his father to Spain, who, provious to his departure, took his son to the altar, and placing his hand on the victim, made him swear that he would never be a friend to the Romans. It does not appear how long Hannibal remained in Spain, but he was at a very early age associated with Hasdrubal, who succeeded his father in the command of the Cathaginian army in that country. On the death of Hasdrubal, B.C. 221, he obtained the undivided command of the army, and quickly conquered the Olcades, Vaccæans, Carpesians, and the other Spanish tribes that had not been subdued by Hasdrubal. The inhabitants of Saguntum, alarmed at his success, sent messengers to Rome to inform the Romans of their danger. A Roman embassy was accordingly sent to Hannibal, who was passing the winter at New Carthage, to announce to him that the independence of Saguntum was guaranteed by a treaty between the Carthaginians and Romans (concluded B.C. 226), and that they should consider any injury done to the Saguntines as a declaration of war against themselves. Hannibal however paid no regard to this remonstrance.

More than twenty years had elapsed since the termination of the first Punic war, during which period the Carthaginians had recovered their strength, and had obtained possession of the greater part of Spain; and the favourable opportunity had arrived for renewing the war with the Romans.

In B.C. 219 Hannibal took Saguntum, after a siege of eight months, and employed the winter in making preparations for the invasion of Italy. He first provided for the security of Africa and Spain by leaving an army of about 16,000 men in each country; the army in Africa consisted principally of Spanish troops, and that in Spain of Africans, under the command of his brother Hasdrubal. He had already received promise of support from the Gauls who inhabited the north of Italy, and who were anxious to deliver themselves from the Roman dominion.

Having thus made every necessary preparation he set out from New Carthage late in the spring of B.C. 218, with an army of 80,000 foot and 12,000 horse. In his march from the Ebro to the Pyrenees he was opposed by a great number of the native tribes, but they were quickly defeated though with loss. Before crossing the Pyrenees he left Hanno to secure his recent conquests with a detachment from his own army of 11,000 men. He sent back the same number of Spanish troops to their own cities, and with an army now reduced to 50,000 foot and 9000 horse, he advanced to the Rhone. Meantime two Roman armies had been levied; one, commanded by the consul P. Cornelius Scipio, was intended to oppose Hannibal in Spain, and a second, under the other consul T. Sempronius, was designed for the invasion of Africa. The departure of Scipio was delayed by a revolt of the Boian and Insubrian Gauls, against whom the army was sent which had been intended for the invasion of Spain, under the command of one of the prætors. Scipio was therefore obliged to remain in Rome till a new army could be raised. When the forces were ready he sailed with them to the Rhone and anchored in the eastern mouth of the river; being persuaded that Hannibal must still be at a considerable distance from him, as the country through which he had to march was difficult, and inhabited by many warlike tribes. Hannibal however quickly surmounted all these obstacles, crossed the Rhone, though not without some opposition from the Gauls, and continued his march up the left bank of the river. Scipio did not arrive at the place where the Carthaginians had crossed the river till three days afterwards; and despairing of overtaking them, he sailed back to Italy with the intention of meeting Hannibal when he should descend from the Alps. Scipio sent his brother Cnæus into Spain with the greater part of the troops to oppose Hasdrubal.

Hannibal continued his march up the Rhone till he came to the Isère. Marching along that river, he crossed the Alps (probably) by the Little St. Bernard, descended into the valley of the Dora Baltea, and followed the course of the river till he arrived in the territories of the Insubrian Gauls. The passage of Hannibal across the Alps has been a matter of much dispute. Whittaker, in a work entitled 'The Course of Hannibal over the Alps ascertained,' Lond., 1794, 2 vols. 8vo., maintains that the passage was made over the Great St. Bernard: those who wish for further information on the subject may consult 'A Dissertation on the Passage of Hannibal over the Alps,' by Wickham and Cramer, 2nd ed., Oxford.

Hannibal completed his march from New Carthage to Italy in five months, during which he lost a great number of men, especially in his passage over the Alps. According to a statement engraved by his order on a column at Lacinium, in Bruttia, which Polybius saw, his army was reduced to 12,000 Africans, 8000 Spaniards, and 6000 cavalry, when he arrived in the territories of the Insubrian Gauls. After remaining some time among the Insubrians to recruit his army, he marched southward and encountered P. Cornelius Scipio on the right bank of the river Ticinus (Tesino). In the battle which ensued the Romans were defeated, and Scipio with the remainder of the army retreating along the left bank of the Po, crossed the river before Hannibal could overtake him, and encamped near Placentia. He afterwards retreated more to the south, and entrenched himself strongly on the right bank of the Trebia, where he waited for the arrival of the army under the other consul T. Sempronius. Sempronius had already crossed over into Sicily with the intention of sailing to Africa, when he was recalled to join his colleague. After the union of the two armies Sempronius determined, against the advice of Scipio, to risk another battle. The skill and fortune of Hannibal again prevailed; the Romans were entirely defeated, and the troops which survived took refuge in the fortified cities. In consequence of these victories the whole of Cisalpine Gaul (the northern part of Italy) fell into the bands of Hannibal; and the Gauls, who on his first arrival were prevented from joining him by the presence of Scipio's army in their country, now eagerly assisted him with men and supplies.

In the following year (B.C. 217) the Romans made great preparations to oppose their formidable enemy. Two new armies were levied; one was posted at Arretium, under the command of the consul Flaminius, and the other at Ariminum, under the other consul Servilius. Hannibal determined to attack Flaminius first. In his march southward through the swamps of the basin of the Arno his army suffered greatly, and he himself lost the sight of one eye. After resting his troops for a short time in the neighbourhood of Fæsulæ, he marched past Arretium, ravaging the country as he went, with the view of drawing out Flaminius to a battle. Flaminius, who appears to have been a rash, headstrong man, hastily followed Hannibal, and being attacked in the basin of the Lake Trasimenus, was completely defeated by the Carthaginians, who were posted on the mountains which encircled the valley. Three or four days after Hannibal cut off a detachment of Roman cavalry, amounting to 4000 men, which had been sent by Servilius to assist his colleague.

Hannibal appears to have entertained hopes of overthrowing the Roman dominion, and to have expected that the other states of Italy would take up arms against Rome, in order to recover their independence. To conciliate the affections of the Italians, he dismissed without ransom all the prisoners whom he took in battle; and to give them an opportunity of joining his army, he marched slowly along the eastern side of the peninsula, through Umbria and Picenum, into Apulia; but he did not meet with that co-operation which he appears to have expected.

After the defeat of Flaminius, Q. Fabius Maximus was appointed dictator, and a defensive system of warfare was adopted by the Romans till the end of the year.

In the following year, B.C. 216, the Romans resolved upon another battle. An army of 80,000 foot and 6,000 horse was raised, which was commanded by the consuls L. Æmilius Paulus and C. Terentius Varro. The Carthaginian army now amounted to 40,000 foot and 10,000 horse. The armies were encamped in the neighbourhood of Cannæ, in Apulia In the battle which was fought near this place the Romans were defeated with dreadful carnage, and with a loss which, as stated by Polybius, is quite incredible: the whole of the infantry engaged in the battle, amounting to 70,000, was destroyed, with the exception of 3000 men who escaped to the neighbouring cities, and also all the cavalry, with the exception of 300 belonging to the allies, and 70 that escaped with Varro. A detachment of 10,000 foot, which had been sent to surprise the Carthaginian camp, was obliged to surrender as prisoners. The consul L. Æmilius, and the two consuls of the former year, Servilius and Attilius, were also among the slain. Hannibal lost only 4000 Gauls, 1500 Africans and Spaniards, and 200 horse.

This victory placed the whole of Lower Italy in the power of Hannibal; but it was not followed by such important results as might have been expected. Capua and most of the cities of Campania espoused his cause, but the majority of the Italian states continued firm to Rome. The defensive system was now strictly adopted by the Romans, and Hannibal was unable to make any active exertions for the further conquest of Italy till he received a reinforcement of troops. He was in hopes of obtaining support from Philip of Macedon and from the Syracusans, with both of whom he formed an alliance; but the Romans found means to keep Philip employed in Greece, and Syracuse was besieged and taken by Marcellus, B.C. 214-212. In addition to this Capua was retaken by the Romans, B.C. 211. Hannibal was therefore obliged to depend upon the Carthaginians for help, and Hasdrubal was accordingly ordered to march from Spain to his assistance.

Cnæus Scipio, as already observed, was left in Spain to oppose Hasdrubal. He was afterwards joined by P. Cornelius Scipio, and the war was carried on with various success for many years, till at length the Roman army was entirely defeated by Hasdrubal, B.C. 212. Both the Scipios fell in the battle. Hasdrubal was now preparing to join his brother, but was prevented by the arrival of young P. Cornelius Scipio in Spain, B.C. 210, who quickly recovered what the Romans had lost. In B.C. 210 he took New Carthage; and it was not till B.C. 207, when the Carthaginians had lost almost all their dominions in Spain, that Hasdrubal set out to join his brother in Italy. He crossed the Alps without meeting with any opposition from the Gauls, and arrived at Placentia before the Romans were aware that he had entered Italy. After besieging this town without success, he continued his march southward; but before he could effect a junction with Hannibal he was attacked by the consuls C. Claudius Nero and M. Livius, on the banks of the Metaurus, in Umbria, his army was cut to pieces, and he himself fell in the battle. This misfortune obliged Hannibal to act on the defensive, and from this time till his departure from Italy, B.C. 203, he was confined to Bruttia; but by his superior military skill he maintained his army in a hostilo country without any assistance from his government at home.

After effecting the conquest of Spain, Scipio passed over into Africa to carry the war into the enemy's country (B.C. 204). With the assistance of Masinissa, a Numidian prince, he gained two victories over the Carthaginians, who hastily recalled their great commander from Italy to defend his native state. Hannibal landed at Leptis, and advanced near Zama, five days' journey from Carthago towards the west. Here he was entirely defeated by Scipio, B.C. 202; 20,000 Carthaginians fell in the battle, and an equal number were taken prisoners. The Carthaginians were obliged to sue for peace; and thus ended the second Punio war, B.C. 201.

After the conclusion of the war Hannibal vigorously applied himself to correct the abuses which existed in the Carthaginian government. He reduced the power of the perpetual judges (as Livy, xxxiii. 46, calls them), and provided for the proper collection of tho public revenue, which had been embezzled. He was supported by the people in these reforms; but he incurred the enmity of many powerful men, who represented to the Romans that he was endeavouring to persuade his countrymen to join Antiochus, king of Syria, in a war against them. A Roman embassy was consequently sent to Carthage to demand the punishment of Hannibal as a disturber of the public peace; but Hannibal, aware that ho should not be able to resist his enemies, supported by the Roman power, escaped from the city, and sailed to Tyre. From Tyre he went to Ephesus to join Antiochus, B.C. 196, and contributed to fix him in his determination to make war against the Romans. If Hannibal's advice as to tho conduct of the war had been followed, the result of the contest might have been different; but he was only employed in a subordinate command, and had no opportunity for the exertion of his great military talents. At the conclusion of this war Hannibal was obliged to seek refuge at the court of Prusias, king of Bithynia, where he remained about five years, and on one occasion obtained a victory over Eumenes, king of Pergamus. But the Romans appear to have been uneasy as long as their once formidable enemy was alive. An embassy was sent to demand him of Prusias, who being afraid of offending the Romans, agreed to give him up. To avoid falling into the hands of his ungenerous enemies, Hannibal destroyed himself by poison at Nicomedia, in Bithynia, B.C. 183, in the sixty-fifth year of his age.

The personal character of Hannibal is only known to us from the events of his public life, and even these have not been commemorated by any historian of his own country; but we cannot read the history of his campaigns, of which we have here presented a mere outline, even in the narrative of his enemies, without admiring his great abilities and courage. Polybius remarks (b. xi., p. 637, *Casaubon*), 'How wonderful is it that in a course of sixteen years, in which he maintained the war in Italy, he should never once dismiss his army from the field, and yet be able, like a good governor, to keep in subjection so great a multitude, and to confine them within the bounds of their duty, so that they neither mutinied against him, nor quarrelled among themselves. Though his army was composed of people of various countries, of Africans, Spaniards, Gauls, Carthaginians, Italians and Greeks—men who had different laws, different customs, and different language, and, in a word, nothing among them that was common—yet so dexterous was his management that, notwithstanding this great diversity, he forced all of them to acknowledge one authority and to yield obedience to one command. And this, too, he effected in the midst of very various fortune. How high as well as just an opinion must these things convey to us of his ability in war. It may be affirmed with confidence that if he had first tried his strength in the other parts of the world, and had come last to attack the Romans, he could scarcely have failed in any part of his design.' (Hampton's *Translation.*)

(Polybius, b. iii., which contains the history of Hannibal's campaigns till the battle of Cannæ, and the fragments of b. vii., viii., ix., xiv., xvi.; Livy, xxi.-xxxix.; Appian; Plutarch, *Life of L. Fabius Maximus*; Nepos' *Life of Hannibal.*)

HANNO'S PERIPLUS is a small Greek treatise, entitled 'The Periplus (*i. e.* voyage) of Hanno, king (*i. e.* commander) of the Carthaginians, round the parts of Libya beyond the pillars of Hercules, which he posted up in the temple of Kronos.' The authenticity of this work has been doubted by many critics; but it appears probable, from the testimony of Pliny (*Nat. Hist.*, ii. 67; v. 1, 36), Mela (iii. 9), and other antient authors, that such a voyage was actually performed; and the description which is given in the 'Periplus' of the western coast of Northern Africa could not have been written by a person who had no knowledge of the localities. The treatise we possess appears to be a translation of the Carthaginian document preserved in the temple of Kronos. The time at which this voyage was performed is quite uncertain; Pliny (*N. H.*, ii. 67) places it in the flourishing period of Carthaginian history.

The object of the expedition is stated at the commencement of the Periplus: 'It was decreed by the Carthaginians that Hanno should sail beyond the pillars of Hercules, and found Libyphœnician cities. He sailed accordingly with 60 ships of 50 oars each, and a body of men and women to the number of 30,000, and provisions and other necessaries.' The first city he founded was Thumiaterion, near the pillars of Hercules, probably in the neighbourhood of Marmora. He then doubled the promontory Soloeis, which Rennell considers to be the same as Cape Cantin, but other commentators to be the same as Cape Blanco, 33° N. lat. A little to the south of C. Cantin, five more cities were founded, namely, Karikon-teichos, Gutte, Akra, Melitta, Arambus, and Kerne. After passing the river Lixus, supposed by Rennell to be the modern St. Cyprian, and doubling Cape Blanco, Hanno founded Kerne. From Kerne the voyage was one of discovery; and after advancing as far south as Sierra Leona or Sherbro, according to Rennell, he was obliged to return through want of provisions.

The Greek text is printed in Hudson's 'Geographiæ veteris Scriptores Græci Minores.' It was also published by Falconer, with an English translation and many notes, 8vo., Lond., 1797. Many remarks upon this voyage are made by Compomanes, 'Antiguedad Maritima de la Republica de Cartago,' Mad., 1756; Bougainville, 'Mémoires de la Académie des Inscriptions,' vols. xxvi., xxviii.; Gosselin, 'Recherches sur la Géographie des Anciens;' Rennell, 'Geography of Herodotus,' vol. ii., p. 409-443, 8vo. ed.; Heeren, 'Researches on the Antient Nations of Africa,' vol. i., p. 492-501, Engl. Transl.

Many other Carthaginians of the name of Hanno are mentioned. Of these the most celebrated was the leader of the party at Carthage which was opposed to a war with the Romans at the time of the first and commencement of the second Punic wars.

HANOVER, THE KINGDOM OF, is situated between 59° 20′ and 53° 51′ N. lat., and 6° 51′ and 11° 51′ long. E. of Greenwich. It is bounded on the north-west by the German Ocean, on the north by the Elbe (which separates it from the territories of Hamburg, Denmark, and Mecklenburg), on the east and south-east by Prussia and Brunswick; on the south-west by Hesse Cassel, Lippe, and Prussia; and on the west by Holland. The whole contains an area of 14,570 square miles.

Divisions.—The kingdom of Hanover is divided into six provinces, called Landdrostei, and one Mining Intendancy (Berghauptmannschaft), the total population being 1,662,500:—

I. Hanover (320,180 inhabitants) consists of, 1, the principality of *Calenberg* (177,920 inh.), containing the towns of Hanover the capital, Pattensen, Hameln; 2, the county of *Hoya* (122,160 inh.), chief town Nienberg; 3, the county of *Diepholz* (20,100 inh.), chief town Diepholz.

II. Hildesheim (352,196 inh.) consists of, 1, the principality of *Hildesheim* (155,014 inh.), chief towns, Hildesheim the capital, Peine, Goslar, Bokenem, Gronau, Alfeld; 2, the principality of *Göttingen* (113,886 inh.), chief towns, Göttingen tho capital, Münden, Moringen, Uslar; 3, the principality of *Grubenhagen* (74,187 inh.), chief towns, Eimbeck the capital, Osterode, Duderstadt; 4, the county of *Hohnstein* (9,109 inh.), chief towns, Neustadt, Ilefeld.

III. Luneburg (303,114 inh.); chief towns, Lüneburg the capital (13,486 inh.), Harburg (5430 inh.), Celle, otherwise Zell (10,137 inh.).

IV. Stade (241,142 inh.) consists of, 1, the duchy of *Bremen* (190,119 inh.), chief towns, Stade (5680 inh.), Buxtehude; 2, the district of *Hadeln* (17,400 inh.), chief town Otterndorf (2050 inh.); 3, the principality of *Verden* (33,563 inh.), chief town Verden (5117 inh.).

V. Osnabruck (263,624 inh.) consists of, 1, the principality of *Osnabrück* (162,534 inh.), chief towns, Osnabrück (12,500 inh.), Fürstenau, Quackenbrück; 2, the lower county of *Lingen* (23,014 inh.), chief towns, Freesen (2840 inh.), Lingen; 3, the county of *Bentheim* (27,209 inh.), chief town Bentheim (1530 inh.); 4, the circle of *Meppen* (44,720 inh.), chief towns, Meppen (1820 inh.), Pappenburg (4700 inh.); 5, the circle of *Emsbühren*, part of tho county *Rheina-Wolbeck* (5141 inh.), chief town Rheina.

VI. Aurich, or the principality of East Friesland (153,671 inh.), chief towns, Emden (12,780 inh.), Norden (6350 inh.), Leer (6573 inh.).

VII. The Mining Intendancy of Clausthal, or the Upper Harz (28,573 inh.), chief towns, Clausthal (8370 inh.), Cellerfeld (3870 inh.), St. Andreasberg (4310 inh.).

The Lower Harz consists of detached districts on the northern and western declivities of the Harz, lying in the territory of Hanover and Brunswick, and belonging to both in common, Hanover having four-sevenths and Brunswick three-sevenths of the revenue.

Hanover, as a member of the German Confederation, is the fifth in rank, with four votes in the full council. It furnishes a contingent of 13,054 men to the army of the Confederation, which forms part of the 10th corps, and contributes 2000 florins annually to the treasury of tho Confederation.

Face of the Country, Soil, Climate.—The southern provinces of Grubenhagen and Göttingen are mountainous: in the former is the Harz [Germany], in the latter the Sollingerwald. Lower ranges, uniting these, traverse tho greater part of Hildesheim and Calenberg; but from the cities of Hildesheim, Hanover, and Osnabrück, to the sea-coast, the whole country is one vast plain, with only occasional and not considerable elevations. The mountains abound in mineral wealth, and are covered with forests of red pino and fir, with some oaks and other timber. The largest oak in tho kingdom is in the village of Hartmannshausen, near Celle. Its circumference close to the ground is 43 feet, and immodiately below the first branches 25 feet. Between the mountains are the most fertile valleys, and where the country slopes from the mountains to the plain there is excellent arable land. Then follows a sandy tract from 50 to 70 miles in breadth, which crosses the kingdom from east to west, and, where left to itself, is covered with heath, and in some places with fir: it is an elevated flat, broken only towards the north by sand-hills. In the lower tracts are great marshes, and the most productive parts are the banks of the rivers. All this part of the country is alluvial, and numerous marine substances are found preserved in it. The climate is on the whole mild and temperate, differing of course according to the relative situation of mountain or plain, and the state of cultivation. In the lower parts fogs are frequent, and on the sea-coast violent hurricanes. The prevailing winds are the north-west in winter, the east in spring, and the south-west in summer. The principal rivers are the Elbe, tho Weser, and the Ems, which receive in their course numerous secondary streams, as the Aller, Leine, Ilmenau, and Lühe, and empty themselves into the German Ocean. There are only two large lakes; the Steinhudermeer and the Dümersee, which latter abounds in fish. In East Friesland is the subterraneous Lake Jordan, the surface of which is so thickly overgrown with vegetation that waggons can pass over it.

Natural Productions.—Agriculture is the chief source of subsistence to the inhabitants, which is much favoured by the facilities for exportation when the harvest is abundant, as well as by the transit trade, and the consumption of the neighbouring maritime towns. The richest corn provinces are Hildesheim, Göttingen, the south of Calenberg, the lower part of Grubenhagen, the marsh lands on the Elbe, Jeeze, Oste, Weser, Leine, and Aller, part of Osnabrück and East Friesland. In the marsh land the breeding of cattle is more followed than agriculture. East Friesland has the finest breed of cattle: it possesses nearly 100,000 cows, 50,000 oxen, &c., 50,000 sheep, and excellent horses, of which above 5000 are annually exported to Italy. The immense heaths in the Duchy of Lüneburg aro partly used as sheep-walks, and when the heath is in blossom the keepers of bees go with their hives (above 60,000 hives) from the villages to the heath: tho honey so obtained is valued at 40,000*l.* per annum. The country produces flax, tobacco, hops, fruit, pulse, potatoes, &c. Timber is abundant, and considerable quantities are exported. If a better system of agriculture were introduced, the produce of the country might be very much increased. Many hundred thousand acres of land susceptible of cultivation still lie waste.

Manufactures and Trade.—Manufactures are not carried on to any considerable extent. Thread and linen are manufactured, partly for exportation, at Osnabrück and some other places, and woollens and calicoes at Göttingen, Münden, and some other towns. Tho commerce of the kingdom, though considerable, is far from being what might be expected from its favourable situation aud fine navigable rivers. It is chiefly confined to the exportation of the produce of tho country, and the importation of colonial articles, English manufactures, French silks, jewellery, and wines, fruits, &c. The principal commercial port is Emden; and Münden, at tho junction of the Werra and the Fulda, has an active trade with the interior of Germany. There are four annual fairs at Hanover, and two at Osnabrück, to which goods are brought from the fairs of Brunswick, Leipzig, and Frankfort.

The Revenue of the kingdom is larger than might be expected. The new system of financial administration began on the 1st of July, 1834. There are two exchequers, the Royal General Exchequer, for the revenues of the state, and the Exchequer of the Royal Crown Demesnes. The latest official account, published in April, 1838, is for the year ending 1st July, 1837. The Royal demesnes and forests had produced a net revenue of 2,660,982 rix-dollars, of which 513,888 wero given into the Crown Exchequer, and the remaining 2,147,094 rix-dollars into the General Exchequer. The remainder of the revenue was produced by the mines and salt-works, tho tolls on the Elbe and Weser, the post-office, direct and indirect taxes, export, import, and transit duties. The total net revenue was 6,306,173 rix dollars, being 445,876 above the estimate. The total expenditure was 5,747,594, leaving a surplus of 558,579 rix-dollars.

The military establishment is 20,000 infantry, 2700 cavalry, and 18,000 militia, or Landwehr. All men able to bear arms, from the age of 17 to that of 50, without exception, are liable to serve in the Landsturm, or local militia. There are 10 garrison towns. The manufactures connected with the army are, one of small-arms at Herzberg, one of gunpowder at Hersen, and a cannon-foundry in Hanover.

Religion, Education, National Church.—The religion is Protestant: of the inhabitants, 1,340,000 are Lutherans, 100,000 Calvinists, and about 2000 Mennonites and Moravians. There are 210,000 Roman Catholics and 10,000 Jews. In 1830 a superior board was established in Hanover for the direction of all matters relative to the schools. Hanover has a university at Göttingen [GÖTTINGEN]; an academy for the equestrian order; an academy for the general staff, founded in 1824; a seminary for schoolmasters; 16 gymnasia; 20 central schools; 5 seminaries; a surgical and two veterinary schools; and 3426 schools in the towns and country, of which 3085 are Protestant, and 341 Roman Catholic. There are besides, numerous poorhouses and work-houses and charitable institutions.

History.—In the remotest times of which we have any record the countries between the Elbe and the Weser were inhabited by small independent tribes of hunters and herdsmen. The Cherusci, celebrated for their victory over the Roman General Quintilius Varus, dwelt about the Harz and far into Westphalia; the Chauci were at the mouth of the Weser; the Longobardi, or Lombards, on both sides of the Elbe. When Charlemagne first introduced the Christian religion, the country was in the power of the Saxons. Though subsequently, as the imperial power declined, many powerful lords, both spiritual and temporal, arose, with almost despotic authority, yet the condition of the people improved; the mines of the Harz and the salt springs of Lüneburg were discovered, and a considerable traffic began, by which Bardowieck and Gandersheim in particular profited. Otho the Great gave, in 970, the investiture of the duchy of Saxony to Hermann Billing, a wealthy lord in Lüneburg, in whose family it remained till the death of the last descendant, Magnus, in 1107. His successor, Henry the black, duke of Bavaria, and brother of Guelf, or Welf, a prince of the north of Italy, marrying a princess of the house of Billing, obtained with her the duchy of Lüneburg, and afterwards acquired Brunswick, Göttingen, and other principalities. His son, Henry the Lion, favoured trade, though he treated with great severity the towns that resisted him; for instance, Bardowieck, which he totally destroyed in 1189.

The broils and troubles which continued for nearly a hundred years after his death proved the advantage of living in fortified towns. Numerous little republics rose, several of which became considerable cities. The Hanseatic League found great favour here, and of the 85 towns composing that celebrated confederation, 13 were in the present kingdom of Hanover. We cannot trace the various partitions of territory which took place in consequence of the division of the family into different branches, all which have however become extinct, except those of Brunswick Wolfenbüttel and Brunswick Lüneburg, the latter of which succeeded to the throne of England on the death of Queen Anne in 1712. [GEORGE LOUIS I.] In consequence of this event the electors of Hanover continued to be kings of Great Britain, till, on the death of his late majesty William IV., the crown of Great Britain devolving on Queen Victoria, and the succession to the throne of Hanover being limited to the male line, the two countries were separated, and the Duke of Cumberland, eldest surviving brother of King William, ascended the throne of Hanover by the name of Ernest Augustus. That Hanover gained great advantages by the union of the two crowns in one person cannot be denied, but whether they were not more than compensated by the disadvantages is a question that has often been discussed, but still remains doubtful. It is at least certain, that with the eighteenth century a period of prosperity commenced such as Hanover had not yet seen. But then it co-operated with Great Britain in the war of 1741, and in the Seven Years' War, which latter was peculiarly disastrous to it, as the country was through the whole time the arena of hostile armies, and suffered both from friends and foes. The tranquillity which Northern Germany enjoyed for nearly 30 years after the peace of Paris, 1763, and the vast increase of the commerce of England in North America, doubled the trade of Bremen, Hamburg, and Altona with the interior of Germany, which was still further augmented from 1792 to 1803 by the ruin of the commerce of France and Holland; and this trade being carried on from those seaports through Hanover, gave an extraordinary impulse to the prosperity of that kingdom.

From the spring of 1793 Hanover took part in the war with France; but in 1795 was included in the convention between France and Prussia for the neutrality of the North of Germany. In the spring of 1801, when differences arose between England and the Northern powers, Prussia occupied Hanover as hostile territory; but the death of the Emperor Paul produced another change, and the Prussians left Hanover. Bonaparte took possession of it in 1803, and treated it like a conquered country. In 1805, when the alliance was concluded between Austria, England, Prussia, and Sweden, it was hoped that Prussia would join, but instead of that, Prussia declared, on April 1, 1806, that Hanover had been ceded by France in exchange for Anspach, Cleve, and Neuchatel, and was for ever incorporated with Prussia. Bonaparte however again took possession of it in the following year; when the greater part of it was included in the new kingdom of Westphalia, and the remaining part administered by a French governor-general. In 1810 the whole of the former electorate, except Lüneburg, was assigned to Westphalia; but before the end of the year Napoleon drew a line opposite Lüneburg, from the Elbe, in a south-west direction, through the kingdom of Westphalia, and all to the north of that line, with the Hanseatic cities, Oldenburg, &c., was incorporated with the French empire. After the battle of Leipzig in 1813, the whole electorate was restored to the lawful sovereign, who assumed in 1815 the title of King of Hanover, that of elector having in fact ceased by the dissolution of the German empire. In 1816 the Duke of Cambridge was appointed governor-general; in 1819 a constitution was introduced with a general assembly of the estates of the kingdom in one chamber. In spite of many improvements, the people became dissatisfied with the government, and the French Revolution in July, 1830, gave the signal for disturbances at Osterode, on the 5th of January, 1831, and for more serious troubles at Göttingen on the 8th of May, which were however suppressed by the intervention of the military. In 1831 the duke of Cambridge was made viceroy, and a new constitution, agreed to by the estates, was in 1833 sanctioned as the constitution of the kingdom by King William IV., who however, without consulting the estates, made of his own authority various changes in fourteen of the articles. According to the constitution of 1833, the general assembly of the estates of the kingdom consists of a first and a second chamber. The first consists of members personally entitled to sit (as princes of the blood, nobles, or by virtue of their offices, such as the hereditary postmaster-general and the abbot of Loccum), and the deputies of the equestrian order. The second chamber is composed of the deputies of the towns, of certain religious foundations, and of the landowners and farmers. The deputies are elected for six years, and meet annually. What the constitution may be when this article is printed is uncertain; for his present majesty, King Ernest Augustus, soon after his accession declared the constitution not to be binding on him, partly on account of the changes arbitrarily made by William IV. (though the estates would not reject the constitution of 1833 on that account), and partly because he had not given his assent to it. He has accordingly abolished it, dissolved the assembly of the estates, and convoked a new assembly according to the constitution of 1819, to which he has presented a plan for a new constitution, which is now (May, 1838) actually under discussion. The result seems very doubtful; many public officers who took the oaths to the constitution of 1833 consider it to be still binding; seven of the professors of Göttingen published a vehement protest against the king's proceeding, and were dismissed by him in consequence. Several of the principal towns have refused to elect deputies, so that there are scarcely members enough present to transact any business. The affair causes an extraordinary sensation throughout Germany, and the conduct of the king has been most bitterly censured by some, though it is defended by others.

HANOVER, the capital of the kingdom and of the principality of Calenberg, lies in 52° 22′ N. lat. and 9° 42′ E. long. It is situated in an agreeable, well-cultivated plain, on the river Leine, which is navigable from the city to its junction with the Weser. The city consists of three parts, the Old Town, the Ægidian New Town, and the New Town on the left bank of the river. In the first the streets are for the most part crooked and narrow, and the houses old fashioned and irregular; but the two other parts are handsomely and regularly built. In the last is George Street, consisting of a row of houses built on one plan, and facing the rampart now converted into public walks. A tract or suburb outside of the walls, called the Gartengemeinde, contains above 500 houses with handsome gardens. The most interesting public buildings are the palace (with the opera-house and palace church), which the French converted into barracks and an hospital, and which is now used for the government offices, the palace of the duke of Cambridge, the mint, the arsenal, the royal mews, the town-hall, with a good library of 40,000 vols., the royal library with the archives, both situated on the esplanade (or parade). Hanover has also four Lutheran, one German Calvinist, one French Calvinist, and one Roman Catholic church, and a synagogue. Among the charitable institutions are the Orphan Asylum, infirmaries, hospitals, and poor-houses. For the purposes of education there is a lycoum, a female school of industry, many elementary schools, and a seminary for schoolmasters. The Georgianum was founded in 1776, for the education of forty sons of Hanoverian nobles, who are admitted at the age of ten years, paying a small sum on their admission, after which the expense of their education is defrayed by the establishment. A flourishing Bible Society has been established here for some years. The manufactures are numerous, and the trade extensive. In the neighbourhood are the royal country palace of Montbrillant, the gardens formerly belonging to Count Walmoden, and now to the crown, with fine collections of works of art, and the royal palace of Herrenhausen. The approach to this building, which is by no means remarkable for its architecture, is by a long avenue of lime-trees. The pleasure-grounds are extensive, in which there are remarkable water-works that throw up a column of water as thick as a man's body to the height of 120 feet. The orangery, greenhouses, and hothouses of Herrenhausen were formerly very celebrated, and the collection of rare exotics supposed to be exceeded only by that of the emperor of Austria at Schoenbrunn. But the French carried away all the finest plants, particularly an almost unique collection of Cape heaths, as they did the swans from the parks, to adorn the empress Josephine's seat at Malmaison. Great efforts have since been made to replace the loss.

Hanover was founded at the latter end of the eleventh century, and in 1203 was assigned to the eldest son of Henry the Lion. In 1641 duke Christian Louis took up his abode in the palace which had been lately erected, and it has ever since been the residence of the prince and the capital of the country. In 1725 the alliance between England, France, and Prussia was concluded here: and in 1745 the convention which preceded the peace of Dresden. The walls, with five gates, and broad ditches, were partly levelled in 1780, and laid out in streets, and the remainder converted into a handsome esplanade, on which is the marble bust of Leibnitz, by an Irish sculptor of the name of Hewetson, placed under a cupola in the antique style; and tho Waterloo Column, 162 feet high, with the figure of Victory on the summit, which was finished in 1832.

(Spielcker's *Description of the City of Hanover*, Hanover, 1819; and W. Lohmann, *Geschichtsabriss und Topog. Gemälde der Stadt Hanover*. H. D. A. Sonne, *Erdbeschreibung des König. Hanover;* H. Lüden, *Das Kön. Hanover;* C. P. Jansen, *Statist. Handbuch des König. Hanover*, besides numerous local and provincial works.)

HANSE TOWNS, called also the Hansa, and the Hanseatic League, a celebrated commercial confederacy, which took its name from the antient German word 'Hanse,' signifying an association for mutual support, in which sense it is used in two charters granted by king John, in 1199, to Dunwich in Norfolk and to the city of York. The cities of Hamburg, Lübeck, and Bremen were in the middle ages the depositories of the manufactures of Italy and Germany, imported by sea, with which they supplied the northern countries of Europe in exchange for their raw produce. The wealth which they acquired by their commerce excited the envy and the rapacity of the princes and nobles; the imposition of new and the augmentation of old tolls were great impediments to trade, which was likewise rendered unsafe by numerous banditti and pirates who infested the roads and the neighbouring seas and rivers. In order to protect the commerce on the Elbe and the German Ocean, Hamburg concluded in 1239 an alliance with the inhabitants of Ditmarsch, at that time independent, and those of the land of Hadeln. Two years later Lübeck concluded a similar alliance with Hamburg; the two cities engaged to maintain ships and soldiers at their joint expense, to clear the road between the Elbe and tho Trave, and the waters from Hamburg to the ocean, from robbers and pirates; and they further bound themselves to promote their commercial interest, and to defend their rights and privileges. The city of Brunswick, which was used by those two cities as a staple, joined the alliance in 1247; for while Italy was in possession of the trade to the Levant and India, a commercial route was opened, through the upper Palatinate, Franconia, and to the east of the Harz, by way of Brunswick to Hamburg. Other cities soon followed the example of Brunswick, and joined the league. The cities were divided into four classes, or quarters, the chief cities of which were Lübeck, Cologne, Brunswick, and Danzig. Lübeck was at the head of the league, issued the summons for the regular assemblies of the deputies of all the cities, which were held once in three years at Whitsuntide (the first in 1260), and also for the extraordinary assemblies, generally held once in ten years, in which they solemnly renewed their league, admitted new members, and excluded those that had not observed all obligations, compacts, &c. Lübeck also had the common treasury and the archives.

In 1266 they established in London their factory called the Steelyard. The number of the towns composing the League fluctuated; the greatest number was eighty-five, among which were Bergen in Norway, Berlin, Bremen, Brunswick, Colberg, Cologne, Cracow, Danzig, Deventer Dorpat, Elbing, Frankfort on the Oder, Goslar, Göttingen, Groningen, Halberstadt, Halle, Hamburg, Hameln, Hanover, Hildesheim, Königsberg, Lübeck, Lüneburg, Magdeburg, Münster, Nimeguen, Osnabrück, Reval, Riga, Ruremonde, Stade, Stettin, Stralsund, Thorn, Venloo, Warberg in Sweden, Wesel, Wisby in the Isle of Gothland, Wismar, Zutphen, and Zwoll in Guelderland. Their four principal factories in foreign countries were at London, Bruges, Novogorod, and Bergen.

This powerful confederacy formed the first systematic plan of commerce known in the middle ages. In its factories a discipline approaching in rigour that of the monasteries was observed, which even extended to the celibacy of factors, clerks, &c. The power of the Hansa rose daily. The cities enjoyed in England the privilege of exporting goods duty-free, and in Denmark of importing duty-free. Their alliance was courted and their hostility feared by the greatest powers. The Hanseatic League defeated kings Erich and Hakon, in Norway, and Waldemar III., king of Denmark, in 1348; they deposed Magnus, king of Sweden, and gave his crown to his nephew Albert, duke of Mecklenburg; they equipped in 1428 a fleet of 248 ships, with 12,000 soldiers on board, against Erich, king of Denmark; and the League concluded commercial treaties with Denmark, Flanders, and England, where Henry III., in 1266, granted them great immunities. But when the roads and seas were no longer insecure; when princes began to be sensible of the commercial interest of their own states; and above all, when the discovery of America, and the way to India by the Cape of Good Hope, gave an entirely new form and direction to commerce, the Hanseatic League gradually declined, and at the last general assembly at Lubeck, in 1630, the deputies from the several cities appeared merely to declare their secession from the League. Hamburg, Lübeck, and Bremen formed an association in 1641, and remained free republics till December, 1810, when they were incorporated with the French empire, but on the deliverance of Germany in 1813 they were again separated from France, and with Frankfort-on-the-Maine are now called the free Hanseatic Cities of the Germanic Confederation. For a particular account of their connexion with England, see Steelyard. There are numerous works treating of this league. In English, vol. i. of Anderson's 'Deduction of Trade and Commerce' may be consulted. The most recent work in German is F. Sartorius's 'History of the German Hansa, 3 vols., 1802-8, continued by Lappenberg, 2 vols., 1830-4.

HANWAY, JONAS, born in 1712, deceased in 1786, was a Russia merchant, connected through his Russian dealings with the trade into Persia. Business having led him into that country, he published in 1753 his 'Historical Account of the British Trade over the Caspian Sea, with a Journal of Travels from London through Russia into Persia, &c.,' 4 vols. 4to., a work of no pretension to literary elegance, but containing much information on the commercial subjects of which he speaks, and on the history and manners of Persia. The latter part of his life was employed in supporting, by his pen and personal exertions, a great variety of charitable and philanthropic schemes: and he gained so high and honourable a name, that a deputation of the chief merchants of London made it their request to government that some substantial mark of public favour should be conferred on him. He was in consequence made a commissioner of the navy. The Marine Society and the Magdalen Charity, both still in existence, owe their establishment mainly to him: he was also one of the great promoters of Sunday-schools. (Pugh's *Remarkable Occurrences in the Life of Jonas Hanway*.)

HA'PALE. The name employed by Illiger, Kuhl, and others, to distinguish the genus of *Simiadæ*, commonly known by the name of *Sanglins*, *Sanguins*, &c. [JACCHUS.]

HAPPISBURGH, a village on the coast of Norfolk, remarkable for bold cliffs of diluvial clay and pebbles. These wasting cliffs are supposed by most geologists to be the original repositories of the numerous remains of the mammoth and other quadrupeds which are dredged from the neighbouring oyster-beds; and though few such specimens have been obtained from the face of the cliffs, it is conceivable that in the course of ages many may have been collected on the bed of the sea, out of the enormous quantity of earthy materials which have been undermined and sorted by the waves. The specimens are in a peculi state of conservation.

HAPSBURGH. [HABSBURG.]

HAQUEBUT. [ARMS.]

HARDICANUTE, HARDECANUTE, or HARDACNUTE, was the eldest of the sons of Canute the Great, king of England, Denmark, and Norway, by Emma, styled the 'Flower of Normandy,' daughter of Richard I., duke of Normandy, and widow of King Ethelred II., whom he had married in 1017. [ETHELRED II.] The death of Canute, in 1035, brought forward as claimants to the inheritance of his dominions Sweyn and Harold, his two sons by Alfgiva, daughter of Alfhelm, earl of Northampton, to whom however it is asserted by most historians that he never had been married; Hardicanute, his son by Emma; and Edward, the elder of the two sons of Emma by her former husband Ethelred. Sweyn, who obtained the throne of Norway, made no pretensions to that of England. Edward (afterwards Edward the Confessor) and his brother were with their uncle, Duke Richard II., in Normandy. Hardicanute was also absent in Denmark, the government of which country had been some time before entrusted to him by his father. It has been supposed that Canute had intended that Hardicanute, as his eldest legitimate son, should succeed him in all his three kingdoms; it is certain that he designed him for his successor in the sovereignty of England, in conformity with a special arrangement which had been made on his marriage with Emma. Harold however had the important advantage of being on the spot at the time of his father's death, and was thus enabled to triumph over the pretensions of both his rivals. A civil war was prevented by an agreement that the authority of Hardicanute should be confined to the country to the south of the Thames, constituting the ancient kingdom of Wessex, and that all the rest of England, including London, should be resigned to Harold. Meanwhile Hardicanute remained in Denmark, leaving the government of his English province in the hands of his mother Queen Emma. This state of things subsisted till the invasion of England, in 1037, by Emma's younger son Alfred, which terminated so calamitously for himself and his followers. [EDWARD THE CONFESSOR.] On the failure of this unhappy attempt, Emma fled to the Continent, and Harold became undisputed king of all England. For the next two years Hardicanute did nothing to vindicate his rights. At last, on the repeated importunities of his mother, who had taken up her residence at Bruges, he fitted out an armament for that purpose, with nine ships of which he proceeded in the first instance to that place, to advise with her before proceeding on his enterprise. While they were together, in 1040, news was received of the death of Harold, and soon after a deputation arrived from the English nobility, offering the crown to Hardicanute, who thereupon immediately came over and assumed the government. His short reign affords scarcely any events requiring to be mentioned. His character appears to have been that of a good-natured debauchee, not wanting in generosity of sentiment, nor stained with any darker vice than the habit of inordinate eating and drinking. His plentiful table however, which was spread for a numerous company four times a day, is said to have won him the strong attachment of his thanes, who were admitted to feast along with him, however much it may have disgusted the body of the people. The chronicler John Rouse, in the end of the 15th century, writes that the anniversary of his death even then continued to be celebrated as a holiday by the people of England under the name of Hog's-tide, or Hock Wednesday. That event happened on the 8th of June, 1042, in consequence of what appears to have been a stroke of apoplexy, by which he had been suddenly rendered speechless four days before, as he was about to swallow a cup of wine at the marriage feast of one of his Danish thanes, held at Lambeth, or, perhaps, Clapham. Hardicanute was never married, and left no issue. He was succeeded by his half-brother Edward, surnamed the Confessor.

HARDNESS (in mineralogy). The different degrees of hardness possessed by minerals of similar external characters will often serve to distinguish them from each other. Mohs has formed a scale, which affords an approximation in estimating the hardness of minerals, and according to which it is expressed in numbers. The substances which he uses are such as are easily obtained in a state of purity. They are,—

1. Talc, white or greenish.
2. Rock salt, pure and cleavable, and gypsum, uncrystallized and semi-translucent.
3. Calcareous spar, cleavable.
4. Fluor spar, which cleaves perfectly.
5. Apatite, the asparagus-stone, from Salzburg.
6. Adularia.
7. Rock crystal, limpid and transparent.
8. Topaz.
9. Corundum, from Bengal, with smooth fractured faces.
10. Diamond.

Any mineral which neither scratches nor is scratched by any one of the substances above named is stated to possess the degree of hardness expressed by the number opposite that mineral. Thus, supposing a body neither to scratch nor to be scratched by fluor spar, its hardness is represented by 4; but if it should scratch fluor spar and not apatite, then its hardness is stated to be from 4 to 5.

Another method of trying the hardness of minerals is passing them very gently over a fine hard file, and judging by the touch and appearance of the file as to the degree of hardness.

HARDOUIN, JOHN, commonly called **PÈRE HARDOUIN**, was born of obscure parents at Quimper in Bretany, in 1647. He entered the society of the Jesuits at an early age, and devoted himself to the study of belles-lettres, the learned languages, history, philosophy, and divinity. A large portion of his life was spent in undertaking to prove, chiefly from medals, that the greater part of those writings which are considered as antient, both classical and of the early Christian age, were forged by monks of the thirteenth century. He excepted only the works of Cicero, Pliny's 'Natural History,' Virgil's 'Georgics,' and Horace's 'Satires and Epistles.' These he supposed to be the only genuine works of antiquity remaining, except a few inscriptions and fasti; and that from these the monks had drawn up and published Terence's Plays, Livy's and Tacitus's Historics, Virgil's Æneid, Horace's Odes, &c. See his 'Chronologiæ ex Nummis Antiquis restitutæ: Prolusio, de Nummis Herodiadum,' 4to., Paris, 1693. His opinions upon religious subjects were not less wild than those upon profane learning.

The Society of Jesuits at last interfered, and Hardouin, in 1708, published the recantation of his fancies.

His edition of Pliny's 'Natural History,' prepared for the use of the Dauphin, was published at first in five volumes, 4to., Paris, 1685; republished with great improvements in three volumes folio, Paris, 1723, with a more copious Index than had up to that period been appended to any classic. In 1715 he edited a new edition of 'The Councils,' printed at the royal press in 12 vols. folio.

Père Hardouin died at Paris, Sept. 3rd, 1729. After his death a volume of his 'Opuscula,' in folio, was published by an anonymous friend.

HARDWICKE, PHILIP YORKE (first Earl of), was the son of an attorney at Dover, where he was born the 1st December, 1690. His father was in very indifferent circumstances, and wholly unable to afford him the education generally bestowed upon young men in his station of life. The great abilities of the son enabled him however to surmount all difficulties. He was a great favourite with Mr. Samuel Morland, a man of considerable learning, who kept a school at Bethnal Green, at which he was placed for a short time. When removed to the office of Mr. Salkeld, an eminent solicitor in London, his diligence and talents won the respect and esteem of that gentleman also. So steady was his perseverance, and so rapid his progress in the knowledge of the law, that Mr. Salkeld caused him to be entered of the Middle Temple, in November, 1708, as a preparatory step to his call to the bar. During the time he was keeping his terms, he became acquainted with Mr. Parker, one of the sons of Lord Chief-Justice Macclesfield, the consequence of which was an introduction to Lord Macclesfield, who highly appreciated Yorke's merits, and employed him as the companion and tutor of his sons. To this lucky acquaintance the rapid and extraordinary success of Mr. Yorke at the bar is mainly attributable. In May, 1715, he was called to the bar, when the support of his old benefactor Salkeld, who was in very extensive practice as a solicitor, together with the favour and patronage of Lord Macclesfield, enabled him at the very outset to acquire an extensive practice: indeed the favouritism of Lord Macclesfield, even in court, justly offended and aggrieved many old and eminent practitioners.

The elevation of Lord Macclesfield to the woolsack (1719) enabled him further to promote the interests of his favourite, and accordingly, through his interference, in the same year Yorke took his seat in the House of Commons as member for Lewes, the whole expenses of his election being defrayed by the ministry. In the same year he married Mrs. Lygon, a young widow, the daughter of Mr. Cocks, a gentleman of good estate in Worcestershire, and the niece of Lord Somers and Sir Joseph Jekyl, then master of the rolls.

In March, 1720, while upon the circuit, and within five years after his call to the bar, he was, through the influence of his patron the chancellor, appointed solicitor-general. This step was a very hazardous one; for besides the professional jealousy which was perhaps not unjustly excited towards him, he had to contend with the doubts felt by all parties whether so young a man could be possessed of sufficient learning and experience to discharge the duties of a leading counsel. The talents however which he displayed in the conduct of the business in which he was employed soon made it evident that he was fully equal to the duties of his new station. Shortly after his appointment he was knighted, and in 1724 he was made attorney-general. It was after this period that his patron, Lord Macclesfield, was impeached for gross corruption in office, and Sir Philip Yorke had great difficulty in procuring himself to be excused from the task of assisting the managers of the Commons in making good their charge. In 1733, having held the office of attorney-general nearly ten years, he was appointed lord-chief-justice of the King's Bench, and created Baron Hardwicke. He presided in the King's Bench for three years and a half, during which period he added largely to his former high reputation. On the death of Lord Chancellor Talbot (1737) he was raised to the dignity of lord chancellor. It is upon his judgments as chancellor that the reputation of Lord Hardwicke is principally founded; he held the great seal during nearly twenty years, dispensing justice throughout that period with the most consummate skill at a time when the principles of equity jurisdiction were by no means in a settled state. His integrity was never called in question; the wisdom of his decrees was the theme of universal eulogy, and it is a remarkable fact that during the whole time that he presided in the Court of Chancery three only of his judgments were appealed from, and those were confirmed by the House of Lords. In 1754 he was created Earl of Hardwicke and Viscount Royston. He continued to hold the great seal until the 19th of November, 1756; the Duke of Newcastle having resigned the premiership on the 11th. After his retirement from public life Lord Hardwicke divided his time between his seat at Wimpole in Cambridgeshire and his house in Grosvenor Square, enjoying unimpaired his vigorous intellect until nearly the close of his 73rd year, when he was attacked by a disorder which proved fatal on the 6th March, 1764. The labours of Lord Hardwicke's mind are recorded in his legal judgments. They are preserved, so far as the points decided by them, in the reports of Atkyns and Vesey, sen., and in a volume recently published from Lord Hardwicke's own notes, by Mr. West. Some notes of his decisions have also been made public by Mr. Lee. These volumes however do not give any notion of the language in which the judgments were delivered. Few specimens of his style of writing remain. A short treatise, 'A discourse of the Judicial Authority of the Master of the Rolls,' has been attributed to him, and some few letters have been preserved by Dr. Birch. It has also been said that he was the author of the paper in the 'Spectator' for the 28th April, 1712, signed Philip Homebred; but this statement is exceedingly doubtful.

This brief memoir and the facts and dates are taken from a very able Life of Lord Hardwicke, in the 3rd No. of the 'Law Magazine.'

HARDYNG, JOHN, one of our old historians, descended of a respectable northern family, was born in 1378, and at the early age of twelve was admitted into the family of Sir Henry Percy, eldest son to the earl of Northumberland, known by the name of Hotspur, with whom he fought as a volunteer at the battles of Homildon and Cokelawe. After the death of his patron, whom he accompanied in the fight of Shrewsbury, as soon as a pardon had been proclaimed for the adherents of the Percies, Hardyng enlisted under the banner of Sir Robert Umfravile, who was connected with the Percies by affinity, and under whom in 1405 he became constable of the castle of Warkworth in Northumberland. How long he remained at Warkworth is unknown; but his knowledge of Scottish geography seems soon to have engaged him in the secret service of his country. The exact time when Hardyng was first sent to obtain restitution of the deeds of homage, which had been given up by Mortimer in the minority of Edward III., does not appear; but it must have been early in the reign of Henry V. He remained in Scotland three years and a half, indefatigable in the search, and obtained some at the hazard of his life. In 1415 we find him, with Sir Robert Umfravile, attendant on the king at Harfleur. His journal of the march which preceded the memorable battle of Agincourt forms one of the most curious passages in his chronicle. In 1416 he accompanied the duke of Bedford to the sea-fight at the mouth of the Seine.

An obscure notice in a rubric of the Lansdowne manuscript of Hardyng's Chronicle intimates that he was at Rome in 1424. Soon after we find him again employed in ascertaining the fealty due from the Scottish kings. In one or two passages of his Chronicle he distinctly alludes to an incurable injury received, as he himself expresses it, for England's right; and in one or two others he states the offer of a thousand marks which had been made to him by king James I. of Scotland, on condition of his embezzling some of the earlier instruments he had procured. The letter of protection from king James, making this offer, is still preserved among the antient deeds in the Chapter House at Westminster. In another passage of his Chronicle, as well as in an address to king Henry VI., Hardyng mentions 450 marks as the price for which he obtained some other of the deeds of homage. Notwithstanding these declarations however several writers have considered our author as a dexterous and notable forger, who manufactured the deeds for which he sought reward. The spurious instruments by which king David II. and king Robert II. were made to acknowledge the superiority of England appear principally to have occasioned this strong change of fabrication. But whether Hardyng in his zeal for his country became the tool of some more powerful person, or was imposed upon in the purchase of the deeds, cannot now be thoroughly ascertained.

Actively as Hardyng was engaged in life, he seems to have been constantly employed in gathering materials for his Chronicle, the first composition of which he finished toward the latter end of the minority of Henry VI. The Lansdowne manuscript already referred to closes with the life of Sir Robert Umfravile, who died January 27th 1436, under whom Hardyng seems to have lived, in his latter years, as constable of Kyme Castle in Lincolnshire.

Of the rewards which Hardyng appears to have received, the first was in the 18th Henry VI., when he had a grant for life of 10*l.* per annum out of the manor or alien preceptory of Wyloughton in the county of Lincoln. In the 19th Henry VI. a confirmation of the grant occurs for seven years, with the further grant after that time of the reversion of the manor for life. In 1457 he received a pension of 20*l.* a year for life, charged in the patent-roll upon the revenues of the county of Lincoln.

The evening of Hardyng's days was passed in the entire recomposition of his work for Richard duke of York, father to king Edward IV., who fell in the battle of Wakefield, December 31, 1460. It was afterwards presented to king Edward IV. himself. The history comes no lower than the flight of Henry VI. to Scotland. But, from a passage in which the queen is mentioned, it is evident that he could not have finished his work before 1465. How long he survived its completion is unknown, but he must then have been at least eighty-seven years of age.

'The Chronicle of Jhon Hardyng, in Metre, from the first begynnyng of Englande, vnto the reigne of Edwarde the Fourth,' was printed by Grafton in 1543; to which Grafton added a continuation to the 34th Henry VIII., a small thick quarto; and it is not a little singular that there should be two editions of this work, both printed in the same month of the same year, January, 1543, differing in almost every page, and one, in Grafton's own portion, containing twenty-nine pages more than the other. A collation of both, together with that of a valuable manuscript of Hardyng, was published by the booksellers of London in 1812, under the care of Sir Henry Ellis.

The present printed text of Hardyng's Chronicle is from the re-composition presented to Edward IV. The Chronicle as written for Henry VI., the only manuscript known of which is preserved in the Lansdowne collection in the British Museum, has never been printed. It differs in every page from the printed copy. Hearne had intended its publication. Several manuscripts of the later text of Hardyng's Chronicle are extant: one in the Harleian Collection, No. 661; one in Selden's; another in the Doucean Collection in the Bodleian; and one in the Ashmolean Library at Oxford. A sixth manuscript was formerly preserved in the library of Basil earl of Denbigh.

HARE-LIP, a malformation in which the lip is divided in one or more situations by clefts extending from its free edge towards its attachment. It has received this name from the resemblance which it bears to the divided upper lip of hares and other gnawing animals, and is one of the most common of the malformations by arrest of development. [MONSTER.] In the embryo each lip is formed of four pieces which project separately from the jaws and unite with each other at different periods of fœtal life; but if by any circumstance their healthy development is checked, they remain permanently in the condition which they had at the time of its occurrence. The separate portions of the lower lip unite long before those of the upper, and fissure of the former is so exceedingly rare as to be seldom the subject of treatment. Of the portions of the upper lip the two middle unite first, and then the two lateral to them; hence a fissure in the middle line is more rare than one on either or each side. Hare-lip may be single or double, that is, there may be one or two fissures—the one may be seated in the middle line of the lip, or opposite to the union of the two incisors with the canine tooth—if there be two, they will be found in the latter situation on each side. It may be simple or complicated with fissures of the gum or palate, which being developed in an analogous manner may be influenced by the same cause as the lips, though being earlier united they are less rarely affected.

The cure of hare-lip is important, not only for the uncouth deformity, but because sucking is prevented in infancy, and in later life the speech is affected. It is accomplished by cutting off quite smoothly the opposite edges of the fissure in its whole length, and then bringing them together and maintaining them in accurate apposition till, like the edges of a common wound, they have firmly united. For this purpose, after fixing the portion of the lip with forceps, each edge of the fissure is to be cut off with a knife or a pair of knife-edge scissors, taking especial care that the wounded surface should be left of the same form and size in each. They are then to be placed in accurate contact by transfixing them with one or two hare-lip pins (according to the length of the fissure), and connecting them with silk wound round them in the form of an 8. These pins should be made of silver, with removeable steel points; the lowest should be passed through full two-thirds of the thickness of the lip, just above its vermillion border, taking care that it penetrates to the same depth in each portion, lest the edge of one should project beyond that of the other. The next pin should be passed midway between the lower edge of the lip and the nostril, and the remaining aperture should be closed with a suture or with sticking-plaster. The intervening portions of the lip are now to be compressed by the silk wound about the pins, and additional security is afforded by placing a compress on each cheek, and there bandaging it firmly, so as to prevent the muscles of the lips from contracting and separating the cut edges. After the operation the part should be kept perfectly quiet and cool; in four or six days the pins and other dressings may be removed, and the edges of the wound, which ought to be completely united, will now need only to be secured by sticking-plaster.

When the fissure is double, it is generally advisable to operate first on one side, and when that is completely healed, on the other; but in some cases the whole may be done at once, by cutting off both edges of the middle and each of the lateral ones, and transfixing the whole by the same pins and sutures. In those cases in which a portion of the jawbone projects much, it may be sufficient to draw the teeth from it, and then the lip may be stretched to unite over it; but often it will be necessary to remove it by cutting-forceps, or to depress it by long-continued pressure. In all cases it must be remembered, that however wide the fissures may be, there is no loss of substance in the lip; its edges are drawn asunder by the muscles on each side, just as those of a cut made in a healthy lip (which may indeed require the very same treatment) are.

The best authorities seem now agreed that after six or eight weeks, the earlier this operation is performed on the infant the better, only avoiding the period of dentition; for besides that very young children are likely to be quiet and asleep all day, and that the healing processes are then very active, it has the great advantage of enabling them to resort at once to their natural food by restoring the power of sucking.

HARFANG, one of the names of the Snowy Owl, *Strix nyctea*. [STRIGIDÆ.]

HARFLEUR. [SEINE INFERIEURE.]

HARIOT. [HERIOT.]

HARLE, the French name for the *Mergansers*. [MERGANINÆ.]

HARLEIAN COLLECTION. [BRITISH MUSEUM.]

HARLES, GOTTLIEB (or THEOPHILUS) CHRISTOPHER, a learned and laborious German philologer, born at Culmbach, 1738, died November 2, 1815, held several academical offices in the university of Erlangen. He published many editions of Greek and Latin authors, which however are not highly esteemed; and has the character of a laborious student rather than of a judicious and able critic. Those of his works most highly recommended are his 'Introductions to the History of the Greek and of the Latin Language;' and his 'Lives of the Most Eminent Philologers of our age,' a very useful collection to those who are concerned with literary biography, 1770, 3 vols. 12mo., Bremæ. See the 'Biog. Univ.' for a list of the persons herein contained. The most important of his publications is an edition of the 'Bibliotheca Græca' of Fabricius, Hamburg, 1790-1811, in 12 vols. 4to., which contains great additions, and a new arrangement of the original matter. [FABRICIUS, J. A.] (*Biographie Univ.*; Watt, *Bibliotheca Britann.*)

HARLEY, ROBERT, EARL OF OXFORD, was born in London in 1661, of a family long of distinguished note in the county of Hereford. His grandfather, Sir Robert Harley, was master of the mint in the reign of Charles I., and his father, Sir Edward, was governor of Dunkerque after the Restoration. In the troubles of the seventeenth century the Harleys acted with the Presbyterian party, of which the family was considered one of the heads, and, although both Sir Robert and his son Sir Edward took the field on the side of the parliament in the early part of the civil war, they went into opposition when the republicans obtained the ascendancy, and Sir Edward afterwards took an active part in bringing about the Restoration. The subject of the present article entered parliament after the Revolution as member for Tregony, and afterwards sat for

Radnor, professing for some time the whig principles of his family. After a transition period however, in which he followed a course that perplexed and successively excited the expectations of all parties, he went fairly over to the tories, and soon became one of their most active and efficient combatants in the House of Commons. In the House which met under the tory administration of Rochester and Godolphin, in February, 1701, Harley was elected speaker by a great majority; and even in the next parliament, which assembled in December of the same year, although his friends now appeared in diminished numbers, they were still strong enough to place him again in the chair. He was a third time chosen to the same office by Queen Anne's first parliament, in October, 1702, and retained it till April, 1704, when he was made secretary of state. He is believed to have been principally indebted for this promotion to the good offices of Miss Abigail Hill, who had been introduced into the royal household by her cousin Sarah, Duchess of Marlborough, and who was by this time beginning to supplant her patroness in the queen's favour. Miss Hill's father, it seems, a merchant in the city, who had fallen into distressed circumstances, was as near a relation of Harley as her mother was of the duchess; and this circumstance had probably something to do in bringing him and the daughter together. According to the scandalous chronicle of the duchess of Marlborough, Miss Hill, having fixed her affections on Mr. Masham, the queen's page, applied to her cousin Harley for his aid in forwarding her object: by Harley's management she became Mrs. Masham; and in return she exerted all her influence to attach the weak mind of the queen to Harley and his friends. It is certain that from this time she and Harley acted in confederacy against the Marlborough interest. In this state of things the latter party began to seek a new support by inclining towards the whigs; and various circumstances chanced for the moment to favour this line of policy. In the parliament which met in October, 1705, the whigs were stronger than they had been since the beginning of the reign; this sufficed to introduce into the cabinet two distinguished members of that party, William Cowper Esq. (afterwards Lord Cowper), as lord chancellor, and Charles, Earl of Sunderland, the son-in-law of Marlborough, as one of the secretaries of state. But the struggle was finally decided against Harley by the public suspicion and odium to which he became exposed in consequence of the conviction of one of his clerks named Gregg, for carrying on a treasonable correspondence with France. Gregg, who was executed for his crime, left a paper with the sheriff, in which he entirely exculpated Harley: even this however did not allay the outcry against the latter; it was said that he himself was the writer of the paper, which he had induced Gregg to sign and to deliver by the promise of a reprieve. On the other hand, Harley's friends asserted that the strongest endeavours were made by the opposite party to suborn Gregg, and to prevail upon him, by the promise of a pardon, to accuse Harley. In the beginning of February, 1708, after the conviction, but before the execution, of Gregg, the Duke of Marlborough and Lord Godolphin intimated to the queen that unless Harley were removed, they would leave her service; on this, although it is believed that the queen was herself willing to incur the threatened risk of continuing to support him, the secretary resigned, along with his friend St. John (afterwards Lord Bolingbroke). Harley remained out of power for about two years and a half; at the end of which time the whig ministry was partly undermined by his intrigues and those of Mrs. Masham, partly destroyed by its own imprudence and over-confidence. In August, 1710, Godolphin was dismissed, and Harley was appointed chancellor of the Exchequer, all the other whig members of the cabinet having at the same time resigned or been turned out, and tories put in their places. A new parliament was soon after called, which completely sanctioned this arrangement; so inflamed was the temper of the public mind against the late ministry, that only about a hundred of their friends were returned from all England. The duke and duchess of Marlborough, and all their connexions, were now completely discarded both from office and from the queen's favour, which continued to the end of her life to be wholly engrossed by Mrs. Masham (whose husband was soon after made a peer), and by those to whom she lent her influence and protection.

On the 8th of March, 1711, an accident happened to Harley, which in the end proved very serviceable to his schemes of ambition: a French emigrant, who called himself the Marquis de Guiscard (he was in fact an abbé, and brother of the Count de Guiscard), having been apprehended on a charge of high treason and brought for examination to the cockpit, suddenly seized a penknife and struck at the minister. Harley's wound was very slight, but he took care to remain as long as possible in the surgeon's hands. In May following he was appointed lord high treasurer, being about the same time created earl of Oxford and earl Mortimer, and invested with the order of the garter. As the victories of Marlborough constituted the glory of the Godolphin administration, the peace of Utrecht, concluded 5th May, 1713, is the event for which that of Harley is chiefly memorable. It was after this that the jealousy between the premier and Bolingbroke assumed the character of an open rivalry, although it is believed to have been fermenting in secret for years before, one account deducing its origin from so remote a date as the affair of Guiscard, of whose blow, which he asserted was intended for himself, Bolingbroke never forgave his colleague for taking all the credit and reaping all the advantage. The ambitious and intriguing dispositions of the men, both, it is probable, equally unprincipled, made it impossible that they should long continue to act together after their one common object, the achievement of peace with France, ceased to unite their efforts. Bolingbroke had now the art to gain the favourite, Lady Masham, whose influence Harley, on the other hand, seems to have erroneously calculated that he was by this time sufficiently established to despise. It was soon proved that he was wrong: on the 27th of July, 1714, the lord treasurer received his dismissal. It is said that a few days before he had excited the determined vengeance of Lady Masham by demurring to a grant of an annuity of 1500*l.* a year which she had obtained from the queen. The queen's death, three days after, put an end for ever to the political existence of both Oxford and Bolingbroke. In August, 1715, both were impeached by the House of Commons. When St. John made his escape to France, Harley was committed to the Tower, and there he lay for nearly two years. At last, in June, 1717, he was on his own petition brought to trial before the House of Lords; but the Commons not appearing to prosecute their impeachment, the prisoner was on the 1st of July acquitted and discharged. After this the earl of Oxford lived in retirement till his death, 21st May, 1724. He was succeeded in his titles and estates by Edward, his eldest son by his first marriage with Elizabeth, daughter of Thomas Foley, Esq., whose brother was made Baron Foley in 1711, being one of the twelve peers then introduced in a body into the House of Lords. The present earl of Oxford is descended from a younger brother of the lord treasurer, the peerage having been bestowed with remainder to the issue male of his grandfather. By his second wife, Sarah, daughter of Thomas Middleton, Esq., he had no issue. Lord Oxford showed his attachment to literature both by his patronage of Swift, Pope, and others, and by the extensive and valuable library of printed books and manuscripts which he spared no pains or expense to collect. [British Museum.] His own writings do not show much literary talent. They are, a Letter to Swift on Correcting and Improving the English Tongue; an Essay on Public Credit; an Essay on Loans; and a Vindication of the Rights of the Commons of England. He has given an account of his own administration in a letter to the queen, written a few days before his dismissal, which is printed in Tindal's History and elsewhere. On this subject also may be consulted the Duchess of Marlborough's Account of her own Life, and the anonymous reply to that work by James Ralph, entitled 'The Other Side of the Question' (8vo., London, 1742), many of the materials of which had evidently been supplied by the Oxford family. The proceedings on the trial of Lord Oxford are in the 'State Trials.' Some very strong evidence, implicating both Bolingbroke and Oxford in the crime of carrying on secret negotiations with the French court for some years before the peace of Utrecht, has been lately laid before the public in the 'Edinburgh Review,' No. 125, in an account of the collections made by the late Sir James Mackintosh, in 1814, from the archives of the foreign office at Paris.

HARLOW. [Essex.]

HARMER, THOMAS, a Protestant dissenting minister, was born at Norwich, A.D. 1715, of pious parents. He received his education under the care of Mr. Eames in London, and was ordained in the twentieth year of his age as the minister of the Independent church of Watesfield, in Suffolk. In this place he continued till his death in 1788, 'beloved by all and useful to many.'

Tho work by which Harmer is principally known is his 'Observations on various passages of Scripture, placing them in a new light; compiled from relations incidentally mentioned in books of Voyages and Travels into the East.' By the interest of Dr. Lowth, bishop of London, who warmly approved of the work, Harmer obtained the MS. papers of Chardin, which furnished him with a variety of curious additions to his book. The last and best edition was published by Dr. Adam Clarke in 1816, in 4 vols. 8vo. Harmer was also the author of 'An Account of the Jewish Doctrine of the Resurrection of the Dead,' and of 'Outlines of a New Commentary on the Book of Solomon's Song,' 8vo., 1768, 2nd ed., 1775.

(*Memoirs of the Life, Character, and Writings of Mr. Harmer*, prefixed to Dr. Clarke's editiou of the 'Observations.')

HARMO'DIUS. [Aristogiton.]

HARMODYTES, a genus of tubular stony corals, proposed by Fischer and adopted by Bronn. The same species were afterwards designated by Goldfuss, Syringopora, a name generally adopted.

HARMONIC PROPORTION. The reciprocals of numbers which are in arithmetical proportion are themselves said to be in harmonic proportion; thus

$$\frac{1}{a}, \frac{1}{a+b}, \frac{1}{a+2b}, \text{\&c.},$$

is a series in harmonic progression.

A line A B is said to be harmonically divided when two

A C B D

points, C and D, ono within it and one on its continuation, are so placed that A C is to C B as A D to D B. In this construction, C D is an harmonic mean between A D and B D, or A D, C D, and B D, are as the reciprocals of terms in arithmetical proportion.

HARMONICS (Acoustics). By the harmonics of a musical note are meant all those other notes in which the number of vibrations per second are twice, three times, four times, or any multiple of, the number of vibrations which produce the note in question. Thus the harmonics of a note which is sounded by 200 vibrations per second are those notes which require 400, 600, 800, &c., vibrations per second. The following explanation will be rendered complete by reference to Acoustics (vol. i., p. 96) and Temperament. It presumes the reader to be acquainted with the fundamental mathematical laws of the scale. The harmonics of a note are infinite in number, theoretically speaking, and proceed by less and less intervals. And since every note may be considered as identical with any of its octaves, every harmonic has a corresponding note in any given octave. Denoting any key-note by C, and the octave above it by C′, there is no possible sound between C and C′ which is not theoretically either an harmonic of C, or as near to one as we please (which is equivalent to the mathematical proposition that a whole number, divided by a whole power of 2, may be made as near as we please to any given number or fraction).

But, in practice, not only is it impossible to produce any number of harmonics we please, that is, to maintain in vibration any aliquot part we please of a string or column of air, but even among the harmonics which we can produce we find a limit to the number of those distinct harmonics which deserve the name, etymologically considered. Some few of the first harmonics are melodious sounds, considered in relation to the key-note, but others are discordant, and find no place in the scale according to any system of temperament. We shall therefore, taking a given note, say C, simply mention the most important harmonics, and reduce them to their proper places between C and C′.

Let a be the number of vibrations per second which produce C; then $2a$ is well known to produce C′, or the first harmonic of a note is its octave. The next has $3a$ vibrations, auswering to G′; so that the twelfth, or octave of the fifth, is the second harmonic. The third has $4a$ vibrations, and answers to C″, the ootave of the octave. The fourth harmonic has $5a$ vibrations, and gives E″, the double octave above the third, in the untempered diatonic scale. The fifth harmonic, with $6a$ vibrations, gives G″, the octave of G′ the second harmonic. In goneral, every harmonic whose vibrations are an even multiple of those in the key-note, is an octave to a preceding harmonic, and presents no new character. The sixth harmonic, having $7a$ vibrations, is an imperfect (being too flat) double octave to the flat seventh above the key-note, or B flat. This last note, in the common mode of tempering, makes $1{\cdot}77a$ vibrations per second; whereas the same note derived from the harmonic makes $1{\cdot}75a$ vibrations. The eighth harmonic, with $9a$ vibrations, is correctly D‴, or three octaves above the untempered major second. The tenth, with $11a$ vibrations, is a little too sharp for F‴, being $11a$ instead of $10\frac{2}{3}a$. The twelfth, with $13a$ vibrations, is a little too flat for A‴, being $13a$ instead of $13\frac{1}{3}a$.

The preceding summation is useful, as giving an account of the scale of all thoso musical instruments which consist of one unaltered pipe. These are the bugle, the French horn, the trumpet, and (but for its slide) the trombone; in all of which (except the last) no note can be produced except an harmonic of the fundamental note of the whole tube. Calling the fundamental note C (which however is not very easily sounded), the ordinary scale of these instruments is—

C C′ G′ C″ E″ G″ (B″ flat) C‴ D‴ E‴ F‴ G‴ A‴,

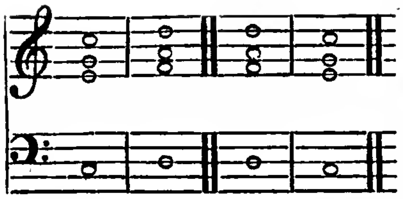
in which B″ flat is too flat, F‴ is too sharp, and A‴ too flat. A short pipe however will not produce many harmonics; the bugle goes no further than G″, at least with common lips. Various contrivances have been introduced to extend and correct this scale; the keyed bugle, the use of the hand in the French horn, the pistons sometimes applied to the same instrumont, and the short slide of the trumpet, to say nothing of the slide which is the principal distinction of the trombone, will suggest themselves to all who are acquainted with musical instruments. In other instrumonts harmonics are much used, particularly in those of the violin class, and in the flute. The performance of Paganini upon a single string, which a few years ago created great sensation among violin players, arose from extraordinary power of producing harmonics. In the fluto C‴ may be attained without much practice, as an harmonic of the fundamental note of the instrument; and we have heard of players who could produce D‴ and even E‴ in the same way. On the long strings of a piano-forte, as the fundamental note subsides, G′, C″, and E″ may be perceived; and we have beard, among the vaulted roofs of a cathedral, several of the harmonics of the notes sounded in chanting. For further information see the references in Acoustics.

HARMONY (in Music), musical sounds simultaneously produced according to certain rules, forming a chord, or a succession of chords. The simplest harmony, namely, the triad, or common chord, is the result of the vibration of all sonorous bodies, and the foundation on which much artificial harmony is built. Under the word Chord the reader will find this matter further explained. M. Catel, a modern French theorist of great authority, has divided harmony into natural and artificial, including in the former all chords not requiring preparation; in the latter, all that are formed by retardation, suspension, &c. But we cannot acquiesce in this arrangemont, for it places the chord of the seventh, which is the source of the three real chords of dissonance, in the same category as the triad, or the chord of nature, which of course will never be admitted. It is true that the chord of the seventh requires no preparation—that is, the dissonant note need not be heard as a concord in the immediately preceding chord [Discord]; nevertheless this privilege cannot make natural that which is essentially artificial.

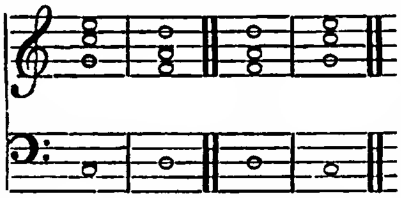
Harmony and Counterpoint are now practically considered as synonymous terms, and for some rules concerning the latter, as well as for examples, we refer to that word. To what has been said under the head Chord, we also again call attention. Chords are tho language in which harmony expresses itself, and the laws whereby the one is governed likewise regulate the other. Besides the rules given under different heads in this work, we here add the few following:—

1. No two perfect concords, namely, two 5ths or two 8ths, are allowed to succeed each other in the same progression, but are permitted in contrary motion; that is, when the one rises and the other falls. Examples:

Similar motion, bad.

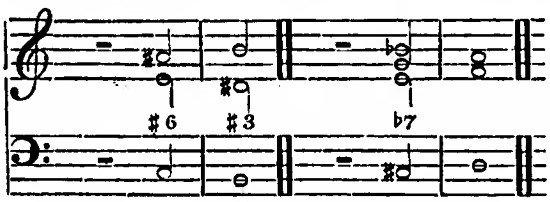


Contrary motion, good.



2. Most discords require to be *prepared*, and all must be *resolved; i.e.* the dissonant note is to be first heard as a concord, and after *percussion*, or being sounded, must pass into a concord, generally by falling a tone or semitone. But sometimes the resolution is brought about by the base, as in the instance of the discord of the 2nd. Examples:

3. It is in the nature of sharpened intervals to rise, and of flattened ones to fall; but extreme sharp intervals almost invariably must rise, and extreme flat ones as invariably must fall. Example:



These examples will also show a reason for giving two names and appearances to that which is, practically speaking, one and the same note; though, theoretically, A sharp and B flat are different sounds.

4. In music in four or more parts, the parts should be dispersed, or separated, in a manner as nearly equal as possible: thus a more perfect symmetry is obtained, and a richer harmony produced. But with a view to some particular effect, a very different distribution of the parts is occasionally made.

5. As a general rule, every composition, whatever its kind, is to commence in its key; but as regards the termination, the rule is without exception, and peremptory: though sometimes the third is changed, from minor to major.

To enter fully into the subject of Harmony would be to give a treatise on musical composition, and require the appropriation of a much larger portion of a volume than the nature of our work admits. The symbols of harmony—or certain figures, some written, some implied—will be explained in the article THOROUGH-BASE, a term of the most inadequate, and indeed unmeaning kind, but which time, and the backwardness of musicians in the march of improvement, have so firmly fixed, that any attempt to substitute a better would be vehemently opposed, and rendered nugatory. For the accompaniment of the scale—*La Règle de l'Octave*, as the French call it—a very important study when properly carried out, see ACCOMPANIMENT.

That the term *harmony* was not used in the same sense by the ancients as by the moderns, seems now to be generally admitted, but admitted without at all affecting the long-disputed and, we believe, undecidable question, as to the knowledge of counterpoint possessed by the Greeks and Romans, or compromising any opinion delivered or entertained on that most obscure and perplexing subject. By Harmónia (ἁρμονία) the Greeks meant simply to express the proper relationship of one sound to another, the pleasing agreement of intervals, in a melody, and nothing beyond. Though, however, they employed the word harmony in a very different sense from that given to it in later ages, it does not thence necessarily follow that they were ignorant of the high branch of the science to which we apply the term. That they played and sung in octaves is undeniable; and it is almost equally certain that they occasionally used simultaneous thirds, instrumentally and vocally. It seems unlikely, then, that so active, so ingenious and musical a people, furnished with an abundance of many-stringed lyres, of double-flutes, as well as other instruments, should not have discovered, even by mere accident, something of harmony, and have been led to investigate its nature and cultivate its practice. But on the other hand, if they were acquainted with the effect of combined sounds, and, as a sure consequence, had converted their knowledge to some useful purpose, they would, to almost a moral certainty, have left, among the numerous disquisitions and lengthened conversations on the subject of music which have reached us, some undeniable evidence of so important a fact.

HARMO'TOME. *Andreolite; Ercinite.* This mineral occurs in attached crystals, generally intersecting each other lengthwise. Primary form a right rhombic prism; cleavage parallel to the primary planes, and to both the diagonals of the prism; hardness 4·5; colour greyish-reddish, yellowish-white; fracture uneven; lustre vitreous, and sometimes pearly; streak white; sp. gr. 2·35, 2·4.

By acids, unless heated, harmotome is scarcely acted upon. Before the blowpipe it fuses into a clear glass. It occurs at Strontian in Scotland, and at Andreasberg and Oberstein in Germany.

The analyses of this substance do not greatly differ in general. The harmotome of Strontian yielded, by the analysis of Mr. Connell—

HAROLD I., surnamed Harefoot, was the younger of the two sons of Canute the Great, by his mistress, or, according to others, his first wife Alfgiva. On the death of his father, in 1035, Harold disputed the possession of the English crown with his half-brother Hardicanute, whom their father had designed for his successor, and succeeded in acquiring the sovereignty of London and all the country to the north of the Thames. [HARDICANUTE.] In 1037 the thanes and people of Wessex also submitted to him, on which he was crowned king of all England, although it is stated that Egelnoth, the archbishop of Canterbury, at first refused either to perform the ceremony himself, or to permit any of his brother bishops to officiate in his stead. No events of the reign of Harold, after he became sole king, have been preserved. Even his character may be said to be unknown —some of the chroniclers representing him as a friend to the church, others as not even professing a belief in christianity. He died in 1040, and was succeeded by his brother Hardicanute. The common account of his surname of 'Harefoot' is that it was given him for his swiftness in running; it is said that, in his favourite amusement of the chase, he used often to pursue the game on foot. According to Brompton it refers merely to his general preference of walking to riding—a most unbecoming taste, says that annalist, for a king. Another explanation is that his foot was all over hairy.

HAROLD II. was the second of the sons of Godwin, earl of Kent. This Godwin, or Gudin, makes his first appearance in English history in the reign of Canute, and appears to have been born a few years before the close of the tenth century. He was undoubtedly of Saxon descent. The English writers call him the son of Wulfnoth, a 'child' (which may perhaps mean a peasant) of Sussex. One writer, Radulphus Niger (whose MS. chronicle is in the

British Museum), says distinctly that he was the son of a cowherd ('filius bubulci'). These statements are consistent, so far as they go, with a curious account which Mr. Turner has translated from the Knytlinga Saga, and which represents Godwin to have been the son of a peasant named Ulfnadr (evidently the same name with Wulfnoth), and to have owed his introduction at the court of Canute to a service which he performed to Ulfr, one of the noble captains of that Danish conqueror, who, having lost himself in a wood after the battle of Skorstein, or Sceorstan [EDMUND II.], accidentally met with Godwin driving his father's cattle, and was by him conducted in safety first to the cottage of Ulfnadr and then to the camp of Canute. This story however makes Ulfnadr to have had an uncle Edric who had already raised himself from the same humble station to be duke or chief governor of Mercia. Godwin's talents and address, his handsome person and fluent speech, speedily enabled him to make his way at court. In course of time he married Gyda, or Githa, the sister of Ulfr, who was himself married to a sister of Canute; and on this Canute made him a jarl, or earl. Earl Godwin's first appearance in political history is after the death of Canute, as a supporter, in concert with Queen Emma, of the succession of Hardicanute. [HARDICANUTE.] On this occasion, as in the general course of his after-life, he attached himself to what was considered the Saxon, in opposition to the Danish or other foreign interest. It seems improbable therefore that he should soon after this have been a party, as the historians after the Norman Conquest allege, to the treacherous murder of Prince Alfred, the younger brother of Edward the Confessor. [EDWARD THE CONFESSOR.] The common story indeed affirms that Godwin in this instance acted again in concert with Queen Emma; but, besides the extreme unlikelihood that the mother should thus plot the destruction of her own child, whose death was, at the moment at least, to benefit nobody except Harold Harefoot, the enemy of herself and of her families by both her husbands, the actual immediate result of this murder was her own exile as a fugitive, and the complete overthrow, for the time, of whatever power she or her son Hardicanute, for whom she was acting, possessed in England. The contemporary author, it may be further observed, of the 'Encomium Emmæ,' addressed to her, and written by her orders, never would have made the murder, as he does, one of the subjects of his detail, if there had then been the least suspicion of her participation in it. If Emma was innocent, Godwin, who was and had all along been her associate in governing Wessex for Hardicanute, was in all probability equally so. It is true that a few years after, in the reign of Hardicanute, he was, in a quarrel with Alfric, archbishop of York, passionately accused by that prelate of having been the instrument through whom the murder was effected; but he immediately met the charge by demanding to be put upon his trial, and the result was his complete acquittal. When Alfred and his followers were fallen upon by the soldiers of Harold, they were under the protection of Godwin, who had met them on their landing, having, as he asserted, been sent by Emma to be their conductor; this circumstance seems to have formed the sole ground for an imputation which pursued him to his grave, and after his death was eagerly taken up by the Norman historians, when everything that could blacken the characters of Godwin and his family was grateful to the reigning dynasty. After the accession of Hardicanute, Godwin was employed in conjunction with Archbishop Alfric to disinter the body of Harold Harefoot, and see the fragments thrown into the Thames. It was a disagreement arising out of this barbarous commission that gave occasion to the quarrel between the archbishop and the earl. The history of Godwin and his family during the next reign has been sketched in the notice of Edward the Confessor. The historians after the Conquest assert that his death, which certainly happened in consequence of a sudden seizure of illness as he sat at the royal table on Easter Monday, 1053, was occasioned by his being choked in attempting to swallow a piece of bread, which, in reply to an observation of the king obliquely hinting that he had been the murderer of Prince Alfred, he had wished might stick in his throat if there was any truth in the charge. The story, which was unknown to the contemporary annalists, is of a kind too well adapted to the credulous superstition of the age in which its first relaters lived, as well as to their interests and prejudices, to leave much doubt as to its origin. At the time of his death Godwin was the most powerful subject in England, he and his sons dividing among them the government of a large portion of the kingdom, while his only daughter was the wife of the king. His eldest son, Sweyn, indeed, after having been repeatedly pardoned for resistance to the royal authority and other crimes, had died abroad a short time before the death of his father. On Godwin's death his earldom of Kent, which, besides that county, comprehended all Wessex and Sussex, was given to his second son, Harold; Harold's own earldom, under which were included the counties of Essex, Middlesex, Huntingdon, Cambridge, and the rest of the antient kingdom of East Anglia, being at the same time transferred to Alfgar, the son of Leofric, styled Earl of Leicester, the potent rival of the Godwin family. This latter arrangement was not tamely submitted to by Harold: Alfgar was outlawed by the witenagemot, on a charge of treason which Harold brought against him; on which flying to Ireland he speedily returned with a force of Danes from that country, and of auxiliaries from Wales, to levy open war against the Saxon king. Harold was despatched by Edward to meet the rebels; but a contest of arms was prevented by a negotiation which restored his earldom to Alfgar, who soon after also succeeded to the honours and estates of his father Leofric, but did not live above a year to enjoy them. Harold meanwhile, as the king's commander-in-chief, turned to chastise the Welsh for the aid they had given to the revolt; and a series of hostilities with that people commenced, which did not finally terminate until, in 1063, after Harold had twice carried fire and sword through their country, they sent him the head of their Prince Griffith, in token of their entire submission. It was about two years after this that Harold was shipwrecked on the coast of Ponthieu, where he was immediately seized by the Earl Guy, and on the demand of William, duke of Normandy (afterwards king of England), delivered over to that prince. William did not permit his prisoner to embark for England till he had compelled him to take a solemn oath, in presence of the assembled Norman barons, that he would do every thing in his power, on the decease of Edward, to promote the duke's succession to the English crown. It would appear to have been already well understood, or at least generally suspected, that the English earl looked to this prize for himself. Immediately after he returned home Harold found himself involved in a new affair of difficulty. This was the insurrection of the people of Northumberland against his younger brother Tostig, who a few years before had been appointed their earl on the death of the great Siward, but whose misgovernment and savage excesses of despotism had at length become insupportable. The insurgents had placed at their head Morcar, the eldest of the two sons of the recently deceased Earl Alfgar; and he and his brother Edwin had come to their assistance, with the men of Lincoln, Nottingham, Derby, and Leicester, and also a body of Welsh auxiliaries. Harold, who was sent to meet them, either deemed their force too formidable, or their demands too just, to be resisted; it was agreed, without coming to blows, that the earldom should be taken from Tostig and given to Morcar. On this Tostig retired to Bruges, brooding, as it presently appeared, on schemes of vengeance. The death of Edward the Confessor (5th January, 1066) followed in little more than a month after this pacification, which had been perhaps the more readily accorded by Harold in consequence of the near prospect of that event: he was at hand when it took place. On the evening of the same day, a report having been circulated that Edward had named him for his successor before he breathed his last, he was proclaimed king in an assembly of the thanes and of the citizens of London, held in the cathedral of St. Paul's. The next day he was solemnly crowned in the same place, a few hours after the interment of the late king.

For more than half a year Harold was left to occupy the throne he had thus obtained in quiet. His accession evidently took place with the general assent of the nation; the nobility with few exceptions, and the bishops with scarcely any, avowed themselves its authors and supporters; the acquiescence of the people was complete everywhere, except, for a brief space at first, among the Northumbrians, who were however easily induced to lay aside their scruples by the influence of their Earl Morcar, whose sister Editha Harold had married; and on the whole there is no reason to suppose that he would have had any trouble in maintaining himself if he had been allowed to remain unmolested by attacks from abroad. Two foreign enemies however at length assailed him nearly at the same time. His brother Tostig, having formed a confederacy with Harold Hardrada, king of Norway, first made a descent upon the Isle of Wight, and after he had levied contributions from the inhabitants, sailed round at the head of his fleet of sixty vessels to the mouth of the Tyne, where he was joined about the beginning of September by Hardrada with a navy of three hundred sail. The invaders had driven back Earls Morcar and Edwin, and made themselves masters of the entire province of York before Harold came up. On the 25th however he engaged them at Stamford Bridge, on the Derwent, when both Hardrada and Tostig fell, and the English king obtained a complete victory. Only three days after this the Duke of Normandy landed at Bulverhithe, between Pevensey and Hastings, on the southern coast, with a mighty armament, which he had spent the preceding eight months in fitting out. Harold, having first proceeded to London, did not reach the Norman camp till the 13th of October. On the morning of the following day battle was joined at a place then called Senlac (now Battle), about nine miles from Hastings. The issue of this memorable engagement, which lasted the whole day, was the complete defeat and rout of the English, after Harold himself had fallen, pierced through the head by an arrow—his two brothers, Gurth and Leofwine, having also been already slain. This victory, as all know, gave the crown of England to the Duke of Normandy, by whose descendants it has ever since been worn.

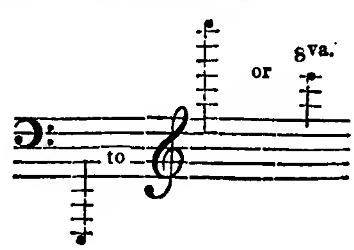
Harold is said to have been twice married. By his first wife, whose name has not been preserved, he had three sons, Edmund, Godwin, and Magnus, who, on the death of their father, fled to Ireland, from which they afterwards attempted some descents on the western coasts of England, but eventually retired to Denmark. His second wife, Editha, otherwise called Algitha, the daughter of Earl Alfgar, is said to have been the widow of Griffith, the Welsh prince, whose head had been sent by his subjects as a peace-offering to Harold. By her Harold is asserted to have had a son and two daughters; but, as it is admitted that he was only married to her some time in 1065 at the earliest, we may doubt if she could already have produced so considerable a family. The son, named Wolf, is said to have been knighted by William Rufus: Gunilda, the eldest daughter, became blind, and passed her life in a nunnery; the second, whose name is unknown, is supposed to have gone to Denmark with her half-brothers. Queen Editha survived her husband many years, during which she is said to have lived in obscurity in Westminster. This lady, according to the Scottish historians, was the mother, by her first husband, of a daughter who married Fleance, the son of Banquo, thane of Lochaber, whose son Walter, marrying a daughter of Alan the Red, earl of Britanny, became the progenitor of the Stewarts. (On this story see appendix No. X. to the first volume of Hailes's 'Annals of Scotland.')

HARP (hearp, *hearp*, Saxon), a musical instrument which, under different forms and denominations, may be traced to the remotest ages. According to Holy Writ, Jubal, seventh only in descent from Adam, was its inventor; he 'was the father of all such as handle the harp and organ,' as Moses tells us. Notwithstanding the wonders related of Amphion's lyre, or harp, we are compelled to believe, judging from representations in sculpture and on coins, that the Greeks themselves did not so much improve the instrument as their writings would lead us to conjecture. But there now seems little doubt that the Egyptians brought the harp to a comparatively high degree of perfection: the fresco painting discovered by Bruce near the ruins of Thebes, which he thinks was executed by order of Sesostris, who reigned between fourteen and fifteen hundred years before the Christian æra, exhibits a harp so much resembling that of the present day, in form, dimensions, and ornament, that it might, upon a hasty inspection, be mistaken for one of modern manufacture. He describes it as wanting the pillar, an omission, most likely, of the painter. 'The back part, he says, 'is the sounding-board, composed of four thin pieces of wood, joined together in form of a cone, that is, growing wider towards the bottom. . . . . . . Besides that the principles on which the harp is constructed are rational and ingenious, the ornamental parts are likewise executed in the best manner. The bottom and sides of the frame seem to be veneered, or inlaid, probably with ivory, tortoiseshell, and mother-of-pearl, the ordinary produce of the neighbouring seas and deserts. It would be now impossible to finish an instrument with more taste and elegance.' This account, among others by the same, was at first received with some suspicion; but later travellers in Egypt, among whom is Denon, have vindicated Bruce and confirmed his statements. Rosellini too, one of the latest and best authorities, in his splendid work, *I Monumenti dell' Egitto*, &c., published at Pisa in 1832, has given coloured engravings of harps corresponding in nearly all respects with the instrument designed and described by Bruce, which prove beyond every reasonable doubt his fidelity in this instance, and the great superiority of the Egyptian harp over every instrument of the kind known to have been in use among the Greeks or Romans.

Many learned persons, observes M. Ginguené, are of opinion that the Europeans are not indebted to the Egyptians for the harp, notwithstanding the resemblance of the instruments used by both the former and the latter; they believe that it originated in the north, that it was introduced into England, and subsequently into Ireland, by the Saxons and other piratical hordes from the Baltic. Martianus Capella found it among the northern tribes which overran the Roman empire in the fifth century. Jones, the Welsh bard, claims for his country the possession of a harp of twenty-six diatonic notes, so early as the beginning of the sixth century, and moreover adds that musical compositions proving the validity of his claim were extant in his time, that is, about fifty or sixty years ago. But he offers no authority for the statement. The Irish were, we are persuaded, well acquainted with the harp from a very early period, and if the inquiries pursuing by Sir William Betham into the origin of their language lead to the results he not very unreasonably anticipates, it may become probable that harps of the Egyptian kind were known in Ireland long before our æra. In Bunting's *Historical and Critical Dissertation on the Harp* is an engraving and description of an antient Irish one still in being, though in an imperfect state. It had in a row forty-five strings, and an additional seven in the centre, as unisons. Its form is not unlike that of the modern instrument, but the pillar is curved outwards, and in point of workmanship the whole is remarkable 'both for the elegance of its crowded ornaments and for the general execution of those parts on which the correctness of a musical instrument depends.' Its height is 3 feet 10 inches, and the longest string is 3 feet 4 inches.

The Welsh triple-stringed harp of the present day extends from G an octave below the first line in the base, to G or A in altissimo on the *right* side; and from G, the first line in the base, to the same upper notes on the left hand; the middle row consists of the semitones of the outward rows. Hence, if the outside rows be tuned in the diatonic scale of G, each parallel note being in perfect unison, the notes of the middle row are tuned a semitone higher; 'that is, G is made sharp, &c., so that in modulating from the key of G to that of D, the performer introduces a finger between the C natural and D of the outside strings to strike C sharp, which is in the middle row.'

The harp, as a generally useful instrument, may be said to date its existence from the time when pedals were added to it. With these it is possible to modulate into all keys, and to execute any music suited to keyed-instruments. We are indebted for the present improved and nearly perfect state of the harp to the late M. Sebastian Erard, who, in 1794, took out a patent for a harp with seven pedals that rendered the chromatic scale. This was a single-action-harp, the pedals only effecting one change on the strings. In 1808 the same admirable mechanist produced his double-action harp, the pedals of which have two actions. This last is tuned in the key of C flat. By fixing the pedals in the first groove the instrument is at once transposed into C natural; and by fixing them in the second groove it is transposed another semitone higher, into the key of C sharp. The compass of the harp thus improved is from double E below the base to E in altissimo; or—



But though the harp in this highly improved stato may be used for the performance of any music written for the piano-forte, yet in executing compositions in which there is much modulation, the difficulty is of an extreme kind, and unconquerable without devoting more time to practice than ought to be bestowed on an accomplishment, however elogant and fascinating.

HARPA (Conchology). [ENTOMOSTOMATA, vol. ix., p. 455.]

HARPA'LIDÆ, an extensive family of Coleopterous insects of the section of Geodephaga, the species of which are distinguished by the tarsi of the two anterior pairs of legs being dilated in the male sex.

In these insects the tibiæ of the anterior pair of legs have always a deep notch on the inner side; the head is almost always short and rounded in front; the thorax is generally broader than long, somewhat convex, but slightly narrower behind than before, and nearly equal in width to the elytra. The body usually approaches more or less to a cylindrical form; the elytra are almost always rounded at the apex, and never truncated at this part. They are usually found under stones.

Of the family Harpalidæ, Dejean, in his 'Species Général des Coléoptères,' enumerates twenty-seven genera: others however have been discovered since the publication of that work.

The number of species known is probably upwards of five hundred.

The most convenient way perhaps of grouping the genera of this family is to take, in the first place, the form of the mentum as a guide. We then find almost all the species divided into two great groups, those in which the mentum is simply emarginated, and those in which there is a small projecting process in the middle of the emargination. Besides these there are certain species (the natural situation of which is perhaps somewhat doubtful) which have the mentum trilobed, and there are others in which the mentum is bilobed.

The various genera described by Dejean are as follows:—

Section I.—*Mentum trilobed.*

Genus 1. Pelecium (*Kirby*), containing two species, both inhabiting the Brazils.

2. Eripus (*Höpfner*), containing two species, one of which is from California· the other inhabits Mexico.

Section II.—*Mentum bilobed.*

3. Promecodorus (*Dejean*), of which there is one species from New Holland.

4. Cyclosomus (*Latreille*), containing two species, one from India, the other from Senegal.

Section III.—*Mentum emarginate, and without central tooth.*

5. Daptus (*Fischer*); two species. Found in North America.

6. Cratognathus (*Dejean*); one species. Probably from Buenos Ayres.

7. Agonoderus (*Dejean*); five species; three of which are from North America, one from India, and one from Senegal.

8. Barysomus (*Dejean*); Two species from India, and one from Mexico.

9. Amblygnathus (*Dejean*); Five species. All inhabitants of Cayenne.

10. Platymetopus (*Dejean*); Ten species. From Africa and India.

11. Selenophorus (*Dejean*); Fifty-nine species. From North and South America.

12. Anisodactylus (*Dejean*); Twenty-three species. Chiefly from Europe and North America.

13. Bradybænus (*Dejean*); Three species. From Senegal.

14. Stenolophus (*Megerle*); Twenty-two species. Almost all European.

Section IV.—*Mentum emarginate, and with a small projecting process in the middle.*

15. Cratocerus (*Dejean*); One species. From Brazil.

16. Somoplatus (*Dejean*); One species. From Senegal.

17. Axinotoma (*Dejean*); One species. From Senegal.

18. Acinopus (*Ziegler*); Six species. Chiefly European.

19. Cratacanthus (*Dejean*); Threo species. From North America.

20. Paramecus (*Dejean*); Two species. From South America.

21. Geodromus (*Dejean*); One species. From Senegal.

22. Hypolithus (*Dejean*); Eighteen species; the greater portion of which inhabit Africa. Four are from South America.

23. Gynandromorphus (*Dejean*); One species. From Italy and South of France.

24. Ophonus (*Ziegler*); Forty-five species. Chiefly European.

25. Harpalus (*Latreille*); One hundred and thirty-four species. From Europe, Asia, Africa, America, and Australia.

26. Geobænus (*Dejean*); Two species. From the Capo of Good Hope.

27. Acupalpus (*Latreille*); Forty-six species. Chiefly European. There are however species found in all the other quarters of the globe.

28. Tetragonoderus (*Dejean*); Africa, India, and South America. One species is found in North America.

29. Trechus (*Clairville*); Twenty-two species. Chiefly European.

30. Lachnophorus (*Dejean*); Four species; three of which are from South America, and one from North America.

For the characters of the genera and species above alluded to, we must refer our readers to M. Dejean's work which has been quoted, and for the British species to Mr. Stephens's *Illustrations of British Entomology*. It will be seen that we have followed the former of these authors in restricting tho family Harpalidæ to such species only as will come under the definition given at the commencement of this article. Two very distinct groups aro included in the family Harpalidæ as defined by Mr. Stephens.

HA'RPALUS. [DEMOSTHENES.]

HARPE, JEAN FRANÇOIS DE LA, was born at Paris in 1739, and educated gratis at the College d'Harcourt. He unfortunately undertook the correction of a pasquinade against one of his instructors, and was accordingly suspected of being its author, and also the author of another which was directed against the tutor who had been his greatest benefactor. In consequence he was imprisoned for nine months in the Bastile. His juvenile poems proving successful, he published a collection of them in 1762. He was fortunate with a tragedy called 'Warwick,' which he produced in the following year, but less so with two others entitled 'Pharamond' and 'Timoleon.' It was about this time that his acquaintance with Voltaire commenced. Ho now began to write éloges for the Académie, and those of Henry IV., Fenelon, and Racine wore highly commended. His poems and dramas, excepting 'Warwick,' and his translations from Sophocles, made comparatively small impression. He afterwards published his 'Lycée, ou Cours de la Littérature,' his 'Mémoires Littéraires,' and a satirical work called 'Correspondenco Turque.' At the commencement of the Revolution he was a zealous republican; but the imprisonment which he suffered from the democrats changed his politics, and he became a warm defender of the church and the monarchy. He was bold enough at the first sittings of the 'Lycée des Arts' to inveigh against the Terrorists, and he would have suffered from their vengeance if he had not escaped by flight. After the 18th Brumaire (9th November, 1799) he began anew his lectures at the Lycée. Shortly before his death his freedom of speech offended the first consul, and he was banished to Orleans. He returned to Paris soon afterwards, and died in 1803.

The reputation of La Harpe rests on his 'Lycée,' which is an invaluablo work to the student of French literature, of which it gives a complete history from its commencement to tho author's own time. The criticisms on tho different writers are not founded on principles acknowledged by the English, but perhaps the value of the book is on that account greater, as it exhibits the object of the French authors, and the standard according to which they aro to be judged when compared with each other. The philological remarks also are highly serviceable in instructing the reader in the niceties of tho language. The part relating to an tient literature is of little value.

HARPER'S FERRY. [VIRGINIA.]

HARPOCRA'TION, VALE'RIUS, a Greek rhetorician of Alexandria. We have no particulars of his life, nor of the time in which he lived. He wrote a 'Lexicon to the Ten Orators,' which contains an account of many of the persons and facts mentioned in the orations of the ten principal orators of Athens, and also an explanation of many words and phrases in their writings.

The 'Lexicon' was first printed by Aldus in 1503, with the scholia of Ulpian on the Philippic orations of Demosthenes. The work has been also published by Massac, 4to., Paris, 1614, with many notes; Blancard, with a Latin translation, Leyden, 1683, 4to.; Gronovius, 4to., 1696; W. Dindorf, Leip., 1824, 2 vols. 8vo.; Bekker, 8vo., Berlin, 1833.

Suidas also mentions another work of Harpocrates, entitled 'A Collection of Flowery Extracts,' which has not come down to us.

HARPSICHORD (originally, and with some reason, written *Harpsicon*), a keyed musical instrument, in form the same as the grand piano-forte, but smaller, strung with steel and brass wires, two to each note, which are struck by *jacks* armed with small pieces of quill, acting as plectrums, and thus made to render a brilliant but somewhat harsh sound, wholly unlike that produced by the hammers of the piano-forte. The compass of the harpsichord did not at first exceed three octaves, but by degrees reached five, from double F below the base to F in altissimo · or—

All harpsichords had *stops*, which increased or diminished the string power: they also were generally furnished with a *swell*, or a means of opening and closing the lid: and many were supplied with two rows of keys, the upper acting on a separate set of strings, which gave a very soft sound, intended as an imitation of a muted violin, &c.

The period at which the harpsichord was invented is quite uncertain. It is not absurd to surmise that the organ speedily suggested some instrument of the keyed kind, in which strings were substituted for pipes, but of that under notice there are no traces before the fifteenth century. Indeed we find no intimation of the harpsichord having been introduced into England till the early part of the seventeenth century; and in less than two hundred years it had fallen into disuse in this, as well, we believe, as in every other, country. During the present year (1838) Mr. Moscheles, wishing at his *Soirées Musicales* to perform some of the lessons of Scarlatti, Handel, and Seb. Bach on the instrument for which they were written, had great difficulty in finding, in the vast city of London, a harpsichord to enable him to accomplish his purpose.

HARPY. HARPY EAGLE. [FALCONIDÆ, vol. x., pp. 174-175.]

HARQUEBUSS. [ARMS.]

HARRIER (Ornithology), a name applied to certain Hawks (*Circus*). [FALCONIDÆ, vol. x., p. 183]; and see, among other works, Gould's *Birds of Europe*, and Yarrell's *British Birds*.

HARRIER, the English name for the hound employed in hunting the *Hare*. The size and breed of the Harrier depend upon the taste of the owner, and that is most frequently regulated by the nature of the country in which the pack is to hunt. Mr. Beckford, a great authority in such cases, says, 'The hounds, I think, most likely to show you sport are between the large slow hunting harrier and the little fox-beagle; the former are too dull, too heavy, and too slow; the latter too lively, too light, and too fleet. The first, it is true, have most excellent noses, and, I make no doubt, will kill their game at last if the day be long enough, but you know the days are short in winter, and it is bad hunting in the dark. The other, on the contrary, fling, dash, and are all alive; but every cold blast affects them, and if your country be deep and wet, it is not impossible that some of them may be drowned. My hounds were a cross of both these kinds, in which it was my endeavour to get as much bone and strength in as small a compass as possible. It was a difficult undertaking. I bred many years, and an infinity of hounds, before I could get what I wanted. I at last had the pleasure to see them very handsome; small, yet very bony; they ran remarkably well together; went fast enough; had all the alacrity that could be desired, and would hunt the coldest scent.'

Hare-hunting, it has been said, is generally followed by sportsmen in the decline of life; though when the district is tolerably open and the hare 'flies the country,' there is often opportunity for a good horse and bold rider to show themselves. But these capital runs come 'few and far between,' and the old fox-hunter can seldom brook the change. In a close or woody district, the constant repetition of the same scene, and the discovery that in consequence of a sudden double of the hare a rustic upon his galloway who knows the country is frequently as near the hounds as the man who is mounted on a first-rate hunter and has taken some daring leaps at the first burst, prove rather disgusting both to the ardour of youth and the experience of age. The rapidity, variety, and dangers of a fox-chace are more congenial to the young man and the good horse, and are not readily forgotten by the old sportsman. In most of the countries where harriers are kept, a bag-fox, or 'bagman,' as he is sometimes facetiously termed, is occasionally procured by way of giving the weary 'thistle-whippers' a taste of the nobler hunting. But the authority to which we have already referred strongly reprobates this practice. 'Harriers to be good,' says Mr. Beckford, 'like all other hounds, must be kept to their own game: if you run fox with them you spoil them; hounds cannot be perfect unless used to one scent and one style of hunting. Harriers run fox in so different a style from hare that it is of great disservice to them when they return to hare again; it makes them wild and teaches them to skirt. The high scent which a fox leaves, the straightness of his running, the eagerness of the pursuit, and the noise that generally accompanies it, all contribute to spoil a harrier.'

HARINGTON, SIR JOHN, was born at Kelston near Bath, in the year 1561. His mother was a natural daughter of Henry VIII., and his father held an office in the court of that monarch. This pair having on one occasion shown great fidelity to the princess (afterwards queen) Elizabeth, she manifested her gratitude by standing godmother to their son John. She was afterwards wont to speak of him as 'that witty fellow, my godson,' or 'that merry poet, my godson,' or in some such way.

Having been educated at Eton and at Christ's College, Cambridge, and having afterwards for a short time made a pretence of studying law, he, by means of his wit and many accomplishments, gained the notice of Queen Elizabeth, and became a member of her court. He had exercised his wit, on one occasion, in translating a tale out of Ariosto's 'Orlando Furioso,' (the story of Giacondo, in the twenty-eighth book), and he circulated this among the ladies of the court, who were greatly pleased with it. When the queen saw it, we are told that she affected great indignation at the indelicacy of some passages, and, by way of punishment, forbad Harington the court until he had translated the whole poem. This he accomplished in 1591, and dedicated it to the queen.

When the Earl of Essex was appointed Lord Lieutenant of Ireland in 1599, Harington was made a commander of horse under Lord Southampton, in his service. When Essex shortly after made his precipitate return to England, Harington was one of the few officers whom he chose to accompany him, and he came in for a share of the queen's indignation. She was angry also, we are told, that Essex had, in Ireland, conferred on Harington the honour of knighthood. 'I came to court,' writes Harington to one of his friends, 'in the very heat and height of all displeasures; after I had been there but an hour, I was threatened with the Fleet; I answered poetically that "coming so late from the land-service, I hoped that I should not be pressed to serve in her majesty's fleet in Fleet Street." After three days every man wondered to see me at liberty.' But the queen shortly relented, and then, writes Sir John in the true style of a courtier, 'I seemed to myself, for the time, like St. Paul, rapt up in the third heaven, where he heard words not to be uttered by men.' On the accession of James I. in 1602, Harington continued in possession of royal favour; for with the new monarch, who affected learning, a literary reputation was everything. He now wrote for the private use of Prince Henry his 'Brief View of the State of the Church,' which is an account of the bishops who lived in the reigns of Elizabeth and James I. He died in 1612.

Besides the translation of the 'Orlando Furioso' and the 'Brief View of the State of the Church,' which have been mentioned, Sir John Harington wrote a satirical poem entitled the 'Metamorphosis of Ajax,' a volume of epigrams, and several occasional pieces in verse, most of which have never yet been published. His epigrams and letters, many of which are preserved in Harington's *Nugæ Antiquæ*, show him to have been a man of wit and taste; and the 'View of the State of the Church' is pleasantly written. On his translation of 'Ariosto' Warton has passed the following criticism: 'Although executed without spirit or accuracy, unanimated and incorrect, it enriched our poetry by a communication of new stores of fiction and imagination, both of the romantic and comic species, of Gothic machinery and familiar manners.' (*History of English Poetry*, vol. iii., p. 485.)

The above sketch of Sir John Harington's Life is taken entirely from an account prefixed to Park's edition of Harington's *Nugæ Antiquæ*, 2 vols. 8vo., 1804.

HARRINGTON, JAMES, descended from an antient and noble family in Rutlandshire, and the eldest son of Sir Sapcotes Harrington, was born in January, 1611. He entered as a gentleman-commoner at Trinity College, Oxford, in 1629, and had there the advantage of Dr. Chillingworth's instructions. At the close of his residence at the university, during which his father had died, he set out on a course of travels; and going first to Holland, resided for some time at the Hague, where he lived on terms of familiarity with the queen of Bohemia, daughter of James I., who was then a fugitive in Holland, and with the prince of Orange. With the latter he visited the court of Denmark; and the prince of Orange subsequently confided to Harrington the management of all his affairs in England. From Holland he proceeded to France and Italy.

On his return to England, Harrington principally passed his time in retirement, cultivating the family affections and pursuing his studies in political science. But in 1646 he was requested by the commissioners whom parliament had appointed to carry king Charles I. from Newcastle nearer to London, to undertake the task of waiting on his Majesty, as being personally known to him, and as being no partisan. He complied with the request, and the manner in which he performed the task having pleased the king, he was shortly after made a groom of the bedchamber. The king now became much attached to him. 'His Majesty loved his company,' says Anthony Wood, 'and, finding him to be an ingenious man, chose rather to converse with him than with others of his chamber. They had often discourses concerning government; but when they happened to talk of a commonwealth, the king seemed not to endure it.' On the king's removal from the Isle of Wight to Hurst Castle, Harrington, who had offended the parliament commissioners at Newport, was removed from the king's service, and on his subsequently refusing to swear that he would not assist or conceal the king's escape, he was placed under arrest, and detained until an application of General Ireton obtained him his liberty. He afterwards showed his attachment to the king by accompanying him to the scaffold.

'After the king's death,' says Mr. Toland, 'he was observed to keep much in his library, and more retired than usually, which was by his friends a long time attributed to melancholy or discontent.' He was engaged however in the composition of his 'Oceana.' And when he had proceeded some way in its composition, making no secret of his views on government and of his partiality towards a commonwealth, he found that he had already brought down upon himself the suspicions both of Cromwell and of the Royalists. His book was seized, while in the press, by Cromwell's order. Harrington, having failed in other attempts to recover the book, bethought himself at last of an application to Lady Claypole, Cromwell's favourite daughter, who was personally unknown to him, but of whose affability and kindness he had heard much. Being ushered into her room, he found there at first only a child of three years old. 'He entertained the child so divertingly, that she suffered him to take her up in his arms till her mother came; whereupon he, stepping towards her and setting the child down at her feet, said, Madam, 'tis well you are come at this nick of time, or I had certainly stolen this pretty little lady. Stolen her, replied the mother, pray what to do with her? for she is yet too young to become your mistress. Madam, said he, though her charms assure her of a more considerable conquest, yet I must confess it is not love but revenge that prompted me to commit this theft. Lord, answered the lady again, what injury have I done you that you should steal my child? None at all, replied he, but that you might be induced to prevail with your father to do me justice, by restoring my child that he has stolen. But she urging that it was impossible, because her father had children enough of his own, he told her at last it was the issue of his brain which was misrepresented to the Protector, and taken out of the press by his order.' Harrington's wit fascinated the lady, and through her intercession he succeeded. Cromwell afterwards read the book, which, according to promise, had been dedicated to him, and professed to admire it.

The 'Oceana' on its appearance excited great attention. Answers were published, and those Harrington in turn answered. Richard Baxter's 'Holy Commonwealth' was written principally against the 'Oceana;' but so far was this work from gratifying the party for whose favour it was designed, that in 1683 it was publicly burnt by a decree of the University of Oxford, together with some of the writings of Hobbes and Milton, and other works, among which however the 'Oceana' was not included. In 1659 Harrington published an abridgement of the 'Oceana,' under the title of the 'Art of Lawgiving;' and he subsequently published several tracts, many of which are quite of a temporary nature, and the others devoted more or less to the same subject as the 'Oceana.' He had also founded a club, called the Rota Club, at which he gave nightly discourses on the advantage of a commonwealth and of the ballot. The club was broken up after the Restoration. But the members of the club had become marked men.

On the 28th of December, 1661, he was seized by order of the king on a charge of treasonable designs and practices, and was carried to the Tower. He was at first ignorant of the precise charge against him; but on a private examination taken by Lord Lauderdale, Sir George Carteret, and Sir Edward Walker, it came out that he was suspected of having taken part in a conspiracy to subvert the monarchy and establish a commonwealth. He stoutly denied all cognizance of the proceedings which those gentlemen with great show of circumstance and detail attributed to him; but his denial was set down, it appears, to faithfulness to an oath. He subsequently presented through his sisters several petitions to the king, praying that he might either be released from confinement or brought to a public trial. Having received no answer to his petitions he made application for a Habeas Corpus; and shortly after this had been granted he was removed without previous notice, and without any communication being made to his friends, to a rock opposite Plymouth, called St. Nicholas's Island. His close confinement here soon produced an effect upon his health, and upon petition he was allowed to be removed to Plymouth. Shortly after he became deranged, owing, it is supposed, to a medicine recommended to him for the cure of the scurvy. Lord Bath, the governor of Plymouth, then made intercession with the king, and Harrington was released from imprisonment. On being removed to London, and obtaining the best medical advice, he rallied considerably as regards bodily health, but his mind was never again right. At his advanced age, and in this unsatisfactory state of health, he married. He died of palsy on the 11th of September, 1677, in the sixty-seventh year of his age.

The 'Oceana,' which is Harrington's chief work, is an imaginary account of the construction of a commonwealth in a country of which Oceana is the imaginary name. It opens with an exposition of the grounds and arguments for a commonwealth; and the principles which are there established are afterwards sought to be applied in detail. Harrington lays great stress on a doctrine which he enunciates thus: that dominion follows the balance of property; by which he means that the form of government in a state must depend on the mode in which property is distributed therein. Proceeding on this doctrine, he requires what he calls an equal Agrarian law as the foundation of his commonwealth. Its other chief features are popular election of councillors by ballot, and the going out at certain periods of a certain number of these councillors, which is also managed by ballot. Harrington is a very powerful advocate of the plan of vote by ballot.

HARRIOT, THOMAS, an eminent mathematician and astronomer, was born at Oxford in the year 1560. He took his degree of Bachelor of Arts in 1579, and in 1584 he accompanied Sir Walter Raleigh in his expedition to Virginia, where he was employed in surveying and mapping the country, and upon his return to England in 1588 he published his 'Report of the Newfoundland of Virginia, the commodities there found to be raised, &c.' Harriot was introduced by Sir Walter Raleigh to the earl of Northumberland, whose zeal for the promotion of science had led him to maintain several learned men of the day, such as Robert Hues, Walter Warner, and Nathaniel Tarporley. This enlightened nobleman received Harriot into his house, and settled on him an annual salary of 300*l.*, which he enjoyed to the time of his death, in July, 1621. His body was interred in St. Christopher's Church, London, and a monument erected to his memory, which, with the church itself, was destroyed by the great fire of 1666. During his lifetime Harriot was known to the world merely as an eminent algebraist; but from a paper by Zach in the 'Astronomical Ephemeris' of the Royal Academy of Sciences at Berlin for the year 1788, it appears that he was equally deserving of eminence as an astronomer. The paper referred to contains an account of the manuscripts found by Zach at the seat of the earl of Egremont, to whom they had descended from the earl of Northumberland. From it we learn that Harriot carried on a correspondence with Kepler concerning the rainbow; that he had discovered the solar spots prior to any mention having been made of them by Galileo, Scheiner, or Phrysius: also that the satellites of Jupiter were observed by him January 16, 1610, although their first discovery is generally attributed to Galileo, who states that he had observed them on the 7th of that month. A correspondence with Kepler on various optical and other subjects is printed among the letters of Kepler. Ten years after Harriot's death his algebra, entitled 'Artis Analyticæ Praxis, ad Æquationes Algebraicas nova, expedita, et Generali Methoda, resolvendas,' was published by his friend Walter Warner. It is with reference to this particular work that Des Cartes was accused of plagiarism by Wallis, whose admiration of its author was so high, that he could not even see the discoveries of Vieta anywhere but in the 'Praxis' of Harriot. This charge however has sunk with time, though the French writers still continue to answer it. The geometry of Des Cartes appeared in 1637, six years after the publication of Harriot's algebra. (Hutton's *Dictionary; Mathematical Tracts*, vol. ii., &c.; and Montucla's *Histoire des Mathématiques*, tom. ii., p. 105.)

HARRIS, JOHN, D.D., born about 1667, died Sept. 7, 1719, a voluminous writer, in the list of whose works we find numbers of sermons, treatises on algebra and fluxions, geometry, trigonometry, astronomy, and navigation. He also wrote, 'Remarks on some late papers relating to the Universal Deluge and the Nat. Hist. of the Earth;' 'Navigantium atq. Itinerantium Bibliotheca, or a complete collection of Voyages and Travels,' &c., 1705, 2 vols. fol., reprinted with additions and corrections in 1744 and 1764; 'Lexicon Technologicum, or an Universal English Dictionary of the Arts and Sciences, explaining not only the terms of Arts, but the Arts themselves,' 2 vols. fol., 1704-10. From this, says Watt, 'have originated all the other dictionaries of arts and science and cyclopædias that have since appeared;' and it is as the originator of this important and useful class of works that his memory best deserves to be preserved. [DICTIONARY.] 'History of Kent,' 2 vols. fol., 1719. Harris was secretary and vice-president of the Royal Society, and possessed considerable church preferment, but was reduced to poverty by neglect of his affairs. He died in want, and was buried at the expense of his friends.

HARRIS, JAMES, born July 20, 1709, was the eldest son of James Harris, Esq., of Salisbury, by the Lady Eliz. Ashley Cooper, sister of Lord Shaftesbury, the author of the 'Characteristics.' He was educated at the grammar-school in his native place, and passed thence to Wadham College, Oxford. In his twenty-fifth year he lost his father, and thereby became independent in fortune, and able to devote his time to studies more congenial to his taste than the law, in which he had been engaged. For fourteen years of his life he did little else than study the Greek and Latin authors with the greatest diligence, and his works show how deeply imbued he was with their spirit. In 1745 he married the daughter of John Clarke, Esq., of Sandford, near Bridgewater, by whom he had five children. In 1761 he was returned for Christchurch, which seat he retained till his death. In 1762 he was appointed to the post of a lord of the Admiralty, and next year to that of a lord of the Treasury, which he held for two years, when his party went out of office. In 1774 he became secretary and comptroller to the queen. He died in 1780.

Harris is best known by his 'Hermes, or a Philosophical Inquiry concerning Language and Universal Grammar,' a work which Lowth characterized as one of the most beautiful pieces of analysis which had appeared since the days of Aristotle. He begins by defining grammar, and giving Bacon's distinction between literary and philosophical or universal grammar, turns directly to the latter, which he proposes to treat in two ways; first, by dividing speech into its constituent parts; and secondly, by resolving it into its matter and form. In pursuing the former inquiry he determines speech to consist of sentences, and these sentences to be resolvable into two grand classes, those which refer to our perceptions, and those which refer to our will; the first including all forms of assertion, the other all forms of command. A sentence he defines, with Aristotle, to be 'a compound quantity of sound significant of which certain parts are themselves also significant, and these parts or words to be 'sounds significant of which no part is of itself significant.' Giving instances of words, he says that in the sentence '*the sun shineth*,' the words *sun* and *shineth* have each a meaning; but that there is 'certainly no meaning in any of their parts, neither in the syllables of the one, nor in the letters of the other.'

Going next to words, he divides them into those significant by themselves, and those significant by relation. The former class, he observes, are significant either of substances or of attributes; the latter from being associated either with one word or with more. Hence he arrives at four species of words, substantives, attributives, definitives, and connectives, which he further explains by giving them the better-known names of noun, verb, article, and conjunction. Substantives he divides into primary and secondary, or nouns and pronouns; the first of which denote things general, special, or particular. On arriving at attributives, which include adjectives, verbs, and participles, he finds it necessary to qualify his assertion that there is no meaning in the parts of words, which he does by saying that the verb *is* becomes a latent part in every other verb, so that *riseth* means *is rising*, and *writeth*, *is writing*. The contemplation of the verb brings him to a discussion of the nature of time, in which he stops just short of the conclusion that it only exists in the mind, but does not quite arrive at it. His argument in this, as well as in many other parts of his book, is taken nearly word for word from Aristotle. In the matter of tenses his exposition is very intelligible, founded on the distinction between absolute and relative time; but when we get to number and person, all he tells us is that they are '*supposed* affections of the verb,' of which 'the most that can be said is that verbs, in the more elegant languages, are provided with certain terminations, which respect the number and person of every substantive, that we may know with more precision, in a complex sentence, each particular substance, with its attendant verbal attributes.' As verbs consist of an attribute, time, and an assertion, by abstracting the last we get a participle, and by abstracting the two last an adjective. Furthermore we have attributives of attributives, or adverbs, which concludes the subject of attributes.

Definitions, or articles, cost him very little trouble, and he passes thence to connectives, or conjunctions and prepositions. What he says on this subject is not so satisfactory as might be wished, as, in defining a conjunction to be a part of speech void of signification itself, but so formed as to help signification, he makes an assertion very hard to understand under any known meaning of the words in which it is couched. This brings us to the end of the second book. The third treats of the matter or sound, and the form or meaning of language, and under the latter head he defines a word to be 'a voice articulate and significant by compact:' under which definition we are at a loss to know, first, how it can include those words which he has before asserted to be without signification; and secondly, by what communication that compact was instituted through which we now derive our only channel of communication.

Having now got through the subject-matter of his essay, he concludes it by a rapid glance at the genius of different languages; and in his admiration of the Greek, what scholar is there who will not go along with him?

The real merit of this work of Harris is perhaps best expressed in the following few words from the first sentence of his sensible preface: 'The chief end proposed by the author of this treatise in making it public has been to excite his readers to curiosity and inquiry.' A careful perusal of the treatise cannot fail to make a man think more accurately, though he may, as he ought to do, reject some of the writer's premises.

Harris's 'Hermes' was published in 1751. Some years before, he had written three treatises, on Art, on Music, Painting, and Poetry, and on Happiness; and in 1775 he published his 'Philosophical Arrangements,' a part of a large work on tho Aristotelian Logic. His last work is called 'Philological Enquiries;' it does not however answer to its title, as it is in fact a history of literature subjoined to dissertations on criticism. It is considerably interlarded with quotations from the authors of antiquity, but not nearly to such an extent as his other works.

His private character appears to have been excellent, and his son's admiration for him proves that his moral nature was so perfect as to secure the respect of those who had the best possible opportunity of judging it. It rarely happens, let a man deceive the world ever so completely, that he succeeds in deceiving his own children.

HARRISON. [HOLINSHED.]

HARRISON, JOHN, was born at Faulby, near Pontefract, in Yorkshire, in the year 1693. He was the son of a carpenter, which profession he also followed during several years. In 1700 the family removed to Barrow, in Lincolnshire. Harrison early displayed an attachment to mechanical pursuits, and his attention was particularly directed to the improvement of clocks. After many failures and many minor improvements, he at length succeeded in constructing a pendulum, the excellence of which depended on the different degrees in which metals are expanded or contracted by variations of temperature. This important principle is now employed in the construction of the balance-wheels of chronometers, and is that on which the accuracy of those timekeepers mainly depends. [CHRONOMETER.]

In the year 1714 an act was passed offering a reward of 10,000*l*., 15,000*l*., and 20,000*l*. respectively, for a method of ascertaining the longitude within 60, 40, or 30 miles. In 1735 Harrison came up to London with a timepiece which he had constructed. Having obtained certificates of its excellence from Halley, Graham, and others, he was allowed, in 1736, to proceed with it to Lisbon in a king's ship, and was enabled to correct the reckoning a degree and a half. On this the commissioners under the act gave him 500*l*. to enable him to proceed with his improvements. After constructing two other timepieces, he at last made a third, which he considered sufficiently correct to entitle him to claim a trial of it, and the commissioners accordingly, in 1761, sent out his son William in a king's ship to Jamaica. On his arrival at Port Royal, the watch was found to be wrong only $5\frac{1}{10}$ seconds; and on his return to Portsmouth, in 1762, only 1 minute $54\frac{1}{2}$ seconds. This was sufficient to determine the longitude within 18 miles, and Harrison accordingly claimed the reward. After another voyage to Jamaica and some further trials, an act was passed, in 1765, which awarded the 20,000*l*. to Harrison, one-half to be paid on his explaining the principle of its construction, the other half as soon as it was ascertained that the instrument could be made by others. After some delays and disputes, Harrison, in 1767, received the whole sum of 20,000*l*.

Next to the principle of the different expansibility of metals, which is applicable both to the pendulums of clocks and the balance-wheels of watches, the most important of the many inventions and improvements which in the course of fifty years he introduced, is perhaps that of the *going fusee*, by which a watch can be wound up without interrupting its movement.

He died at his house in Red Lion-square in 1776, in his 83rd year. His phraseology is said to have been uncouth. On mechanics and subjects connected with that science he could converse with considerable clearness; but he found great difficulty in expressing his sentiments in writing, as is evident in his 'Description concerning such Mechanism as will afford a nice or true Mensuration of Time.' In the last volume of the *Biographia Britannica*, published in 1766, there is a memoir of Harrison drawn up from materials furnished by himself. See also Hutton's *Mathemat. Dict.* and the *Gallery of Portraits*, vol. v., p. 153.

HARROW. [MIDDLESEX.]

HARROWGATE. [YORKSHIRE.]

HARRY, BLIND, as he was commonly called, or *Henry the Minstrel*, lived towards the close of the fifteenth century. Major, the Scottish historian, remembered him to have been alive in his own boyhood, and he was born about the year 1470, according to Warton. The work for which Blind Harry is celebrated is a poem on the adventures of Wallace. It is in eleven books, in the heroic metre. Readers of Walter Scott will remember a note to one of his poems where he relates from Blind Harry the account of Wallace's meeting with Fawdoun in the 'Gask Hall.' There are many other very spirited descriptions in the poem, particularly those of fighting and war. Blind Harry is chiefly remarkable as affording a modern and true parallel to the account, true or false, which we have of Homer. (Warton, vol. i.; *The Bruce and Wallace*, by Jameson, preface passim.)

HARTE, WALTER, was educated at Marlborough school and Oxford. The dates of his birth and academic life are uncertain; he seems to have been born about 1700, and to have graduated as M.A. of St. Mary Hall, January 21, 1730, according to the Catalogue of Oxford Graduates. At an early age he became acquainted with Pope, whose style he imitated; and in return the great poet corrected his admirer's verses. With this advantage Harte published 'Poems on Several Occasions,' 1727; 'Essay on Satire,' 1730; 'Essay on Reason,' 1735, to which Pope is said to have contributed very considerably; 'Essay on Painting,' date unmentioned; 'The Amaranth,' 1767, his last work. As a poet however he is not distinguished from other once successful but now forgotten imitators; but he has made a valuable addition to our literature in his 'History of the Life of Gustavus Adolphus,' 2 vols. 4to., 1759; republished in 8vo., corrected and improved, in 1763. An affected, harsh, and pedantic style has done much to throw discredit and neglect on this laborious and able work. It is translated into German, with preface, notes, and corrections by J. Gottl. Böhme, and, if the translator has done his work well, will probably appear to most advantage in its foreign garb. Harte left unfinished, in MS., a 'History of the Thirty Years' War.' The account of his life is soon told. He took orders, acquired reputation as a preacher, was appointed Principal of St. Mary Hall, and through the interest of Lord Chesterfield, whose son's tutor he had been, canon of Windsor. He died at Bath in 1774. (*Biog. Univ.*)

HARTLEPOOL. [DURHAM.]

HARTLEY, DAVID, was born on the 30th of August, 1705, and was the son of a clergyman of Armley in Yorkshire. Having been first educated at a private school, he entered, at fifteen years of age, at Jesus College, Cambridge, and became in time a Fellow of that society. Scruples which would not allow him to subscribe the Thirty-nine Articles prevented him from afterwards entering the church, as had been originally intended: and he applied himself to the medical profession. In this profession he practised with success, and attained to considerable eminence.

He commenced the composition of the work by means of which he has become universally known, the 'Observations on Man, his Frame, his Duty, and his Expectations,' at the age of twenty-five. It had been the subject of his thoughts even previously to this. He tells the world in his Preface, that the fundamental idea of the work, the possibility of explaining all states of mind by association, was first suggested to him by Mr. Gay's admirable 'Essay on the Fundamental Principle of Virtue or Morality,' prefixed to Law's translation of Archbishop King's 'Origin of Evil.' Having been begun so early as 1730, the work was not finished until sixteen years after; and it was ultimately published in 1748. It had constantly occupied his thoughts during the best and most important period of his life; and when his labour was completed, and his work had been given to the world, he felt, as it were, that he had performed his part, and that he might now rest. He lived nine years after the publication of his work.

Dr. Hartley was twice married, and had children by both marriages. He practised medicine successively at Newark, Bury St. Edmunds, in London, and at Bath, where he died on the 25th of August, 1757, at the age of fifty-two years. Combining as he did with his profession the pursuit of learning, he enjoyed through life the friendship of many distinguished literary men of his time. Among these may be mentioned Bishops Law, Butler, Warburton, and Hoadley, Dr. Jortin, Young the poet, and Hooke the Roman historian. One of his children thus writes concerning the qualities of mind and heart which endeared Dr. Hartley to his private friends: 'His thoughts were not immersed in worldly pursuits or contentions, and therefore his life was not eventful or turbulent, but placid and undisturbed by passion or violent ambition. From his earliest youth his mental ambition was pre-occupied by pursuits of science. His hours of amusement were likewise bestowed upon objects of taste and sentiment. Music, poetry, and history were his favourite recreations. His imagination was fertile and correct, his language and expression fluent and forcible. His natural temper was gay, cheerful, and sociable. He was addicted to no vice in any part of his life, neither to pride, nor to sensuality, nor intemperance, nor ostentation, nor envy, nor to any sordid self-interest: but his heart was replete with every contrary virtue. The virtuous principles which are instilled in his works were the invariable and decided principles of his life and conduct.'

In an article like the present nothing more than the most general notion can be furnished of the character and object of Hartley's great metaphysical work. Its chief end and its great achievement is the application of the principle of association to all our states of mind, or, as he himself calls them not perhaps very happily, 'our intellectual pleasures and pains.' But before proceeding to set forth and apply the principle of association, he attempts to explain physically sensations and ideas, which he resolves into vibrations of the medullary substance. The first hints of this his doctrine of vibrations were derived, he tells us, from Sir Isaac Newton; but, while such speculations as these do not properly belong to the province of the psychologist, it is obvious that they can never rest upon any better foundation than conjecture. The commencement therefore of Hartley's work detracts from rather than enhances its value. But the doctrine of vibrations being dismissed, the principle of association, of which little more than hints had previously been given by Hobbes and Locke, is explained and applied by Hartley with a fulness and acuteness which will ever render the work valuable. The second part of the work is wholly occupied with natural and revealed religion.

HARTSHORN, the horn of the Cervus Elaphus, the common stag [Deer], which has a place in the pharmacopœia because it contains less earthy matter, and more gelatine, than other bones. It is kept in the form of shavings, of which a sufficient quantity boiled in water yields a jelly suitable to convalescents, which may be flavoured with lemon-juice or wine, &c.; but there is no proof that it is superior to jelly made from calves' feet. It is sometimes a useful addition to milk for young children, but it possesses no alkaline properties, and the further addition of a little lime-water is often necessary to fit it for irritable stomachs.

HARTSHORN, SPIRIT OF. [Ammonia, *Carbonates*.]

HARUN AL RASHID. [Abassides.]

HARUSPICES, a class of priests in antient Rome, whose principal duty was to inspect the entrails of the victims which had been sacrificed, and thereby to foretel future events. They also interpreted various phenomena, such as lightning, earthquakes, &c. (Cicero, *Cat.*, iii. 8.; *Div.*, i. 41.) This art, called *Haruspicina*, was derived from Etruria, where it is said to have been discovered by one Tages. (Cic., *Div.*, iii. 23.) The Romans used frequently to send their children to Etruria in order to be instructed in this art (Cic., *Div.*, i. 41); and Etrurian haruspices often practised their profession in Rome. The duties of the Haruspices in many respects resembled those of the Augurs; but they were not reckoned so important, and they never acquired that political influence which the Augurs possessed. (Augurs.) They were formed into a college or corporation at Rome, of which the chief was called 'Summus Haruspex,' or 'Magister Publicus.' Their art fell into disrepute amongst the well educated Romans in the later times of the republic. Cicero ridicules their pretensions of foretelling future events, and relates a tale of Cato, who used to say that he wondered how one haruspex could meet another without laughing. (Cic., *Div.*, ii. 24.) The Emperor Claudius wished to revive the study; and under his directions a decree of the senate was passed for that purpose (Tac., *Ann.*, xi. 15); but it probably produced little effect.

HARVEST is a most important period to the husbandman. When by his skill and industry the ground has been well prepared to receive the seed, and every circumstance has been favourable to the growth and ripening of his crops, he may be deprived of a great portion of his reward by an unseasonable time of harvest. Although the state of the weather is beyond his control, he may, by an attentive observation of the usual changes at particular periods of the year, anticipate its influence in any particular situation. The precautions which are necessary in a northern climate, where the fruits of the earth come late to maturity, would be superfluous in more southern latitudes. It is from the inhabitants of northern and mountainous countries that we are likely to learn the means of obviating the effects of an unfavourable season and a late harvest.

In those southern climates where the heat and want of moisture are not too great for the growth of corn, the only care of the farmer is to procure hands sufficient to reap it. The heat of the sun and air soon dry the straw, and harden the grain. A spot is levelled in the field, and the corn is threshed out immediately, either by the tread of cattle driven over it, or by the flails of numerous threshers. The corn is winnowed and stored in granaries; and the straw is reserved till winter, when it forms the chief fodder of horses and cattle. In these regions the harvest is a continued feast; no ungenial weather disappoints the hopes of the husbandman. But in northern climates, where the harvest is later, and cold rains and storms are frequent in autumn, the ingenuity is often taxed to save the corn from being entirely spoiled, after it has been severed from the ground; roomy barns are erected to secure it in the straw, till it can be threshed; and the joy of harvest is frequently interrupted by the anxiety which is the consequence of sudden changes of weather.

To lessen the casualties of harvest in a moist climate, the experienced husbandman endeavours to arrange the time of sowing each kind of grain, so as to insure its coming to maturity in a regular succession. Thus he has more time to attend to the precautions of which experience has taught him the utility; and if the duration of harvest is longer, there is less danger of all his crops being spoiled by a wet season.

It was long the custom through the whole of the north of Europe to store all the produce of the farm into barns, especially the corn; and it was thought that as soon as the sheaves were collected under a roof, all danger was past The increase of the produce raised on most lands by an improved system of agriculture gave rise to the practice of stacking corn in the open air, and securing it by a covering of thatch. It was soon found that the grain thus stored in the straw was better preserved than that which was in the barn; and the invention of stone, or cast-iron pillars, as supports for the frames on which the grain was stacked, not only secured it from the depredations of vermin, but kept it in a much drier state than when stacks were made on the ground. This was a great improvement; and now, in the best managed farms, the only barns required are those in which the corn is threshed; and if there is sufficient room to hold the contents of one stack of the usual dimensions, it is all that is absolutely required.

The want of room in the barns was probably one of the reasons why the reapers were permitted to cut the straw half-way between the ear and the root, leaving more than half the straw in the field. Another reason also was the profusion of weeds which grew amongst the corn, and which retarded its drying, by retaining the wet much longer than the ripe straw. It was thought also that the seeds of weeds were thus prevented from mixing with the grain in the threshing, and giving more trouble in the winnowing. The usual prohibition against selling any straw also made the farmers less careful to secure the whole. The stubble was mown after harvest, and formed into broad walls, called in some places *haulm-walls*, round the yards where the cattle were fed in winter, for the double purpose of fodder and shelter. But it is evident that this practice is defective; there can never be too much straw to be converted into manure by the dung and urine of cattle, and what is left as stubble is much wasted before it is mown and carried into the yard. The seeds of noxious plants remain on the land, whereas they would be much more effectually destroyed if they were stacked with the corn. The subsequent separation of them is a very trifling additional labour, where a winnowing machine is in use. It may therefore be admitted as a general rule in reaping, to cut the straw as near to the ground as possible: this is best done by an instrument called a *cradle scythe*, which mows the straw, and collects it so as to be readily gathered into sheaves.

The Hainault scythe has a very short handle, and is used with one hand, while the other collects the straw into a sheaf by means of a large hook at the end of a wooden rod. It is a most useful instrument, and greatly preferable to the fagging-hook in use in Middlesex and the neighbouring counties, where straw is valuable and sells at a high price. It cuts more straw at each stroke, and is less fatiguing to the reaper, because his position is nearly upright when he uses it. In many places it is not usual to tie up any corn into sheaves, except rye, wheat, and beans. Barley and oats are usually mown, raked into heaps, and carried into the stack or barn when dry, like hay; but this is a slovenly practice, which should not be recommended. With good tillage and proper manuring the straw of barley and oats will be strong, and of sufficient length to require being tied up into sheaves; and much less of the grain is shaken out and lost in this way than by the usual method.

In rainy seasons it frequently happens that the sheaves remain a long time in the field before they are sufficiently dry to be carried and stacked. If the ears are not secured from the wet they become soaked, and the grain sprouts in the ear. This is a great loss; for sprouted grain is very inferior, and can only be sold at a low price. A little attention will often prevent the bad effect of rains. In some places six or eight sheaves are set up in a circle, with the butt-ends diverging, so as to admit the air to circulate among them; a sheaf is opened by spreading out the ears, and is placed inverted over the ears which lean against each other, forming a truncated cone. Thus the butt-end of the top sheaf is the only part in which the rain can lodge; and the first sunshine will soon dry this: the rain runs off the sides of the inverted sheaf, and the ears, pointing downwards, will not long retain the wet.

When the stack is building, the butts of the sheaves are placed outwards, and project gradually over the sides of the frame, and over one another, so as to build the stack in the form of a bowl, with a cone or pyramid over it, according as the frame is round or square; this is carefully thatched with straw, and the outer surface is cut smooth by means of shears. This not only saves all the ears which chance to lie outwards, and which would have become the prey of birds, but it also prevents the rain from beating into the stack and injuring the corn. It may then be considered as safe.

Where there are no raised frames, and the stack is built on the ground, or on a bottom made of faggots to keep it dry, a belt of plastering or stucco is sometimes laid, a foot wide, round the stack, about 18 inches from the ground, after the surface has been cut quite smooth and even. This contrivance is intended to prevent the rats from lodging in the stack, and it is very effective. A frame made entirely of iron, and supported upon iron columns, has lately been invented. It may be readily taken to pieces and put together again when it is wanted. The advantage of it is, that it is cheaper and more easily moved than any other; and it is very convenient for a temporary purpose.

Harvest is proverbially a joyous time, and one when hospitality is practised with more good-will than at any other season. The custom of giving a supper to the harvest men and women, when the last corn is carried, has been observed from time immemorial; and it is much to be regretted that in many farms it is now omitted, or a mere gratuity is given instead. The community of good feelings which ought ever to exist between the master and his servants or labourers, is most effectually kept up by occasional friendly intercourse; and a harvest-home supper was formerly a kind of Saturnalia in which every exuberance of spirit was allowed without fear of offence. The anticipation of it was an incitement to exertions in the field; and the farmer was amply repaid the expense which the feast occasioned. The stimulus of strong beer is still applied at harvest, and frequently to such a degree as to defeat its own object. In some places the labourers have a certain sum in addition to food *to finish* the harvest, whether it is a longer or shorter time. In others they have the usual weekly wages, and a gratuity at the end, with plenty of beer so long as it lasts: accordingly as labourers are abundant or not, the price is less or greater. Many thousands of Irishmen come over to England and Scotland in the time of harvest, and are of great use in finishing it in a short time.

HARVEY, WILLIAM, was born at Folkstone on the 1st of April, 1578, and after having been some years at the grammar-school of Canterbury, was admitted at Caius College, Cambridge, in the year 1593, being then in his sixteenth year. Having devoted himself to the study of logic and natural philosophy for six years in that university, he removed to Padua, at that time a celebrated school of medicine, where he attended the lectures of Fabricius ab Aquapendente on anatomy, of Minadous on pharmacy, and of Casserius on surgery. He was admitted doctor of medicine there, and returned home at the age of twenty-four. At thirty he was elected fellow of the College of Physicians, and shortly after appointed physician to St. Bartholomew's Hospital. On the 4th of August, 1615, he was chosen by the College to deliver the Lumleian lectures on anatomy and surgery, and upon this occasion he is supposed to have first brought forward his views upon the circulation of the blood, which he afterwards more fully established, and published in 1628.

The importance of this great discovery was such, that it will be necessary to investigate from the writings of the author the steps by which it was attained. We are informed by Boyle in his 'Treatise on Final Causes,' that in the only conversation which he ever had with Harvey, he was told by him that the idea of the circulation was suggested to him by the consideration of the obvious use of the valves of the veins, which are so constructed as to impede the course of the blood from the heart through those vessels, while they permit it to pass through them to the heart. Before the time of Harvey the opinions on the circulation were numerous and inconsistent. The blood was supposed to be distributed to the various parts of the body by means of the veins, and that intended for the nutrition of the lungs by the action of the right side of the heart. According to the same doctrines the arteries were destined for the conveyance of the vital spirits, which were formed in the left side of the heart from the air and blood derived from the lungs. These vital spirits were supposed to be taken in by the arteries during their diastole, and distributed by them during their systole, whilst the vapours or fuligines, as they are called by Harvey, were returned to the lungs by the action of the left ventricle. Opinions did not agree upon the mode in which the blood found its way to the left side of the heart, for whilst some supposed that it was conveyed with the air from the lungs, others maintained that it transuded by certain imaginary pores in the septum between the ventricles. These opinions, it is evident, rested more upon imagination than any careful observation of facts. Those of Harvey, on the contrary, were drawn from the most accurate dissections of dead and living animals, and supported by arguments depending entirely upon the anatomical structure and obvious uses of the parts. The result of these observations is thus stated by him. The heart has periods of action and of rest, but in warm-blooded animals its motions are so rapid, that the different steps of them cannot be distinguished. In cold-blooded animals they are more slow, and in warm-blooded also after the examination of its action, by opening the chest in a living animal, has been continued some time. During its action the heart is raised, and its point tilted forward so as to strike against the parietes of the chest. It contracts in every direction, but more especially on its sides; it also becomes harder, as other muscles do during their contraction. In fishes and cold-blooded animals the heart may be observed to become paler during its systole, and assume a darker colour during its diastole. If a wound be made in the ventricle, the blood is ejected from it during its contraction From these facts Harvey concluded that the essential action of the heart is its systole, and not its diastole, as was supposed by physicians before his time, and that the result of this contraction is the expulsion of the blood into the pulmonary artery and aorta. The diastole of the arteries or pulse is synchronous with and caused by the propulsion of the blood during the systole of the ventricle, and is a passive, and not, as was previously supposed, an active operation of the vessels. If the motions of the heart be carefully observed for some minutes, it will be seen first that the two auricles contract simultaneously, and force the blood contained in them into the ventricles; and secondly, that the ventricles in their turn assume the same action, and propel most of the blood into the pulmonary artery and aorta, from which it is prevented from returning by the valves situated at the entrance of those vessels. The author next proceeds to describe the manner in which the blood passes from the right to the left side of the heart.

During fœtal life, says he, this is sufficiently evident. Part of the blood passes directly from the right to the left auricle through the foramen ovale, whilst the rest is conveyed into the right ventricle, and by its contraction forced into the pulmonary artery, and so through the ductus arteriosus into the descending aorta; for, as he observed, the lungs do not admit of its passage through them in the fœtus. In the adult a new condition is introduced, namely the function of the lungs, by which, as Harvey observed, the question was so much obscured that physicians were unable to give a correct explanation of the phenomena. However the consideration of the obvious use of the valves of the pulmonary artery had led Galen to maintain that a portion of the blood contained in that vessel passed through the lungs into the pulmonary veins, but this passage he supposed to depend more upon the action of the lungs themselves than of the heart. Harvey carried out this argument still further, and maintained from it that the whole of the blood which is propelled from the right side passes through the lungs to the left side of the heart. In like manner he showed that the blood is propelled from the left ventricle into the arteries and so distributed to all parts of the body. He next proceeded to give approximate calculations of the quantity of blood which passes from the veins through the heart in a given time. This he showed to be so much more than is required for the nutrition, or can be supplied to the veins by the absorption of alimentary substances, that the surplus must of necessity return through the various tissues of the body to the veins again. He then argued from the construction of the valves of the veins that the course of the blood in them must be from the smaller to the larger divisions, and thus to the heart again. These views he still further confirmed by reference to the now well-known effects of ligatures placed on a limb with different degrees of tightness. If the ligature be so placed as to compress the veins alone, they become swelled and tumid beyond the ligature, and quite empty between it and the heart, whilst the pulsations of the artery remain unaltered. If it be drawn a little tighter the pulsations of the artery cease beyond, but are felt more violent than usual just within the ligature.

Such is a brief abstract of the principal steps in this the greatest and most original discovery in physiology, which was so directly opposed to all the previous notions of physicians, that its author might well observe, 'Adeo nova sunt et inaudita ut non solum ex invidiâ quorundam metuam malum mihi, sed verear ne habeam inimicos omnes homines: tantum consuetudo aut semel imbibita doctrina altisque defixa radicibus quasi altera natura, apud omnes valet, et antiquitatis veneranda suspicio cogit.' This anticipation proved correct; for Harvey afterwards complained to one of his friends, that his practice fell off considerably after the publication of his treatise 'On the Circulation of the Blood,' and it is well known that the doctrine was not received by any physician who was more than 40 years old. His opinions were violently opposed by Primirosius, Parisanus, Riolanus (1645), and others. Parisanus was ably refuted by his friend Dr. George Ent, Fellow of the College of Physicians, and other advocates of Harvey's views appeared on the Continent. The only man who was honoured by a reply from Harvey himself was Riolanus, professor of anatomy in Paris, in answer to whom he published two letters. In 1652 Harvey had the satisfaction of seeing one of his early opponents, Plempius, professor at Louvain, declare himself a convert to his opinions, and by his example many more were induced to withdraw their opposition. In the whole of this controversy, says Sprengel (*Hist. of Med.*, sect. xii., c. 1), the discretion and rare modesty of Harvey afford the best model for naturalists and scientific writers. Harvey had been so much disgusted by the disputes in which he was involved on the publication of his views on the circulation of the blood, that he had determined to publish nothing more, and it was only at the earnest request of his friend Dr. Ent that he was induced to allow his 'Exercitationes de Generatione' to be printed. This work consists partly of a commentary upon the writings of Aristotle and Fabricus ab Aquapendente on the same subject, and partly of details of his own observations and experiments. The earlier 'Exercitationes' contain a description of the organs of generation in the common fowl, of the formation of the egg and its extrusion from the body, and of the use and nature of its various parts, as well as the changes which it undergoes during the process of incubation. He then proceeds to enter upon some discussions on the nature of the act of generation, and of the degree in which the male and female respectively contribute to its performance, in the course of which he examines the opinions of Aristotle upon this abstruse subject, and advances some of his own. The concluding treatises contain a description of the analogous processes in the deer.

Without venturing upon an abstract of the whole contents of these papers, we shall endeavour to give some idea of the knowledge possessed by Harvey, and especially of his own discoveries and additions to this most interesting branch of physiology. He described the organs of generation in the fowl: he observed that the vitellus or yolk is at first in vascular connection with the parent; that this connection is afterwards broken off, and that in its passage through the oviduct the layers of albumen are added, and that before its final extrusion from the body of the mother the hard shell was formed: he asserted that all these parts, even the shell itself, are formed from the same substance under the influence of the assimilative power of the egg itself, and are not mere secretions from the organs of the parent, as was previously supposed: he was the first to describe accurately the two layers of albumen, and to show that each is contained in its own proper membrane: he was aware that the shell is porous, and admits of the respiration of the chick through it: he described the chalazæ at each end of the egg, and showed that they exist in the unimpregnated as well as the impregnated egg; whereas it had been previously supposed, and especially by his master, Fabricius, that these parts represent the germ from which the future chick was to be formed. The greatest discovery however made by Harvey in this branch of physiology was the use and importance of the 'cicatricula,' which he showed to be the true germ in which all the future changes take place, and for the increase and nutrition of which all the other parts of the egg are destined. He showed that it is present before the yolk has left the ovary, and pointed out the error of Fabricius, who considered it the remains of the pedicle by which the vitellus was attached to the ovary: he was aware that eggs occasionally contain a double yolk, and asserted that twins are produced from such eggs, but that they do not survive. The fifteenth and seven following 'Exercitationes' contain a description of the changes which the egg undergoes from the first to the fourteenth day of incubation. He described minutely the changes which take place in the cicatricula at the end of the second day. These observations appear to have been quite original. 'At this time it attains the size of the finger-nail nearly; two and sometimes three concentric layers may be observed in it. The central one is the more transparent of the two. In the middle of it is a white speck, which from its appearance may be compared to a cataract in the centre of the pupil of the eye. During this day the central layer especially enlarges and entrenches upon the external one.' This description appears to accord with that of the 'area pellucida,' to which so much importance is attached by later writers on this subject. 'At the end of the third day a pulsating spot may be observed in the centre of the "cicatricula," which forms the rudiment of the future heart.' He observed that the pulsations may be called forth afresh, when languid or intermitted, by the employment of various stimuli: he showed that the liver is formed round the umbilical vein, but he does not seem to have been aware that the liver, as well as all the other glands whose ducts communicate with the intestinal canal, is a prolongation or growth from the intestinal sac: he described five umbilical vessels, of which three are veins and two arteries, one of the veins being distributed to the albumen, the other four vessels to the vitellus. The first-mentioned vein goes to the vena cava, the other two to the vena porta, just before it enters the liver. The arteries are branches of the common iliacs. On this point, though his observations are correct as far as they go, his knowledge fell short of that of later inquirers; for he does not appear to have had any very accurate acquaintance with the uses of the allantois. He was aware that the vitellus is drawn into the intestine of the chick shortly before hatching, and serves for its early nutriment; and in this relation he well compared it to the milk. This fact was known to Aristotle. He corrected the error of Fabricius, who supposed that the egg is chipped by the hen, and showed on the contrary that this process is performed by the chick itself.

His observations on the process of generation in mammalia were confined chiefly to the deer species, of which he was enabled to obtain numerons specimens by the liberality of Charles I., who allowed him to take them from the royal parks. He supposed conception to take place either in the uterus or its born. This view, as is now well known, is incorrect. His description of the vessels and of the placenta is of considerable value. 'The smaller divisions of the umbilical veins coalesce into two trunks, which go to the vena cava and porta. The two arteries arise from the branches of the descending aorta. These vessels arise from and pass to the cotyledons of the placenta. In like manner the maternal vessels are distributed to the same cotyledons. A layer of honey-like matter is interposed between the maternal and fœtal portion of the placenta; and it is by absorption from this substance that the nutrition of the fœtus is carried on, for there is no vascular connection between the mother and the fœtus.'

He noticed the late union of the lateral parts of the upper lip and assigned it as a cause of the frequency of hare-lip. He claims to have been the first to discover the connection between the bronchi and the abdominal cells in birds, and to show that in all birds, serpents, oviparous reptiles, quadrupeds, and fishes, kidneys and ureters exist, a fact unnoticed by Aristotle and all succeeding writers. This account is, we apprehend, sufficient to show the extent and importance of the discoveries of Harvey in this branch of physiology, and to make us withhold our assent to the assertion of Sprengel (sect. 12, ch. 6), that the Treatise *De Generatione* is unworthy of the discoverer of the circulation.

In 1623 Harvey was appointed physician extraordinary to James I., with a promise of succeeding on the first vacancy to the physicianship in ordinary, the duties of which he actually performed. He was afterwards physician to Charles I., and was in the habit of exhibiting to him and to the most enlightened persons of his court the motion of the heart and the other phenomena upon which his doctrines were founded. During the civil war he travelled with the king, and while staying for a short time in Oxford was made by him master of Merton College, and received the degree of Doctor of Medicine. He held the mastership however for only a few months, when Brent, who had been expelled by the king for favouring the parliamentary cause, was replaced by that party, which had now gained the ascendency. Soon after his house was plundered and burned by the same party, and unfortunately several unpublished works, of which we have only notices in his other writings, were destroyed. The latter years of his life were chiefly spent at his country-house at Lambeth, or at his brother's near Richmond. In 1654 he was elected president of the College of Physicians, but in consequence of his age and infirmities he was induced to decline that honourable office. But he testified his regard for the society by presenting them with his library, and conveying over to them, during his lifetime, a farm which had been left him by his father. He died on the 3rd of June, 1657, in the 80th year of his age, and was buried at Hempstead in Essex, where a monument was erected to his memory. The best edition of his works, which were written in correct and elegant Latin, is that published by the College of Physicians in 1 vol. 4to., in 1766, with an engraving by Hall from the portrait by Cornelius Jansen, in the college library. They consist of the 'Exercitatio de Motu Cordis et Sanguinis;' 'Exercitationes duæ Anatomicæ de Circulatione Sanguinis, ad J. Riolanum, Fil.;' 'Exercitationes de Generatione Animalium;' 'Anatomia Thomæ Parri;' and nine Letters to celebrated contemporaries on different anatomical subjects. Among the works destroyed were, 'Observationes de usu Lienis;' 'De Motu Locali;' 'Observationes Medicinales'—'De Amore Libidine et Coitu Animalium;' 'De Insectorum Generatione;' 'De Quantitate Sanguinis Singulis Cordis Pulsationibus Protrusâ;' and 'Tractatum Physiologicum.' Two other MS. works by him are preserved in the Library of the British Museum; one, 'De Musculis et Motu Animalium Locali;' the other, 'De Anatome Universali;' in the latter of which, bearing date April, 1616, the principal propositions of the doctrine of the circulation are contained.

(*Life*, prefixed to his Works; Sprengel's *History of Medicine.*)

HARWICH, a parliamentary and municipal borough and seaport town in the hundred of Tendring, and county of Essex, 71 miles north-east from London. On the east it is bounded by the sea, and on the north by the æstuaries of the Stour and Orwell. The town is of Saxon origin, and its name is derived from two Saxon words, *Here*, an army, and *Wic*, a fortification (Morant's *Essex*, vol. 1, p. 499), from which circumstance it is supposed that a Saxon army was always stationed here to oppose the descents of the piratical Danes. It was not a place of any importance till after the Norman conquest. In 1318 Edward II. made it a borough corporate, and several charters and letters-patent were granted by succeeding kings, but none of these, prior to that of James I., are now extant. Under the Municipal Corporation Act the council of the borough consists of a mayor, four aldermen, and twelve councillors. The revenue of the corporation, in 1831, arising from lands, port dues, and other property, amounted to 671*l.*, and its expenditure for the same year was 585*l.* The borough returns two members to parliament, a privilege which it had enjoyed previous to the time of Edward III., in whose reign it was discontinued, and was not restored till the commencement of that of James I. The town consists of three principal streets, is well paved, and lighted with gas. The church, dedicated to St. Nicholas, is a spacious structure of brick, with stone buttresses and steeple, and occupies the site of an antient chapel, founded, about the commencement of the 13th century, by Roger Bigod, earl of Norfolk. The living is a vicarage in the patronage of the crown, with an average net income of 221*l.* The inhabitants are chiefly employed in ship-building and other maritime occupations, but the trade of the town is in a declining state, which is partly attributed to the removal of the government packets. Within the last twenty years the number of vessels belonging to the port, and the custom-house receipts, have fallen off considerably. The harbour is deep and spacious, the anchorage good, and there is a lighthouse, erected upon a hill below the town for the safe guidance of vessels into port. The population in 1831 was 4297. There is a free grammar-school for the education of 32 boys, the children of residents. The master, who is always the vicar of the parish, receives a salary of 40*l.* per annum, besides being provided with a house rent-free. Immediately opposite to Harwich, and at the south-east extremity of the county of Suffolk, is situated Languard Fort, a fortification of considerable strength, erected in the reign of James I. for the defence of the harbour, the entrance to which it completely commands. (Morant's *Essex; Beauties of England and Wales; Parliamentary Papers*, &c.)

At Walton, near Harwich, the crag yielding many fossils may be seen resting on the London clay, a rare and important occurrence.

HARWOOD, EDWARD, a biblical and classical scholar of the last century, was born in Lancashire, in 1729 and educated as a dissenting minister. In that capacity, after going through various other employments, he accepted the charge of a congregation at Bristol, in 1765, which however, at the end of five years, he was obliged to quit, in consequence of reports (unfounded it is said) touching his religious opinions, which gave offence to his congregation, and also of a slur cast on his moral character. He then removed to London, devoted the rest of his life to private tuition and literary labour, and died in distress, Jan. 14, 1794. He used to say that he had written more books than any living author, except Dr. Priestley. (For the list, see Watt, *Bibl. Britann.*) His reputation as a scholar rests chiefly on his 'View of the various editions of the Greek and Roman Classics,' 1775, fourth and best edition 1790, 'a valuable little book, no doubt far from being perfect, but that can hardly be expected in a work of the kind.' (Watt.) It has been translated into German and Italian. His 'Biographia Classica, the Lives and Characters of the Greek and Roman Classics,' 1778, a new edition of an old book, with additional matter, is another useful work. Dr. Harwood also published an 'Introduction to the Study of the New Testament,' 1767; a New Translation of the New Testament, 1768; a new edition of the Greek Testament, with English Notes, 1776, &c. &c.

HASDRUBAL, the name of several Carthaginians.

1. Hasdrubal, the son-in-law of Hamilcar. [HAMILCAR.]

2. Hasdrubal, the son of Hamilcar and brother of Hannibal. [HANNIBAL.]

3. Hasdrubal, who commanded the Carthaginians in their last war against the Romans, B.C. 146.

HASLINGDEN. [LANCASHIRE.]

HASSE, ADOLPH, a composer of great celebrity during the early part and middle of the last century, was born at Bergedorf, near Hamburg, in 1705. When very young, he distinguished himself as a superior tenor singer, but soon left Germany for Italy, and became first the disciplo of Porpora, then of Alessandro Scarlatti. In 1725 he produced an opera, *Sesostrate*, at Naples, which was followed by others in different parts of Italy. In 1733 Hasse, being then in London, was engaged by the noblemen hostile to Handel to compose for the opposition Italian theatre, at which he brought out with success his *Artaserse*. He could however be persuaded to remain in London, the head-quarters of a cabal he did not approve, but went to Dresden, where he remained several years. It was there, in 1745, that Frederick of Prussia heard his *Armenio*, which so pleased that warlike, musical, and commonly parsimonious prince, that he sent the composer 1000 dollars and a diamond ring.

In 1760, at the bombardment of Dresden, Hasse lost all his property, including his valuable manuscripts, by fire. This was his first affliction. In 1763 he experienced a second, having been obliged, by changes made in tho court of Dresden, to leave that city, and proceed to Vienna. In that capital he wrote several operas. He finally retired to Venice, where he produced a grand *Te Deum*, which was performed before the pope in the church of Santo Giovanni. He died in 1783. Some years previous to his decease he composed a *Requiem* for his own funeral, which was duly applied to the intended purpose, and is a work affording evidence of his powers in an advanced period of life. Hasse is certainly entitled to be considered as one of the best composers of his day. Some of his productions, and among these his *Pellegrini* and two Litanies, are much admired by real unprejudiced judges, and are occasionally heard at that asylum for what is classical and rejected of fashion—the Antient Concerts. But it must be acknowledged that many of his operas have sunk into an oblivion by no means unmerited.

HASSELQUIST, FREDERIC, a Swedish naturalist, and pupil of Linnæus, was born at Törnvalla, in East Gothland, on the 3rd January, 1722, old style. His father, Andrew Hasselquist, a poor curate, having died young, without having made any provision for his family, his wife's brother, a clergyman of the name of Pontin, took charge of young Hasselquist's education, and placed him with his own children in the school of Linköping. After the death of his benefactor, Hasselquist was transferred to the university of Upsal, where he entered in 1741. He there acquired a taste for natural history, became a pupil of the great Linnæus, and was led very particularly to apply himself to the study of the properties of plants. An inaugural thesis, called 'Vires Plantarum,' which appeared in 1747, evinced him to be a young man of a strong original turn of mind, and worthy of his master. He showed how puerile were the notions at that time entertained regarding the medical properties of many plants, how much the whole of vegetable materia medica stood in need of reformation; and he pointed out a philosophical mode of investigating the facts connected with it, by insisting upon the old doctrine of 'liko forms, like virtues.' This truth, which is one of the most important among those connected with the practical application of botany to useful purposes, had been so obscured by want of science in the age immediately preceding Linnæus, that it had ceased to be a point of belief, and was rather set down as a fanciful speculation of forgotten theorists. Hasselquist however maintained its accuracy, and with so much skill that he may be said to have established it upon a solid foundation, from which it could never afterwards be shaken. This, and his general proficiency in other branches of science, procured Hasselquist some of the royal stipends provided for travelling students, and he was thus eventually enabled to carry into execution a favourite project of visiting tho Holy Land for the laudable purpose of investigating its natural history. Having sailed from Stockholm in August, 1747, he proceeded to Smyrna, thence to Egypt, and afterwards to the Holy Land. His constitution sunk however under the exertions of his enterprising spirit, and he died at Smyrna, on his return homewards, on the 9th February, 1752, in the 31st year of his age. The result of his investigations of these, at that time little known, countrics, was given to the world by Linnæus in the year 1757, under the name of 'Iter Palæstinum.' Like most travellers' books of that age, this work showed that the author had combined with energy and industry great attainments in the sciences of his day. It is rich in observations upon the quadrupeds, birds, reptiles, fishes, insects, mollusca, plants, minerals, and materia medica of the countries he visited, and is to this day a standard work of reference. His science was not the flimsy, superficial, and unintelligible gossip of most modern travellers, but the sound matter-of-fact, precise, and definite information of which use may be made so long as science endures, whatever changes it may undergo in its forms. His name is perpetuated in botany by having been given to a curious genus of Egyptian Apiaceæ.

HASSELT. [LIMBURG.]

HASTINGS, a parliamentary borough and the chief town of the rape to which it gives name, is situated in the hundred of Guestling and county of Sussex, 64 miles south-east from London. Hastings is a town of considerable antiquity, but nothing is known with certainty respecting its origin, or whence it derived its present name. Dallaway, in his 'History of Western Sussex,' says, 'In 893 the Danes, in 250 ships, commanded by the pirate Hastinges, landed at the mouth of the river Rother, near Romney Marsh, and immediately possessed themselves of Apuldore, where and at Hastings (so called from thoir leader) they constructed forts and ravaged all the coast to the westward of the country,' but it is probable that the town had an earlier origin, as in the reign of Athelstane, A.D. 924, it was a place of sufficient importance to havo a mint. Edward the Confessor granted it a charter, and several other kings did the same down to James II., but the governing charter is that of Queen Elizabeth, dated 1588, and subsequently confirmed and enlarged by Charles II. The borough council consists of a mayor, six aldermen, and eighteen councillors, and the style of the corporation is the 'Mayor, Jurats, and Commonalty of the town and port of Hastings in the county of Sussex.' (5 and 6 Will. IV., cap. 76.) Hastings has returned two members to parliament since the reign of Edward III. It is one of the Cinque-ports, and is next in importance to Dover, the chief of those antient communities. [CINQUE-PORTS.] The town is pleasantly situated on the sea-coast, in a hollow, sheltered on every side, except the south, by lofty hills, and has of late years been much resorted to during the bathing season. It consists principally of two streets, running nearly north and south, and separated by a small stream called the Bourne, which runs into the sea. To the westward of the town, upon a lofty cliff, are the ruins of an antient fortress, supposed to have been erected prior to the Norman conquest. The town-hall, recently rebuilt, is a handsome structure, supported on arches, with a market-place beneath it; but the gaol is small and inconvenient. There are five principal hotels, which are said to be generally well conducted. The places of amusement and public resort are numerous, and comprise the theatre, marine parade, Royal Pelham Arcade, &c., besides subscription libraries. Tho inhabitants are chiefly employed in the coasting trade and fisheries, but a considerable number are engaged in boat-building and in the making of lime. The kilns are situated to the west of the town, and produce on an average 120,000 bushels a year. Hastings is in the diocese of Chichester. There are two churches, both very antient edifices, dedicated to All Saints and St. Clement. Tho living is a rectory, with an average net income of 300*l.* The port is divided into eight parishes, the aggregate population of which, in 1831, was 10,097. There is a school for the education of boys, founded and endowed by the Rev. William Parker in 1619, and another founded and endowed by James Saunders, Esq., in 1708. The average yearly income of Parker's charity is about 210*l.*, that of Saunders's is about 240*l.*

About a mile to the west of Hastings is situated the new and well built town of St. Leonard's. The principal range of buildings extends along the coast, about three-fourths of a mile in length, and is fronted by a very beautiful esplanade. As the town was only commenced in 1828, the public buildings are not yet very numerous. There is however abundant accommodation for visitors, and the three principal hotels are erected upon a very splendid scale.

(Allen's *History of Sussex*, 8vo., 1830; Dallaway's *History of Western Sussex*, 4to., 1830; *Parliamentary Papers*, &c.)

HASTINGS SANDS. The middle group of the Wealden formation, which constitutes the uppermost part of the oolitic system in England, is thus named from its characteristic development around Hastings in Sussex. In the Hastings sands we may distinguish four divisions, which lie in the following order:—

The Horsham beds.	Fawn-coloured sand and friable sandstone: good flagstone occurs here.
The Tilgate beds.	Sandstones often calcareous, with various grits and conglomerates, resting on blue clay. These have yielded a considerable number of organic remains, plants, mollusca, fishes, and reptiles of gigantic dimensions. [IGUANODON and HYLÆOSAURUS.]
"	White sand and friable sandstone, alternating with clay.
The Ashburnham beds.	Nodules and beds of limestone, alternating with clays and sandstones.

The axis of elevation or forest ridge of the Weald of Kent and Sussex is chiefly formed of Hastings sands, which rise in Crowborough Beacon to 804 feet above the sea. [GEOLOGY.] (Mantell's *Tilgate Forest;* Fitton's *Geology of Hastings*, &c.)

HASTINGS, WARREN, a memorable name in the history of British India, was born in the rank of middle life in 1733, and after receiving the usual education at Westminster School, went out in 1750 as a writer in the service of the East India Company. His first advancement was due to his own industry and discernment, which led him to master tho Persian and Hindustanee languages, a study at that time almost universally neglected; and he was therefore chosen for more than one useful and honourable employment, commercial and diplomatic, in the interior. After residing about fourteen years in India, he returned home with a moderate fortune, intending apparently to pass the remainder of his life in tranquillity. In 1769 however he unexpectedly received the appointment of second in council at Madras, and in 1772 was appointed to the highest office in the Company's service, that of President of the Supreme Council of Bengal. His powers were enlarged by the alteration of the Indian constitution by act of parliament, in virtue of which he became, January 1, 1774, governor-general and supreme head of all our Indian dependencies. Affairs were at this time in great disorder. The territories of the Company had been greatly extended by the conquests of Clive and his successors; but their dominion, authority, and influence were still unconsolidated, and were exposed during the government of Mr. Hastings to great danger from the inveterate enmity of Hyder Ali, rajah of Mysore, supported by the Mahrattas, and others of the native powers. That he did many things under the pressure of circumstances, which nothing but expedience could justify, is hardly denied by his defenders or himself: indeed it seems to have been part of his defence, that Indian statesmen were not to be bound or judged by European rules of justice and morality. Right or wrong, he weathered the dangers to which the British Empire in India was exposed; and if he left the provinces under his charge wasted and depopulated, the increased revenue more than counterbalanced by the increased debt, he also left the power of our enemies broken, our own consolidated, and an easier task to his successors than fell to his own share. Notwithstanding his services, he gave satisfaction neither to the home administration nor to the Court of Directors. The public ear was offended by rumours of cruelty, corruption, and unjust aggression; the directors censured the lavish and corrupt expenditure, and the presumptuous independence of his conduct. Repeated attempts were made to obtain his dismissal, but those were uniformly defeated by the Court of Proprietors. Thus supported, he carried matters with a high hand; neglected or positively refused to obey the orders sent by the Directors; overruled tho opposition of the Council, of which a majority was, in the first instance, opposed to his views [FRANCIS, SIR PHILIP]; and practically exercised an absolute and irresponsible power until February, 1785, when he resigned his office and set sail for England, well aware that a storm awaited his arrival.

As soon as Mr. Hastings had arrived, Mr. Burke intimated his resolution of instituting an inquiry into the late Governor-General's conduct. Proceedings however were not commenced until the session of 1786, in the course of which articles of impeachment were brought forward by Mr. Burke, charging him with numerous acts of injustice and oppression committed against native princes and people dependents or allies of the Company; with the impoverishment and desolation of the British dominions; with the corrupt and illegal reception of presents himself; with the corrupt exertion of his great influence by conniving at unfair contracts, and granting inordinate salaries, and with enormous extravagance and bribery, intended to enrich his dependents and favourites. The several accusations were finally confined to four heads:—the oppression and final expulsion of the rajah of Benares; the maltreatment and robbery of the Begums (or princesses) of the house of Oude; and the charges of receiving presents and conniving at unfair contracts and extravagant expenditure. The sessions of 1786-7 having been consumed in preliminary proceedings, the House of Lords assembled in Westminster Hall, February 13th, 1788, to try the impeachment, and on the 15th, the preliminary forms having been gone through, Mr. Burke, in the name of the Commons of England, opened the charges against the prisoner in a comprehensive, elaborate, and most eloquent speech [BURKE], which lasted upwards of three days. He was assisted in the management of this most arduous cause by Fox, Sheridan, Grey, and others. The sessions of 1788, 1789, and 1790 were consumed in going through the caso for the prosecution. In 1791 the Commons expressed their willingness to abandon some part of the charges, with the view of bringing this extraordinary trial sooner to an end; and on the 2nd of June, the seventy-third day, Mr. Hastings began his defence. This was protracted until April 17, 1795, on which (the 148th) day he was acquitted by a large majority on every separate article charged against him.

There seems no doubt but that public opinion changed greatly during the trial; and that Mr. Hastings came to be regarded as an oppressed, instead of an offending man. This feeling was probably caused in a great measuro by the suspicious appearance of so great a delay of justice, and the skilful manner in which Mr. Hastings and his counsel threw all the blame on the managers of the prosecution, when in truth the smallest share of it seems to have belonged to them The extreme violence of their invective was perhaps calculated to hurt their cause, and the upper ranks, more especially the powerful interest connected with India, were disposed to look jealously at so close a scrutiny into the conduct and gains of an official man.

Mr. Hastings attempted to refute the oharges of extortion by publicly asserting in the most solemn manner, that never at any time of his life was he worth 100,000*l.* The law-charges of his defence amounted to 76,080*l.* In March, 1796, the Company granted him an annuity of 4000*l.* for twenty-eight years and a half, and lent him 50,000*l.* for eighteen years, free of interest. He retired completely from public life, to an estate which he purchased at Daylesford, in Worcestershire, formerly in the possession of his family. Ho died August 22nd, 1818, having been raised to the dignity of privy-counsellor not long before.

On his real character as a man and a statesman it is somewhat hard to decide. That his talents and his services were alike ominent, is admitted; that the means which he used were often most culpable, appears to be equally certain. His apology is to be found in the necessities of his situation, in the general neglect of justice in our dealings with the Asiatic princes, and in the notorious laxity of Anglo-Indian morality, where making a fortune was concerned, in those days. Mr. Mill, after exhibiting without reserve or favour the errors and vices of Mr. Hastings' administration, thinks it necessary to recommend him to the favourable construction of the reader, on the ground that he 'was placed in difficulties and acted on by temptations, such as few public men have been called on to overcome:' and adds, 'It is my firm conviction that if we had the advantage of viewing the conduct of other men, who have been as much engaged in the conduct of public affairs, as completely naked and stripped of all its disguises as his, few of them would be found whose charaoter would present a higher claim to indulgence; in some respects, I think, even to applause. In point of ability he is beyond all question the most eminent of the chief rulers whom the Company have ever employed; nor is there any one of them who would not havo succumbed under the difficulties which, if he did not ovorcome, he at any rato sustained.

He had no genius, any more than Clive, for schemes of policy, including large views of the past and large anticipations of the future; but he was hardly ever excelled in the skill of applying temporary expedients to temporary difficulties; in putting off the evil day, and in giving a fair complexion to the present one. He had not the forward and imposing audacity of Clive; but he had a calm firmness, which usually by its constancy wore out all resistance. He was the first, or among the first, of the servants of the Company who attempted to acquire any language of the natives, and who set on foot those liberal inquiries into the literature and institutions of the Hindoos, which have led to the satisfactory knowledge of the present day. He had that great art of a ruler, which consists in attaching to the governor those who are governed; aud most assuredly his administration was popular, both with his countrymen and the natives in Bengal.' (Book v., ch. 8.)

We have thought it fair to give at length the testimony of Mr. Mill, who has dissected the events of Hastings' government with an unsparing hand. At the same time, assuming Mr. Mill's representations of particular events and his strictures on them to be just, we feel bound to dissent from the meed of comparative praise conveyed in this passage, and believe that most persons, on perusing the fifth book of the 'History of British India,' will do the same. (Mill's *British India; Obituary*, for 1819.)

HAT. In every civilized community it has been the custom for men to wear a covering on their heads in the open air; and in Western Europe, and those countries which have been peopled from it, the form of covering employed since the fourteenth century has been that which we call a hat. The difference between a hat and a turban, the covering generally used throughout Asia and a part of Eastern Europe, is sufficiently marked. The distinction between a hat and a cap consists in the shape, as both may be made of the same materials. The hat has usually a cylindrical crown, or receptacle for the head, and a rim or brim encircling the base, and perpendicular to it, which brim does not form part of a cap; but this distinction is not sufficient, as hats such as those worn by naval and military officers, and those which until late years were employed in polished society, on occasions of ceremony, and known as cocked-hats, have not any brim, properly so called, but a part, of ample dimensions, answering to it, and turned up so as to be parallel with the crown.

Hats are made of straw, of silk, or of wool. Straw-hats are little used by men in this country. The material chiefly used in making them is wheat-straw plaited in strips and sewed together in the required form. Silk-hats are composed of a form made of chip or of felt, and covered with woven silk plush, or shag, fashioned to the required shape and drawn over the form. A considerable number of these hats are made for exportation to different places in the Mediterranean and to our Colonies. The greater part of the hats used in England are made of wool by felting, a process peculiar to that substance. There are three descriptions or qualities of hats made of wool, viz. beaver-hats, plate-hats, and felt-hats. Each of these has the body composed of felt: the first has a covering or nap of beaver; the second, a nap of the fur of the musk-rat, or the nutria, or some other fur of small value; and the third kind is without a nap. It will be sufficient to describe the mode of making beaver-hats.

According to the general belief the art of felting was brought to Western Europe by the Crusaders, who found the tents of their enemies covered with that substance. Wool in the yolk, that is, with the natural grease, will not felt, and it is necessary to the process that it should be well scoured, when the fibres being brought together have a tendency to mat together. This tendency is so strong that it is not possible to spin woollen yarn without previously oiling the wool. Hats of the very finest quality are made with lamb's-wool imported from Spain or Saxony, and the fur of English rabbits. The nap is composed of the fur of the beaver and nutria and the down from the back of the English hare mixed together. To form the body of the hat the wool and rabbit's-fur are separately *bowed* in the manner employed for freeing cotton from its seeds. [COTTON.] The two substances are next bowed together until they are intimately mixed, after which the mass is spread evenly, covered with an oil-cloth and pressed, first gently and afterwards more strongly, by which means the fibres will become tangled or interlaced. A very loose and imperfect felt is thus produced. The next process is to cover the felt with a triangular piece of damp brown paper, and then to fold it in a damp cloth and work it well with the hand, pressing and bending, rolling and unrolling it, until the interlacing or felting is much more perfect, and the mass is compact. The felt thus prepared is next taken to the wide brim of a boiler charged with water and beer-grounds and a small quantity of sulphuric acid. In wine countries the lees of wine are substituted for beer-grounds. This mixture is kept near to the boiling point. The workmen having the palms of their hands protected by a covering of thick leather, lay the felt on the margin of the boiler, and then proceed to sprinkle it with the hot liquor and to work it about with the palms of their hands; by this means it shrinks and becomes more compact; it is then dipped into the boiler and worked, first with the hands, and next by the help of a rolling-pin, which admits of more force being used, and this process is continued until the felt no longer contracts.

The next process is that of stiffening. The substance employed for this purpose is shell-lac, a solution of which is applied by means of a brush to one side, and sometimes to both sides of the felt, after which it is stoved, and by this means the whole substance becomes duly impregnated with the resin. Shell-lac being insoluble in water, spirit of wine is usually employed as the solvent, but rectified naphtha made from coal-tar is sometimes substituted for it. The use of this resin is the greatest modern improvement in hat-making; the substance is thus rendered perfectly waterproof, and hats are not now, as formerly, spoiled by exposure to rain. The stiffening of hats was formerly composed of gum-arabic, or of glue, which are both soluble in water. To form the nap of a hat one half or three-fourths of an ounce of beaver, and some other less costly fur, are bowed together and imperfectly felted in the manner already described, and shaped the same as the body to which it is to be applied; that body is then softened by immersing it in the boiler, when the nap is applied and worked as in felting, until the required union is effected between the two bodies.

The felt thus covered is in the form of a cone, and must be brought to the cylindrical shape in which it is worn by means of a wooden block of the requisite form. This operation, which is called blocking, is performed by working it with the hand on the block to which it is tied. It is then dyed in a bath composed of water, logwood, sulphate of iron, verdigris, and gall-nuts, in which the hat is boiled during some hours; it is then drained and dried. After this it is softened by steam, the crown is strengthened by placed it in a disc of scale-board, and linen is pasted over this. The nap is raised and a uniform direction given to its fibres by means of warm irons and hair brushes. The last processes are binding and lining, when the hat is ready to be worn.

It is not possible to form any correct estimate of the extent of the hat manufacture in this country. The quantity and value of felt hats exported in the ten years, 1827 to 1836, were as follows:—

Years.	Dozens.	Value.	Years.	Dozens.	Value.
1827	75,497	£175,462	1832	55,458	£144,596
1828	83,114	197,581	1833	43,138	130,232
1829	81,182	189,469	1834	40,155	125,970
1830	77,061	209,849	1835	46,849	135,800
1831	62,854	170,188	1836	53,894	148,282

The great bulk of these shipments are made to our own colonies and dependencies. The exports so made in 1836 amounted to 45,019 dozens, valued at 112,228*l*.

A duty of 10*s*. 6*d*. each is imposed on the importation of hats of foreign make, which operates as a prohibition.

HATCHETINE. *Mineral Adipocire.* This substance occurs in thin flakes in the cavities of the ironstone of South Wales. It is very soft, somewhat granular in appearance; translucent; colour yellowish-white or greenish; not elastic; inodorous; combustible. It melts at 170°, and is soluble in æther.

According to Professor Johnston it consists of—

One atom of carbon	85·910
One atom of hydrogen	14·624
	100·534

HATFIELD. [ESSEX.]

HATHERLEIGH. [DEVONSHIRE.]

HATTERAS, CAPE. [CAROLINA, NORTH.]

HAUKAL, ABUL KASEM MOHAMMED IBN, a celebrated Arabic traveller and geographer. The few particulars we possess concerning his life are derived from his own work. From this we learn that he paid great attention to the study of geography from his earliest years, and collected all the books he could obtain which treated of foreign nations; that partly with a view to obtain farther information, and partly to avoid the tyranny of the reigning sultan, and to improve his own fortune by trade, he set out from Bagdad, A.H. 331 (A.D. 942-3), in order to visit foreign countries. He does not tell us into what countries he travelled: but we learn from his own account that he was in Mesopotamia A.H. 358 (A.D. 968-9); in Africa A.H. 360 (A.D. 970-1); in Sicily A.H. 362 (A.D. 972-3); and in Mecca A.H. 364 or 5 (A.D. 974-5 or 975-6).

Haukal's work on geography is entitled 'A book of Roads and Kingdoms.' He states in the preface that he composed the work to give a description of all the countries in which the Mohammedan religion prevailed, together with the revenues, natural productions, and commerce of each. After giving a general view of tho earth, and a brief description of the nations which do not profess the Mohammedan religion, he first describes Arabia, since it contains Mecca and the Caaba, and afterwards the seas and other countries subject to Mohammedans. The description of each country is accompanied by a map; but Abulfeda, who frequently quotes Haukal in his treatise on Geography, complains that the names are inaccurately spelled, and that the latitudes and longitudes are not put down in these maps. Haukal mentions the names of other writers on Geography, from whom he derived great assistance; namely, Ibn Khordadbeh, Al Jihani, and Abul Faraj Kodama Ibn Jafar, whose works he always carried with him in his travels.

Manuscripts of Haukal's work on geography are rarely met with even in the East; there is a copy in the Bodleian Library at Oxford, and another at Leyden. From the latter MS. Uylenbroeck has given an interesting account of the work in his 'Iracæ Persicæ Descriptio; præmissa est Dissertatio de Ibn Haukali Geographi codice Lugduno-Batavo,' 4to., Lug. Bat. 1822; to which we are indebted for the greater part of the preceding remarks.

Ouseley published, from what he conceived to be a Persian translation of the Arabic of Haukal, a work entitled 'The Oriental Geography of Ebn Haukal, a traveller of the 10th century,' Lond. 1800; and De Sacy gave a further account of this work in the 'Magasin Encyclopédique,' vol. vi, pp. 32-76, 151-186, 307-333. But Uylenbroeck has shown, in the work already referred to, that the Persian treatise translated by Ouseley cannot be regarded as either a translation or an abridgment of the Arabic of Haukal, since, independently of other differences, it appears to have been written in the beginning of the 4th century of the Hegira, while Haukal's work was not composed till A.H. 366 or 367. But he considers it probable from many circumstances that the Persian work was one of those which Haukal made use of in compiling his Geography, and that it was written by Ibn Khordadbeh.

HAUKSBEE or HAWKSBEE, FRANCIS, was born in the latter part of the seventeenth century. The exact year of his birth is unknown, and also that of his death; but it appears from the minutes of the Royal Society that he was admitted a Fellow of that body in 1705, at which period it is probable he was appointed to the office of curator of experiments to the Society. Previous to the time of Hauksbee, electricity could not be said to exist as a science. Dr. Gilbert of Colchester had published a book on magnetism about the beginning of the seventeenth century, wherein he gave a list of certain substances which, when rubbed, acquire the property of attracting light bodies; and similar phenomena had likewise been observed by Boyle, but with the exception of these insulated facts nothing was known concerning electricity. Even the electrical discoveries of Mr. Hauksbee were not of any great importance in themselves, but, as Dr. Thomson observes in his 'History of the Royal Society,' 'they constituted the beginning of the science, and, by drawing the attention of philosophers to that particular subject, were doubtless of considerable service in promoting electrical investigations.' Between 1705-11, there appear several papers in the 'Transactions of the Royal Society,' giving a detailed account of his experiments. In 1706 he had recognised the electricity of glass by friction, and was thence led to the first rudiments of the electrical machine. In 1709 he published his 'Physico-Mechanical Experiments on various subjects; touching light and electricity producible on the attrition of bodies,' London, 4to., which was shortly after translated into Italian by Thomas Dereham. The work was also translated into French by M. Bremond, but the latter having died before completing the translation, the publication was delayed till 1754, when it was revised and edited by M. Desmarest, who added the more recent discoveries of Hauksbee, and tho yet more important ones of Mr. Gray. In addition to the works already mentioned, Hauksbee has left 'Proposals for a Course of Chemical Experiments,' London, 1731, 4to.; 'An Essay for introducing a Portable Laboratory,' London, 1731, 8vo.; besides numerous papers on various philosophical subjects in the Society's Transactions.

HAUTBOIS. [OBOE.]

HAUTES PYRENE'ES. [PYRENEES, HAUTES.]

HAÜY, RENE'-JUST, ABBE', a distinguished French mineralogist, was born February 28, 1743, at St. Just, in the present department of Oise. He commenced his studies at the college of Navarre, to which college he was appointed professor in 1764, and subsequently also to that of the Cardinal Le Moine. His attention was first drawn to tho subject of mineralogy by attending the lectures of M. Daubenton, but the accidental fracture of a beautiful specimen belonging to his friend M. France de Croisset is said to have led him to the discovery of the geometrical law of crystallization. Haüy was anxiously employed in collecting the scattered fragments of the crystal which he had broken, when M. Croisset, whom the accident had rendered almost inconsolable, desired he would not give himself that trouble, and directed a domestic to remove the pieces, which, in his own opinion, were no longer of any value. But Haüy, who regarded them with extreme attention, requested permission to remove them himself, remarking that the conformity of the superposed plates of crystalline matter with the planes of the central prism or nucleus had revealed to him a secret which he wished more fully to explore. From this moment he applied himself sedulously to the development of the truth which his genius had detected, and his efforts were rewarded with the success they merited. He was the first to show that the structure of crystalline substances was regulated by laws as invariable as thoso to which organized bodies are subjected, and thus crystallography for the first time assumed the character of a regular science. His theory rests upon the supposition that all the crystalline forms belonging to any single species of mineral are derivable from some one simple form which may be regarded as the type of tho species; it likewise supposes that the angles at which the planes of crystals can be inclined to each other are confined within certain limits, an erroneous supposition which may probably be attributed to the imperfection of the instruments employed to measure them. (See the article 'Crystallography' in the Encyclopædia Metropolitana.) In compliance with the request of MM. Daubenton and Laplace, Haüy communicated the result of his researches to the Royal Academy, and was elected a member of that society in 1783. During the Revolution he was thrown into prison for refusing to take tho oath of obedience required of the priest, but the exertions of Geoffroy Saint-Hilaire, one of his pupils, and the remark of a citizen, that 'it were better to spare a recusant priest, than to put to death a quiet man of letters,' obtained his release, and probably saved his life. In 1794 he was appointed conserver of tho mineralogical collections of the School of Mines, and the following year he received the appointment of secretary to the commission of weights and measures. Under the consulship of Napoleon he became professor of mineralogy at the Museum of Natural History, and professor of the Faculty of Sciences at the Academy of Paris.

Haüy died at Paris, June 3, 1822. Besides numerous memoirs upon mineralogy and electricity, inserted in the 'Journal des Mines' and the 'Annals of the Museum of Natural History,' he has left tho following works:—'An Essay on the Structure of Crystals,' 1 vol., 1784; 'Exposition of the Theory of Electricity and Magnetism,' 1 vol.; 'Treatise on Mineralogy,' 4 vols., 1822; 'Treatise on Physics,' 2 vols., 1821; 'Treatise on Crystallography, 2 vols., 1822; and some others.

HAÜYNE. *Latialite.* This mineral occurs in attached rhombic dodecahedral crystals, also granular and massive. The primary form is the cube. Cleavage parallel to the diagonal planes of the cube, indistinct; fracture uneven; brittle, hardness 5·5 to 6·0; sp. gr. 2·68, 3; colour when opaque, indigo blue, when translucent, blue or bluish-green; streak white; lustre vitreous. The massive varieties are amorphous; structure granular, compact. When heated in an acid it becomes gelatinous and transparent. Before the blowpipe it fuses with borax into a clear glass, which becomes yellow on cooling. This mineral is found in the cavities of lavas and in the fragments of rocks ejected from Vesuvius, and also embedded in pumice and lava near Andernach on the Rhine, &c. According to Gmelin, the mineral from Marino yielded—

Lime	12·
Sulphuric acid	12·39
Oxide of iron	1·16
Water	1·20
	96·55

HAVANA, the capital of the island of Cuba, is situated in 23° 9′ N. lat. and 82° 2′ W. long., on the northern shore of the island. Its harbour, which is one of the most secure and commodious in the world, communicates with the sea by a channel little more than half a mile in length, and from 300 to 350 yards wide; its depth varies from 8 to 10 fathoms. The harbour itself is a basin, of an oblong form, measuring in length from south-south-east to north-north-west nearly two miles and a half, but its greatest width does not exceed one and a half. Its depth varies from five to six fathoms, except on the small shoal De la Luz, where it is less. This basin is surrounded by heights which shelter it from every wind. The town is built on the western side of the basin, near the channel, on a kind of promontory. The channel is protected by two strong fortresses, El Morro and La Punta, and a continuous series of batteries along both shores. The town is equally strong towards the land. A well-built wall runs across the isthmus of the promontory on which it stands, and at a distance of respectively 1240 and 660 fathoms from it are two fortresses erected, Del Principe and De Atures, both well fortified. The space between the walls of the town and these fortresses is occupied by the suburbs, six in number, Horcon, Jesus Maria, Regla, Cerro, S. Lazaro, and La Salud. The population of the town was estimated in 1827 at 39,980, and that of the suburbs at 54,043; the whole therefore was 94,023, of which number the whites amounted to 46,600, the free people of colour to 23,600, and the slaves to 23,800. In the same year there were also 18,000 foreigners in Havana, and the garrison consisted of 6000 men; the whole population consequently amounted to 118,000 souls. In 1828 it was estimated at 125,000 individuals.

The streets are narrow, crooked, and generally unpaved: in the rainy season they are full of mud. A few of them contain well-built houses, especially the Calle de los Mercaderes. There are several good buildings among the churches, one of which now contains the remains of Christopher Columbus, which were formerly at S. Domingo, but were removed to this place when that town was ceded to the French (1795). The other large buildings, as the palace of the government (casa del gobierno), that of the commandant of the marine, the arsenal, the post-office (correo), and the buildings used for the manufacture of tobacco, are less remarkable for their architecture than for their solidity. The town has a theatre, a circus for bull-fights, and two fine promenades, one called L'Alameda, within the town, and the other Passeo Extra Muros, without the town. There is a university, a seminary for Catholic priests, a patriotic society, and a botanic garden. Havana is the seat of the capitano-general, and of a bishop. The manufactures are not important, except those of cigars and chocolate. The commerce is very great and still on the increase, though several other ports of Cuba have been opened to foreign vessels. More than half of the produce of the island destined for foreign markets is shipped at Havana. [CUBA.] To what is said of the climate of the town under CUBA, we need only add, that it is very unhealthy, and that more than one-half of the Europeans who arrive there are carried off in the course of one year, mostly by the yellow fever. (Humboldt; *The Present State of Columbia, by an Officer*.)

HAVANT. [HAMPSHIRE.]

HAVERCAMP, SIGEBERT, was born at Utrecht, A.D. 1683. He studied philology at Leyden under Gronovius, whom he succeeded as professor of Greek. He was also appointed afterwards professor of history and eloquence. He died on the 25th of April, 1742, in the 60th year of his age.

He edited many of the classical writers with numerous notes, which were principally selected from former commentators, of these the most important are 'Tertulliani Apologeticus,' 8vo., Leyd., 1718; 'Lucretius,' 2 vols. 4to., Leyd., 1725; 'Josephus,' 2 vols. fol., Amst., 1726; 'Eutropius,' 8vo., Leyd., 1729; 'Orosius,' 4to., Leyd., 1738; 'Sallust,' 2 vols. 4to., Amst., 1742; 'Censorinus,' 8vo., 1743. He was also the author of many original works, of which the most important are, 'A Universal History,' fol. 1736, in Dutch; 'Introductio in Historiam Patriæ à primis Hollandiæ comitibus,' 8vo., Leyd., 1739; 'Sylloge scriptorum qui de linguæ Græcæ vera et recta pronunciatione commentaria reliquerunt,' 2 vols., Leyd., 1736-40; 'Dissertationes de Alexandri Magni Numismate,' 4to. Leyd., 1722; 'Thesaurus Morellianus,' 2 vols. fol., 1734; 'Introductio in Antiquitates Romanas,' 8vo., Leyd., 1740. The list of Havercamp's writings shows that he was a laborious scholar; but many of his works bear traces of having been written in a hasty and careless manner.

HAVERFORDWEST. [PEMBROKESHIRE.]

HÂVRE, LE, or LE HÂVRE DE GRACE (the Haven of Grace), on the right bank of the Seine, at its mouth, which is several miles wide, in the department of Seine Inférieure; 108 miles from Paris in a straight line north-west, or 127 miles by the road through Rouen, in 49° 29′ N. lat., 0° 6′ E. long.

Up to the time of Louis XII. Le Hâvre was a mere fishing town, having a small chapel, covered with straw and dedicated to Notre Dame de Grace. Louis XII. laid the foundation of the importance of the place: François I. surrounded it with walls; and Cardinal Richelieu in A.D. 1628 added to its fortifications a strong citadel, which has since been dismantled and converted into quarters for the garrison. In the reign of Louis XVI. and in that of Napoleon, Le Hâvre received considerable improvement and augmentation. The site of the town and the neighbourhood are for the most part low and flat, traversed by several water-courses, one of which formed the origin of the port, which is comprehended within the circuit of the town, and has communicating with it three basins capable together of receiving upwards of 500 vessels. At the entrance of the port is an old tower built by François I., from which signals are made to vessels out at sea. Connected with one of the basins is a canal from Le Hâvre to Harfleur. There are also two roadsteads. The rise of the tide at Le Hâvre is from 22 to 27 feet, and by taking advantage of it the largest merchantmen can enter the port.

The town is divided into the Old Quarter, of which the streets are tolerably regular but the houses ill built, and the New Quarter, skirting the basin of Ingouville, the buildings of which are regular and handsome; the streets are neat, well watered, and well lighted. There is an arsenal and a custom-house, which is a large building: the town-hall, the office of the sub-prefect, the exchange, and the two churches are insignificant. There is a handsome square planted with trees and forming a public walk; there is also a handsome modern theatre. The populous suburb of Ingouville contains many pleasant country-seats. At Cape La Hève, a headland about 130 yards high, at the mouth of the Seine, 2½ miles west of the town, are two handsome lighthouses about 50 feet high. There is also a brilliant harbour-light on the extremity of the western jetty, at the entrance of the port.

The population of Le Hâvre in 1836 was 25,618; but including the suburb of Ingouville, it may be estimated at upwards of 30,000. Several manufactures are carried on in the town—tobacco, soap, earthenware, starch, vitriol, pitch, cordage, paper, and cards. There are several breweries and sugar-refining houses, and building-yards for vessels. The wives of the sailors and artisans are much engaged in making lace. The whale and herring fishery, the curing of herrings, and the Newfoundland cod fishery are also carried on. But the importance of the place depends upon its commerce. It is the principal port of Paris, most of the foreign and colonial produce designed for the consumption of that city being imported into it. Beside colonial produce, as sugar, coffee, indigo, dyewoods, and spices, the imports chiefly consist of cotton (for the manufacturers of the district of which Rouen is the capital), tobacco, hides, iron, tin, dried fish, &c. The exports are silk and woollen stuffs, lace, gloves, trinkets, perfumery, wines, brandy, &c. Grain and flour are sometimes imported, sometimes exported. The value of the imports in the year 1829 was 250,000,000 francs, or above 10,000,000*l.*: of which the value of the cotton imported was estimated at 26,000,000 francs or nearly 1,100,000*l.*; that of the French colonial sugars 44,000,000 francs, or above 1,800,000*l.* Le Hâvre has regular communication by packets with Southampton (some of the packets on this station are steam-boats), New York, Vera Cruz, Bahia, Lisbon, and Hamburg. Steam and other boats ply between Le Hâvre, Rouen, and Paris, and between Le Hâvre and Honfleur, on the opposite bank of the Seine.

This town has a subordinate court of justice and a court for commercial disputes, a Calvinist church, a nunnery, a poorhouse, a foundling hospital, and three prisons. There are also a public library of 15,000 volumes, and other literary establishments; a museum of natural history, a high school, a school of navigation, and one of geometry applied to the arts. There is a military hospital; and a yearly fair, that of St. Michael, is held in a field belonging to this institution outside the town. Le Hâvre was the birth-place of St. Pierre.

Le Hâvre is the capital of an arrondissement which comprehends an area of 344 square miles, has 9 cantons and 121 communes, and had in 1836 a population of 142,292.

It was near the site of this town that Henry V. of England landed previous to the siege of Harfleur and the battle of Agincourt. In the year 1759 preparations were made at Le Hâvre for an invasion of England, which drew upon the town a severe bombardment from an English squadron under Admiral Rodney.

HAWARDEN. [FLINTSHIRE.]

HAWES, STEPHEN, author of 'The Pastime of Pleasure,' lived at the beginning of the sixteenth century, but the date of his birth and death are alike uncertain. He calls himself 'gentleman and grome of the chamber to the famous Prynce and seconde Salomon, Kynge Henrye the Seuenth.' He was a native of Suffolk, and refers in his poems to Lydgate as his master. His accomplishments made him a favourite with Henry VII., who had some taste in literature, particularly French, in which Hawes's travels had given him uncommon skill, and poetry such as that of Lydgate and Chaucer, in the repetition of which Hawes was a great proficient.

His 'Pastime of Pleasure' is an allegorical poem, 'containing the knowledge of the seven sciences and the course of Man's life in this world.' Graund Amour goes through the town of Doctrine, where he meets the Sciences, becomes enamoured of La bell Pucel, whom he marries, and with whom he spends his life.

It is by courtesy to metre, and scarcely for any other cause, that we call 'The Pastime of Pleasure' a poem. We have already endeavoured [EPIC] to point out what appears to us the natural order of poetical creation; and this work seems to belong to that period when the epic element (the poetry of action) had been worn out, but having long held undisputed sway in the romances, as action itself had in real life, compelled those who lived in a more thoughtful and therefore lyrical age to clothe their reflective poetry in an epical dress.

Another poem, 'The Temple of Glas,' is ascribed to Hawes, but there are almost equally strong reasons for believing it to be Lydgate's, as Hawes himself tells us that Lydgate composed a work under that name, and there is something about the run of the verses which reminds us rather of Lydgate than of Hawes. (Warton, *Hist. of Eng. Poet.*, ii. 210; Southey's *Brit. Poets;* Wood's *Ath. Oxon.*)

HAWFINCH. *Haw Grosbeak*, *Grosbeak*, of the modern British; *Gylfinbraff* of the Antient British; *Le Grosbek* and *Pinson Royal* of the French; *Frogione*, *Froccione*, *Frosone*, *Frisone*, *Friggione*, of the Italians; *Kernbeisser*, *Kirsch Kernbeisser*, *Kerschfink*, *Nusbeisser* of the Germans; *Appel-vink* of the Netherlanders; *Loxia Coccothraustes* of Linnæus; *Fringilla Coccothraustes* of Temminck; *Coccothraustes vulgaris* of Brisson.

Description.—*Rump*, *head*, and *cheeks* red-brown; edging round the *bill*, space between that and the eye, a line beyond the eye and throat, deep black; a large ash-coloured collar just below the *nape;* back and greater part of the *wings* deep brown, but there is an oblique white stripe upon the wing and beyond it a considerable space of a light whitish colour going off into chestnut; secondary quills as if cut off square at the ends, or, as Edwards says, with justice, like the figures of some of the antient battle-axes, glossed with rich blue, less conspicuous in the female; *Tail* feathers white within, of a blackish brown on the external barbs; lower parts of the bird vinous red; iris pale red (according to Temminck), feet and bill greyish brown. Length seven inches.

Female. Generally like the male, but with the colours much less brilliant.

Young of the year before the moult.—Very different from the adults and old birds. *Throat* yellow; face, cheeks, and summit of the head dirty yellowish; lower parts white, or whitish; sides marked with small brown streaks, with which all the feathers are terminated. *As the young bird advances in age* some red vinous feathers appear disposed irregularly upon the belly; the upper parts are of a tarnished brown, spotted with dirty yellowish; bill whitish brown, except at the point, where it is deep brown. (Temminck.)

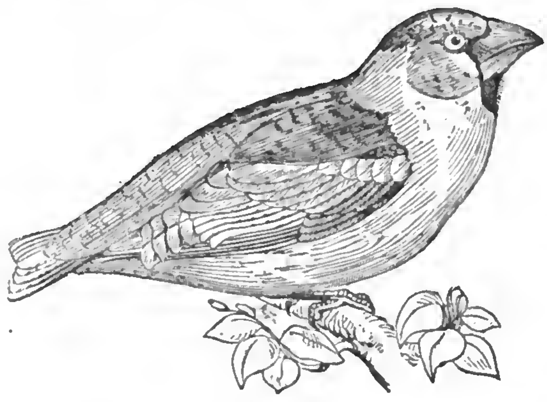
Mr. Gould (*Birds of Europe*) says that in the male the beak and feet in winter are of a delicate flesh-brown, the former becoming in summer of a clear leaden hue, the ends straw-colour, and in some instances white; the top of the head, the cheeks, and rump, of a chestnut-brown. The rest of the description does not differ much from M. Temminck's.

Varieties.—White, yellowish, or greyish. Wings and tail often white. Plumage often variegated with white feathers.

Food, Habits, Reproduction, &c.—Hard seeds and kernels form the principal food of the Grosbeak, but we have seen it feeding on the berries of the hawthorn (whence its name), and shot it when so employed; so that it is probable that the soft part of fruits is not disagreeable to it, although the bill is evidently formed for cracking the stony kernel. Willughby states that it breaks the stones of cherries, and even of olives, with expedition. The stomach of one which he dissected in the month of December was full of the stones of holly-berries. The majority of ornithologists give the Hawfinch credit for forming a nest beautifully constructed of lichens and vegetable fibres with a lining of feathers and other soft materials. But, according to Mr. Doubleday, who has thrown much light on the history of this bird, and discovered it breeding in Epping Forest in May and June, the nest, which is made in some instances in bushy trees at the height of five or six feet, and in others near the top of firs at an elevation of twenty or thirty feet, is remarkably shallow and carelessly put together, being scarcely deeper than that of the dove. In materials it resembles that of the bullfinch, but is not to be compared with it in neatness and compactness of construction. Eggs, from four to six in number, of a pale greenish white, varying in intensity, spotted and streaked with greenish grey and brown. Mr. Gould states that he has known the bird to breed near Windsor, and a few other places; but certainly nowhere so abundantly as on the estate of W. Wells, Esq., at Redleaf, near Penshurst, Kent. This gentleman informed Mr. Gould that he had, with the aid of a small telescope, counted at one time eighteen on his lawn.

Mr. Selby remarks that in the pairing season it probably utters a superior song, as Montagu says that even in winter, during mild weather, he has heard it sing sweetly in low and plaintive notes.

Geographical Distribution.—Plentiful in some districts of France; permanent and not uncommon in Italy; common in Germany, Sweden, and part of Russia. In Mr. Selby's 'Illustrations,' and indeed in most other English works, the Hawfinch is noticed as an occasional visitant. Dr. Latham says that 'the Hawfinch visits us chiefly in winter, but one was shot in the summer months near Dartford, in Kent.' He goes on to remark that White records another instance at the same season, and says that it had the kernels of damsons in its stomach. 'These,' continues Dr. Latham, 'might possibly have bred here, though we have no authority for its ever being the case.' This authority now exists in the observations of Mr. Doubleday. 'The Hawfinch,' says Mr. Doubleday, 'is not migratory, but remains with us during the whole of the year.' This observer sufficiently accounts for the rarity of its appearance,—'its shy and retiring habits leading it to choose the most secluded places in the thickest and more remote parts of woods and forests, and when disturbed it invariably perches on the tallest tree in the neighbourhood.'



Coccothraustes vulgaris.

HAWICK. [ROXBURGHSHIRE.]

HAWKESWORTH, JOHN, LL.D., was a successful writer of the last century. The date of his birth (1715 or 1719) and the occupations of his early life are variously stated: in so short a notice, all that is essential to record is that he was bred to some mechanical occupation, and therefore deserves the more credit for his talent and industry in supplying the defects of a rude and illiterate education. His first appearance was as a contributor to the 'Gentleman's Magazine,' in which he succeeded Dr. Johnson as compiler of the parliamentary debates in 1744. In 1752, encouraged by the success of the 'Rambler,' he undertook, assisted by Johnson, Warton, and one or two others, a series of essays, called the 'Adventurer.' They extended to the number of 140 (70 of which are ascribed to Hawkesworth himself), were received with great approbation, and contributed much to the increase of his reputation and friends. Herring, archbishop of Canterbury, was so much pleased with the work, that he procured a degree in civil law for the conductor. This compliment however produced a permanent alienation on the part of Johnson, who had not yet received the same distinction. He probably regarded the man so patronised as a mere imitator of himself; and in fact Hawkesworth's style appears to have been modelled upon Johnson's, though less remarkable for pomp and inflation of diction. In 1761 he published an edition of Swift, with a life prefixed, to the merits of which Dr. Johnson has borne handsome testimony in his 'Lives of the Poets.' On the return of Capt. Cook from his first voyage of discovery in the South Seas, it being thought desirable to entrust the task of compiling an account of the voyage to a literary man rather than to one of the travellers, Dr. Hawkesworth's reputation as an able writer obtained for him the commission. He completed the task in three vols. 4to., 1773 [COOK], illustrated with maps and plates at the expense of government, including the prior voyages of discovery of Byron, and of Wallis and Carteret, and received for recompence the liberal sum of 6000*l.* The work however did not give entire satisfaction: the warmth of his descriptions of manners, in some respects, was thought to verge upon immorality; and exceptions were taken to some religious speculations, which, right or wrong, were certainly out of place. The chagrin occasioned by these censures is said to have shortened the author's life, but as he died in November of the same year, the statement is probably incorrect; the effect of criticism on a practised author is seldom so rapid and deadly. The accounts of Cook's subsequent voyages were written by Cook himself, and gained more in simplicity and correctness than they lost in literary elegance. Dr. Hawkesworth translated 'Telemachus,' and wrote 'Almoran and Hamet,' an eastern romance, which was much admired. He was a regular contributor to the 'Gentleman's Magazine.'

HAWKING. [FALCONRY.]

HAWKINS, SIR JOHN, a distinguished seaman of the reign of Elizabeth, was born at Plymouth, about 1520. His youth was spent in trading to Spain, Portugal, and the Canaries; and the information and experience which he thus obtained made him well aware of the gain to be derived from supplying the Spanish colonies with slaves from Guinea. With the assistance of some merchants, he fitted out a small squadron in 1562, and obtained, partly by purchase, partly by force, a cargo of 300 negroes, whom he carried to Hispaniola, and there sold. This, we believe, was the first adventure of Englishmen in that inhuman traffic. He made a second voyage in 1564, and a third in 1567: the latter turned out unfortunately. All trade between the Spanish settlements and foreigners being prohibited by the mother-country, though often, from interested motives, connived at by those in power, he was at last attacked by the Spanish authorities in the port of S. Juan de Ulloa, and saved but two ships of his squadron, with which, after suffering great hardships, he returned to England in January, 1568. This seems to have been his last commercial enterprise. The queen's approbation of his services, and sanction of that abomination, which, after the lapse of more than two centuries, the tardy voice of Europe has branded as piracy, was conveyed in the expressive grant to wear as his crest 'a demy-moor in his proper colour, bound with a cord.' In 1573 Hawkins was appointed treasurer of the navy. In 1588 he served as rear-admiral against the Spanish armada [ARMADA]; and his bravery on this occasion was rewarded by Elizabeth with the honour of knighthood. Being sent with Frobisher in 1590 to intercept the plate fleet and harass the trade of Spain, he failed in the first object, but succeeded in the second. In 1595 he was appointed, jointly with Drake, to command a more important expedition against the Spanish settlements in the West Indies. This enterprise proved fatal to both these hitherto successful commanders. They disagreed upon the conduct of operations, and soon separated. [DRAKE.] Hawkins died November 21, 1595, chiefly, it was supposed, through annoyance and agitation; and Drake expired in the following month. Sir John Hawkins sat in parliament for Plymouth, and founded an hospital at Chatham for poor and sick seamen.

HAWKINS, SIR JOHN, the senior of the two chief historians of music, the friend and executor of Dr. Johnson, and a descendant of the Sir John Hawkins who commanded the Victory, as rear-admiral, at the destruction of the Spanish armada, was born in 1719. His father, a surveyor and builder, at first brought his son up to his own profession, but eventually bound him to an attorney, 'a hard taskmaster and a penurious housekeeper.' At the expiration of the usual term, the clerk became a solicitor, and by unremitting assiduity, united to the most inflexible probity, he, unfriended, established himself in a respectable business, while by his character and acquirements he gained admission into the company of men eminent for their accomplishments and intellectual attainments. He was an original member of the Madrigal Society, and at the age of thirty was selected by Mr. (afterwards Dr.) Johnson as one of the nine who formed his Thursday-evening Club in Ivy-lane; a most flattering distinction, which confirmed his literary habits, and powerfully influenced his future pursuits when, not many years after, he relinquished his profession. About this time he contributed much to the Gentleman's Magazine, and other periodicals of the day. He also wrote the poetry of the cantatas set by the blind composer, Stanley, from which he derived considerable profit.

In 1753 Mr. Hawkins married Sidney, the second daughter of Peter Storey, Esq., with whom he received an independent fortune, which was greatly augmented in 1759 by the death of his wife's brother. He then retired from all professional avocations, giving up his business to his clerk, Mr. Clark, who subsequently became chamberlain of the city of London. With this increase of wealth is connected an anecdote of far too honourable a nature to be omitted here. The brother of Mrs. Hawkins made a will, giving her the whole of his fortune, except a legacy of 500*l.* to a sister from whom he had become alienated, and communicated the fact to Mr. and Mrs. Hawkins, who, by representing the injustice of this act, and by adding entreaty to argument, prevailed on him to make a more equitable distribution of his property, and an equal division was the consequence. 'We lost by this (says Miss Hawkins, her father's biographer) more than 1000*l.* a-year; but our gain is inestimable, and we can ride through a manor gone from us with exultation.'

Upon retiring from the law Mr. Hawkins purchased a house at Twickenham, intending to dedicate his future life to literary labour and the enjoyment of select society. But in 1771 he was inserted in the commission of the peace for the county of Middlesex, and immediately became a most active magistrate. Among other useful acts, be wrote, 'Observations on the State of the Highways, and on the Laws for amending and keeping them in repair;' subjoining the draught of a bill, which passed into a law. In 1764 he successfully opposed tbe attempt made by the corporation of London to throw on the county two-thirds of the expense of building the gaol of Newgate. For tbis service he was, in 1765, elected chairman of the Middlesex quarter-sessions. Here again his independent spirit and charitable disposition were manifested. Acting as a magistrate, he at first refused the customary fees; but finding that this generous mode of proceeding rather increased the litigious disposition of the people in his neighbourhood, he altered his plan, took what was his due, but kept the amount in a separate purse, and at fixed periods consigned it to the clergyman of his parish, to be distributed at his discretion. When the riots at tbe Brentford election took place in 1768, ho was active in their suppression; and the dispersion of the Spitalfields weavers in 1769, who had collected in a very threatening manner, was mainly owing to his decision and boldness. For these services he received, in 1772, the honour of knighthood.

Sir John Hawkins now set seriously about finishing his great work. He went to Oxford, and there remained some time, to examine the books in the Bodleian and otber libraries, connected witb his inquiry. He was accompanied by an artist, whom he engaged to make drawings of the portraits in the music-school, all of which were engraved for his History. From the Rev. Mr. Gostling of Canterbury, whom he visited two years consecutively for the purpose, he also gained much valuable information, as well as from Doctors Boyce and Cooke, and others qualifiod to aid bim in his pursuit. In 1776 appeared, in five quarto volumes, the work on which bo had been 16 years engaged, under the title of 'A General History of the Science and Practice of Music,' which he dedicated to George III., and presented it to his majesty at Buckingham House, during a long audience granted for the purpose. Tbe king no doubt appreciated the work as it deserved; and the university of Oxford showed their estimation of it, by offering to confer on the author the degree of doctor-in-law, whicb he had reasons for declining: but that learned body paid him the compliment of requesting his portrait. With the public however the reception of tbe History was widely different. The best judges, it is true, discovered its value; its research and accuracy were obvious to those who were qualified to form an opinion on the subject; but five large volumes were alarming to tbe public, and, unfortunately for the work, he closed it at the death of Handel, leaving untoucbed those matters in wbich the living many were most interested. Moreover, on the appearance of tbe History, Sir John was immediately attacked in the *St. James's Evening Post*, by Steevens, the commentator on Shakspeare, in the most virulent and uncandid manner; and every engine was set in motion to damage the reputation of tbe work. Subsequently it was assailed by the ridicule of Dr. Lawrence, in the *Probationary Odes*. The consequence of these persevering efforts to destroy a very learned and most useful, though not well written history, was, that it fell nearly dead from the press. Stevens and Lawrence were the friends of Dr. Burney, which may account for, though it cannot palliate, their illiberal conduct: but it is to be hoped that tbe rival bistorian neither instigated nor sanctioned proceedings so unfair and so cruel. Time however has done that justice to tbe author which his contemporaries denied him. The work now fetches a price beyond that at which it was published; it is found in every good library, and the more it is read and known, tbe more it will rise in public estimation and demand.

While pursuing his historical inquiries, Hawkins accumulated a fine musical library; and it was his singular good-fortune to become possessed, by purchase, of several of the most scarce and valuable theoretical treatises on the science itself, which were collected by tbe celebrated Dr. Pepuscb, F.R.S. This collection he, after the completion of bis work, most liberally gave to the British Museum, where it remains.

In 1760 Hawkins published bis edition of Walton's Angler,' with notes, of which three or four editions have since appeared. On the death of Dr. Johnson, in 1784, Sir John undertook, in consequence, it is supposed, of some conversation between them, to write the life of his friend, and to become editor of a completó collection of bis works. In this task, as in his 'History of Music,' it was bis fate to meet with unexpected competition and unmerited criticism. But he had scarcely entered on the work when his whole library—a library which no expense could replace—was destroyed by fire. The blow was severe, though the sufferer never murmured, but began again to collect. In 1787 he closed his literary career, by the publication of his Life of Dr. Johnson, and an edition of his works.

In tho month of May, 1789, Sir John Hawkins suffered a paralytic attack, which from the first was considered of a fatal nature. It increased on the 21st of the same month, when be expired. His remains lie in the cloisters of Westminster Abbey, where, by his own direction, a simple tablet with his initials and tbe date of his death is tbe only monument to his memory. He left two sons and one daughter. The latter is well known in the literary world: her novels are too didactic for tho multitude, but tbe cause of virtue and right feeling has never found a more zealous advocate.

HAWKS. [Falconidæ; Falconry.]

HAWKSHEAD. [Lancashire.]

HAWKSMOOR, NICHOLAS, wbo, although not included in Cunningham's 'Lives of British Architects,' executed many buildings of note in the early part of the last century, was born in 1666, and at the age of seventeen became the pupil of Sir Christopher Wren. Beyond tbis we possess very few personal details relative to him. His works, if tbey do not display a very refined taste, give evidence of talent and a certain degree of originality. Like that of Vanbrugb, with whom be is said to bave been associated both at Blenheim and Castle Howard, his style partook of the massive and heavy, combined with a certain coldness and baldness. Of this we have proof in the churcb of St. George's in the East, Ratcliffe Higbway, commenced by him in 1715, which is no less ponderous in its ensemble than hard and dry in its details, besides being most extravagant and anomalous. That of St. Mary Woolnoth's in Lombard street is very much better; there is a certain degree of richness and picturesque cbaracter in tbe north side, which, until the late alterations, was tbe only one exposed to view. This façade is remarkable for baving no windows, but in lieu of tbem three large niches, decorated with columns and external rustics, and in themsolves not ill-imagined, although too much cut up by the smaller nicbes inserted between the pedestals of the columns; bad the rustics been continued uniformly below them, and the smaller blank windows or panels been entirely omitted, the effect of the whole would have been decidedly improved. The interior, which is lighted chiefly by a square dome or lantern extending over the centre above three Corinthian columns at each angle, and having a large semicircular window on each of its sides, is one of the best specimens of church arcbitecture of tbat day, though the effect is greatly impaired by the pewing and galleries. But it is chiefly as tbe architect of St. George's, Bloomsbury, tbat Hawksmoor is entitled to notice, that being a work whicb of itself ought to confer a lasting reputation. It is true, Walpole has stigmatised the steeple as 'a masterstroke of absurdity,' and adopting that smartly expressed opinion others have continued to repeat his censure. Malton was one of the first who ventured to express a contrary judgment, and it has more recently had ampler justice done to it by a writer in tbe 'Quarterly Review,' who very desorvedly gives it the preference over every other steeple in London. It is certainly the happiest as well as the most original in its idea; picturesque and graceful in outline; well combined together; consistent though varied; with a due expression of solidity, remote from heaviness on the one hand, and on the other from that species of lightness which, though a merit in Gotbic, becomes a fault in Roman architecture. One leading fault imputed to this steeple is that it is surmounted by a statue of George II., which gave rise to a paltry epigram that bad perhaps quite as much influence in exciting a prejudice against the structure as Walpole's dictum. Yet if there be any inconsistency or absurdity in terminating the steeple by a statue, it is assuredly equalled if not surpassed by that of erecting a column, for no other purpose than to elevate a statue upon it: because in the latter case the figure, though put almost out of sight, is presumed to be the principal object, while in the other it is intended to be no more than an ornamental accessary and termination to the structure. The portico of this church, which is, like that of St. Martin's, a hexastyle Corinthian, is very little inferior to it in execution, and displays itself still more advantageously, being considerably raised above the street by a flight of steps, enclosed by pedestal walls, which gives it an air of dignity beyond that of any other building of the kind in the metropolis. Besides which it possesses the further advantage of its roof not being interrupted by a steeple immediately behind the portico, the campanile spoken of being attached to the body of the church at the south-west angle. In short, if St. Martin's justly entitles Gibbs to the reputation he has hitherto maintained, St. George's, Bloomsbury, ought to acquire for Hawksmoor a much greater share of commendation than he has hitherto received. St. Anne's, Limehouse, is another church by him, which deserves more praise than has fallen to its share. With much that is incorrect, and with very little that is positively beautiful, its ensemble has an air of grandeur very frequently missed where it seems to have been more studiously aimed at.

Among his other works were Easton Neston, in Northamptonshire, and a mausoleum at Castle Howard. He was also employed to repair the west front of Westminster Abbey. The south quadrangle and street front of Queen's College, Oxford, have by some been attributed to him, though they are generally supposed to have been the work of Wren. That he did much at All Souls College, in the same university, is unquestionable, and Dallaway informs us that he had seen a very grand design by him for rebuilding Brazenose College, somewhat in the style of Greenwich Hospital, where he had at one time the appointment of clerk of the works. Besides this he gave a design for the Radcliffe Library, but that of Gibbs obtained the preference. He died in March, 1736, at the age of 70.

HAWKWOOD, SIR J. [CONDOTTIERI.]

HAWTHORN. [CRATÆGUS.]

HAYDN, JOSEPH, the father of modern orchestral music, the most original and imaginative of composers, was born at Rohrau, about fifteen leagues from Vienna, on the 31st of March, 1732. His parents were humble; his father was a small wheelwright, and his mother, previous to her marriage, was cook to the lord of the village; but both, true Austrians, were musical: the former had a fine tenor voice, and could play on the harp; the latter sang, and with the aid of a relation they got up little concerts on Sunday afternoons, in which the young Haydn, when five years of age, pretended to join them with two pieces of wood cut in imitation of a violin and bow. The accuracy with which his motions kept time with the domestic music attracted the notice of a cousin, a schoolmaster at Hainburg, and a good musician, who made an offer, which was readily accepted, to take the child into his house as a scholar. Under the friendly roof of that kinsman he learned music as an art, soon became capable of using a real violin, and acquired some knowledge of Latin. He was also taught to sing in the parish church, where he was heard by Herr Reuter,—Kapellmeister of the cathedral of St. Stephen at Vienna, who was travelling in search of boys for the use of his choir,—and immediately engaged as a chorister in the metropolitan church of the empire.

Under Reuter, Haydn continued till he arrived at the age of thirteen, practising almost incessantly, but receiving only such instructions from his master as qualified him for the duties of the choir. At that period failing, for want of sufficient knowledge, in an attempt at composition, and being utterly destitute of the means of obtaining the assistance of a master, he contrived to procure the well-known treatise on counterpoint by Fuchs, with one or two other works on the theory of music, by means of which, and his own indefatigable industry, he speedily surmounted the first difficulties encountered by a youthful composer. He now made himself known to the famous Porpora, who was living in the hotel of the ambassador from Venice, and by very assiduous attentions to the old musician gained much knowledge from him, particularly in singing, in which he made such progress that the ambassador, having heard him, took him into his service, and bestowed on him a trifling salary. But at the age of seventeen his soprano voice left him, and with it fled the present means of living. His father could render him no assistance, and, sorely distressed, he was offered an asylum in the house of Keller, a wig-maker, who had often been charmed by his vocal powers. The hospitality was accepted, and Haydn was, in obscurity, enabled to pursue his studies. But his residence with the friendly tradesman powerfully influenced his future domestic life. Keller had a daughter, who was offered to the young musician in marriage. He gave his promise to her, which after a time he honourably fulfilled; the union however did not contribute to the happiness of either party, and ended in a separation not very long after it had taken place.

By giving a few lessons in music, and occasionally performing in the orchestra for what he could get, Haydn supplied himself with absolute necessaries; and frugality being one of the German virtues, he managed to preserve a tolerably decent appearance; till fortune first began to smile on him, by leading him into the house of the Abate Metastasio, where he gave instructions to the poet's niece, and gained not only a thorough acquaintance with the Italian language, but a general knowledge of literature, and the most useful advice on the subject of setting words to music, from the imperial laureate. This connection also introduced him to the Count Martzin, a noble patron of music, into whose service he entered in 1759: and hence, in 1761, he passed into that of the rich Prince Esterhazy, to whom he remained attached, as *Maestro di Capella*, to the end of his life.

Comfortably settled in the palace of Eisonstädt, in Hungary, enjoying in moderation his favourite diversions of hunting and fishing, and relieved from care for the future, Haydn there composed all the great works which he produced prior to the year 1791, and under advantages which few, if any, have possessed:—he had a full, choice band, living under the same roof with him, at his command every hour in the day; he had only to order, and they were ready to try the effect of any piece, or even of any passage, that, quietly seated in his study, he might commit to paper. Thus at leisure he heard, corrected, and refined whatever he conceived, and never sent forth his compositions till they were in a state to fearlessly challenge criticism.

We now arrive at that period in the life of Haydn in which were produced most of those works that have raised his fame to the high point it has attained. In 1790 Salomon, the celebrated violinist, having determined to give a series of subscription concerts in London, went to Vienna to engage either Haydn or Mozart, not only to produce certain compositions in aid of his design, but to superintend in person the performance of them. It was mutually agreed by the three parties that Haydn should be the first to visit London, and that Mozart should follow the year after; but it was destined that the latter should not live to fulfil his part in the agreement. In 1791 Haydn arrived, and produced during that and the following year, at 'Salomon's Concerts,' in the Hanover-square Rooms, six of his *Twelve Grand Symphonies*, which immediately made an extraordinary sensation in the musical world, and have ever since rather increased than diminished in public estimation. Here also he composed, by agreement with Corri and Dussek, music publishers, his two sets of English canzonets, which for originality, for musical expression of every kind, and for richness and propriety of accompaniment, have no rivals. Besides these his prolific imagination gave birth to many quartets, sonatas, &c.

In 1794 Haydn accepted a second engagement from Salomon for the same purpose. He reached London in January, and in the course of that and the succeeding season brought forth the remaining six of his grand symphonies, with the same brilliant result. For these twelve symphonies, and for superintending their performance, he received a sum—including two benefit concerts, the profits guaranteed by Salomon—amounting to 1550*l*. To this is to be added, as the fruits of his visits to England, what he gained by his canzonets and other compositions: it was therefore with reason he declared that in London he discovered the real value of the reputation he enjoyed in Germany. His reception here was of the most flattering kind: the university of Oxford conferred on him the degree of Doctor in Music; at the tables of the prince of Wales and the duke of York he was a frequent guest; and nearly all classes vied in showing him attention. The satisfaction which he felt he gratefully acknowledged and evinced in a diary he kept while in England, a translation of a part of which (a curious document), with notes, appears in the fifth volume of the *Harmonicon*.

In 1798 Haydn gave to the world his oratorio *The Creation*, the greatest of his works, though composed in his sixty-fifth year. It is enough to say of this fine production of his advanced years, that it is the only oratorio, of many that have been produced, that can bear comparison with those of Handel. The design was suggested, his biographer, M. Beyle, tells us, by an English gentleman named Lidley (Liddell, we suspect, is the true name). The German text however, and the barbarous English translation (which to our shame is still in use), were furnished by the Baron Von Swieten. Two years after this he composed *The Seasons*, a work of as much originality as the *Creation*, but not exhibiting, nor intended to exhibit, the same depth of thought. The subject is not of so grave a nature, and is treated with more freedom. The last offsprings of his genius were two sets of quartets, 'which betray no abatement of his vigour; on the contrary, the second of his Op. 80 is perhaps the most original and exquisitely-finished of all the works of the kind that ever proceeded from his pen.'

'When Haydn's *Creation* reached Paris the *Institut National* elected him a member, an honour contested with him by some of the greatest men of the time in Europe: but the decision was just; for who among the candidates had contributed so much to the happiness of civilized nations? His few remaining years were spent in the enjoyment of a great and well-earned reputation, and a small independence created by his talents; and the last hours of his mortal life were crowned with honours.' (*Supplement to Musical Library*, i. 27.) His death is supposed to have been accelerated by the bombardment of Vienna, which powerfully agitated his weakened frame. Though it must be mentioned, to the honour of Napoleon, that he issued strict orders that the abode of Haydn should be respected; and when the troops entered the city a French guard was placed at his door to protect him from every kind of injury. He died on the 29th of May, 1809, and was privately buried at Gumpendorff, his country then suffering all the horrors of war, and the capital of the empire being in possession of the enemy. He left no children. His property, except about 500*l*. bequeathed to two faithful servants, came into the hands of a blacksmith, his distant relation. His works are astonishingly numerous, embracing every class. Among them are 116 symphonies, 83 violin quartets, 60 pianoforte sonatas, 15 masses, 4 oratorios, including the *Seven Last Words*, a grand *Te Deum*, a *Stabat Mater*, 14 Italian and German operas, 42 duets and canzonets, upwards of 200 concertos and divertissements for particular instruments, &c., &c. Many of these, but not the most valuable, were irretrievably lost in the fire which consumed the palace of his patron at Eisenstädt: the best are out of the reach of danger; they have been printed and reprinted in half the capitals of Europe.

HAYLEY, WILLIAM, best remembered as the friend and biographer of Cowper, during the end of the past and the beginning of the present century enjoyed a considerable reputation, less perhaps from his sterling merit as a poet, than from his combining a very respectable share of taste, talent, and devotion to art and literature, with an easy fortune, and a certain position in society. Of epitaphs and other occasional verses he was a frequent, willing, and elegant author; but the credit acquired by this ephemeral branch of composition is as fleeting as it is commonly excessive. Mr. Hayley was born at Chichester, in 1745, and studied in Trinity Hall, Cambridge, intending to practise as a barrister. Finding the law not to his taste, he settled on his patrimonial estate of Eartham, in Sussex, in 1774, a name memorable by its frequent occurrence in the history of Cowper, with whom the proprietor became acquainted in 1792. Hayley died November 20, 1820. Of his numerous poetic works, the 'Triumph of Temper,' 1781, has been the most popular, probably in consequence of the domestic interest of the subject. The 'Essay on Painting,' 1778, and 'Essay on History,' 1781, addressed respectively to his friends, Romney the painter, and Gibbon, rank among his best productions. We may add, as the most important of his other numerous works, the 'Essay on Epic Poetry,' 1782; 'Life and Poetical Works of Milton,' 1794-9; 'Essay on Sculpture,' 1800, addressed to his friend Flaxman; 'Life of Cowper,' 1802. (*Life of Hayley*, by himself, 1823.)

HAYTI. [HISPANIOLA.]

HAZEBROUCK, a town in France in the department of Nord, on the road from Paris to Dunkerque: distant from Paris 128 miles in a straight line almost due north, or 140 miles by the road: in 50° 43′ N. lat., 2° 32′ E long.

This town is situated in one of the richest and most delightful plains in France, devoted chiefly to pasturage, or to the raising of tobacco, hops, pulse, rape and colza for oil, and fruit. The streets of the town are well laid out, the houses handsome, and the place has the air of being inhabited by a wealthy and thriving population. There is a large and handsome market-place, in which is the town-hall, with a Doric colonnade, built of freestone. There are a subordinate court of justice, an agricultural society, a high school, and two theatres. The population in 1836 was 7674.

Hazebrouck is the capital of an arrondissement having an area of 267 square miles, and comprehending 7 cantons and 53 communes: the arrondissement had in 1836 a population of 105,879.

HAZEL-NUT, the fruit of the wild bush of Corylus Avellana, unchanged and unimproved by cultivation. It differs from the domesticated varieties only in being smaller and rather more hardy. [FILBERT.]

HAZLITT, WILLIAM, the son of a Unitarian minister of the same name, was born at Maidstone on the 10th of April, 1778. When he was five years old his father transferred the scene of his ministerial exertions to America, and remained with his family in the United States for two years. On his return to England the father became pastor of the Presbyterian congregation at Wem in Shropshire; and it is here that the work of Hazlitt's education was commenced. At the age of nine he was put to a day-school at Wem. Some letters written by him, between the ages of nine and twelve, which have been preserved, indicate a very forward mental development; and in addition to these specimens of private correspondence, there is a letter, which he published at the age of thirteen, in a newspaper, in defence of Dr. Priestley, which displays very considerable knowledge as well as literary skill. In 1793 Hazlitt was entered as a student of the Unitarian college at Hackney, in order to be educated for his father's profession. But for this profession he had no liking; and having devoted himself, while at the college, principally to moral and political philosophy, and having comparatively neglected theological pursuits, he returned home in 1795, having determined, much against his father's wishes, to change his profession.

Hazlitt had from a very early age shown a love of pictures and a taste for drawing, and it was now determined that he should follow the profession of a painter. He commenced with great ardour and assiduity, continuing to cultivate metaphysics in his intervals of leisure. We are told by his son that the first rough sketch of the essay on the 'Principles of Human Action' was thus begun at the age of eighteen. In 1802 he visited Paris for the purpose of studying the paintings in the Louvre; and on his return to England in the next year he made a professional tour through some of the midland counties and the manufacturing towns, and painted a considerable number of portraits; but he did not persevere. His notion of success was so exalted, and his fastidiousness so great, that he could never satisfy himself, and he determined on again changing his plans.

He now proceeded, in the autumn of 1803, to the metropolis to start as a literary adventurer. He commenced his almost endless series of publications with the essay on the 'Principles of Human Action,' and on which, we are told by his son, he always prided himself as much as on any other of his numerous works. As a metaphysical essay it is however of little value, though to a certain extent ingenious and acute; while, so far as the merits of composition are concerned, it is inferior to his writings on miscellaneous literary subjects. This essay was published anonymously in 1805, and was followed up quickly by other works. In 1808 he married a Miss Stoddart, the sister of Dr. (afterwards Sir John) Stoddart; and after his marriage retired into Wiltshire, where he continued without intermission his literary pursuits. In 1811 he returned to London, and we find his residence in a house in York-street, Westminster, which had been once inhabited by Milton, and which then belonged to Bentham. His admiration for genius led him to erect, in the garden of this house, a tablet 'inscribed to the Prince of Poets;' and he was afterwards much scandalized by a plan of Mr. Bentham's to cut down two beautiful cotton-trees which inarched this tablet, and to expose the garden and the tablet to the continual inroad of the members of a Chrestomathic school. The passage however in the 'Spirit of the Age,' in which Hazlitt speaks of this contemplated profanation, as he deems it, is perhaps not altogether free from an affected sentimentality, of which, it must be allowed, he is not often guilty.

In 1813 Hazlitt delivered a course of lectures at the Russell Institution, on the history of English philosophy; and subsequently he lectured on the English poets generally, the comic poets, and the poets of the age of Elizabeth, in separate courses, at the Surrey Institution. The three last series of lectures have been published, but not those on the history of philosophy. He acted for a short time also as reporter to the 'Morning Chronicle,' and after giving it up he still wrote occasionally in that paper, and also in the 'Examiner.' He was also, in the latter part of his life, a contributor to the 'Edinburgh Review,' and to some smaller magazines. His life was indeed one unintermitting course of literary exertion; and his labours brought him in a considerable income, which however his imprudence always quickly dissipated.

In 1822 he was divorced from his wife, and two years afterwards he married a second time. He died on the 18th of September, 1830, of cholera, and was buried in the churchyard of St. Anne's, Soho, where a friend has raised a monument to his memory. A long and eloquent inscription concludes thus: 'This stone is raised by one whose heart is with him in his grave.'

Hazlitt's principal works, besides those which have been already mentioned, are the 'Round Table,' in which he was assisted by Mr. Leigh Hunt, the 'Table-talk,' the 'Plain Speaker,' which three are collections of essays in two volumes each; the 'Characters of Shakspeare's Plays;' the 'Spirit of the Age,' which is a series of interesting sketches of his most distinguished contemporaries; his 'Political Essays,' which are collected from different newspapers and magazines, and published in one volume, with a preface, by Hone; and the 'Life of Napoleon,' which Hazlitt himself looked upon as his great work, and which was his last. The article 'Fine Arts,' in the 'Encyclopædia Britannica,' was also written by Hazlitt.

The principal merits of Hazlitt as a writer are force and ingenuity of illustration, strength, terseness, and vivacity. Another characteristic, which, by excess, often becomes a fault, is abundance of quotation. And while, as has been said, one good quality frequently exhibited in his writings is terseness, it often happens that he is chargeable with the opposite faults of verbiage and diffuseness. There is also a want of repose in his style, which prevents its pleasing for a long time, and which, despite the splendour of particular passages, tends to leave an unsatisfactory general impression. But in a number of fine passages which one would read, not only once, but again and a third time, or short, stinging, nervous sentences, which, without an effort, would impress themselves on the memory, there are few writers who can match Hazlitt. We hardly know, in the whole circle of English literature, not even Jeremy Taylor's writings being excepted, a finer specimen of accumulative eloquence than the account of the intellectual life of Coleridge in the 'Spirit of the Age.'

Hazlitt's chief title to fame is derived from his Essays on subjects of taste and literature, which are deservedly popular. For an historian he was too prejudiced, to say nothing of the unfitting luxuriance of his style; and he was not clear-headed enough for a metaphysician.

His personal qualities were doubtless not of that kind which gains the good-will or affection of men. Yet there was something in his moral conformation, and that not little, to be admired. If amiability was wanting, strength was there; and the regret with which one contemplates his irritable temper and its constantly distressing consequences is in some degree at least compensated by admiration for the moral courage with which he was ever ready to withstand the conventions of the world and despise the frowns of the great.

Since Hazlitt's death, two volumes of his 'Literary Remains' have been published by his son, with a short life, which shows much taste and good feeling, and to which we are principally indebted for the above account.

HEAD. [BRAIN; SKULL.]

HEAD, INJURIES OF THE. From the many peculiar and important features which they present, injuries of the head have properly received a separate consideration in all systems of surgery. For not only is the brain so essential to life that even its least injury must be regarded as serious, but the parts around and guarding it have many peculiarities. The skull, composed of two thin layers of bone, much exposed to external violence, and protected from it by only slight coverings, is extremely liable to fracture, and it is covered by a very dense and tightly applied membrane, the pericranium, of which the injuries and diseases exhibit all the peculiarities of those of other fibrous membranes. By the free communications of its vessels with those of the similar membrane (the dura mater) lining the interior of the skull, and less directly with those of the brain, disease is very liable to spread from the pericranium to these more important parts; and it is itself covered by firm unyielding muscles, and tendons, under which disease is always prone to extend widely. The injuries of the head are best considered as they affect the parts enclosing the brain or the brain itself.

In mere bruises of the scalp two circumstances are worthy of notice. A vessel of some size may be burst without the skin over it being wounded, in which case a most copious effusion of blood takes place, raising up the scalp from the skull, and producing rapid swelling of the whole of the upper part of the head. It needs however no particular treatment; no incision should be made into it, for if cold wet cloths be diligently applied, the blood will be again rapidly absorbed. If the effusion of blood from the bruise take place between the pericranium and the skull, the former is raised into a tumour, with sharp defined edges, and yielding to pressure in a manner so similar to that of fracture with depression of the skull, that the most experienced surgeon might be deceived and induced to apply the trephine, but for the rule that it should never be employed except in cases in which the brain itself is implicated.

A common superficial wound of the scalp needs no particular treatment. It should be closed with sticking-plaster after the hair around it has been shaved off, and it should be kept cool; but to guard against mischief to the adjacent parts, the patient should avoid all stimuli, and all exertion of either body or mind, till it is completely well. Not unfrequently a violent oblique blow will strip off a large flap of the scalp so as even to denude the bone. In cases of this kind, the part, after being carefully cleaned, should be accurately replaced: if absolutely necessary, a suture may be inserted to ensure more exact adaptation, and the rest should be closed by adhesive-plaster; the head around, being shaved, must be kept perfectly cool; the patient must be placed on a low diet, take aperient medicine, and remain quiet; on the first appearance of general excitement blood must be taken from the arm, and by leeches applied round the wound; under this treatment many cases get well with almost singular rapidity; but if irregularities be permitted, serious consequences may ensue even from the slighter injuries.

One of the most common of these sequels of injuries of the scalp is erysipelas of the head and face. It generally occurs in persons of an unhealthy habit, in hard drinkers, and in the full and plethoric. It commences about the third or fourth day after the injury; the patient begins to complain of headache and a feeling of general illness; he has a shivering fit, followed by nausea, thirst, and restlessness; a quick and hard pulse, and a thickly-coated tongue; he cannot sleep, and is perhaps slightly delirious. Soon after these symptoms have commenced the head and face feel very hot, and become red and swollen, appearances which increase, and after a day or two are accompanied with an eruption of small blisters, full of yellow fluid. There is no pain on touching the parts; but by the great swelling the eyes are often closed, and the features almost obliterated. Active reducing measures should, as a general rule, be early employed, and continued, if the disease does not yield, as far as the patient's strength will permit; and purgatives, with small doses of mercury, should be given, for the liver is very generally affected. After a period of from five to eight days the inflammation in most cases subsides, the cuticle scales off, and the wound, which had assumed an indolent unhealthy appearance, acquires a vigorous aspect, and rapidly heals. But in some cases the cellular tissue thus affected suppurates and sloughs, the scalp is separated, and there is profuse discharge from the wound. One or two incisions should in such case be made into the sloughing part, to admit of the free separation of the sloughs; but even with this the disease will sometimes spread and prove fatal.

Another affection which sometimes follows injuries (and especially punctured wounds) of the external coverings of the skull is inflammation and consequent extensive suppuration in the loose tissue connecting the tendon of the muscle covering the top of the head with the pericranium.

The general symptoms of fever are in these cases less severe than in erysipelas; the scalp is less hot and swollen, but more painful and very tender; the face is never affected. After a few days of general illness, a feeling indicating a collection of fluid may be perceived over some part of the head; and on making an opening into the swelling which has formed there, a quantity of matter may be pressed out of it from beneath a large portion of tho scalp. When this affection is suspected to be coming on, leeches should be put on the head in large numbers about the wound, and cold diligently applied; but if matter should form, one or more free incisions should be made through the scalp to let it out, and the part afterwards treated like a common abscess.

In cases in which the bone has been exposed, the same general and local treatment should be employed. The scalp when replaced may at once unite to the bone; or if it do not, granulations may spring up from the surface of the bone and close the wound: in worse cases, the outermost layer of the skull may die, and require a tedious process for its exfoliation and healing; in the worst, the whole thickness of the skull may perish, and the dura mater be exposed. In all these cases the mildest treatment is requisite, but as the disease is extremely liable to spread to the interior of the skull, the general health should be carefully watched, and if any indications of mischief arise, general or local bleeding should be at once employed.

When the bone itself is injured, no active treatment should ever be adopted, unless there are evident signs that the brain is suffering from compression or other palliable injury. These fractures of the skull get well even more rapidly than those of other bones; and in somo cases, especially in children, the skull may be forced in to some extent, but when it does not produce any derangement of the functions of the brain the injury will be repaired, and health perfectly restored. Cases of fracture of the skull in which the brain is not at first injured may be amongst either the most simple or the most dangerous in surgical practice—for the least intemperance or irregularity committed within some time after their reception may produce irreparable inflammation of the brain or its membranes.

Injuries of the dura mater (the membrane lining the interior of the skull) are of yet more importance, because they more immediately affect the brain. The dura mater is connected with the skull by a tissue in which numerous vessels ramify, and these may be ruptured by the jar from a blow which does not even break the skin. The blood that flows from them, accumulating between the dura mater and the skull, produces compression of the brain. The chief indication of this very dangerous accident having occurred is that the patient, who for some time after the blow had seemed only stunned, or had been even quite sensible, gradually becomes dull, sleepy, comatose, and at last totally insensible, just like one suffering from apoplexy. These symptoms supervene with a rapidity corresponding to the size and number of the vessels ruptured; the most rapid are those in which, by a blow on the side of the head, the main artery, supplying the dura mater and upper part of the skull, and which ascends just before the ear, is wounded. The only hope in these cases is to bleed the patient largely, to check the flow of blood in the head, and if that be not evidently beneficial, to apply the trephine wherever it is most probable that the blood may be found and removed. It must be confessed however that there is little prospect of doing good by trephining in these cases; it is seldom possible to decide at what part of the skull the blood is effused, or whether it may not be between the dura mater and the brain, or even in that organ itself. The symptoms in each case are the samo, but tho mechanical removal of the blood is possible only when the blood is immediately beneath the upper parts of the skull.

Instead of blood, purulent matter may collect between the dura mater and skull, and produce equally fatal results. This is indicated by the patient (usually some considerable time after the accident) complaining of headache, restlessness, and extreme languor; he has frequent irregular shiverings, his pulse is quick and hard, and he cannot sleep: if unrelieved by treatment, all these symptoms increase, and are shortly followed by delirium, convulsions, insensibility, or paralysis, which are no distant precursors of death. Early after their first appearance, a puffy, soft, but not very hot nor painful tumour, forms over the part struck. If this be opened, the pericranium will be found detached for some extent from the skull, which when exposed is seen to be dead, of a dull yellow colour, and covered by purulent fluid. In this case it may be expected that the dura mater is separated from the interior of the skull to the same extent that the pericranium is from its exterior, and the only hope of relieving the patient is to perforate the dead portion of bone with tho trephine, and let out the matter collected between it and the dura mater, and which compressed the brain.

The brain itself may suffer injury either from blood effused in it by rupture of its vessels, from compression by fractured portions of bone being forced down upon it, from wounds, from concussion, or from inflammation, and its various effects following any of these injuries. The first need not here be particularly treated of; it does not differ in its symptoms from the casos of common apoplexy with effusion of blood [APOPLEXY], and admits of no mechanical treatment. The second class comprehends the most important injuries of the head; those of 'fracture with depression,' as they are called, and those which occasionally happen in children, in which the skull is indented without being broken. The symptoms of such an injury are insensibility, generally in direct proportion to the degree of pressure; the breathing is slow, laboured, and snoring, and at every expiration the cheeks are puffed out and elevated; the pulse is slow and irregular; the pupil widely dilated and insensible to light; the patient neither feels nor moves, and lies as if in a fatal state of apoplexy. The part struck may of course present most varied characters: it may be *starred* from the centre of the blow, so as to have a shallow conical depression; it may be fissured, and one edge have passed under tho other; or it and tho scalp may be broken up confusedly, and the brain be protruding through the openings in them. It is worth remembering that the inner part of the skull may, in consequence of its brittleness, be much more widely fractured than the external, so that the degree of pressure on the brain is not always indicated by the depth of the indentation felt in the scalp. If unrelieved by treatment, the patient from the time of the accident grows more and more insensible; his pulse becomes more irregular, and he rapidly dies. The evident and indeed the only mode of affording relief is to remove the pressure from the brain, by exposing the fractured part of the skull by enlarging the wound in the scalp, or making a fresh one, and taking away or elevating all the portions of bone that are depressed. The mode of doing this will be determined in each caso by the form of the fracture and other circumstances; in some it may be sufficient to remove the loose pieces with forceps; in others, to saw off portions with a Hey's saw, or to apply the trephine and raise tho other depressed parts to their proper level with an elevator. These proceedings however must of course be limited to the cases in which the fracture is in a part within view; when it extends across tho base of the skull no mechanical means are applicable, and recovery is therefore extremely rare. Such cases, and all others in which compression cannot be mechanically relieved, can only be treated like common apoplexy, by bleeding the pationt, by cold sedulously applied, and by rigorous reducing measures. The after-treatment of cases in which the trephine or analogous means have been usod is nearly the same as in wounds of the skull and soft parts; the edges should be brought gently together, and slight pressure employed to support the dura mater where it is exposed by the aperture in tho skull; and the other usual precautionary and curative measures, as cold, local bleeding, &c., resorted to.

The immediate consequences of wounds of the brain vary greatly, and indeed unaccountably: in some cases a very slight injury is rapidly fatal, as in those (of which many are now recorded) in which a pointed instrument has passed in through the orbit, and produced almost instant death; whilst in others severe and extensive injuries, as from gun-shots, have been followed by serious symptoms at only a late period from their reception. In most of the cases whore the dura mater is perforated, whether by wound or by ulceration, the wounded or exposed brain protrudes through the aperture in the form of a darkish dirty-looking fungous mass, called 'Hernia Cerebri.' Its surface discharges purulent matter abundantly, and often bleeds slightly: pressure on it, as on tho brain itself, produces immediate insensibility; but the whole mass may be cut off without producing any pain or ill consequence. This is indeed the best treatment of it. If after having protruded to some distance it shows no disposition to decrease or to slough, it should be cut down to the level of the skull, and gentle pressure by compresses covered with the mildest ointment applied, so as to compensate, if possible, for the deficiency in the dura mater. Should the mass again sprout forth, the same treatment may be repeated. In a few cases the growth is checked, and the brain produces healthy granulations, which unite to the surrounding parts and skin over; in others the fungous mass sloughs and the remaining parts heal; but in the large majority the exposure of the brain and its irritation by surrounding parts produce such continued inflammation of it as proves fatal.

The last injury of the brain that needs particular notice is that called concussion or commotion. The exact nature of it is totally unknown; the name indicates only that which has been supposed, viz. a shaking or general disturbance of the minute parts of the brain. In its slightest degree it is merely a stunning, from which perfect recovery takes place in a few minutes; in its most severe, it is rapidly fatal; but even in these, a post-mortem examination discovers no alteration whatever in the structure of the brain. One of the most interesting points in surgery is the diagnosis of concussion from compression of the brain. As the latter seldom occurs without the former (for of course a blow which would fracture or indent the skull would violently shake the brain), compression has the symptoms of concussion, with the addition of some of the most severe which we have already mentioned. In concussion the patient is insensible only to slight impressions, for if he be loudly called to, he will wake up, answer a word or two, perhaps even rationally, and then relapse into the same state. If he be severely pinched or otherwise irritated he will withdraw the part so injured: he occasionally moves his limbs; he appears, in short, as if in a sound heavy sleep like that of a drunken man. The breathing is not stertorous, but generally quite natural; the pupil is contracted and irritable; the pulse is sometimes unaffected, but in severe cases small and weak; there is nausea or vomiting, and the extremities feel cold. If the case is about to terminate fatally, the whole body grows rapidly cold, the pulse becomes irregular and weaker, the breathing short and interrupted, and the insensibility increases. In treating cases of concussion much caution is needed: it has not appeared that bleeding, which is the remedy popularly expected for all such accidents, has at all diminished its primary symptoms, nor has the contrary treatment by stimulants been more successful. The patient, while suffering from the immediate stunning consequences of the blow, should merely be kept quite warm in bed, and carefully watched; if the pulse grow weaker, the extremities colder, and the other symptoms of sinking seem increasing, stimulants are first called for, and should be given till he is completely roused to his former state; but if, instead of being depressed, he remain stationary, no active means of any kind should be employed. Cases are not rare in which, after remaining in a nearly insensible state, as if in a sound sleep, for four, six, or eight weeks, with only very slight temporary alterations, the patient wakes, complaining of but little inconvenience, and rapidly recovers. If instead of waking nearly well, he is observed to grow restless, to seem suffering from headache, or should he be delirious or convulsed—if his pulse becomes quick and hard, and his eyes are hurt by strong light—he has in all probability inflammation of the brain, which is a most frequent consequence of concussion, and must be at once met by the active depleting and reducing measures necessary for its cure, from whatever cause it may arise. In some cases the symptoms of concussion gradually change into those of compression, which may then be suspected to arise from effusion of blood into or on the brain, as in the cases already mentioned.

The account here given is only a sketch of the most prominent and constant symptoms, progress, and treatment of the effects of injuries of the head. There are other symptoms that occur occasionally, and as it were accidentally, which it is necessary briefly to advert to. Furious delirium, lasting for some days and requiring active depletion, sometimes immediately follows concussion; violent convulsions also ensue, either on slight compression or on concussion; paralysis or hemiplegia is not unfrequently produced directly by compression, and they still more commonly occur as its sequels. Loss of memory, sometimes most singularly limited to particular classes of events or things; impairment of individual sensations, and various forms of insanity, are all the occasional consequences of these injuries, or of the inflammation and disorganization of the brain which follow them, and to the prevention or cure of which the chief attention is, in the majority of cases, to be directed.

HEARING. [EAR.]

HEARNE, THOMAS, an eminent English antiquary and editor of books and manuscripts, was born at White Waltham, in Berkshire, in 1678, where his father was the parish clerk. In 1692, under the patronage of Francis Cherry, Esq., of that place, with whom he had till then lived as a menial servant, he was placed at the free-school of Bray; and subsequently, in 1695, at that gentleman's expense, was entered of Edmund Hall, Oxford, where Dr. White Kennet, afterwards bishop of Peterborough, was his tutor. Dr. John Mill, who was principal of the hall, and Dr. Grabe, gave Hearne much employ in his younger days in the collation of MSS. He became B.A. in 1699. In 1701 he received his first employ in the Bodleian Library, of which Dr. Hudson had just been chosen keeper. He was afterwards made janitor of the library, and in 1712 succeeded to the place of second librarian. In January, 1715, he was elected architypographus and esquire beadle of civil law in the university, which post he held with his under-librarianship till the month of November following, when, finding the two places untenable together, he resigned the beadle's place, and soon afterwards his post in the Bodleian Library, on account of the oaths to the government, with which he could not conscientiously comply. He continued a non-juror to the last, much at the expense of his worldly interest. In the latter part of his life he resided principally at Edmund Hall, preparing and publishing his various works; but his constant recurrence to Jacobite sentiments, even in the prefaces to publications which could have no connection with them, kept him as constantly at variance with his neighbours in the university; and he underwent more than one prosecution. Hearne's temper was naturally irritable, and he was far from being either an amiable or a happy man. His life however was one of unwearied literary industry, and English antiquaries and historians will be for ever indebted to him. He died June 10th, 1735, in consequence of a cold, succeeded by a fever which was improperly treated.

Hearne's publications, almost exclusively printed by subscription at Oxford, were very numerous. Among the most valuable were an edition of Livy, 6 vols. 8vo., 1708; the 'Life of Alfred the Great,' from Sir John Spelman's MS. in the Bodleian Library, 8vo., 1710; Leland's 'Itinerary,' 9 vols. 8vo., 1710; Leland's 'Collectanea,' 6 vols. 8vo., 1715; the 'Acts of the Apostles,' in Greek uncials, from a very antient MS. in Archbishop Laud's Collection, 8vo., 1715; Livius Foro-Juliensis's 'Life of Henry V.,' 8vo., 1716; Alured of Beverley's 'Annals,' 8vo., 1716; Roper's 'Life of Sir Thomas More,' 8vo., 1716; Camden's 'Annals,' in Latin, 3 vols. 8vo., 1717; 'William of Neubridge,' 8vo., 1719; the 'Textus Roffensis,' 8vo., 1720; Fordun's 'Scotichronicon,' 8vo., 1722; 'History and Antiquities of Glastonbury,' 8vo., 1622; Heming's 'Chartulary,' 8vo., 1723; 'Robert of Gloucester's Chronicle,' 2 vols. 8vo., 1724; 'Peter Langtoft's Chronicle,' 2 vols. 8vo., 1725; 'Adam of Domerham,' 2 vols. 8vo., 1727; the 'Liber Niger Scaccarii,' 2 vols. 8vo., 1728; 'Hemingford's History,' 2 vols. 8vo., 1731; Otterbourne and Whethamstede's 'Chronicles,' 2 vols. 8vo., 1733; the 'Annals of Dunstaple,' 8vo., 1733; and 'Benedict, Abbot of Peterborough,' 2 vols. 8vo., 1735.

Hearne left his manuscript collections, by will, to Dr. William Bedford, of whom they were purchased by Dr. Richard Rawlinson for a hundred guineas, and by him bequeathed, together with his own manuscripts, to the Bodleian Library. Hearne's MS. Diary, in a hundred and fifty small paper books, is amongst them.

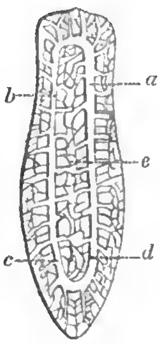
Several of Hearne's pieces were reprinted at different times, and in 1810 the project was entertained of reprinting the whole series in a uniform manner; but after the publication of four volumes, containing Robert of Gloucester and Peter Langtoft's Chronicle, the scheme was abandoned.

(*Lives of Leland, Hearne, and Wood*, 8vo., Oxford, 1772; Nichols's *Lit. Anecd. of the Eighteenth Century*; Chalmers's *Biog. Dict.*, vol. xvii., 275-284.)

HEART is the central organ of the circulation, and by its alternate contractions and dilatations exercises the principal power by which the blood is moved through the bodies of the higher animals.* Its anatomy and physiology will be made most easily intelligible by considering first the principal varieties of the circulation or other motion of nutritive fluid which occur in the animal kingdom; bearing in mind that the main objects for which such a motion is required are a constant supply of fluid adapted for their nutrition to all parts of the body, and its regular exposure to the influence of atmospheric air, that by the process of respiration it may be fitted for maintaining the life of the animal.

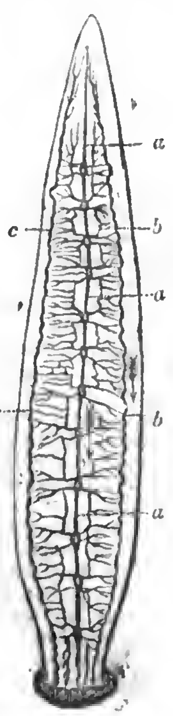
The simplest mode by which a distribution of nutritive fluid is effected is by means of ramifications proceeding from the stomach or intestinal canal to various parts of the body, which occurs in the polyps, infusoria, intestinal worms, echini, medusæ, and other zoophytes. In all these the digestive canal and the circulating system form but one apparatus: the food, which in the higher animals requires a complicated process of assimilation before it is fitted to move with the blood, is in them already adapted for nutrition. In most of them currents can be seen passing in opposite directions along the canals opening into the digestive cavity, exactly like those well known to exist in the stems of charæ, and probably produced by the motion of ciliæ which line the tubes, but are too minute to be discerned even with the microscope.

In the planariæ and some of the trematoda a separate vascular system has been discovered in addition to the ramified digestive tubes. In the former the main trunk has the shape of an oval loop (*a*, *b*, *c*, *d*), from which capillary networks arise and communicate freely together, and with a dorsal median vessel (*e*).



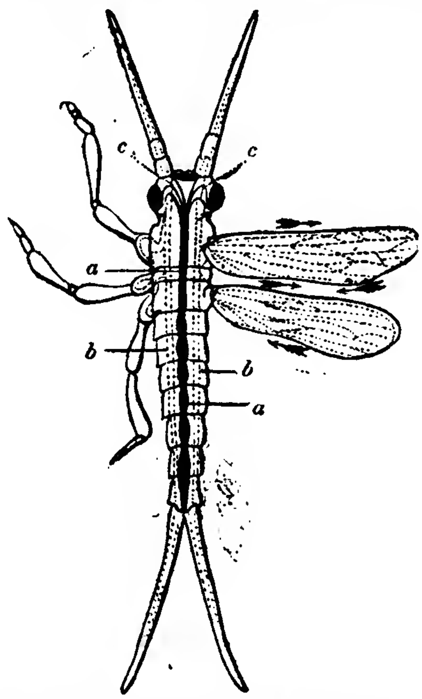
These vessels have been seen contracting and dilating, but no regular course of fluid has yet been discerned.

A more perfect form of circulation of this kind is found in the annelida, and it has been closely observed by Müller in the leech, as shown in the annexed drawing. There are



two main lateral vessels (*b*, *b*, *c*, *c*), communicating at their extremities and by transverse branches with each other, and with a third central vessel (*a*, *a*, *a*), which contains within it, bathed in its blood, the nervous cord, and presents knot-like swellings at the same situations as that cord does. Alternate motions of the blood may be seen in these vessels: at one moment the lateral vessel (*b*, *b*), and the central (*a*, *a*, *a*), with the communicating branches between them, are seen filled with blood; while the other lateral vessel (*c*, *c*) and its branches are empty. In the next moment *c*, *c* and its branches are filled, while *a* and *b* are empty; so that one lateral vessel, and the central one, are always opposed in action to the other lateral one. The central continues acting with one of the lateral for twenty or twenty-five pulsations, and then its relation changes and it acts in unison with the other. During the contraction of a lateral vessel the blood evidently flows from it through the middle transverse vessels over to the other side, and in the next moment returns. The contraction proceeds gradually from behind forwards, so that a wave (as it were) of blood is seen passing from one end of the lateral and of the central vessel to the other, and then returning in the contrary direction through the other lateral vessel. In this manner it is probable that a constant circulation is maintained along the sides of the animal, and its direction seems to be changed after every eight or thirteen pulsations. The same general type of circulating system is found in earthworms and all the other annelida.

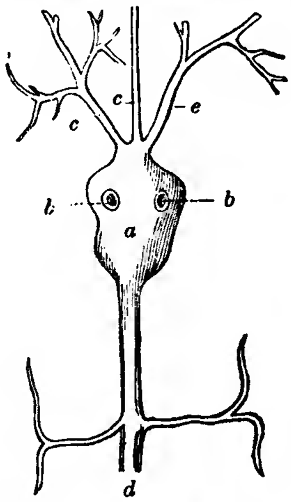
Hitherto nothing has been seen which could fairly be called a heart, nor have the vessels presented any characters by which they could be separated into systems of arteries and veins, for all alike seem to perform at different times the functions of both. A more distinct division of the parts of the circulating system is found in insects. They have a



large vessel (*a*, *a*) running along the back, divided by numerous constrictions into a series of communicating cavities, between which there are lateral openings through which the blood is received, and which are guarded by valves to prevent the blood from flowing out. Through this, which is commonly called the dorsal artery, but which may rather be regarded as a series of ventricles, the blood passes from behind forwards, diverging into small streams, one of which flows to each of the antennæ, feet, &c. No distinct vessels can be detected in which these minor currents may run; they seem simply to pass through the various tissues, and having arrived at their destinations, to form there into arches, and return and empty themselves into abdominal vessels, *b*, *b*, which may be regarded as veins, and through which the blood flowing from before backwards is returned into the dorsal artery through the communications which exist between them at the posterior part. This is also the plan of the circulating system which with various modifications prevails in the arachnida and the lower crustacea.

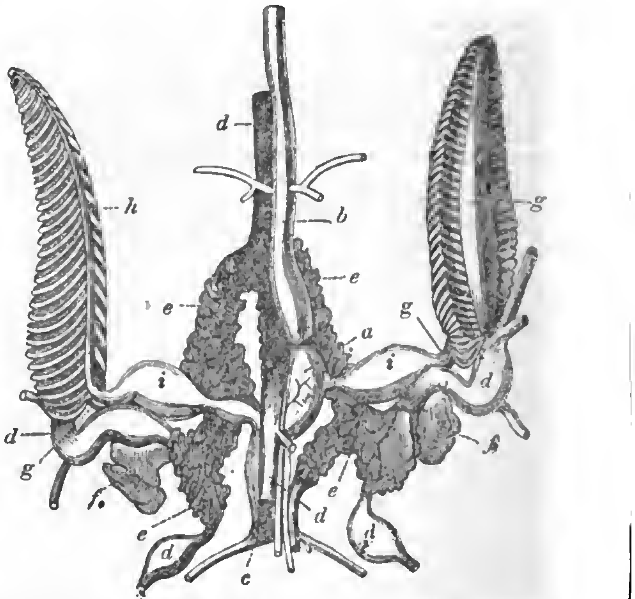
In the orders already mentioned no special arrangement of vessels has been found for the purpose of exposing tbe blood to the influence of the air. Either the whole or part of the blood undergoes respiration on the whole surface of the body, or at the tracheæ, or the vesicles arranged in especial systems for that purpose. In those which follow however, we shall observe a separate and complicated respiratory apparatus; and that the form of the heart and its large vessels are adapted in accurate correspondence with that of the gills or lungs, and according as the whole or part of the blood is required to be exposed at each round of the circulation to the influence of the air.

The simplest kind of a heart, forming a defined cavity, is found in the larger decapoda, and some other crustacea. The annexed sketch represents the heart and large



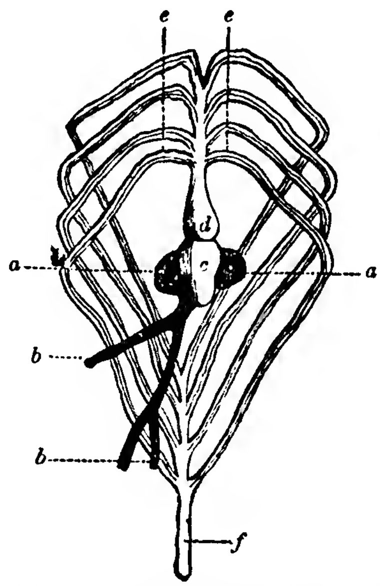
arteries of the lobster. There is a single cavity or ventricle (*a*), into which tbe arterial blood flows from the gills by vessels which unite into two trunks, whose orifices (*b*, *b*) are protected by valves. Six main arteries proceed from the heart; the three anterior (*c*, *c*, *c*) go to the head; two from its inferior part to the liver; and the largest of all (*d*) from its posterior part.* This last gives off a superficial and a deep artery to the tail, and then curving forwards under the sternum, gives branches to the feet and deep arteries to the head. From these the blood returns by veins into a number of venous sinuses which lie at the sides by the articulations of the legs with the chest, and all communicate together. From them branchial arteries proceed, which run on the outer edge of the gills, and pass through capillary vessels in them, terminating in branchial veins which unite into the two trunks that open into the heart.

In most of the mollusca the blood flowing through the branchial veins, instead of being poured directly into the ventricle, is received first into an auricle, presenting the first instance of a heart with more than one cavity. In most of the gasteropoda and pteropoda the auricle is single; in the bivalves the auricle is double. In the latter division, the blood, collected from the systemic veins into one venous reservoir, before going to the gills passes by numerous branches into a spongy tissue wbicb Bojanus calls a lung, and others a kidney, but whose real nature is as yet unknown. From this a few branches pass at once into the auricles, but the greater number go as branchial arteries to the gills. In the brachiopods the systemic ventricle is also double, each cavity giving rise to an aorta. But the most singular form of heart in this class, and one of much interest as presenting all the cavities separated, which in higher classes are united in one body, is tbat of the cuttle-fish. The blood passes in it from a systemic or central ventricle (*a*), through the aorta superior (*b*), and inferior (*c*), and is thence distributed throughout the body, whence it is collected into six venæ cavæ (*d*, *d*, *d*, *d*, *d*, *d*), which open into two branchial auricles (*e*, *e*), conducting into two branchial ventricles (*f*, *f*), by which it is forced through branchial arteries (*g*, *g*, *g*). From the extremities of these it is received into branchial veins, of which that of the left side (*h*) is here shown, which open into tbe two systemic



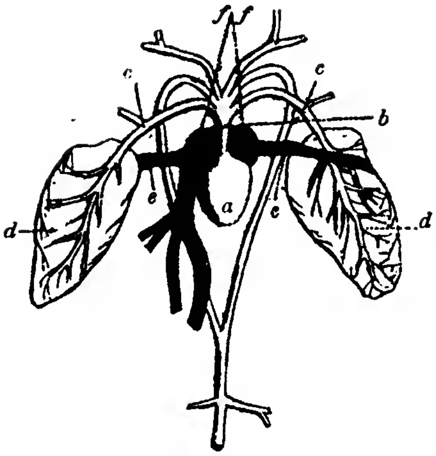
auricles (*i*, *i*), conducting again into the systemic ventricle (*a*). Here then we have the first appearance of a separate heart for the respiratory circulation, and the elements of all the compound forms which we have now to notice.

Among vertebrate animals the simplest form of heart is found in fish. They have a single auricle (*a*, *a*), which re-



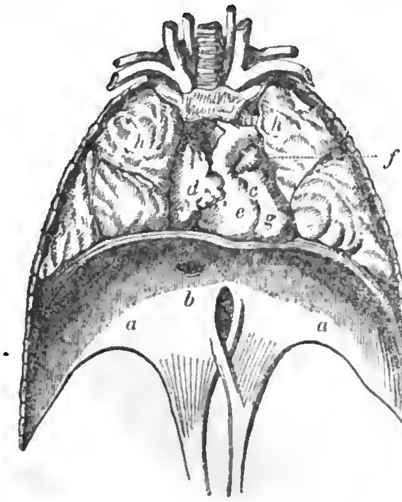
ceives the blood from the trunks of the veins of the whole body (*b*, *b*), and communicates with a single ventricle (*c*), which forces tbe blood into an arterial trunk with a contractile bulb (*d*). From this trunk all the branchial arteries (*e*, *e*) arise, and passing on each side in arches to the gills, divide there into capillary branches. The blood thus aerated passes on, and the arches again unite into a common trunk (*f*), the true aorta, which runs along the under surface of the spine, and sends the blood to all parts of the body. From these it collects again into the systemic veins (*b*, *b*), by which it is carried back to the auricle. The same type of formation is found in the reptiles which have gills, as in the proteidæ in their adult state, and in the larvæ of many which at that period also breathe by gills.

In fish all the blood is subjected to the respiratory process before it passes to the body: in tbe reptiles, which breathe in air, and have therefore a much more complete exposure of the blood to it than fish, who breathe only the air that is dissolved in the water, only a part is exposed before entering the general circulation, but the modes in which this is effected vary greatly. The annexed sketch represents the circulatory system of the frog in its perfect state. It has



a single ventricle (*a*), from which arises a single aortic trunk (*b*), from which proceed the two pulmonary arteries (*c, c*), conveying that part of the blood which is to undergo respiration to the lungs (*d, d*), whence it is returned by pulmonary veins (*e, e*). From the same aortic trunk four other arteries arise, two of which, forming arches, unite to form the dorsal aorta, while the two uppermost are distributed to the head and upper extremities. From the terminations of these arteries in all parts of the body the blood is collected into large venous trunks, which open into the double auricle (*f, f*), from which the aerated blood from the lungs and the impure blood from the system pass separately into the common ventricle, in which they are intimately mixed. In other reptiles the ventricle is more or less completely divided by a septum, which in the crocodilus lucius separates it into two distinct cavities, one connected with a pulmonary, the other with a systemic aorta; in some others the septum is nearly complete, and the mixture of the two kinds of blood is supposed to be prevented by a valve, but in the rest of the order the septum is so small that the blood must necessarily be mixed. In all of this order however the abdominal aorta, which runs along the spine, is formed, as in the frog, of two arches, and in those which have separate ventricles a branch proceeds from each to form it, so that while the head and upper extremities are supplied with pure arterial blood from the left side of the heart, the lower portion of the body receives a mixed blood from the left side and the right.

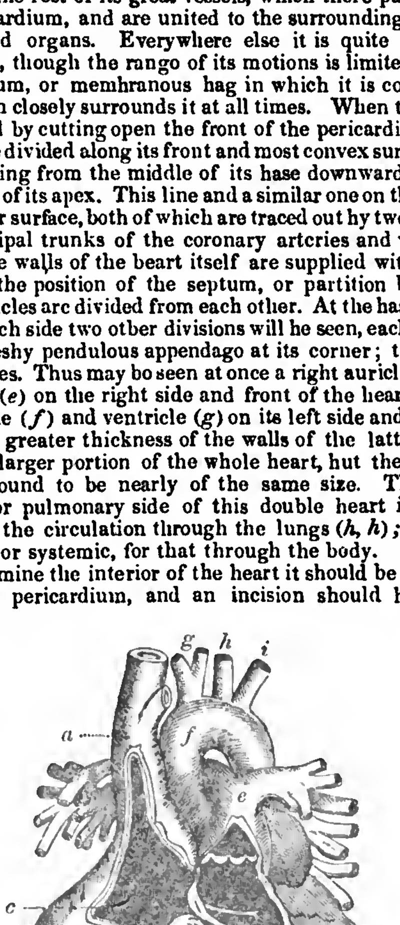
Lastly, we arrive at the complete double circulation of man, mammalia, and birds, to which some of the forms just described make very close approximations. In all of them the blood arrives at the heart from the veins of all parts of the body by two large trunks, the venæ cavæ, superior et inferior, from which it is received into the right auricle, and thence passes into the right ventricle. The right ventricle, by contracting, forces it into the pulmonary artery, in whose branches it is exposed to the air, and passes from them to the pulmonary veins, which open into the left auricle, from which it proceeds to the left ventricle, thence



through the single aorta into all parts of the system, and again into the veins and right auricle.

We may now consider the anatomy of the heart, and the chief phenomena of the circulation, in man.* The heart is of a somewhat conical form, having its base directed backwards towards the spine, and its point forwards, downwards, and to the left side, so that at each contraction it may be felt striking between the 5th and 6th ribs, about four inches from the middle line. It rests upon the diaphragm (*a, a*,) the muscular partition between the chest and abdomen, and the surface upon which it lies is much flattened. It is firmly attached to the diaphragm at its right side, and behind by the inferior cava, which passes through that muscle at the aperture *b*, and above and behind it is fixed, though more loosely, to the upper and back part of the chest by the rest of its great vessels, which there pass out of the pericardium, and are united to the surrounding cellular tissue and organs. Everywhere else it is quite free and moveable, though the range of its motions is limited by the pericardium, or membranous bag in which it is contained, and which closely surrounds it at all times. When the heart is exposed by cutting open the front of the pericardium, it is seen to be divided along its front and most convex surface by a line running from the middle of its base downwards to the right side of its apex. This line and a similar one on the under and flatter surface, both of which are traced out by two vessels, the principal trunks of the coronary arteries and veins by which the walls of the heart itself are supplied with blood, indicate the position of the septum, or partition by which the ventricles are divided from each other. At the base, above and on each side two other divisions will be seen, each having a little fleshy pendulous appendage at its corner; these are the auricles. Thus may be seen at once a right auricle (*d*) and ventricle (*e*) on the right side and front of the heart, and a left auricle (*f*) and ventricle (*g*) on its left side and behind. From the greater thickness of the walls of the latter, they form the larger portion of the whole heart, but the cavities will be found to be nearly of the same size. The right anterior or pulmonary side of this double heart is exclusively for the circulation through the lungs (*h, h*); the left posterior, or systemic, for that through the body.

To examine the interior of the heart it should be removed from the pericardium, and an incision should be made

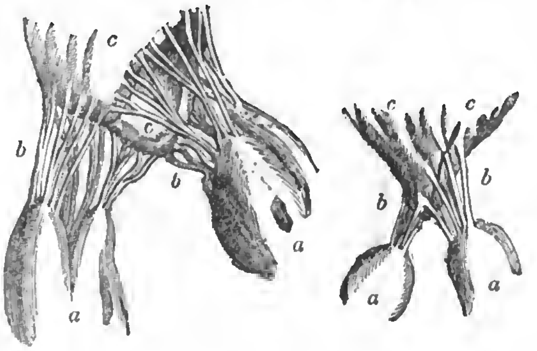


into the front of the right or front auricle, so that an angular flap may be cut out of its walls, and the whole view of the back part and sides of its interior may be exposed. There will then be seen, behind and to the right side, two large apertures; the upper leading to the vena cava superior (*a*), through which all the blood is returned from the head and upper extremities, and the lower leading to the vena cava inferior (*b, b*), by which all the blood is conveyed from the abdomen and lower extremities. These apertures will be seen to be surrounded by a few muscular fibres continuous with those of the auricle itself, and that of the inferior cava is partially guarded by a thin semilunar membranous fold, called the Eustachian valve, varying much in size, and often much torn. The left side of the cavity, on the partition which

* The heart and large vessels of any of the larger of our domestic quadrupeds may be used for popular dissection; their structure differs so little from that found in man, that the present description will almost exactly apply to them.

separates it from that of the right auricle, presents an oval depression (the fossa ovalis) surrounded by an elevated border, indicating the situation of the foramen ovale, through which, during the fœtal state, the blood, which was prevented by the Eustachian valve from passing into the ventricle, was conveyed directly from the right into the left auricle, and thence into the left ventricle. Lastly, at the anterior and left angle of the cavity another and the largest aperture *c* is seen, which leads into the right ventricle, and has attached to its sides a membranous curtain *d*, by which it is occasionally closed, and which is called the tricuspid valve. The general form of the cavity of the right auricle is that of a quadrangular sac, from the right and anterior part of which a small flattened triangular process stands out, from the remote similarity of which to the ear (*auris*) of a dog, the cavity has received its name. Its interior is tolerably smooth behind, by the orifice of the superior cava, on the partition, and about the opening into the ventricle; but to the right and front side, about the auricular appendage and the inferior cava, it is rendered uneven by prominent bands of muscular fibres (the *musculi pectinati*) which seem to radiate from the auricles.

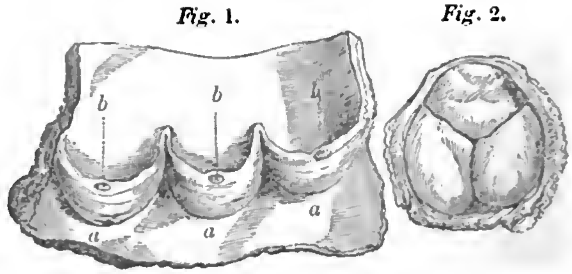
Proceeding in the course of the circulation, a cut should be made from the right auricle through the aperture leading from it into the right ventricle, and along the front of the heart nearly to its apex, and then another from the end of the first upwards into the pulmonary artery, as it arises from the front and upper part of the ventricle. By raising the portion thus cut out, a complete view of the cavity of the right or pulmonary ventricle, and of its communication with the auricle, will be seen. The cavity of the right ventricle has a somewhat conical form, with its base uppermost; that part of its walls which is formed by the septum projecting somewhat into it. Its walls are rendered extremely irregular by prominent bands of muscular fibres crossing each other in every direction, and enclosing spaces of various size and form, which after death are generally found filled with coagulated blood entangled in and adhering to them. Here and there stand out short columns of muscle projecting into the interior, and pointing towards the right auricle; these are called *columnæ carneæ*, and they have attached to their summits fine tendinous cords (*chordæ tendineæ*), which pass thence to be attached to the edges of the curtain-like membrane (the tricuspid valve), which guards the orifice between the auricle and ventricle. This orifice is of a broadly oval form, surrounded by a ring of firm dense tissue, to the whole interior circumference of which is attached the fold of membrane, strengthened by tendinous fibres, forming the valve. The edges of this valve are very irregular, but it may be roughly divided into three principal portions (whence its name), the largest of which lies so as to separate this orifice from that leading into the pulmonary artery. If this valve be pushed inwards towards the cavity



of the ventricle, as in the larger of these figures of the mitral valve, of which the construction though similar is more simple, it will lie nearly flat against the walls, and would in this position present no obstacle to the passage of a fluid from the auricle into the ventricle; but if, on the contrary, it be pushed from the ventricle towards the auricle, its edges will be found to meet so as to close the orifice as in the smaller figure: *a, a, a, a*, the columnæ carneæ; *b, b, b, b*, chordæ tendineæ; *c, c, c, c*, valves. This we shall see is the mode in which it acts during life.

From the front and upper part of the ventricle a smooth short passage leads to the origin of the pulmonary artery *e*, which is attached firmly to the dense ring to which many of the muscular fibres of the ventricle are affixed. At their

Fig. 1. *Fig.* 2.



union, and at the very orifice of the pulmonary artery, three little valves, *a, a, a*, *fig.* 1 (the semilunar, sigmoid or pulmonary valves) are seen, of a semilunar form, attached by the whole length of their convex edges to the walls of the artery, and hanging loosely in it with their free festooned edges directed upwards, enclosing behind them three small spaces, where the artery bulges somewhat outwards. If one looks from the cavity of the ventricle along the interior of the artery, and blows gently into it, the valves will be seen to lie nearly flat against its walls, as in *fig.* 1, and will offer no obstacle whatever to the passage of any fluid in that direction; but if one looks and blows in the opposite direction, from the artery down into the ventricle, the valves will fall inwards, so that their edges will meet, and they will completely close the tube of the artery, as at *fig.* 2, so that unless driven with force sufficient to rupture them, no fluid could pass into the ventricle. It is evident that if the artery be circular, the edges of these semilunar membranes could not exactly meet to close it, but would leave a little space, of a triangular form, between them. This is filled by three little bodies, *b, b, b*, Corpora Arantii, one of which is attached to the middle of the edge of each valve, and which, at the same time that they effect this, afford a strong point of attachment for the tendinous fibres by which the valve is strengthened. The pulmonary artery proceeds upwards, and to the left, in front of the other vessels, and, after a course of about an inch, divides into two branches, one of which turns sharply round to go to the right lung, while the other goes straight onwards to the left. In these organs each artery divides into numerous branches, which become smaller as they become more numerous, and terminate in a most delicate network of vessels, ramifying on the walls of the air-cells, from which, after the blood which they contain has been exposed to the air, it is received into equally delicate pulmonary veins, and through them conveyed in gradually increasing branches to the four main trunks of the pulmonary veins, which open into the left auricle.

It would be useless repetition to describe in detail the left posterior or aortic ventricle and auricle, which differ in no important particular from the right. The walls of both cavities on the left side and all the parts contained in them are thicker and stronger than those on the right; the orifice between them is guarded by a valve which has only two principal divisions, and is therefore call the mitral valve; and the aortic semilunar valves have larger and more prominent bodies (Corpora Arantii) on their edges. The aorta, *f*, proceeds upwards, and to the right side, then arches backwards and to the left, and, turning over the main air-tube of the left lung, passes down along the spine, at the lower part of which it divides into two large arteries (the common iliacs) which supply the pelvis and lower extremities. From the upper part of its arch it gives off the main trunks of the head and upper extremities in three large trunks—that most to the right, called arteria innominata, *g*, is the common trunk which divides into the right carotid for the right side of the head, and the right subclavian for the right arm and side of the neck and chest. Next to it is the left carotid, *h*, and next the left subclavian, *i*, of which the distribution is similar to that of those on the right side.

During life the blood, returning from the whole body by the veins which unite to form the two venæ cavæ, enters the right auricle and gradually distends it, at the same time that the blood returning from the lungs by the pulmonary veins enters the left auricle and distends it; when completely filled a kind of vermicular motion is seen commencing at the point of each auricle, which is rapidly propagated along their walls, and simultaneously empties the contents of the one into the right, and of the other into the left ventricle. The ventricles are no sooner completely filled than they contract suddenly and with much greater force than the auricles, and propel the blood into the pulmonary artery and aorta. They drive it indeed in all directions, but in each ventricle there is but one orifice into which it can find a passage, for that by which it entered is closed by the valve surrounding it. The same contraction of the walls of the heart which propels the blood serves to raise and fix the valves by which its regurgitation into the auricle is prevented; for as soon as any blood is forced under their edges they are lifted up and pressed towards the auricles; and they would be forced into them, but that when they have arrived at such an elevation as to close the orifice they are restrained from passing further by the cordæ tendinæ, which are attached at one end to the edges of the valves, and at the other to the summits of the columnæ carneæ—those muscular pillars, which we have described as standing out into the cavity of each ventricle. The length of these little tendons is exactly measured to the distance to which the valves may be allowed to flap back, and as the carneæ columnæ contract so as to narrow the cavity of the heart, and force the blood out of it, they tighten and fix the edges of the valves against which some of the blood is forced, and thus keep them steady, till the ventricles being emptied their walls relax and permit the valves to be forced down again by the next current coming from the auricles. The blood forced into the artery pushes on that which was already there (for the whole circulating system is throughout life completely filled) and distends the lower part of the vessel, which, by its elasticity, recoils, and contracting would tend to force the blood as well back into the ventricle as forward into the branches. It would accomplish both, and half the power of the ventricles would be thus wasted, but that the semilunar valves, which are prevented from adhering to the walls of the arteries as well by their form as by the little projecting bodies on their edges, as soon as any blood gets behind them, are pushed down and close the passage into the ventricle. The whole of the blood is therefore driven on along the arteries, displacing that which had just before been thrown into them by the ventricles, and itself in turn displaced by the next succeeding wave.

Through the arteries it is distributed to all the body, and returned by the veins; but the veins of the intestinal canal and the organs connected with it unite into a large trunk, the vena portæ, which, instead of at once entering the heart with the others, passes into the liver, and there again divides into minute capillary vessels, from which the bile is secreted, and which pass into the ultimate divisions of a series of hepatic veins, which collect into three or four large trunks which open into the vena cava inferior just before it passes through the diaphragm to enter the right auricle.

A point of much interest is the consideration of the changes which the circulating system of man and the higher animals undergoes in the various periods of their life in the fœtal and in the perfect state. At the very earliest periods, it has been clearly proved that in the embryos of both man and the higher animals the first appearance of the motion of any nutritive fluid is in the form of a circular canal running round the edge of the area in which the future development of the animal is to be effected, an arrangement in some measure analogous to that of the planariæ, and those of the lowest animals, in which a circulating system is first added to the digestive. The first appearance of a heart is in the form of a long tubular pouch, lying beneath the spinal cord, analogous to the dorsal vessel of the insects. The first trace of a separate respiratory system is in that of gills, for at very early periods of fœtal life fissures may be seen by the sides of the neck, in birds and many mammalia, and therefore in all probability they exist in man, beneath which arches of vessels run from the anterior part of a single heart, and collect at their opposite extremities into a single aortic trunk; an arrangement most closely analogous to that of fish. After this, and to the end of fœtal life, the arrangement is adapted to the respiration by a placenta, previous to the possibility of the action of the lungs, which are only formed for respiration in open air. The purified blood coming from the placenta circulates in great measure through the liver, before it enters the right auricle by the inferior cava; from this cavity it passes straight through the foramen ovale, over the Eustachian valve, into the left auricle, whence it is conveyed into the left ventricle, and by it forced through the aorta and its three principal branches to the head and upper extremities, from whence it returns by the superior cava to the right auricle, and passes through it (without mingling with the other current going through it from the inferior cava to the left auricle) to the right ventricle. From this it is carried into the trunk of the pulmonary artery; but as the lungs are at present incapable of performing their functions, it is conveyed through a direct passage, the ductus arteriosus, from the pulmonary artery into the aorta, just below the origin of the left subclavian artery, and from this part it passes along the aorta through the chest and abdomen, and is conveyed through the trunks of the iliac arteries to the placenta, to be again purified. Thus there is a single auricle, but through the right side of it two currents are constantly running in opposite directions; and two ventricles, one forcing the blood to the head and upper extremities, of which the former is at this time peculiarly active in development, while the other forces the blood through the ductus arteriosus to the placenta, and therefore now, as during perfect development, may be regarded as the respiratory portion of the heart. At this time the two ventricles, having nearly equal extents to force the blood through, are of nearly equal size. After birth the left becomes much larger, and is thus enabled to accomplish the more extensive purpose of propelling the blood through the whole body. Directly after birth changes commence which in a few days convert the arrangements for the fœtal circulation into those adapted for the circulation of the completely formed animal: the foramen ovale is completely closed; the ductus arteriosus becomes consolidated; the branch of the umbilical vein, which had passed directly into the inferior cava, is obliterated; and the terminations of the iliac arteries, which had carried the blood to the placenta, contract, gradually close, and are ultimately traceable only in the form of dense solid cords.

We may now consider the powers by which the motion of the blood is effected in man, and the chief phenomena of the circulation in the various parts through which it takes place.

When the ventricles of the heart contract, they are shortened, and become narrower, harder, and firmer. The heart lying loosely in its pericardium, and fixed only where the great vessels pass out of that cavity, recoils from the blood which the ventricles force out; its point is tilted up, and strikes at each ventricular contraction, or *systole*, as it is called, against the wall of the chest, producing that impulse which may be felt by the finger or hand placed just beneath the left breast, and which is almost exactly coincident with the pulse felt at the wrist. At the relaxation or *diastole* of the ventricles they regain suddenly and forcibly their previous conditions. These actions are accompanied with certain sounds. If the ear be placed directly, or on a stethoscope, on or near the part where the heart is felt beating, a sound like that of a gentle breathing is heard coincidently with the impulse of the heart. This is immediately followed by a second sound, which is shorter, sharper, more defined, like the falling back of a light valve, coincidently with which the heart seems to fall back from the wall of the chest. A short pause of perfect silence succeeds, and then the first long sound is again heard. They take place in regular rythm. Dividing the whole period occupied between each two impulses of the heart into four parts, the first sound would occupy two, the second one, and the pause one.

It is unnecessary to allude to various explanations given of these sounds; the most probably correct is that founded on an extensive series of experiments made by a committee of the British Association, and reported at their meetings in 1836 and 1837, viz.:—that the first sound is produced by the vibrations of the muscular fibres of the ventricles during their contraction, assisted in a very slight degree by that of the heart striking against the chest, and that the second is in all probability the result of the falling back of the semilunar valves when the blood just expelled from the ventricles regurgitates. The succession of actions in the heart has been described: the contraction of the auricles is coincident with the pause, for their vermicular and slight contraction does not produce any audible vibrations; the pause lasts till the ventricles are completely distended by the contraction of the auricles: then comes the first sound coincidently with the ventricular contraction, the forcing of the blood into the arteries, the elevation of the valves to prevent the blood from going into the auricles, and to permit it to go into the arteries, the impulse of the heart against the wall of the chest, the pulsation of the great arteries, and followed after a scarcely appreciable period by the pulse at the wrist and other parts distant from the heart. Lastly, the second sound is heard coincidently with the relaxation of the ventricles, the falling down of the valves to permit the blood to pass from the auricles into the ventricles, and to prevent its passing from the arteries back into the ventricles; and the rush of blood from tho auricles into the ventricles, which continues through the whole time of the second sound and the pause.

At each contraction of the ventricles a very large proportion of the blood which they contained is expelled into the arteries, and a very little may flow back into the auricles, especially tho right, before the valves are completely closed, producing the slight dilatation of the venæ cavæ which may often be seen at each contraction of the ventricles. At each contraction of the auricles also it is probable that some blood flows back into the cavæ and pulmonary veins, for they are seen distended rather more suddenly at this time than can be explained by the mere arrest and consequent accumulation of blood in them. However, so large a portion of the heart's power is exerted in propelling the blood into the arteries, that these slight influences in the contrary direction need scarcely be taken into account in calculating its amount. At each contraction of the ventricles about an ounce and a half of blood is forced into each artery, with such force, that Hales found that the blood as it rushed from the open main artery in the thigh of a horse would rise 8 or 9 feet in a glass tube of the same size as the vessel, while in the temporal artery of a sheep it rose 6½ feet, and in those of dogs from 4 to 6 feet. Poiseuille (Magendie's *Journal de Physiologie*) also calculated, by deductions from accurate experiments on animals, that the force of the blood as it streams in the human aorta was sufficient to support a weight of 4lb. 3 dr. and 43 grains. Now if the quantity of blood in the whole body be assumed to be 30 (tr. wt.) pounds, which is probably about an accurate average, and if 1½ oz. be forced from the ventricle at each pulsation, of which, on an average, there are 70 per minute, a portion of blood will go the complete round of the circulation in about 3½ minutes, which is however a somewhat slower rate than we might deduce from the experiments of Hering (Tiedemann's *Zeitschrift*, t. 3), who found that substances injected into the veins of horses could be detected in distant arteries in half a minute.

Harvey considered the heart to be the sole agent by which the circulation is effected, but it is certain that several other agents exercise auxiliary powers. That the heart has however an influence on all parts of the circulation is quite evident. In the larger arteries its effect is seen in the increase of the current which it had set in motion, in exact coincidence with the contraction of tho ventricles; in the smaller ones, by the same increase at a scarcely appreciable interval; in the capillaries, by the occasional pulsatile motion which may be seen in them, when, after an animal has been largely bled, its transparent parts are examined with the microscope, and this though the heart is acting very weakly. Lastly, in the veins we find its influence still exerted; for if the main artery and vein in a limb be exposed and isolated, and the latter be wounded, the flow of blood from the orifice may be exactly regulated by compressing the artery, that is, by preventing, to a greater or less extent, the blood from flowing to the vein with the impulse given to it by the heart. There are cases again in which the veins have distinctly pulsated, and the pulsations have been clearly proved to have been communicated from the heart through the capillaries. To these we may add that the rapidity of the current in the arteries, veins, and capillaries, is always in direct proportion to the strength and frequency of the ventricular contraction, and always more rapid in the parts near them than in those remote from the heart; that it ceases in all the instant the heart is removed, or its influence on a part cut off by dividing the main artery; that in old persons, in whom the whole arterial system of the lower extremities is sometimes ossified and rendered incapable of contraction, the heart alone is sufficient to maintain the circulation through the affected parts; while on the contrary, when the heart's power is by any cause weakened or interfered with, partial stagnation and an extremely languid motion of the blood is found in all the organs. In cases of suspended animation no motion of the blood can be produced till the heart begins to act; but when this is the case, it has of itself sufficient power to set all the blood of the body in a current.

These are so many proofs that tho contraction of the ventricles has a share in propelling the blood throughout the whole course of the circulation; but the heart also assists, by the enlargement of its cavities after their contraction, which, whether it be the effect of mere elasticity, or of an active power of dilatation, certainly takes place with great force. The heart, in short, acts at once as a forcing and as a sucking-pump. The proofs of this are, that the auricles, and still more the ventricles, dilate, not gradually, but suddenly, and with more force than they could be distended by the blood being impelled into them; that the currents observed in living animals aro often seen to be increased coincidently with the dilatation of the auricles; by the velocity of the flow of blood from the auricles into the ventricles being disproportionate to the degree of contraction of the former. This part of the heart's action will be further illustrated in speaking of the influence of atmospheric pressure.

From the heart the blood is poured into the arteries, a series of ramifying tubes through which the current is distributed, divided into a gradually increasing number of streams, which progressively diminish in size, till it arrives at a net work of the most minute canals, the capillaries. As a general rule, when an arterial trunk divides, the sum of the diameters of the branches is greater than the diameter of the trunk—thus in the annexed diagram (in which the arrows indicate the course of the blood), the sum of the diameters of the branches 2 2 is greater than that of 1, and the sum of those of 3 3 3 greater than that of 2, from which they arise. Hence the arterial system has been

1, Trunk of the artery; 2, large branches into which it subdivides; 3, small branches, successively becoming smaller and smaller until they terminate in 4, the capillary branches.

compared in form to a cone, of which the heart is at the apex—and tho stream of blood will be like a current gradually growing wider, so that if no additional impulse be given to it, it will become slower as it becomes more distant from the heart, an effect to which the friction of the blood against the walls of the vessels will also contribute. The effect of both these causes however is so slight that M. Poiseuille has found that the force of the current of blood in all arteries sufficiently large to be experimented on is relatively the same; that in the aorta, for example, bears the same relation to its diameter as that in the artery at the wrist does to its diameter. Thus the diameter of an artery may be taken as a measure of the force of the current of blood in it. It does not appear moreover that the direction in which a branch is given off from the trunk has any appreciable influence on the velocity of the current in it—most frequently the branches of arteries are given off so as to form an acute angle with the continued trunk as 2, from 1 2,—but often they separate at right angles, and less frequently so as to form obtuse angles. Neither can the effect of the tortuosity of an artery be calculated, though there can be little doubt that, *cæteris paribus*, the current in it will be slower. An important point in the arrangement of arteries is the frequent union, or anastomosis, of branches with each other. The purpose of this is evidently to prevent any part being cut off from its supply of blood, by the compression or obliteration of one of its arteries. Hence it is that even when the main artery of a limb has been tied, the nutrition has still been amply effected by the current of blood being diverted into the collateral channels, which subsequently become enlarged. [ANEURISM.]

The chief property of the arteries by which they affect the circulation is their extreme elasticity. It is by this that when dilated they contract on the blood that had been forced into them, and propel it in every direction—and that when elongated they again shorten, and that when empty they remain open and tubular. The chief effect of the action of this elasticity is the gradual conversion of the jetting pulsatile motion which the blood receives from the forcible and successive contractions of the ventricle into an even and steady current. The elastic contraction of any part of an artery after its distension can have no general influence to accelerate the blood, for it would press that fluid equally in all directions, and thus would retard the current coming from the heart to any part to exactly the same degree that it accelerated that passing from that part towards the veins—the one influence exactly nullifying the other.

To convert the pulsatile motion however into a uniform one no more admirable property could have been imagined than this elasticity, which by continually acting to contract the arteries (which are always during health in a state of slight distension) maintains a propelling force upon the blood during the intervals in which the ventricles are at rest. If the elastic power were not exercised, we should see, on opening an artery, a jet of blood, and then a pause, then another jet, followed by a second stoppage of the current, just as when by the successive strokes of a piston we force water through a rigid tube—the jets of blood being coincident with the contractions of the ventricles, and the pauses with the intervals of their dilatation and rest. But the arteries being elastic, when the impulse of the ventricles, which at the same time distends them and forces a jet of blood through an orifice in them, ceases, their elasticity, making them contract, forces some more blood out of the orifice, and thus makes the stream from it continuous. In the arteries near the heart indeed the force of the ventricular contraction is so great that it predominates over that of the elastic contraction; and the current, though continuous, is irregular, presenting a succession of jets—but as we recede from the heart, this predominance becomes less, the succession of jets becomes less distinguishable, and in the veins we find a perfectly equable stream. An artificial contrivance for effecting the same object, viz. the conversion of a series of motions of a fluid into a continuous one, may be seen in an organ. The air is forced into the wind-chest by a series of strokes of the bellows, and if the walls of that chest were fixed it would issue from it into the organ-pipes in the same intermitting manner; but the top of the chest is movable, and is loaded with weights (proportioned to the size of the instrument), so that it maintains a constant and steady pressure on the air below it, which therefore, though driven in by a succession of small forces, passes out into the organ-pipes under the influence of the single force from the top of the chest in a continuous steady current. A similar arrangement is employed in fire-engines, where the elastic power is the air which partly occupies the chest into which the water is forced. [FIRE-ENGINE.]

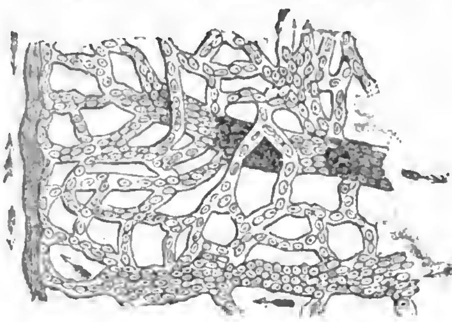
We have said that the arteries are dilated slightly by each column of blood poured out by the ventricles: from this arises their pulse, which may be said to be owing to the dilatation of the arteries produced by the wave which is propagated along the column of blood contained in them. One may form an idea of what is here called the *wave* by observing a ripple in a running stream. There are in that case two different motions of the particles of the fluid: they move all together, with an absolute change of place, and this constitutes the stream; but again, they move separately; one particle or series of particles rises, and the next falls, and as the first falls again, the second rises—this constitutes the ripple or wave. In it the particles undergo only a relative and temporary change of position, for they all return to rest in their former places, as is shown by any light body that may be floating in them, which merely rises to the top of the wave, and again descends to precisely the same place as it had before the wave arrived. So in the circulation there is a constant stream running through the vessels, and at every contraction of the ventricle an impulse is given to that part which is next the heart, producing a wave which is propagated with incalculable rapidity through all the arteries, and causes at each part of them a slight dilatation as it passes within them. The repeated contractions produce a series of such impulses, waves, and dilatations, and when a finger slightly compresses an artery, it feels the tendency to dilatations, in what is called the *pulse*. The degree of dilatation is so slight that its existence was much disputed; but M. Poiseuille has proved that in the larger arteries it is equal to about 1-11th of their average diameter. In feeling the pulse however we perceive a greater impulse than so slight a dilatation could produce, because the finger flattens the artery, and therefore we feel the force of the wave over a large part of its circumference, and we increase its velocity by diminishing the size of the channel. From this description it will be evident that the characters of the pulse by which the conditions of health or disease in any person are decided will depend on two circumstances—the state of the heart, and that of the artery itself. The frequency of the pulse will depend entirely on the number of contractions of the left ventricle in a certain time, and hence the varieties of frequent, slow, irregular, and intermitting pulses are entirely referrible to the heart. The size and degree of contraction of the artery will produce the fullness or smallness, the hardness or softness, and all the other characters which are determined by the touch rather than by mere counting.

But the arteries have another power besides that of their elasticity, by which they influence the circulation, though the mode and extent of its operation are less clear. This is the power of contraction which they possess during life, and which is sometimes, but erroneously, called muscular. The vital contraction of the arteries differs from the muscular contraction, in being slow and gradual, in not being at all times excitable by any of the stimuli that excite the muscles to contract, as mechanical irritation, electricity, &c., but following generally some peculiar influence, as that of cold, or some particular local excitement, as inflammation, &c. From elastic contraction it is distinguished by being exercised only during life, and then tending to reduce the artery often to a smaller calibre than its elasticity would, so that on the complete cessation of life the artery dilates to the size which its elasticity, the consequence of its mechanical structure, would in any circumstances tend to give it. It must be regarded as an instance of that vital contractility which is observed in many tissues quite distinct from the muscular, as in the skin, the dartos, &c. It is best seen by exposing an artery during life, and cutting it directly across; the orifice will then contract slowly, but powerfully, till it is completely closed, either at its very extremity or at a short distance within the tube; if the animal be killed the artery will remain closed for some time, but will then again gradually dilate under the influence of its elasticity.

It does not appear certain that this vital contractility of the arteries exercises any constant influence on the circulation; but, on the contrary, the immediate cessation of the flow of blood from a vein and in the capillaries, when the influence of the heart is cut off by tying the main artery (after separating the collateral vessels), or by removing the heart, and the possibility of exactly regulating the velocity of the current in the vein of a part by permitting or preventing the supply from the heart, seem sufficient to prove the reverse. There are many occasions however in which it evidently acts, and in none more importantly than in cases of wounded arteries, in which it is among the most effectual means of arresting hæmorrhage. [HÆMORRHAGE.] It is shown also in the paleness and shrinking of a part when exposed to cold, and in the smallness of the pulsations then felt in the main artery; and Schwann has seen the diminution in size of the arteries in the mesentery of a frog, when cold was applied. It is probably the principal cause of the emptiness of the arteries after death; for as they will contract long after the heart has ceased to act and to force blood into them, they will pour much of that which they contained into the veins, in which it will be retained by the valves. Hales found that this power of contraction resisted the passage of stimulants during life through the arteries; for a much larger quantity of water could be driven with a given force through the vessels of a part than of brandy, though the latter passed most easily after death. For some time too after the heart has ceased to act, this power is sufficient to resist the injection of fluids into the vessels, and hence in making preparations it is advisable to wait a few hours after death, that the fluids may run with more ease along the arteries.

It is probable that the vital contractility of the arteries is principally useful by regulating, according to their need, the supply of blood to certain organs, for it seems to exist in the greatest degree in arteries which run most tortuously and which are distributed in parts requiring occasionally increased supplies or velocity of blood, as the spleen, &c.; perhaps too it is exerted in maintaining the portal circulation, which can receive but little assistance from the heart, whose influence must be nearly expended in forcing the blood through the capillaries of the digestive apparatus. However, it must be acknowledged that at present we only know that such a power exists; the amount and manner of its action are quite problematical.

Much has always been said of the influence of the capillaries on the circulation, but little has yet been proved. They form a dense network of extremely minute tubes, in which the arteries seem to terminate and the veins to arise, for their delicacy prevents the possibility of discovering any such structure as could decide to which set of vessels they belong, and indeed it is only by observing that the currents of blood-globules pass in regular directions, that we can prove that they are canals with definite membranous walls. When the circulation is examined in the web of the foot of a frog (from which the annexed highly-magnified sketch is taken), or in the transparent parts of other animals, as the fins, tails, or lungs of fish, frogs, lizards, &c., we see



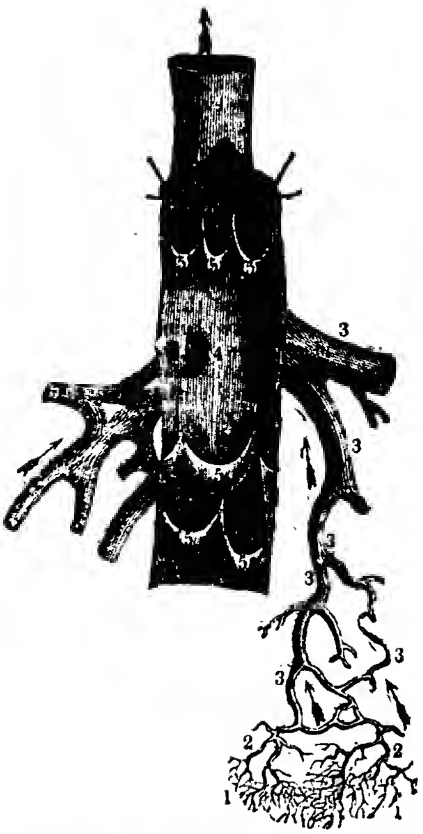
a number of minute globules coursing along in little streams, in some parts in a confused multitude, as in the vessels which are sufficiently large to admit several to pass together, at others in only a single line, where the vessel is but little larger than the globule itself. Here and there a globule is seen to be checked in its course, as if the canal were too narrow for its passage; then it turns a little, and again rolls on. The currents run generally in the same direction in the same vessels, all tending to a larger branch, which may be regarded as the commencement of a vein, and setting out from the minutest termination of the artery. The capillaries are the most delicate of all organic tissues, measuring from $\frac{1}{2000}$ to $\frac{1}{3000}$ of an inch in diameter; they exist in all tissues of the body, varying in arrangement only in the greater or less closeness of the network which they form, and of which the meshes are in some organs so fine as not to exceed in width the diameter of the capillaries themselves, as is the case in the iris and lungs. It is through these vessels that all the important processes of secretion, nutrition, and absorption are effected, for there is no sufficient evidence for believing in the existence of a still more minute series traversed only by the colourless parts of the blood, and which some have described as vasa serosa, vasa exhalantia, &c. But hitherto no observations have been made which can give any idea as to the precise manner in which these processes are performed; no pores can be discovered at the sides of the capillaries for the passage of fluids, which it is therefore probable is effected by simple transudation; nor can any open terminations be seen, for all appear to arise from arteries and terminate in veins.

The influence of the minutest arteries and veins, and of the capillaries, on the circulation, is best seen in the phenomena of local action, as inflammation, blushing, turgescence, &c. If the web of a frog's foot placed in a microscope be irritated, the capillaries are seen slowly contracting, so as sometimes to prevent the flow of blood through them, and if the stimulus be so great as to produce inflammation, then they dilate, and a larger number of globules is seen passing along them with great rapidity. The same may be seen in the human eye, the vessels in the front of which are so minute that they give no colour to it; but if they be irritated by a particle of dust, at once they dilate, and more blood-globules entering them, they are seen as tortuous canals filled with blood. On a larger scale one sees, after a wound or other injury, the parts around grow redder, and swell from the afflux of blood to its capillaries, and if the inflammation arise in a part which can be compared with another similar one, as in the hand, one feels that the pulse is fuller and stronger on the injured than on the sound side, indicating that a larger quantity of blood is passing through it. A still more evident accumulation of blood is shown in blushing, in which, from a mental impression, in an instant all the minute vessels of the face, neck, head, &c., become distended with blood. The paleness of fear is produced by the opposite condition, and we have other cases in which a decrease of the quantity of blood in a part is seen in the deficient nutrition and shrinking of parts which have become useless, as in the gills of tadpoles, the horns of deer, &c. All these circumstances are clearly sufficient to prove that, independent of any influence extending from the heart or arteries, there is in the very minute vessels of all parts a power by which the supply of blood passing through them may be either increased or diminished, whether it be effected by an alteration in the propelling power of the vessels themselves, or, as some imagine, by an increased attraction or repulsion between the tissues and the blood. In any case, we have only proofs of its occasional influence, and that in many it is intimately connected with the nervous system, for it constantly follows pain or mental excitement; but we have no evidence that it exercises any constant influence on the course of the blood.

Following the course of the circulation we come now to the veins, which may be regarded as the most passive of the parts engaged in it, though they are constructed so as to permit many important external agencies to act upon the motion of the blood. While the arteries form a series of branching canals in which the main current is diverted into streams whose number increases as their individual size decreases, the veins are made up of a series in which a vast number of currents gradually unite into others whose number decreases as their size increases (as shown in the following figure), and which all at last meet in two great trunks, the venæ cavæ. In addition to other peculiarities of structure the veins have valves, 5, 5, 5, very similar to those at the origins of the arteries, which are arranged in pairs, or in 3's, at different distances, in the course of nearly all those veins in which the blood has to rise against the power of gravitation. Their simple use is evident; the blood, returning slowly through the capillaries, and much of the force of the heart being expended in propelling it so far, would be apt to retrograde, or remain stationary, if the weight of the whole column in the veins bore down upon the arteries, and through them on the heart. As soon however as a portion is raised into a vein, when it tends to return to the arteries it forces down the valves, which close the canal of the vein and support the blood above them, till another portion rising sends it onwards. Thus while they permit the blood to pass without obstacle towards the heart, they entirely prevent it from retrograding; and if it were stationary, the column of blood would be like a stream branching out, and divided by a number of closed locks in which the portion of fluid between any two is prevented from exercising any influence on the portions adjacent to it.

The veins, like the arteries, are elastic, and this power is occasionally exerted in recovering them from too great distension; they too have a vital contractility whose influence is remarkably shown in their shrinking when cold is applied, but its effects have been even less calculated than in arteries.

We have seen that pressure exerted equably on all parts of the walls of an artery would force the blood as much in one direction as the other, so that it could be of no use in



1, capillary venous branches; 2, small branches formed by the union of the capillary; 3, larger branches formed by the union of the smaller and gradually increasing in size, to form the great trunk, 4, a portion of which is laid open to show its inner surface and the arrangement of 5, the valves formed by its inner coat.

accelerating the circulation; hut from the arrangement of the valves equal pressure on the veins has a very different effect, for it will be prevented by them from producing any retrograde current towards the extremities of the arteries, and thus the greater part of the power exerted will be gained in favour of the flow of blood towards the heart. Such pressure is exercised by the muscles surrounding the veins; as they contract they compress the veins, and thus force the fluid to flow in the only possihle direction, viz. towards the heart. Their influence in this way is shown in the greater tendency to diseased and permanent dilatation of the veins immediately under the skin and other parts remote from the muscles, than in the deep-seated branches in which this varicose state (as it is called) very rarely occurs, although the number of valves in the former is always much greater; in the henefit derived hy supplying the place of muscles by artificial pressure on the veins by bandages, &c.; by the increased fullness of the veins, and velocity of the current commonly seen in bleeding when the bleeding-staff is compressed and moved about in the hand; hy the general acceleration of the circulation by muscular exertion; and, on the contrary, hy the tendency to stagnation and swelling of tho veins in the indolent, or those whose muscular systems are greatly debilitated.

But a still more important influence which is permitted by the presence of the valves is that of atmospheric pressure. It acts principally in respiration. When the chest is expanded for the purpose of inspiration, it is evident that the atmosphere will press with equal weight on all parts to fill up the vacuum thus produced. From without it will pass at once into the most open course through the trachea into the lungs, which it distends; but at the same time the hlood will he forced towards the heart and the great vessels contained in the chest, and will assist in filling up the vacuum to a degree directly proportionate to their volume as compared with that of the lungs. An experimental proof of this influence in the veins (for in the arteries its effect is prevented hy the valves at their origins) is afforded by introducing a tube into the jugular vein of an animal, and placing its opposite extremity in a vessel full of fluid. At every inspiration tho fluid will be seen to rise, and at every expiration to descend a little, indicating first a suction towards the heart, and next a slighter expulsion of fluid from it. It is seen also in cases in which the brain is exposed by removing a portion of the skull; and in cases of Hernia Cerebri [HEAD, INJURIES OF THE], in which, in addition to its slight elevation by the pulsation of tho arteries at its base, the brain is seen to enlarge and rise at every expiration and to become flattened at every inspiration. All these phenomena are still more evident when a strong inspiratory effect is made, as in sighing.

As inspiration draws the blood into the chest, so expiration acts hy compressing all the large vessels to force it out of that cavity away from the heart. Its principal influence must be exerted on the arteries, for the blood would be prevented from passing far along the veins by their valves. In the arteries (and to a less extent in the veins) it is seen to act in the increased velocity of the current that issues from a wound; in the fullness of the vessels of the face and other parts during a strong expiration, or when holding the breath, coughing, or sneezing, actions which are sometimes the causes of rupture of the smaller vessels, and produce an evident alteration in the pulse.

Atmospheric pressure on the veins must also act to some extent in filling up tho vacuum which the sudden contraction of the ventricles must produce in the pericardium. Of course the lungs will expand, and in part effect this by pressing the pericardium towards the heart; but at the same time the blood will tend to rush towards the auricles and dilate them, so that they may fill up the vacant space. Dr. Barry proved this further, by shewing that if a tube be introduced into the sac of the pericardium, without allowing any air to entor with it, a fluid placed in it will be seen to he drawn towards and driven from the sac, at each contraction and dilatation of the ventricles.

Such are the powers concerned in the circulation, and the principal effects which they produce. The influence of each is certain, but what is its extent, and what are the circumstances under which it is chiefly exercised, cannot be accurately determined. In order of importance, the contraction of the ventricles must undouhtedly be placed far highest; then would come the auricular contraction, the ventricular dilatation, the auricular dilatation; then inspiration, expiration, and the cavity in the pericardium when the ventricles contract. All these assist at all times in moving the blood; the elasticity of the arteries tends at all times to equalize the velocity of the current, while their vital contraction and that of the veins, the action of the capillaries, and the muscular pressure on the veins, influence it only at particular periods. It is probable that one of these powers may sometimes replace another whose influence is prevented, as in the lungs on which muscular and atmospheric pressure can have no influence, but in which many circumstances prove an intimate relation between the hlood and the action of the capillaries; and in the liver, in which the ventricular contraction can have little power, but in which the constantly patulous state of the hepatic veins would make them peculiarly fitted for the influence of pressure.

HEART, DISEASES OF THE. When we consider the compound, or rather the mechanically complicated nature of the heart; its constant action, from the hour of hirth to the hour of death; the extent to which every organ depends upon it for power to perform its functions in the animal economy; and the frequent derangement of some one of these organs, which tends to impede or render more laborious the heart's unceasing action—we cannot be surprised at finding that this central organ of life is subject to many diseases, and that there is great difficulty in assigning to each unhealthy state its peculiar cause.

In giving some account of the disorders to which the heart is liahle, it would perhaps be best to arrange them according to their causes; but as it is much easier to obtain a knowledge of the structure of this organ than of the remote causes of its several diseases, we shall here enumerate and describe first those lesions which occur in its investing membrane; secondly, those which affect it as a whole; and thirdly, those met with in its various parts. Those who desire to be further acquainted with this subject are referred to the works of MM. Corvisart, Laennec, Cruveilhier, Bouillaud, Bertin, and Drs. Elliotson, Hope, &c.

Diseases of the investing Membrane of the Heart, the Pericardium; Absence.—The pericardium has been reported as absent in a case published by Mr. Robinson in the 'American Journal of the Medical Sciences,' February, 1833; but the evident exaggerations of his account render it unsafe to give credit to any portion of it.

Pericarditis, Inflammation of the Pericardium, resembles much, in its pathological conditions, inflammation of other serous membranes, and is induced by similar causes, as exposure to damp and cold. It of course presents peculiar symptoms, arising from the situation and nature of the individual organ; thus the patient will complain of tenderness over the region of the heart, amounting, when pressure is made, to acute lancinating pain, which prevents him from lying on the left side, and is much increased by drawing deep inspirations or coughing, this latter symptom frequently depending on the pleura being involved in the inflammatory attack. This pain however is not always so severe; frequently only a sense of oppression is felt. The pulsations of the heart are frequent, sometimes regular, but at other times intermittent, and so strong as to constitute palpitations; but still, if much effusion has taken place into the pericardium, the hand when applied to the chest will have difficulty in perceiving them. The præcordial portion of the thorax is often bulged out by the forcible action of the heart and the quantity of fluid effused into the cavity of the pericardium. This effusion varies much in quantity and consistence at different periods of the disease; thus in many cases only a little bloody serum will be found; in others, pus in large quantities, coagulated lymph, bands of fibrinous matter uniting the two layers of the serous membrane, and even cartilaginous or osseous deposits. The dull sound discovered by percussion in the præcordial region of a person in health is always, in this disease, increased in proportion to the quantity of fluid in the pericardium, and in proportion as this fluid becomes organized sounds will be heard by the application of the stethoscope, and often of the unassisted ear, varying in their nature according to the state of the organizing process, and resembling at one time the creaking of new leather, at another the rubbing together of paper or parchment, the noise made by a file, &c. Other sounds also are frequently heard, which depend upon the disease being accompanied by lesions within the heart itself. Although at the commencement of the disease the patient may have symptoms of acute inflammation, the accompanying fever having a type sufficiently tonic, this state does not endure long; the effusions into the pericardium hinder the heart's action; the free passage of the blood through its cavities becomes further impeded by various internal parts of the organ sharing in the inflammation; and, the circulation being no longer vigorously and equably carried on, a crowd of distressing symptoms, such as inability to sleep, startings, faintness, shortness of breath amounting to suffocation, dropsies, &c., render life almost insupportable, and if not speedily relieved, soon put an end to existence. It is worthy of remark that this disease frequently accompanies acute rheumatism, particularly of the joints; and also that patients, when apparently recovering from acute rheumatism, are sometimes suddenly attacked and carried off by inflammation of the pericardium. So marked is this latter occurrence, that many distinguished physicians have considered that the pericarditis takes the place of the rheumatism, constituting what is termed a 'metastasis.'

The serious nature of this disease and the rapidity of its progress demand very prompt antiphlogistic treatment; but on the contrary some physicians exhibit tonic medicines. A distinction ought to be drawn however between recent acute cases and those in which, from previous attacks, the constitution is weakened, and the heart's action impeded by old adhesions and deposits between the two layers of the pericardium, and perhaps within the organ itself.

Hydro-pericardium; Dropsy of the Pericardium.—In addition to the morbid effusions which may occur in the pericardium, as the result of inflammation of that membrane, it is found in some few instances distended, and sometimes to an enormous degree, by an increase of its internal lubricating secretion: this constitutes dropsy of the pericardium. The fluid may vary in quantity from a few ounces to several pounds; it differs from the effusion of pericarditis in being merely a morbid increase of the natural secretion, not separating into a fibrinous clot, or forming false membranes, like the pericarditic effusion which is the result of inflammation.

The sounds of the heart will in this disease appear to be removed from the surface, and dull in proportion to the quantity of the effusion, but no abnormal sound is produced, unless, by the amount of pressure, some obstruction to the circulation arises in the interior of the heart. The action of the lungs becomes much impeded when the pericardium is greatly distended with fluid, and when this obstruction to the breathing is conjoined to pressure on other neighbouring organs many very distressing symptoms are produced.

The treatment resembles much that of other dropsics; and it has been a question whether or not the operation of puncturing the membrane might be practised.

Diseases of the Heart itself; Absence.—Though the circumstance may seem rather to belong to a treatise on monstrosities, we may remark that this organ has been found wanting in some acephalous beings who have shown, for a short time, evident signs of life.

Displacement.—The heart is not always found in its usual situation at the time of birth, there being cases on record where it occupied the right instead of the left side of the chest, the other organs of the body presenting at the same time a relative change of position without any disturbance of their functions. It has also been found pushed out of the left into the right side of the chest by tumours, or, what is more common, by extensive effusion of fluid into the pleura of the left side of the chest. The whole heart has been found hanging without the thorax, also in the abdomen, and forming a portion of a tumour projected beyond the abdominal parietes, constituting what are termed hernias of the heart. For a more elaborate account of these last-mentioned anormal conditions the reader should consult a memoir on this subject by M. Breschet.

Carditis; Inflammation of the Heart.—The proper muscular structure of the heart is not free from the attacks of inflammation, though whether the morbid action commences in this structure, or in the membranes, is difficult to determine. This however is certain, that when inflammation of the muscular structure exists, there will also be found traces of it in the pericardium, or in the lining membrane of the heart, or in both; and we cannot point out symptoms of the one distinct from those of the other disease: the treatment consequently will be similar in both. The progress of this inflammation may be traced at its different stages. Thus we shall find at one period the muscular structure softened and of a deeper colour than usual, at a further period presenting a greyish or yellowish softened mass; pus also may be found, or abscesses, which will so thin the walls of the heart as to occasion perforations.

Cancerous and Tubercular Development.—In the heart these deadly changes of structure are not of frequent occurrence; still, in support of the fact that they do occasionally occur, we have the authorities of MM. Andral and Laennec.

Hypertrophy of the Heart.—Independently of any morbid process existing in itself, the muscular structure of the heart is often greatly increased in bulk, as if the nutritive process were too active in proportion to the absorbent, and new matter were deposited more rapidly than the old could be removed. From the peculiar nature of the functions of the heart this disease becomes very important, and its effects not less dangerous than manifold. It is usually divided into three kinds; namely, simple hypertrophy, the least common, in which the parietes are thickened without any change of capacity in the cavity; excentric or aneurismal hypertrophy, the form most frequently met with, in which the parietes are thickened and the enclosed cavity or cavities proportionally enlarged; and concentric hypertrophy, where the cavity is diminished in proportion to the thickness of the parietes. Any one of these kinds of hypertrophy may affect the parietes of either cavity of the heart, or the whole organ. The extent to which this increase of size may proceed is enormous; hearts have been found weighing upwards of twenty ounces, whereas the average weight of a healthy heart is from seven to nine ounces. In hypertrophy the shape of the heart is often much altered, the transverse often exceeding the vertical diameter; but these changes must depend upon whether the whole organ, or only a part, be implicated in the disease. The chest is often bulged out towards the left side, the sound produced by percussion more dull than in the healthy state, and the pulsations very strong; indeed the bed-clothes are often visibly raised and the head or hand of the observer when applied to the chest forcibly repulsed, yet the pulsations are for the most part regular, unless palpitations be induced by over exertion. The sounds perceived by auscultation will be found very loud, but not otherwise unnatural, if the disease be not combined with some obstruction to the passage of the blood; and unless some obstruction exists, the functions of other organs will not be much deranged, provided that the hypertrophy be not of great extent; but it seldom does exist to considerable extent without the simultaneous occurrence of some impediment to the passage of the blood, already circulating with extraordinary force.

The accidents referrible to hypertrophy of the left ventricle of the heart are apoplexy and hæmorrbages; it will also contribute to the production of aneurism of the aorta. It frequently happens that the rupture of vessels in the brain by the too forcible expulsion of blood from an hypertrophied left ventricle is materially facilitated by an earthy or osseous state of the coats of those vessels. When the right ventricle, being hypertrophied, sends its blood too forcibly through the lungs, there will be a disposition to congestion of those organs. These effects will be combined when the whole heart is hypertrophied.

This is a disease in which great perseverance is required on the part of the patient and the practitioner, but with proper care it frequently admits of much alleviation. Rest, abstinence, sedative medicines, and more or less depletion, according to the circumstances of the case, are the most efficacious plan of treatment.

Atrophy of the Heart is a wasting of the heart's structure, dependent on deficiency of the nutritive process. This disease is the reverse of hypertrophy, and, like it, may affect the whole organ or only parts of it; its extent is often such that the heart does not exhibit more than half its ordinary weight. Like hypertrophy, it has been divided into simple atrophy, when the walls of one or more cavities are thinned without any change of capacity in the cavity itself; excentric or aneurismal atrophy, when the enlargement of the cavity keeps pace with the thinness of the walls; and concentric atrophy, where the cavity is diminished, but the walls maintain their usual thickness. This state of the heart is usually accompanied by general emaciation, and the pulsations and sounds of the organ will be found feeble in proportion to the extent of the atrophy. In concentric atrophy however the pulse will be firm and resistant, though small, whilst in the excentric form of the disease it will be proportionally soft, feeble, and large.

In atrophy the powers of the patient are all below par, and the proper treatment will be to support the system by wholesome, generous, but unexciting diet, and a salubrious atmosphere. Medicines may be prescribed as auxiliaries, when any additional symptoms appear indicating obstruction to the nutritive functions.

With respect to the causes of hypertrophy and atrophy we can only say that everything which increases the nutritive process in the one case and diminishes it in the other may be considered respectively as causes of either disease.

Dilatations of the Heart.—It has been shown that the heart may be increased or diminished in substance, or, in other words, may be hypertrophied or atrophied; it is also found that the whole organ, or either of its cavities singly, or the orifices of these cavities, may be dilated, the solid parietes being merely extended, without any increase of substance, and the contained cavities proportionally enlarged. As in hypertrophy, so in this disease, according to its extent, the shape of the heart will be much changed. The muscular parietes being thinned and feeble, the circulation of the blood will not be carried on with vigour, and the patient will be weak and unfit for exertion, easily exhausted by small losses of blood, and sometimes carried off by what under ordinary circumstances would be deemed a trifling hæmorrhage. Partial dilatations sometimes occur after carditis; the muscular structure being thinned at some spot by ulceration, the parietes give way, and form a dilated aneurismal pouch. This disease, though it doubtless does sometimes occur in persons of relaxed muscular fibre without any pre-existing impediment to the circulation, is most frequently the consequence of some obstruction to the free passage of the blood from the dilated cavity, and is the natural effect of distension from within. It however not unfrequently happens that when the obstruction occurs at the orifice situated between the ventricle and artery the corresponding auricle will be the cavity dilated, its parietes being so much less strong than those of the ventricle. When the orifice of either of the cavities of the heart is dilated to such extent as to preclude its proper closure by the valves, a reflux of blood will be the result, causing the anormal bellows sound, and a sensation of purring, or of vibration such as would be produced by putting a chord in motion; and should this defective closure exist in the right auriculo-ventricular opening, it will give rise to a fluctuating motion in the jugular vein, called 'venous pulse.' Excessive exertions and strong passions seem to be exciting causes of this disease, and from the influence of these causes the patient should be sedulously guarded, and at the same time every remedy must be adopted which may contribute to equalize the circulation.

Endocarditis; Inflammation of the interior lining membrane of the Heart.—This disease, frequent in its occurrence and productive of consequences distressing and fatal to the patient, was little known prior to the year 1824, when some excellent observations on the subject were published by M. Bouillaud. Subsequently that active and accurate observer has written more largely on this disease, the nature and effects of which he has minutely described, not however without having been considered by many physicians, both of this country and the Continent, to have ascribed to its influence some organic changes, such as cartilaginous and osseous formations, not strictly speaking referrible to it. A recent acute case of endocarditis is not very frequently met with uncombined with some other inflammatory disease; rheumatism, pericarditis, carditis, or inflammation of the internal coat of some of the veins, will be usually found, if not to accompany, at least to have preceded it.

The symptoms of endocarditis are more or less fever and anxiety; some bulging of the præcordial region, if accompanied by pericarditis; an extension of the dull sound heard on percussion in the healthy state; the pulsations of the heart unusually strong, and sometimes very rapid and intermittent, repulsing the hand when applied to the chest, and producing a peculiar vibratory sensation. Upon auscultation the bellows sound will be heard, masking one or both of the normal sounds, and sometimes, during the ventricular contraction, a metallic tingling is heard, resembling the sound produced by dropping sand into a bell of metal. The pulse as felt at the wrist will not always accord with the beatings of the heart; often whilst the latter are very forcible, the former will be found small and weak, and sometimes less frequent: this indicates some obstruction to the free passage of the blood from the heart, notwithstanding the forcible contractions of that organ to propel it, and the patient will exhibit symptoms of much distress, as great anxiety of countenance, restless tossings of the body, dazzlings of the sight, and faintings; if the obstructions in the right side of the heart are extensive, as they often are from fibrinous concretions, thickenings, and other morbid growths of the valves, the venous circulation will be affected, as indicated by the livid bloated state of the countenance, and serous effusions into the extremities; various apoplectic symptoms seem to be sometimes induced by the same cause. The breathing is not affected generally beyond a sense of oppression, unless a considerable impediment is experienced by the circulation, but then the distress and restlessness of the sufferer is often extreme, accompanied by an inability to lie down, and a state of alarm and wandering amounting almost to delirium.

The causes of this serious malady are similar to the causes of pericarditis, and the treatment, which should be actively antiphlogistic, must not be deferred if the practitioner be desirous of saving his patient.

In giving this slight sketch of endocarditis, allusions have been made to effects produced by obstructions to the circulation; the nature of these obstructions should therefore be explained. Upon examination after death there will often be found, particularly in the right cavities of the heart, and entangled in the muscular fibres, clots or concretions of fibrinous matter, which, according to M. Bouillaud, are not only caused by stagnation of the blood at the time of death, but also by inflammation of the internal lining membrane. This membrane is also often thickened, especially at the valves; and after repeated attacks, or a long chronic form of endocarditis, the valves will not merely be thickened, but will become the seat of a variety of warty excrescences, or even cartilaginous and osseous formations of considerable size, extending into the cavities of the heart. This ossification is most frequently met with in old persons, and especially those who have been addicted to a too generous mode of living. The morbid sounds produced by these obstructions at the various orifices will resemble those of the bellows, file, or saw, according to the degree of the obstruction; and sometimes a triple or even a quadruple sound will be perceived instead of the two normal sounds. The effects of these obstructions will be sanguineous and serous congestions, oppressions of the breath, apoplectic seizures, and other symptoms of embarrassed circulation.

Ruptures of the Heart.—Ruptures are sometimes found to occur, not only in the valves and columns of muscular fibres within the heart, but also in its parietes. The effect of such injuries will depend upon their extent and situation. A valve or one of the bundles of muscular fibre cannot be broken through without causing much inconvenience to the free circulation of the blood; but it seldom happens that the parietes of either cavity of the heart are sufficiently injured to allow the free passage of blood into the pericardium without instant death being the consequence.

Pressure from without and pressure from within will both give rise to these accidents. Under the first head may be included all wounds, whether produced by cutting or pointed instruments, by falls from great heights, or by violent contusions of the chest. Pressure from within will operate whenever an orifice of the heart is so narrowed or blocked up by thickenings or adhesions of its valves, or diseased deposits, as to prevent the blood from passing freely through it; there will then be a tendency in the cavity to dilate in proportion to the extent of the obstruction, and this dilatation may end in rupture. Under such circumstances violent exertion or a previous thinning of the parietes by abscess will greatly promote the rupture.

Persistance of the Foramen Ovale.—It is by no means very uncommon to meet with cases in which the opening leading from the right to the left auricle of the heart has not been properly closed up at the time of birth. According to the extent of the communication thus remaining, a greater or less proportion of venous blood will pass into the left side of the heart, and being there mixed with red blood circulate through the arterial system. The arterial blood being adapted to produce in the animal economy certain effects and changes necessary to life, and the blood of the veins being unable to produce these effects until it has in its turn been submitted to the action of air in the lungs, the health of every individual in whom the mixture of arterial and effete blood occurs will suffer in proportion to the extent of that mixture.

The symptoms of this disease are blueness of the skin, lips, and nails; a temperature of the body below that which is natural and healthy; shortness of breath, palpitations, faintings, a sense of suffocation induced by slight exertion, and sometimes a great disposition to hæmorrhage and depression from small losses of blood. This disease has from the colour of the skin been named 'blue disease,' 'morbus caeruleus,' or 'cyanosis.' The persistance of this opening between the two auricles is not the only though the most frequent cause of this disease; sometimes the partition between the two sides of the heart is ruptured or ulcerated through, and at others the duct communicating between the aorta and pulmonary artery has remained unclosed; indeed any anormal state of the cavities of the heart, or of the great vessels proceeding from it, which gives rise to an extensive admixture of venous and arterial blood, will produce the disease. Hypertrophy of the right side of the heart, with or without dilatation, and contraction or obstruction of the orifice of the pulmonary artery, and of the right auriculo-ventricular opening, frequently occur at the same time with persistance of the foramen ovale, and increase all the painful symptoms produced by it. Little in the way of treatment can be done in these cases, but every cause of excitement should be carefully avoided, and during the attacks of suffocation and faintness small doses of diffusive stimulants, as æther and ammonia, may be advantageously employed.

Nervous Diseases of the Heart.—The last class of diseases affecting the heart which remains to be noticed differs from all the preceding in not presenting any organic changes. They are met with chiefly in women suffering from anæmia, chlorosis, hysteria, and other nervous symptoms; and in men in whom a naturally nervous temperament has been rendered more irritable by the too free use of stimuli or by depressing passions. In these cases strong pulsations of the heart are experienced, increased by exertion to such an extent as to produce palpitations, a sense of faintness, and shortness of breath amounting to suffocation. Sometimes a slight bellows sound is heard at the heart, and in patients labouring under anæmia and chlorosis this is frequently accompanied by a noise like snoring, heard chiefly in the carotid and crural arteries. In all these cases great attention should be paid to the general health; in the cases of anæmia and hysteria, iron medicines and the shower-bath will be of the greatest service; and, as far as possible, sources of anxiety should be removed. The morbid sounds will all disappear as the mind and body of the patient are restored to their healthy condition, but it must be borne in mind that the heart is essentially a muscular organ, and by severe exercise it may be increased in bulk like other muscles; consequently if these nervous states which give rise to so much action of the heart be not removed, they may in process of time lay the foundation for more permanent and serious disease.

HEARTSEASE, or PANSY, is the cultivated state of the plant called Viola tricolor by botanists, improved by crosses with V. altaica and other allied species.

Several hundreds of beautiful varieties are now common in gardens. Although they will all grow in almost any kind of soil, yet, in order to bring the finer sorts to any degree of perfection, a loam, mixed with sand, and highly manured, is absolutely necessary. By proper treatment they may be had in full flower at two different seasons—from April to June, and from September until the frost destroys them. The ground chosen for the first planting should not be fully exposed to the mid-day sun, as the plants are liable to be scorched by it, but should be open to the east or west; the second planting must be in ground fully exposed, as the influence of the sun is not so powerful as to injure them at the later season of the year.

The original species from which all these varieties sprang are easily preserved; but this is not the case with many of the finer sorts, which, as in animals and in other plants, the higher they are bred, and the finer the kinds, are in proportion difficult to keep in health. The principal causes which affect them are excessive heat in summer, and wet and cold in winter. They are however easily propagated, and only require to be looked over frequently, when, if any of them are found damping or decaying at the bottom of the stem, the top must be taken of, and struck. When there is danger of losing any of the sorts during winter, the best way is to strike a quantity in autumn, and to place hand-glasses over them until spring; at that time those which are alive may be soon multiplied in abundance.

Where fine large flowers are wanted, the plants should always be struck from cuttings the same season, and grown rapidly. In striking them, artificial heat is altogether unnecessary, unless when the operation is performed early. All that is required for the purpose is a small hand-glass to place over the cuttings, and a mat to shade them during bright sunshine. After they are well rooted, they must be taken carefully up, and planted in a bed previously prepared for them. They will then flower in great profusion from April to June.

At this period other plants must be propagated for the autumn flowering: they must again be kept in a shaded situation, until the intense heat of summer is over, when advantage must be taken of dull rainy weather for planting them out in beds, where, if the soil and situation be good, they will soon flower, until destroyed by frost.

Varieties are obtained from seed. In order to have them fine, considerable care is requisite in selecting the seed. It must always be gathered at those seasons when the plants flower in the greatest perfection, and from the best formed and largest blossoms. They will generally be found in this state in the early part of the season, from April to June, or in autumn, after the greatest heat of summer is past; at other seasons the flowers are smaller, and it is found that this affects the seed. The seed should be sown in spring, in light soil, with the protection of a cold frame. When the plants are very young, they must be removed from the frame, and planted thinly under hand-glasses, where they will remain until they are sufficiently strong to be planted out in the flower-garden. At every shifting they must have plenty of water, and be carefully shaded during bright sunshine.

Like all other florists' flowers there are certain characters which are deemed indispensable to the formation of a good bloom. Mr. Gorrie (*Gard. Magazine*, vol. viii., p. 573) thus defines it—'Large and round petals, the flower forming nearly a circle, not much undulated—($1\frac{1}{4}$ inch across is large enough, but some are broader); colours brilliant, distinct, and permanent; eye rather small, and not deeply pencilled; flower-stalk strong and upright; and the stigma filling the open part of the eye.'

HEAT. This great natural agent, which is universally diffused, becomes sensible to us in the first instance by our bodily sensations, but we find afterwards its effects in the various changes which it is capable of producing on all substances. Expansion, fusion, evaporation, thermo-electric currents, and various physiological phenomena, are effects of heat, or at least accompany its absorption.

Every existing substance may be regarded as a source of heat. In this respect the sun is the most important natural source which our system possesses, its heat when condensed in the focus of a lens being exceedingly intense. When concentrated by a number of powerful lenses on one scale of a balance of extreme sensibility, no derangement of equilibrium ensues; as far therefore as experiment can inform us it is imponderable, and the increase or diminution of heat in any body is therefore unaccompanied by any alteration of weight.

Heat may be produced artificially by any means which propagate agitations internally in bodies: hence friction, hammering, percussion, sudden condensation, chemical combination, and electrical discharges, are all proper to produce or rather to develop heat.

As to the nature of heat, whether it should be regarded as a substance or an accident, has been discussed from the time of Bacon to the present day. Those who regard it as having a material existence suppose that a subtle fluid, called caloric, capable of permeating the densest substances, is universally diffused; that its parts are mutually repulsive, but are attracted by the material particles of bodies, and hence they account for the expansions and contractions of bodies, while the effects of radiant heat are explained on principles analogous to those on which the undulatory theory of light is founded.

Those who regard heat as only accidental to matter rest their opinion on the fact that the artificial production of heat is accompanied by vibratory motions in the material molecules of the heated substances. The measure of the quantity of heat produced mechanically would on this hypothesis have a direct connexion with the sum of the *vis viva* of the system of vibrating particles. Hence the communication of heat by contact would be the same as the propagation of vibratory motions from the system of particles composing the heated body to that of the touching body. This hypothesis is liable to a great objection; for heat is propagated through a vacuum, and if even we suppose all space filled with some fluid, in order to explain solar radiation, the hypothesis loses its simplicity, and differs from the former principally by its greater vagueness. It has been suggested by Brewster, that the solar rays are nothing more than heated light, but this opinion is open to several objections founded on the different laws by which heat and light are transmitted and modified.

It is of greater advantage to study the properties of heat, and make those properties the ground for its measurement and the calculation of its effects, than to speculate on the nature of an agent intimately connected, not only with light and electricity, but with the absolute nature of the material molecules.

Heat radiates from all bodies in straight lines and in all directions, and in the law of its emanation it resembles light, its intensity diminishing in the same proportion as the sine of the angle of emanation. If we conceive two balls which are heated unequally to be enclosed by a concave surface which by any means is preserved at a uniform temperature, the radiation of heat from the warmer ball, directed on the colder, being more copious than the radiation from the latter on the former, the temperature of the hotter will sink, and of the cooler rise, in proportion to the difference of radiations, and this will continue until the temperatures become permanent, in which case the radiations are necessarily equal. In the same manner, when the different parts of a room in which there are one or several sources of heat have acquired a permanent temperature, that temperature for each part will then be such that the heat which it emits by radiation must be equal to the quantity absorbed, and which it has received by radiation from all other parts of the room.

One consequence of the free radiation of heat in open space is that its intensity must vary inversely as the square of the distance from the origin. Hence every portion of space has a determinate temperature due to the amount of radiation, not only from the sun and fixed stars, but also of the non-luminous bodies of each system. It seems however difficult to conceive with Poisson, that in addition to such temperature from heat emitted, it can have any temperature peculiar to its locality; in fact, that vacuum can possibly have any proper heat.

But though the laws of the free emanation of heat and light are similar, those of their transmission through substances are very different. When a metallic body is but a little heated in a fire, we have heat unaccompanied by sensible light; and in the lunar rays the light, though originally transmitted from the sun, arrives at our planet without any sensible heat, even when collected in the focus of a burning-glass. Again, a plate of glass placed before a common fire will intercept the heat until it becomes itself sufficiently heated to radiate. When however the source of heat is more intense, a small portion will be directly transmitted; while for the solar rays we find the heat is transmitted as well as the light. It is still more remarkable that when the solar rays are decomposed by transmission through a glass prism, the differently coloured rays of the spectrum have each a different intensity of heat, the least refrangible possessing the greatest portion; the greatest heat is found at the place occupied by the extreme red rays, or even a little beyond them.

Not only may radiant heat be collected in a focus by refraction through a lens, but also by reflexion from a polished concave mirror. If we employ a pair of mirrors, and if a heated body be placed in the focus of one, and a thermometer in the other, the reflected heat falling on the bulb of the instrument will cause the mercury to rise; and conversely, a colder body will make the column of mercury descend, for the excess of radiation proceeds in this case from the thermometer. Recent experiments on heat show that the analogy of the laws of heat and light extends even to polarization.

The experiments of Leslie have shown how greatly the quantity of radiant heat may be affected by the state of the surfaces from which they finally emanate. The method adopted by Leslie for examining the powers of radiation possessed by different substances was extremely simple and ingenious. Having employed the system of two specula above mentioned, he placed a tin canister filled with hot water in the focus of one, and a differential thermometer [THERMOMETER] in the other focus. The four sides of the tin canister were covered with the substances of which he proposed to seek the radiating powers; when three of the sides were respectively covered with lamp-black, paper, and crown-glass, and then turned so as to radiate directly on the speculum, the heat reflected by the other raised the thermometer accordingly to 100°, 98°, and 90°; but when the fourth side, which was uncovered, was similarly directed, the thermometer fell 12°. Thus it appears that polished metallic substances are bad radiators, which may be attributed to the internal reflexion of the heat from their surfaces, for the sources of radiation must evidently be at some small depth below the geometrical surfaces. A similar apparatus served to measure the absorptive power of different substances, by covering the bulb of the thermometer as uniformly as possible with an envelop of the substance to be examined; this power is thus found to be nearly in proportion to that of radiation. The maximum effect of the reflected heat was not however in the strict geometric focus, but, in consequence of aberration, it was found to be a little beyond it.

The power of radiating heat is certainly the most universal mode of its propagation between different particles of matter as well as through considerable spaces. However, it is usual, for greater simplicity, to designate this propagation through solid bodies as *propagation of heat by contact*. Poisson has shown in his memoirs on that subject that the general equations which express the law of the distribution of heat in solids may be derived from the internal radiation of the particles which compose them. Whichever of these two views may be adopted, we are led to important physical distinctions between different homogeneous substances, viz. their conducting powers internally and externally. If we take two substances, as a piece of metal and of wood, at the same temperature as indicated by the thermomoter. when held in the warm hand the metal will feel colder than the wood, the heat of the hand being more rapidly absorbed by the metal, as being the better conductor of heat. Or if we place the extremities of a rod of copper and of glass in a fire, and hold with the hands the other extremities, the heat will be found to ascend rapidly through the metal and very slowly through the glass rod. Though such plain observations are sufficient to give a general idea that bodies conduct heat differently, yet, to obtain exact measurements of conducting powers, it will be necessary to have a more precise idea, since such power is a constant coefficient belonging to every body in particular, and without the knowledge of which it would be impossible to compare the result of theory with observation.

Newton remarked that, when two substances of unequal temperatures were placed in contact, the colder received from the other in a given small time a quantity of heat proportional to the difference of their temperatures. This simple law has recently been found not strictly correct, but is sufficiently so when the difference of temperatures is inconsiderable. If t, t' represent the temperatures of two bodies of the same physical nature placed in contact, and if we leave out of consideration the heat escaping by radiation from their surfaces, the quantity of heat communicated may, by Newton's law, be represented by $h\,(t-t')$; where the coefficient h is a constant peculiar to the given substance, and is proportional to the interior conductibility.

If now we conceive the surface of the body to be of a uniform temperature, and subject to a current of air also of a uniform but inferior temperature T, the loss of heat by a unit of surface in a unit of time indefinitely small will, by the same law, be represented by $H\,(t-T)$, where the coefficient H is proportional to the exterior conductibility under such circumstances.

The exterior conductibility may be very different in the same body by slight alterations in the smoothness or even colour of the surface; it is by this antagonist principle that heat acquires a permanent state corresponding to the different positions of the parts of bodies relative to the sources of heat and the dispersing surfaces.

The mathematical theory of the distribution of heat is founded on the principle that when a body has arrived at a permanent state of temperature the quantity of heat given out by any particle to the adjacent colder region must be equal to that received from the warmer particles near it, and conversely. For example, suppose a solid body to be contained by two parallel planes of indefinite extent, the lower plane being preserved by any means at a uniform temperature represented by o, and the upper likewise preserved at a uniform temperature. In this case it is easily seen that the temperature would be uniform in any section of the body parallel to its bases, but would increase from the lower plane in an arithmetical progression to the upper, for with this law the temperature of any point of the body taken in the transverse direction will differ by equal quantities from the temperatures of any two points which are at equal distances, the one above and the other below it; hence the flux of heat from the warmer region to this point is equal to that from this point to the colder. Though there is therefore a constant flux of heat from the upper to tho lower plane, the distribution of heat has then acquired a permanency.

In the above instance we have had no regard to the external conductibility through the sides by supposing the planes of indefinite extent. A simple instance will now be adduced in which we can show the manner in which this consideration may be introduced into the calculus.

Suppose a thin cylindrical rod to be placed in a medium of which the temperature is constantly zero, whilo its extremities are maintained at constant but different temperatures; in this case the distribution of heat will follow, at equal distances along the rod, a geometrical progression increasing from the colder extremity to the hotter, for on this supposition the heat which would be retained by any section in consequence of the unequal differences of its temperature with those of sections similarly placed above and below it, if there were no radiation, will be exactly lost by the external means of conduction, for it is a property of the terms of a geometrical progression that the second differences are proportional to the terms thomselves; the heat which would be retained is proportional to this second difference, and the heat externally emitted is proportional to the temperature itself. Thus this law, which renders the internal gain of heat equal to its loss externally, represents the law of its permanent distribution. Those who are acquainted with the calculus of partial differences may find these principles applied, not only to tho permanent distribution of heat, but to the laws of cooling in bodies warmed from any sources, and bounded by any surfaces, in the excellent work of Fourier (*Théorie de Chaleur*), and in the memoirs of Poisson, Libri, and others.

The propagation of heat in liquids depends very little on any communication by contact. If we place a heated plate on the surface of water in a vessel, but so as not to touch tho edges, a thermometer placed in the water will indicate little or no alteration of temperature; liquids are therefore heated by the transposition of their parts. Thus, if with a blowpipe we apply heat to the bottom of a vessel containing water, in which are floating some small particles of dust, a current will be perceived of the warmed liquid rising from the point to which heat has been applied, and another descending current of the colder parts, which being heated in turn rise also; in this manner the heat is distributed through the wholo liquid, for as the heat expands the particles of liquid which it first meets, they become specifically lighter than the adjacent fluid, and they must therefore ascend by the laws of hydrostatics, while the heavier take their places.

Little as is the conducting power of liquids, that of gases is probably much less, if any; but there would be great difficulty in establishing this experimentally. The effect of heat on gases is to increase proportionally their elasticity, and this disturbing force produces violent motions in their parts, so that the whole shortly acquires a uniform temperature, when other forces, such as gravity, are not taken into consideration, and when the bounding surfaces are not essentially subjected to constant unequal temperatures.

These three modes of the propagation of heat exist in our globe, and are the cause of important phenomena in the distribution of climate.

First, the great mass of the earth, considered in reference to its solid parts, has an external source of heat in radiation principally from the sun. The maximum quantity of this heat is bestowed on the region between the tropics, while the poles are at a temperature which, but for the action of the sea and atmosphere, would probably be that of space; the internal heat of the earth would in a homogeneous sphere be distributed symmetrically relative to its centre, diminishing towards the surface, which would lose heat by external radiation; but the external source of heat alluded to, by producing a flux from the equator to the poles, forms a permanent compensation for this radiation.

If we suppose the mass of the earth to have been at any remote period at a very high temperature, of which, besides its general form, there are many striking geological proofs, the effect of the radiation of its heat through the colder surrounding space would be to cool first the superficial strata, and successively, though in a less degree, the internal strata, until a permanent state was reached, when the diminished radiation would be exactly compensated from external sources. Hence, on descending below that comparatively shallow envelop affected with diurnal or annual variations of temperature, we ought to find a continually increasing temperature towards the centre, a result which has been verified in the mines in several countries in Europe. Poisson deems these experiments inconclusive, in consideration of the small depth which we are able to penetrate; for without assuming any increase of heat towards the centre, the same superficial phenomenon would occur on the supposition that the whole solar system had been transferred into a region of space possessing a different temperature from that in which it formerly moved; but this view, which is purely speculative, cannot be verified by facts.

The propagation of heat by motion in fluids has an immense tendency to equalise the temperatures of different latitudes, and the unequal depths of different places in the bed of the sea would, from the same cause, produce currents warmer than the adjacent water. The elasticity acquired by portions of the air in contact with the warmer regions of the globe destroys the equilibrium of that fluid, and generates winds of which the heat is communicated to the districts traversed, while the counter-currents, or cold winds, rush forward to occupy the abandoned spaces. The earth having always had a rotation, a limiting surface necessarily existed beyond which the centrifugal force prevailed; hence if the surface of the earth has ever had a temperature of

212° Fahrenheit, the waters now occupying the bed of the sea, being in a state of vapour, could have filled no more than the space between that limiting surface and the surface of the earth; but the greater cold would necessarily convert the vapour in the upper regions into water, which, descending in rain, would be again vaporised, and this reciprocal action going on during the process of cooling, would be capable of producing immense alterations on the earth's surface. It has been suggested by Mr. Babbage that a cause of a similar nature may have led to the rings and belts of the superior planets.

Most of the instruments constructed to measure heat are founded on its general tendency to produce expansion, but a few of them on other properties of heat. Beside the various thermometers, we may notice the calorimeter of Lavoisier and Laplace, in which an internal chamber of a box is preserved at the temperature of melting ice, being constantly surrounded with that substance, guarded against the contact of the air: in a division of this chamber, a cell furnished with a stop-cock, a body is plunged at any temperature, and remains until it ceases to melt the ice, when the quantity of melted water conducted through the stop-cock is taken as a measure of the quantity of heat given out by the body. This instrument is of use in determining the specific heats of substances, and the calculation of latent heat; but this subject more properly belongs to heat regarded relatively to its chemical effects. For the measurement of high temperatures, see PYROMETER.

The dilatation of substances by heat is nearly proportional to the increase of temperature, except when they are about to change their physical or chemical states; thus water near the freezing-point expands when the temperature is diminished, which is probably owing to the different arrangement assumed by its constituent particles preparatory to crystallization. From the experiments of Dulong and Petit, the pure gases appear to afford the most strictly proportionate expansions, and to correspond to mercury between the freezing and boiling points. Water and alcohol, when near boiling, have very irregular expansions; and crystallized bodies expand unequally in the directions of their different axes: the slow propagation of heat in glass causes very unequal expansions, and consequently fractures. In gases the law of Gay-Lussac is very simple; their expansion (even when containing vapour) is 0·375 of their volume at the freezing-point, when their temperature is raised to the boiling-point; and is equable during the interval. [GAS, p. 84.]

Experiments by Fresnel, Trevelyan, Powell, Forbes, and others, have greatly tended to prove that a repulsion due to heat exists between particles at small distances. If a heated poker be laid slantingly on a block of lead at the ordinary temperature, it will commence to vibrate, first slowly, and will increase with such rapidity as to produce a musical note, which continues for some time, at the termination sometimes changing to an octave. Though a different hypothesis may partly explain this circumstance, yet the number of phenomena of a similar nature adduced of late years render the hypothesis of repulsion extremely probable.

The following table gives the dilatation of a unit length of different solids from the freezing to the boiling point, and is a *mean* taken from several observers:—

Glass tube	·00083	Copper	·0017
Crown glass	·00089	Brass	·0018
Platinum	·00093	Silver	·0020
Palladium	·0010	Tin	·0022
Cast iron	·0011	Pewter	·0023
Steel	·0012	Grain tin	·0025
Do. Tempered	·0013	Lead	·0028
Gold	·0015	Zinc	·0030
		Glass	·00009

Chemical Agency of Heat.—The agency of heat in promoting chemical action is important and extensive; in some cases no combination can take place without it, and in others it greatly facilitates chemical combination, while in some instances it decomposes compound bodies and resolves them either into simpler or elementary forms of matter. If we add any salt to water at common temperatures they will combine and the salt will be dissolved as long as their mutual affinity exists at the degree of heat employed; but if we increase the temperature we augment the affinity, and thus it is that most salts and other substances are more soluble in hot than in cold water, the increased affinity subsiding as the temperature falls; this however is true of fixed bodies only, for gaseous substances, such as ammonia and carbonic acid, are much more soluble in cold than in hot water, and at high temperatures the gases are totally expelled.

In the above cases of solution of salts in water, heat merely increases affinity, but is not requisite to the production of chemical action; if however we mix oxygen and hydrogen gases, they will remain diffused throughout each other for any length of time, unless heat be applied to them, and they then readily combine, with the formation of water. In other cases, as those of some solids, it is probable that heat increases affinity only by rendering the bodies fluid; thus lead and sulphur do not combine at common temperatures, but if we render them fluid by heat, they readily unite; whereas mercury being a fluid metal, although there is no reason for supposing that its affinity for sulphur is greater than that of lead, yet when triturated at common temperatures with powdered sulphur readily combines with it.

Again, some metals unite with oxygen at common temperatures, especially if moisture be present, but there are others which require the application of heat to cause any notable combination to take place between them; thus tin and lead at common temperatures are but little acted upon by exposure to oxygen gas, but if we heat them in it, the oxides of these metals are readily procured.

There are some gaseous compounds which can scarcely be procured by the direct action of heat on their elements: thus oxygen and azote do not unite, even when strongly heated, so as to form nitrous acid or any other compound; but the heat which accompanies the electrical spark seems capable of producing this effect. On the other hand, ammonia cannot be obtained even by the heat so generated, when the gases which form it are subjected to it.

Although the instances are not so numerous, yet there are many cases in which heat by direct action and without the aid of any intervening affinity is capable of decomposing compounds; thus when ammonia is heated in earthen tubes it is resolved into its elementary gases by the mere action of the heat, unaided by any affinity between the gases and the material in which it is heated. With water the case is different: it is not decomposed by heat, unless exposed to some substance capable of uniting with its oxygen, so that when its vapour is passed through an ignited earthen tube it suffers no change; but if we substitute an iron one, then this metal at a high temperature takes its oxygen and evolves the hydrogen.

In other instances heat is capable of decomposing compounds when they consist of two substances of very different degrees of volatility: thus when phosphate of ammonia is heated the alkali is expelled and the acid left; but when the volatility is nearly equal they then rise in combination: this is the case with muriate and carbonate of ammonia.

Heat has also great power in modifying as well as in causing chemical action, and different degrees of it produce very opposite effects in some cases. If we heat mercury to about its boiling point exposed to the air, it becomes peroxide; but if we expose this product to a higher temperature than required for its formation, it is then again resolved into metallic mercury and oxygen gas. At common temperatures sulphur retains three equivalents of oxygen, and does not yield even one equivalent to copper; sulphuric acid is constituted of the above numbers of equivalents, and on putting a piece of copper into it no change occurs; but if the mixture be heated the order of affinity is to a certain extent reversed; the copper takes one equivalent of oxygen, and becomes black oxide, while the sulphur united with the two remaining equivalents of oxygen is expelled in the state of sulphurous acid gas.

It is impossible to refer to or peruse any account of a chemical investigation without perceiving the important and widely extended range of the chemical agency of heat, from which we have selected a very few, and those perhaps not the most striking cases, by which this subject might have been illustrated.

HEAT OF VEGETABLES. That plants possess a temperature higher in winter than that of the air which surrounds them is known by the obvious fact that snow melts at the foot of a tree sooner than at a distance from it; that the temperature is lower in summer is equally well proved by the coldness of the fluid which is discharged from many vines and vine-like plants when cut across. These phenomena have been examined with care by several observers: John Hunter found that a thermometer whose bulb was plunged 11 inches deep in the trunk of a walnut tree generally indicated in the autumn a higher temperature than that of the external air by 2° or 3°; Schöpf at New York, and Bierkander in Sweden, Pictet, and Maurice, and various other observers, have obtained similar results; they have found even tubers and bulbs with a temperature higher in winter than that of the external air by 6° or 7° Réaum., while on the other hand from the spring to the autumn it is lower.

The former fact accounts in some measure for the power possessed by some plants of resisting cold in winter, and for the protection given to the upper parts of trees by heaping straw up against their trunks in winter. During every season of the year trees are absorbing water from the earth; water when absorbed parts with its heat very slowly through the carbonated matter of a trunk; in winter the temperature of the earth, which determines that of the water it contains, is uniformly higher than that of the atmosphere, and consequently the temperature of the interior of a tree is also higher, in proportion to the difference between the heat of the soil and that of the air. In the spring and summer, on the contrary, the earth is cooler than the air, and the temperature of trees is cooler also.

These considerations throw some light upon the effects of frost upon trees. A young tree is, *cæteris paribus*, affected more than an old one of the same species; either because its roots derive their food from a smaller distance under the soil, or because the heat obtained from the soil is sooner parted with on account of the thinness of the bark and the smallness of the whole mass. Unhealthy trees, which also suffer in like manner, may be supposed to do so in consequence of the weakness of their power of pumping warmer fluid up from the soil in winter.

Independently of this source of heat in vegetables, there is another that deserves attention. Whenever oxygen combines with carbon to form carbonic acid, an extrication of heat takes place, however minute the amount; such a combination occurs much more extensively during the germination of seeds and the impregnation of flowers than at any other time. At the first of these periods extrication of heat takes place to a considerable amount, as is remarked in the germination of barley heaped in rooms, previously to being manufactured into malt: in the latter it also occurs, but in consequence of flowers not being confined in close cases, the heat is lost as soon as it is disengaged, and never accumulates, except in a few special instances. Saussure found the temperature of the male flowers of the common gourd, at between seven and eight o'clock in the morning, half a centigrade degree higher than that of the air; and those of the tuberose 9-10ths of a similar degree. It is however only when large quantities of flowers expand within close cases that this phenomenon is particularly remarkable. Accordingly, in the spathe of araceous plants it has been remarked at its greatest intensity. Lamarck, Senebier, and De Candolle, found the flowers of Arum maculatum, between three and seven o'clock in the afternoon, as much as 7° Réaum. warmer than the external air. Schultz found a difference of 4° to 5° between the heat of the spathe of Caladium pinnatifidum and the surrounding air at six to seven o'clock P.M. Hubert and Bory de St. Vincent assert that at sunrise the spathe of Arum cordifolium acquires in the Isle of France an elevation of 30° R. above the atmosphere. Finally, Messrs. Vrolik and Vriese at Amsterdam, and Adolphe Brongniart at Paris, have confirmed the fact by new observations in the hothouses of those cities.

Hence it appears that plants not only have, under all circumstances, a temperature different from that of the external air, being warmer in winter and cooler in summer, but that under particular circumstances the heat of certain parts is elevated in a very remarkable degree. We know that heat is necessary for germination and for vegetable impregnation. May we not therefore conclude that nature has given to plants the power of extricating for themselves an additional supply of caloric at these important periods?

HEATH. [ERICA.]

HEBERDEN, WILLIAM, M.D., was born in London in 1710. In 1724 he was sent to St. John's College, Cambridge, of which, six years afterwards, he was elected a Fellow. He studied medicine in Cambridge and London, and after taking his degree practised as a physician, and delivered an annual course of lectures on materia medica in that university. In 1746 he was elected a Fellow of the Royal College of Physicians, and soon after left Cambridge, and commenced practising in London, where he at once met with the greatest success, and obtained the highest reputation. After thirty years' extensive practice, finding his health declining, he gradually withdrew himself from his profession to retirement in Windsor, where he died in 1801. In 1750 he was elected a Fellow of the Royal Society, and in 1778 an associate of the Royal Society of Medicine in Paris.

It was at the suggestion of Dr. Heberden that the publication of the Medical Transactions of the College of Physicians was commenced. He contributed many valuable papers to the first volume, which appeared in 1768, and to two succeeding volumes: among them may especially be noticed his paper on the Angina Pectoris, a disease not previously described, and that on the Chicken-pox, which he first distinguished from the Smallpox. He contributed also some papers to the Transactions of the Royal Society; but his principal work was the 'Medical Commentaries,' which he wrote in 1782, and which was published after his death. It contains the practical results of his lengthened experience, and was compiled from observations which he had always been in the habit of writing by the bedside of his patient. It was written in very elegant Latin, and affords sufficient evidence of an accomplished and observing mind, and of very extensive practical knowledge. (Memoir prefixed to the *Commentaries*.)

HEBRADENDRON. This is a new genus of the natural family of Guttiferæ, established by Professor Graham of Edinburgh, for the gamboge tree of Ceylon, to which reference was made from GARCINIA. Under the article GAMBOGE, the two commercial varieties of this substance, known by the names of Ceylon and Siam gamboge, were mentioned; the plant yielding the former has been clearly made out, that producing the latter is still unascertained.

The gamboge of Siam is in cylinders, either solid or hollow, usually called *pipes:* it is supposed to have this form from being so rolled, or from being poured into the hollow of bamboos, according to Lieutenant White, in his 'Visit to Cochin China.' It is usually of the best quality, but Mr. Pereira has shown that some very impure is occasionally in the form of pipes. As this pipe gamboge is usually exported from Singapore, it has been doubted whether it was actually the produce of Siam; but we have specimens from Mr. G. Swinton, which were sent to him direct from Siam when he was chief secretary of the Indian government, as the produce of that country, and which are identical with the best pipe gamboge of commerce. The only information respecting its preparation which we possess is that given to Kœnig by a Catholic priest, who officiated as such to the Catholics of Cochin China, and who stated that the inspissated juice obtained from breaking the leaves and young shrubs, as well as the fragrant lignum aloes, is given as a tribute to the king of Siam by the Christians residing there. The tree must therefore be common, and probably near inhabited places, and therefore very likely to be Oxycarpus cochinchinensis of Loureiro (now referred to the genus Garcinia), who names it from its acid fruit, and describes it as cultivated in Cochin China. We have specimens of a plant something similar to this in the form of its leaves from Mr. Malcolmson, collected by him in Rangoon, which he thought might be the gamboge plant, as it contained a yellow purgative juice in the rind of its fruit. Dr. Graham thinks that the Siam plant may be a nearly allied species of the same genus as the Ceylon plant.

The Ceylon gamboge is usually considered inferior; that which forms an article of commerce no doubt is so, and we have been informed by one of the principal merchants of Ceylon that finding the gamboge there very cheap, he had been induced to purchase and send it to England, but had not been able to sell it from its inferior quality. No doubt however some of very excellent quality is produced in Ceylon by the tree which has been called *Hebradendron cambogioides*, and Mrs. Colonel Walker describes it as 'brilliant and excellent,' and 'as good for water-colour drawings as any she ever used.' Dr. Graham ascribes its inferiority to want of care in preparing the article for market; though it is yet doubtful whether the Ceylon gamboge of commerce is all yielded by this tree; but Mrs. Walker on one occasion, in passing through a forest of these trees, saw all of them with the bark cut off in various places. Dr. Christison has shown that there is all but an identity of composition with that of Siam; and its medicinal effects are precisely the same as proved in Ceylon by Dr. Pitcairn, and by Drs. Graham and Christison in Edinburgh.

This plant, though new named, is far from being new. Dr. Graham considers it to be identical with the Carcapuli of Herman, the Cambogia gutta of Linnæus, the Garcinia Morella of late authors, and the Stalagmitis cambogioides of Moon's 'Catalogue of Ceylon Plants.' The last name might have been retained, as it was originally intended for it, had it not been discovered by Mr. Brown that the specimens in the 'Banksian Herbarium' collected by Kœnig, and from which Murray's character of the genus and species was established, consist not of one, but of two distinct plants, the flowers of Xanthochymus ovalifolius being stuck by sealing-wax upon a branch of what appears to be this Ceylon plant. The genera Stalagmitis and Xanthochymus are therefore one genus, as was previously inferred by Cambessedes, who has retained for it the former, as the prior name.

The genus Hebradendron has diœcious flowers; the male having the calyx membranaceous, four-sepalled, persistent; corol four-petalled; stamens monadelphous; column four-sided; anthers terminal, opening by the circumcision of a flat and umbilicate terminal lid. The inflorescence of the female tree is similar to that of the male, the flower white and a little larger, with a germen precisely in miniature of the fruit, and surrounded (like it) with several (ten?) abortive stamens. The berry is many (four) celled; cells one-seeded, surrounded at the base with some free abortive stamens, crowned by a lobed and muricated sessile stigma; cotyledons fleshy, united; radicle central, filiform; trees with entire leaves.

1, a flowering branch of Hebradendron cambogioides; 2, a flower seen from below; 3, a flower seen laterally; 4, anther with its umbilicate lid.

The species called H. cambogioides forms a moderate sized tree, with the leaves obovate, elliptical, abruptly subacuminate; the male flowers clustered in the axils of the petioles, on short single-flowered peduncles; sepals yellow on the inside, yellowish-white externally; petals yellowish-white, red on the inside near the base; berry about the size of a cherry, round, with a firm reddish-brown external coat, and sweet pulp; ripe in July. It is called in Ceylon *kana* (eatable) *Goraka*. G. cambogia is called simply Goraka. The gamboge is used by the natives both as a pigment and medicinally. Mrs. Walker describes it as being collected by cutting pieces of the bark about the size of the palm of the hand early in the morning. The gamboge oozes out in a semi-liquid state, but hardens on exposure to the air, and is scraped off by the collectors next morning.

This tree is found in various parts of Ceylon, but not very abundantly near Colombo. In a tour through different parts of the island, Mrs. Walker writes, 'We found the Ceylon gamboge tree several times in forests distant from the habitation of man, which proves the tree to be indigenous.' Colonel Walker writes to Dr. Wight, that 'it is found in great abundance along the western and eastern coast in the neighbourhood of Battocola; but it also grows inland, where it could not have been planted by the Dutch. Its favourite abode seems to be low sandy ground, as about Kanderaane, Negombo, and towards Chilaw; also, 100 miles inland, at so high an elevation as 2000 feet above the sea.' Garcinia elliptica, a native of Silhet, and G. pictoria of the Wynaad district, are thought to be other species of this genus.

We are indebted to Dr. Graham's papers in the 'Companion to the Botanical Magazine' and the 'Edinburgh Philosophical Journal,' and to Dr. Wight's letters in the 'Madras Journal,' for most of the above information; and to Dr. Lindley for the accompanying figure.

HEBREW LANGUAGE forms a branch of that extensive family of languages which are known by the name of Semitic; a name which is derived from the real or supposed descent of the people who speak these languages from Shem the son of Noah. The Semitic languages may be divided into three branches: the Arabic, to which the Ethiopic is closely allied; the Aramæan, consisting of two dialects—the Babylonian or East Aramæan (sometimes but erroneously called Chaldee), and the Syriac or West Aramæan; and the Hebrew, to which the Phœnician and Punic are closely related. Of these languages the Arabic is the most copious, and the Aramæan the poorest and least developed; the Hebrew holds an intermediate rank between these, being more perfect than the Aramæan, and inferior to the Arabic.

The Hebrew language derived its name from the Hebrews, who date their origin from Abraham, who is called 'the Hebrew' (הָעִבְרִי) in *Gen*. xiv. 13. The etymology of this word is doubtful. According to the Jews it is derived from Eber (עֵבֶר), an ancestor of Abraham (*Gen*. x. 24, 25; xi. 15); but Gesenius and many other critics maintain that Eber cannot be regarded as a historical person, and that his name has been invented in the same manner as the names of Ion, Dorus, Æolus, &c., by the Greeks, to account for the origin of the people. It has been supposed with some probability that the name of 'Hebrew' was originally applied to designate all the Semitic nations west of the Euphrates, which appear to have emigrated from Mesopotamia. According to this etymology, the word 'Hebrew' is derived from the root עָבַר, 'to pass over.' This appears to have been the opinion of the translators of the Septuagint, who render *Gen*. xiv. 13, 'Abram the Hebrew,' by Ἄβραμ τῷ περάτῃ, that is, 'Abram, the passer-over.' All the descendants of Abraham were, according to this view, originally called Hebrews; and the name was only restricted afterwards to the inhabitants of Palestine. (See Ewald's *Hebrew Grammar*, § 3; and Gesenius, *Hebrew Lexicon*, under עִבְרִי.) This name is never applied to the language of the Hebrews in the Old Testament; in *Isaiah*, xix. 18, it is called the language of Canaan (שְׂפַת כְּנַעַן); and in *Is*. xxxvi. 11, 2 *Kings*, xviii. 26, 2 *Chron*. xxxii. 18, and *Neh*. xiii. 24, the Judaic or Jewish language (יְהוּדִית). The language spoken in Palestine in the time of Christ is frequently called Hebrew (Ἑβραϊστί) in the New Testament (*John*, v. 2; xix. 13; *Acts*, xxi. 40; xxii. 2; xxvi. 14); by which the Aramæan is probably intended. In the writings of the Rabbinical Jews the Hebrew is generally called the 'holy language' (לְשָׁן קֻדְשָׁא).

The Hebrew language appears to have been formed in Palestine by a union of the antient Aramæan, which was brought by the Abrahmites from Mesopotamia, with the Phœnician or Canaanitish, the language of the original inhabitants of the country. That the Phœnician and Hebrew languages were very closely allied is evident from the Phœnician names of persons and places, and from the specimens of the Phœnician language which we possess in coins and inscriptions. (Bochart, *Geographia Sacra*, b. ii. cc. 1—7; Bellermann, *Handbuch der Bibl. Lit.*, vol. i. sect. 56; Bellermann, *Versuch einer Erklärung der Punischen Stellen im Pönulus des Plautus;* Dessen, *De Phœnicum et Pœnorum inscriptionibus*, Berl. 1810; Dessen, *Bemerk. über Phönizische und Punische Münzen;* Gesenius in an Excursus entitled *Uber die Phöniz. und Punische Sprache und ihr Verhältniss zur Hebraischen*, in his *Geschichte der Hebr. Sprache;* Gesenius, *Versuch über die Malthesische Sprache*, 8vo., Leip. 1810; and *Paläographische Studien, über Phöniz. und Punische Schrift*, 4to., Leip. 1835.) The long settlement of the Hebrews in Egypt, and their forty years' wandering in the wilderness, must have had an important influence upon their language; but the number of Egyptian words received into it appears to have been small.

Many critics have divided the history of the language into four periods:—I. From Abraham to Moses. II. From Moses to Solomon. III. From Solomon to the Babylonish captivity. IV. From the Babylonish captivity to its final extinction as a spoken language. But there are in reality only two periods in which any difference can be traced in the language; the first extending from the time of Moses to the reign of Hezekiah, and the second from the reign of Hezekiah to its final extinction as a spoken language. The language in which the Pentateuch is written differs so little from that of David, Solomon, and Isaiah, who lived many centuries after the time of Moses, that many critics, supposing it impossible that a language should have remained stationary for so many centuries, have maintained that none of the books of the Old Testament were written previous to the time of David and Solomon. It is not very easy to disprove this opinion; but the remarks of Ewald on this subject appear worthy of attention. He observes in his 'Hebrew Grammar,' § 7 (Eng. trans.), that 'the Hebrew language in the first four books of the Pentateuch, which contain records of unquestionable antiquity, partly by Moses or from his time, appears already, a few minutiæ excepted, fully developed.

'From Moses until about the year 700 it underwent two changes: for as the structure of the Semitic language is in general more simple, so also is it less changeable than that of languages of greater development, as Sanskrit. To which is to be added, that in that period the Hebrews did not experience those influences which materially affect a language; they did not advance much in civilization, were never long subjected to nations of foreign tongue, and lived almost entirely separated from all nations, especially from nations of foreign language. Their language therefore advanced little in development, but it also suffered little from corruption. There are however in those books of the Pentateuch some certainly important differences which afterwards disappear, and many differences of that kind have become less distinguishable by us, because the more modern punctuation has treated all words according to one standard, and that the standard of the language at a late period.' The study of the Hebrew language appears to have been greatly promoted by the schools of the prophets, which were founded by Samuel; and it is to the influence of these schools that we are probably indebted for the lyric poems of David and the didactic and amatory poetry of Solomon.

The conquests of the Assyrians and Chaldæans from about B.C. 720 tended to introduce the Aramæan language into Palestine. It appears from Isaiah (xxxvi. 12) that the principal people in Judæa, even in the reign of Hezekiah, found it necessary to study Aramæan. The Aramæan colonies (2 *Kings*, xvii. 24), which were planted in the kingdom of Israel to supply the place of the Israelites who had been carried into Assyria by Shalmaneser, must have caused the spread of the Aramæan language in the northern parts of Palestine even before the destruction of the kingdom of Judah. The long residence of the Jews in Babylon after the destruction of Jerusalem by Nebuchadnezzar caused the extinction of the Hebrew as a spoken language, at least among the common people. After their return to Judæa, according to the edict of Cyrus, it appears from a passage in Nehemiah (viii. 8), that the common people did not understand the Scriptures when read to them in the Hebrew language. But Hebrew continued to be spoken by the upper classes for a considerable time after the Babylonish captivity. The prophecies of Haggai, Zechariah, and Malachi, who lived in the latter part of the sixth century, are written in tolerably pure Hebrew. The inscriptions of the coins of the Maccabees are in Hebrew; and the Hebrew language does not appear to have been discontinued in writing and conversation among the upper classes till the century preceding the birth of Christ.

But the Hebrew, from the period of its extinction as a spoken language, has been always more or less cultivated by the Jews. After the destruction of Jerusalem by the Romans, numerous schools were established by the Jews, in which their language and literature were taught. Of these schools the most celebrated were those of Tiberias and Babylon. The Mishna, which contains the traditions of the Jews and interpretations of the Scriptures, is supposed to have been compiled in the latter part of the second or the beginning of the third century, by Rabbi Jehuda. The Mishna was considered from this period one of the principal works of Hebrew literature, and the Rabbis of Tiberias and Babylon wrote numerous commentaries upon it. These commentaries were at length collected into two separate works, and entitled the Jerusalem and Babylonian Talmuds. The Jerusalem Talmud appears to have been compiled in the third or fifth century, by Rabbi Jochonan; and the Babylonian Talmud in the sixth century, by Rabbi Asci. Each Talmud is divided into two parts, the Mishna, or text, and the Gemara, or commentary. The 'Mishna' has been edited by Surenhusius, 6 vols. fol., Amst., 1698; the Babylonian Talmud was published at Berlin and Frankfort, 12 vols. fol., 1715; and the Jerusalem Talmud at Amsterdam, fol., 1710. To the same schools we are also indebted for the system of punctuation and accents which we have in the Hebrew Bible. This system, which no doubt represents faithfully the traditional interpretation of the Scriptures and pronunciation of the language by the Jews, is entitled Masora (מָסוֹרָה), that is, 'tradition.'

It is uncertain how long the school of Tiberius lasted; but the Babylonish school was broken up by the Arabs, A.D. 1040, after a long period of prosperity, and most of the scholars took refuge in Spain, where they founded schools in most of the principal cities. These schools produced a succession of writers; of whom the most celebrated was MAIMONIDES, who lived at the latter end of the twelfth century. After remaining in Spain for nearly four centuries they were banished by the Christians in 1492.

The Christians paid very little attention to the Hebrew language before the Reformation. The publications of the Buxtorfs in the seventeenth century tended to diffuse the language among Christians, but their works contained no philosophical views of the language, since they implicitly followed the decisions of the Masorites. The Grammar of Schultens, which appeared in 1731, and which may still be consulted with great advantage by Hebrew scholars, contained a much clearer development of the principles of the language than the Buxtorfs had given. His knowledge of Arabic enabled him to compare the forms of that language with the Hebrew, and thus to draw the attention of scholars to the important fact that the study of the cognate languages is necessary to obtain an accurate knowledge of Hebrew. But the publications of Gesenius and Ewald in the present century, which are enumerated at the end of this article, have done more to facilitate the acquisition of the language than the works of all preceding writers.

It appears probable that the language of a country, which was divided both physically and politically into several parts, must have contained various dialects; but this cannot easily be proved, since almost all the Hebrew writers belonged to the kingdom of Judah. The language of Galilee and the northern parts of Palestine appears at all times to have inclined to the Aramæan; in the time of Christ, the Galilæan dialect differed from the language spoken in Judæa. (*Matt.* xxvi. 73.) In the book of Judges (xii. 6), the pronunciation of the Ephraimites is distinguished; and many critics think that they can discover traces of the northern dialect in the song of Deborah (*Judges*, v.)

Few literary subjects have occasioned greater discussion than the letters, vowels, points, and accents of the Hebrew language. But with regard to the letters it appears probable, that the present square characters in which Hebrew is written were not employed previous to the Babylonish captivity, but that the Phœnician letters were used, which are still preserved with a slight alteration in the Samaritan alphabet. According to the Jewish tradition, the present square characters, which belong to the East Aramæan language, were first introduced by Ezra when he revised the canon of Scripture; but they could not have been universally adopted till a later period, since the Samaritan Pentateuch, which was not introduced into Samaria till after the Babylonish captivity, was written in the antient character, and the coins of tho Asmonæans in the second century before Christ also employ the same character. It is difficult to say when the change was introduced. It has been conjectured that the square characters were in use in the time of Christ, from his referring to the letter *yod* as the smallest letter in the alphabet; a fact which is true of the present Hebrew alphabet, but would not apply to the antient Hebrew or Phœnician alphabet.

It is a characteristic of the Hebrew language, according to the system of most modern Hebrew grammars, that the alphabet consists only of consonants, and that the vowels are expressed by means of small points placed above and below the letters. The antiquity of these points has occasioned great controversy among the learned. Some have maintained that the points are as antient as the letters, and that both the points and letters were taught Moses by God himself; others, that the points were first introduced by Ezra when he transcribed the Scriptures in the present square characters; others, that the Hebrews had originally three vowel points, *a*, *i*, and *o*, answering to the three letters א, י, ע, and that the present system of punctuation was not introduced till the time of the Masorites; but it is now generally considered by eminent Hebrew scholars, Gessenius, Winer, Ewald, &c., that the whole system of punctuation was first introduced by the Masorites, of whom some account has been given above, perhaps as early as the sixth or seventh century, and certainly not later than the tenth or eleventh. It appears certain from many circumstances that the Hebrew letters were originally written without points. They are not found in antient Jewish coins and inscriptions; they are not once mentioned or alluded to in the Talmud; they appear to have been unknown to Origen and Jerome; the antient versions, such as the Chaldee paraphrases of Jonathan and Onkelos, and the Greek translations of Aquila, Symmachus, Theodotion, and the Septuagint, must have been made from Hebrew MSS. without points, since they frequently give a different interpretation to the words from that which they must mean according to the present system of punctuation; and it is allowed that all the other Semitic languages had antiently no points. The best arguments on both sides of the question are given in Buxtorf's 'Tiberias, sive Commentarius Masorethicus,' 4to., 1620, in which the antiquity of the points is maintained, and in Capellus's 'Arcanum Punctationis revelatum,' 4to., 1624, in which their antiquity is denied. Further information on the subject will be found in most of the grammars which are mentioned at the end of this article. The system of accentuation depends on that of points, and was in all probability introduced at the same time. The accents mark the relation of one word to another in a sentence, and thus serve an important purpose in the syntax of the language. Many scholars have considered the accents almost useless; but one of the most eminent Hebraists of the present day remarks (Ewald, 'Hebrew Grammar,' § 642, Engl. transl.), 'We everywhere find a beautiful harmony between the accentuation and the syntax, so that they mutually support and explain each other. Whether we set out from the syntax, and learn to comprehend it without knowing any thing of the accentuation, or whether we proceed from the accentuation to the syntax, an accurate investigation will always lead to the same results, so that he who thoroughly understands the syntax is for the most clearly possessed of the accentuation also, and he who understands the latter becomes throughout more easily at home in the former. This is however at the same time the best commendation of the accentuation.' We must distinguish however the accentuation of the historical and poetical books. The remarks of Ewald apply only to the accentuation of the historical books. Many of the accents in the poetical books serve the same purpose as those in the historical; but the greater part were intended to indicate the tone according to which the Scriptures were chanted in the synagogue. Tho accents aro explained with great clearness in Stuart's 'Hebrew Grammar.'

Further information respecting the Hebrew language and literature is given in Hezel's 'Geschichte der Hebr Sprache und Litteratur,' 8vo., Halle, 1766; Kopp's 'Bilder und Schriften der Vorzeit,' 1820-1; Gesenius's 'Geschichte der Hebr. Spracho und Schrift,' 8vo., Leip., 1815; Lowth's 'De Sacri Poesi Hebræorum;' best edition by Michaelis, 2 vols. 8vo., Gött., 1768-9: this work has been translated into English by Gregory; Herdor, 'Geist der Hebraïschen Poesie,' best edition by Justi, 2 vols. 8vo., Leip., 1825: this work has been translated into English by Marsh, Burlington, U.S., 1833; Bellermann, 'Versuch über die Metrik der Hebräer,' 1813: Saalschütz, 'Von der Form der Hebr. Poesie,' 8vo., 1825; the introductions to the Old Testament by Eichhorn, Jahn, De Wette, and Augusti; Hurwitz, 'Hebrew Tales, selected and translated from the Writings of Antient Hebrew Sages; to which is prefixed an Essay on the Uninspired Literature of the Hebrews,' 12mo., Lond., 1826; the article Bible, in this work.

Grammars.—The following list is only intended to direct tho attention of the student to the principal grammars. Buxtorf, 'Thesaurus Grammaticus Linguæ Sanctæ Hebrææ,' 8vo., Basel, 1615: this work is taken from the Hebrew grammar of the Rabbi David Kimchi, and is the best grammar according to the Rabbinical System; Schultens, 'Institutiones ad Fundamenta Linguæ Hebrææ,' 4to., Leyden, 1731; Robertson, 'Grammatica Linguæ Hebrææ,' 8vo., Edinb., 1758; Jahn, 'Grammatica Linguæ Hebraicæ, Leip., 1788; Gesenius, 'Ausführliches Grammatisch-kritisches Lehrgebäude der Hebr. Sprache,' 8vo., Leip., 1817; but his smaller grammar, forming the first volume of his 'Hebräisches Elementarbuch,' is better adapted for beginners. The Hebrew grammars of Gesenius formed the basis of a very good Hebrew and English grammar by Stuart, published originally at Andover, U.S., in 1821, and reprinted at Oxford in 1831. The 'Elémens de la Grammaire Hebraïque,' by Cellerier, 8vo., Genève, 1820, is also formed upon the Hebrew grammar of Gesenius. The grammars of Ewald contain the most philosophical exhibition of the language that has yet appeared: his larger grammar, entitled 'Kritische Grammatik der Hebr. Sprache,' was published at Leip., 1827, 8vo. The writer of a review of this work in the 13th No. of the 'Journal of Education' remarks that 'the reader will not expect to find in the work of Ewald the *elementary* parts of Hebrew grammar entirely different from those which were stated by the Buxtorfs, and by Gesenius and his followers in Europe and America. The characteristics of Ewald's grammar consist in his manner of accounting for the general rules, and in his attempts to refer the rules and their apparent exceptions to more general principles. But this laudable aim leads Ewald into a number of new conjectures, which in his Critical Grammar he pronounces authoritatively against his predecessors. The conjectures of Ewald were however generally supported by independent investigations.' A smaller Hebrew grammar was published by Ewald in 1828, which has been translated into English by Nicholson, 8vo., Lond., 1836. Lee's 'Grammar of the Hebrew Language,' 2nd ed., 8vo., 1831, contains many excellent observations, but it is deficient in clearness of arrangement, and cannot be recommended to beginners. Hurwitz, 'Grammar of the Hebrew Language,' 8vo., Lond., 1831, is well calculated for beginners, but it does not give a philosophical development of the language. Those who wish to use a small grammar will find the following works useful:—Yeates, 'Hebrew Grammar,' which has been frequently printed, and Hincks, 'Grammar of the Hebrew Language,' Belfast, 1832. In the schools and universities of Holland the two following works are principally used: Schroeder, 'Institutiones ad Fundamenta Linguæ Hebrææ,' reprinted at Glasgow, 1824, 8vo.; and Roorda, 'Grammatica Hebræa,' 2 vols. 8vo., Leyd., 1834. Stier's 'Neugeordnetes Lehrgebäude der Hebr. Sprache,' 2 vols. 8vo., Leip., 1833, is said by the writer of a review in No. 13 of the 'Journal of Education' to be the 'best work now extant in any language on the elements and what is usually called the etymology of the Hebrew language.'

Grammars without vowel points:—Masclef, 'Grammatica Hebraica,' 2 vols. 8vo., Paris, 1731; Parkhurst's 'Methodical

Hebrew Grammar,' prefixed to his Hebrew and English Lexicon; Wilson's 'Elements of Hebrew Grammar,' 4th ed., 8vo., 1810; Newton's 'New and Easy Introduction to the Hebrew Language,' 12mo., Lond., 1806.

Lexicons.—Buxtorf, 'Lexicon Hebraicum et Chaldaicum,' 8vo., Basel, 1634; reprinted at Glasgow in 1824; Stock, 'Clavis Linguæ Sanctæ Veteris Testamenti,' 8vo., Jena, 1753 (best ed.); Winer's edition of 'Simonis Lexicon Manuale Hebraicum et Chaldaicum,' 8vo., Leip., 1826: this work is said by the writer of a review in No. 11 of the 'Journal of Education' to belong 'to the most useful works of its kind, especially for students who have overcome the first difficulties of the language;' Leopold's 'Lexicon Hebraicum et Chaldaicum,' 12mo., Leip., 1832, a useful lexicon for beginners; Gesenius, 'Thesaurus Philologico-criticus Linguæ Hebrææ et Chaldææ,' 4to., 1828-35, of which two parts have as yet only appeared. Gesenius's first work on Hebrew lexicography was entitled 'Hebräisch-Deutsches Handwörterbuch über die Schriften des Alten Testaments,' 2 vols. 8vo., 1810-12, which was translated into English by Leo, 2 vols. 4to., Lond., 1825. In 1815 Gesenius published a smaller Hebrew and German lexicon, which has gone through several editions, and formed the basis of 'A Manual Hebrew and English Lexicon,' by Gibbs, Andover, U.S., 1824; reprinted in London, 1827 and 1833. The most recent Lexicon by Gesenius, entitled 'Lexicon Manuale Hebraicum et Chaldaicum,' was published at Leip., 1833, and has been translated into English by Robinson, Boston, U.S., 1836. Parkhurst's 'Hebrew and English Lexicon,' which was published originally in 1762 in 4to., and has since been frequently reprinted, is intended for the use of those who are unacquainted with the vowel-points. A review of the most important Hebrew grammars and lexicons is given in Nos 9, 11, and 13, of the 'Journal of Education.'

Those who are commencing their Hebrew studies without the assistance of a master will find the following works useful:—Leusden's 'Clavis Hebraica Veteris Testamenti,' 4to., Utrecht, 1683; Robertson's 'Clavis Pentateuchi,' 8vo., Edinb., 1770; reprinted at Norwich, 1824; Bythner's 'Lyra Prophetica, sive Analysis critico-practica Psalmorum,' reprinted at Glasgow in 1823; Meisner's 'Nova Veteris Testamenti Clavis,' 8vo., Leip., 1809; Reay's 'Narratio de Josepho,' Oxf., 1822; Olivant's 'Analysis of the Text of the History of Joseph, upon the principle of Professor Lee's Hebrew Grammar,' 8vo., 2nd ed., Lond., 1833; Greenfield's 'Book of Genesis in English-Hebrew; accompanied by an Interlinear Translation, Philological Notes, and a Grammatical Introduction,' 8vo., Lond.

HEBREWS. [Jews.]

HEBREWS, EPISTLE TO THE, a book of the New Testament. The absence of the initiatory formula usual in the apostolic epistles has led some to doubt whether this book is an epistle or a dissertation. But it contains allusions to particular circumstances, which prove it to be an epistle (v. 11, 12; vi. 9, 10; x. 32-34; xiii. 19, 22, 23). The general opinion respecting the persons to whom this Epistle was addressed is that they were the Jewish converts in Jerusalem or Palestine generally. This opinion, as Michaelis has shown, is supported by the contents of the book itself. (Marsh's *Michaelis*, vol. iv., pp. 193-7.) Others suppose it to have been addressed to the Jews of Asia Minor, and Dr. Noesselt contends for its having been written to the Thessalonians. Concerning the language in which this epistle was written critics have been much divided; some supposing that it was written in Greek, and others that it was written in Hebrew and translated into Greek. The latter opinion was held by Clement of Alexandria, (who states 'that it was written by Paul in the Hebrew language for the use of the Hebrews, and that Luke translated it for the benefit of the Greeks'); by Eusebius, and by other fathers; and is strongly advocated by Michaelis. The other opinion is supported by Lardner, Macknight, Rosenmüller, Professor Stuart, and most modern commentators. But the arguments on either side are far from being conclusive.

The author of this Epistle is equally uncertain. The general voice of tradition assigns it to the apostle Paul, but it has also been ascribed to Barnabas, to Luke, to Silas, and to Apollos.

In the first ages of the church it appears to have been generally considered as a production of the apostle Paul, though great doubts were very early entertained on the subject. In the Alexandrian church we have the testimony of Pantænus (A.D. 180) to its Pauline origin, as well as that of Clement, in the passage quoted above, and in other parts of his writings. These testimonies are preserved by Eusebius (*Hist. Eccles.*, book vi., c. 14). Eusebius also quotes a passage from Origen (*Ibid.*, c. 25), which has been variously understood, but which seems to imply that an objection had been raised against the Pauline origin of the epistle from the superiority of its style to that of the acknowledged Epistles of Paul, and that to meet this objection Origen supposed the sentiments to be Paul's, but the diction that of some other person, a disciple of Paul. But he adds—'If any church therefore hold this epistle to be Paul's, let it receive commendation for this. For it is not without reason that the antients have handed it down as Paul's.' In Origen's own writings it is frequently quoted as being written by Paul; and after his time the Alexandrian fathers unanimously ascribe it to the same apostle. Turning to the Eastern church we find passages in the writings of the fathers, which are thought by some to be indirect quotations from this epistle. The earliest direct testimony is that of Eusebius, who mentions fourteen epistles as being clearly and certainly Paul's, but adds that 'some have rejected that which is written to the Hebrews, alleging, with the church at Rome, that it is spoken against as not being Paul's.' He frequently cites it as written by Paul. The Western church seems to have been greatly divided on this subject from about the close of the second to the middle of the fourth century, when Jerome states that the Epistle was received as Paul's by all the Greek and some of the Latin churches, though rejected by most of the Latins, who ascribed it to Barnabas or Clement of Rome, but held it in high esteem, and read it in their churches. Jerome himself, and Augustin, constantly refer to it, sometimes as an apostolic production, and sometimes as St. Paul's. Their authority appears finally to have established the belief in its Pauline origin among the Western churches. The modern advocates of the same opinion have attributed the doubts which prevailed in the Western church at the end of the second century to the disputes with the Montanists, who relied on this Epistle in support of some of their opinions. On the other hand, those who believe that Paul did not write the Epistle ascribe the strong testimony of the Alexandrian fathers in its favour to their great fondness for the allegorical interpretation of Scripture, which the style of this Epistle is thought to sanction. The passage in 2 *Peter*, iii. 15, is thought by some to refer to the Epistle to the Hebrews.

The internal evidence in favour of Paul being the author is drawn from the reference (c. xiii., v. 23) to Timothy, who is known to have been Paul's intimate friend and frequent companion; and from other incidental allusions (see x. 34; xiii. 18, 19, 24). In the arrangement of the Epistle, the former part being doctrinal and the latter part hortatory, in the mode of using quotations from the Old Testament and the style of argument adopted, in the doctrines most prominently stated and the phraseology employed, there are great resemblances between this book and St. Paul's acknowledged epistles. (For examples see Prof. M. Stuart's *Commentary on the Hebrews*, Introd., sects. 20—24, and Horne's *Introduction*, vol. iv., p. 415, &c., ed. 1834.) The chief objections against the Pauline origin of the epistle are drawn from the absence of the usual address at the beginning, the superiority of the style to that of Paul's acknowledged epistles, and the resemblance between its style and that of the Alexandrian school. The points above stated are discussed with great ability and candour by Prof. Moses Stuart in favour of the Pauline origin of the epistle, and Prof. Bleck on the other side.

The opinions which assign the authorship to Barnabas, Apollos, Luke, and Silas, rest on very slight grounds. The second of them was first started by Luther, a conjecture founded on the resemblance which the epistle bears to what we might expect to have been written on such a subject by a man of the character given to Apollos in *Acts*, xviii. 24—28.

The date depends partly on the settlement of the former question. The internal evidence of the Epistle shows that it was written while the temple at Jerusalem was standing (see viii. 4-5; ix. 9), and probably not long before its destruction in A.D. 70. If Paul was the author, it was probably written during his first imprisonment at Rome, and immediately before he was released (see xiii. 18, 19, 23).

Accordingly most critics refer it to A.D. 61 or 62; some say A.D. 58.

The canonical authority of this Epistle depends partly on its authorship; but may be argued on other grounds. It is repeatedly quoted by Clement of Alexandria, and apparently by Barnabas, Hermas, Polycarp, Ignatius, and Justin Martyr. It is contained in the Peshito Syriac version, the date of which is not later than the second century, and in the old Latin versions made about the same period. From that time the questions of the canonical authority and the authorship are very much mixed up together.

The design of the writer of this Epistle appears to have been to sustain the faith of those to whom he wrote, while they were suffering under persecution and inclined to apostacy. With this object he argues the dignity of Christ as superior to angels (c. i., ii.), to Moses (c. iii.), and to the race of Jewish priests (iv. 14—16; v.—viii.); the superiority of the Christian to the Jewish religion, inasmuch as the latter was only typical of the blessings conferred by the former, and was intended only to last for a time, while Christianity is to be permanent (c. ix.; x. 1—18). He proceeds to apply these arguments to encourage the Hebrews to constancy in their faith, and to enforce his exhortations by the example of eminent men (x. 19—xii.). After urging them to the practice of various Christian duties, he concludes with the usual salutations. In warmth of feeling, elegance of language, and force of argument, this epistle yields to no book of the New Testament.

(Lardner's *Credibility;* Marsh's *Michaelis*, vol. iv.; Prof. Moses Stuart's *Commentary on the Hebrews;* of Prof. Bleek's *Brief an die Hebräer*, perhaps the best commentary on this epistle, two vols. only have appeared, the first (8vo., Berlin, 1828) containing Dissertations, &c., and the 2nd the Commentary as far as c. iv., v. 13, Berlin, 1836; Hug and Horne's *Introductions;* for a list of commentators see Watt's *Bibliotheca Britannica*, and Seiler's *Biblical Hermeneutics.*)

HEBRIDES, THE (or Western Islands of Scotland), are scattered in the Atlantic Sea, along the western coast of North Britain, between 55° 35′ and 59° N. lat., and 5° and 8° W. long. They amount to the number of nearly 200, but more than one-half of them are so small or so sterile as not to be inhabited. In 1808 only 79 were regularly peopled all the year round, but in eight more houses were found, which were tenanted during the summer, and abandoned at the approach of winter.

These islands are commonly divided into the Northern and Southern Hebrides, the most western point of the main land, the promontory of Airdnamurchan (56° 40′ N. lat.), being considered as the point from which the line of division between them runs westward into the Atlantic. But geographically they should be divided into the Eastern and Western Hebrides, as the greater number of them are at no great distance from the coast of Britain, and one extensive group is much farther to the west in the ocean. The wide and open strait which divides the last-mentioned group, which is comprehended under the general name of Long Island, from the former islands and the mainland of Scotland, is called the Minch; and in its narrowest part (about 20 miles), between Skye and North Uist, it is called the Little Minch.

The surface of the Hebrides is stated to exceed 3184 square miles, which is nearly one-twelfth part of Scotland and one-thirtieth of Great Britain. They are larger than Corsica, or the two provinces of Holland, and than any county of Great Britain, excepting Yorkshire and Inverness.

The surface of these islands varies considerably. Some of the larger islands, especially those which approach the mainland, are mountainous, such as those of Arran, Jura, Mull, and Skye, in which the elevated masses rise to the height of 2000 or 3000 feet and more above the sea. The rest are in general only hilly, the most elevated parts not exceeding 1500 feet; and in a few of them the hills do not rise to more then 300 or 500 feet, as in Tyree and in the southern islands which belong to the group of Long Island. The coasts are everywhere rocky, and in many parts high, and particularly so along the western shores towards the Atlantic, with the exception of the innermost angles of the bays and inlets, where they are frequently low. The southern islands of Long Island have a series of sand-hills on their western coast, and the shores are generally indented by large bays and inlets, which form a vast number of harbours of every description, some of which, in security and capaciousness, are equal to any in the world. It is stated that there is no place, even in the larger islands, which is more than seven miles from the sea-shore. The rivers are small, but numerous, and all of them abound in salmon, trout, and eels; many of them contain also several other kinds of fish. Some of the islands abound in lakes. Those of Long Island alone cover 25,000 acres, and in the small island of Tyree they are stated to occupy about 700 acres. The soil is in general as good as in other parts of Scotland, except a few tracts particularly favoured by nature. The islands of Bute and Islay are considered fertile, and also several districts in the island of Skye. But a comparatively small portion of the surface of the whole is under cultivation. The whole area of the islands comprehends 1,592,000 Scotch acres, of which only 210,000 are arable or meadow land; 600,000 acres mountains, morasses, and lakes; 70,000 acres pasture ground, commonly on hills, and of little value; 25,000 acres are barren sands tossed about by the winds; 22,000 are occupied by peat-mosses; and 30,000 acres are dry at ebb-tide, and serve as kelp-shores. There are no natural woods on the islands, but about 5000 acres have been planted.

The backward state of these islands is chiefly to be attributed to the want of timber, their great distance from towns and markets, and the difficulty of intercourse on account of the boisterous seas which surround them, and the storms which frequently prevail nine months of the year, especially from the south-west. This wind brings torrents of rain almost annually from August to the beginning of March. Early in March, and often also in October and November, a north-east or north-north-east wind prevails; and although the coldest that blows here, it is generally dry and pleasant. The climate is upon the whole mild. Frost and snow are almost unknown in the smaller isles, and they seldom prevail in the larger to any considerable degree. On the sea-shores the thermometer rarely falls more than 5° below the freezing-point. The annual quantity of rain which falls in the higher islands may be between 30 and 36 inches; but in the lower it probably does not exceed 25 inches. Grasses and corn ripen very quickly: in Uist, Lewis, and Tyree, big, or bear, is frequently cut down within ten weeks after being sown.

The great mass of the population resides within a mile of the sea-shore. The traveller meets with scarcely an inhabited house 1000 yards from the sea-mark, or 300 feet above the level of the ocean, except in the islands of Bute and Islay. From their language and customs it is evident that they are of the same stock with the inhabitants of Ireland and of the Highlands of Scotland. In most of the islands they gain as much by catching herrings, cod, and ling, with which the surrounding sea abounds, or by burning kelp, as by their agricultural industry.

The Hebrides belong politically to four Scotch counties. Those of them which lie in the Frith of Clyde, between the peninsula of Cantyre and the coast of Ayrshire, constitute a county by themselves. [BUTE; ARRAN.] All the other Southern Hebrides, together with the islands of Muck, Rum, and Canna, which are included in the Northern Hebrides, are annexed to the county of Argyle. [ARGYLE.] The Long Island, except Lewis, constitutes a part of Inverness-shire. Lewis is a part of Ross-shire; and Skye belongs to Inverness.

The Hebrides are mentioned by Ptolemy under the name of Ebudæ, and by Pliny (iv. 16) under that of Hebudes. Pliny makes the Hebudes thirty in number.

(M'Culloch's *Highlands and Western Islands;* Macdonald's *General View of the Agriculture of the Hebrides.*)

HEBRUS. [MARITZA.]

HECATÆUS of Miletus, son of Hegesander, was one of the earliest Greek prose writers. He was present at the deliberation of the Ionians (B.C. 501), and attempted to dissuade them from revolting against the Persian king. (Herod., v. 36.) He is also mentioned by Herodotus (v. 125) as being alive at the time of the flight of Aristagoras, B.C. 497.

His works, which consisted of histories, genealogies, and geographical pieces, were held in considerable esteem by the antients. Herodotus (vi. 137) quotes one of his historical works. Strabo (i. p. 12, *Casaubon*) complains that his geographical works only contained the descriptions of the poets written in prose; but he is mentioned by Ammianus Marcellinus (xxii. 8) in conjunction with Eratosthenes and Ptolemy. Hecatæus appears, like Herodotus, to have visited distant countries for the purpose of acquiring information respecting the history, customs, and physical peculiarities of foreign lands. Herodotus (ii. 143) gives an account of a conversation of Hecatæus with the priests at Thebes in Egypt, which was apparently derived from his works.

The fragments which remain of the writings of Hecatæus have been published by Creuzer in his 'Historicorum Græcorum Antiquissimorum Fragmenta,' 8vo., Heidel., 1806, by Klausen, 'Hecatæi Milesii Fragmenta,' 8vo., Berl. 1831; and in the 'Museum Criticum,' vol. i., p. 88-101, Camb., 1814.

HE'CATE, one of the antient Greek divinities, the daughter of the Titan Perses and Asteria, according to Hesiod (*Theog.*, 411). Her attributes correspond in most respects with those of Artemis; and it has therefore been conjectured that she may originally have been the same as Artemis. Her name, the feminine of Hecatus (' the far-shooting'), one of the names of Apollo, the brother of Artemis, is thought to favour this supposition. Hecate presided over hunting and fishing, the deliberations of the popular assembly and the courts of justice. She seems also to have appropriated to herself part of the duties of Persephine (Proserpine); since she was regarded as the mistress of the lower world, and the patroness of magic. She was considered a beneficent deity, who answered the prayers of her worshippers. Her statues were placed at cross-roads and before houses. She was held in much respect in Athens, where she was regarded as the patroness of families and children. She was greatly venerated by the inhabitants of Ægina, who held a festival once a year in honour of her; which was said to have been instituted by Orpheus. (Pausan., ii. 30.)

HECLA. [ICELAND.]

HE'DERA, a genus of Araliaceous plants consisting of nearly fifty species, inhabiting chiefly the warmer parts of the world, is interesting to Europeans for containing among others the common ivy with its numerous varieties. This plant, the Hedera Helix of botanists, does not exactly represent the habit of the genus, for many of the exotic species, instead of being creepers, adhering to other plants, or to rocks and walls by their sucker-like roots, are trees of considerable size

Common ivy is dispersed through many distant parts of the Old World, lying between the Canaries and Europe on the west, and the northern parts of China on the east. In the Canaries it acquires its largest size, being what is called in English gardens the Irish or giant ivy, which grows so much faster than the European form. In the north of India, and indeed occasionally in Italy, the berries, instead of being black as with us, are bright yellow, and it is supposed that this is more particularly the Hedera of the Roman poets. The leaves vary much in form, and there is a kind which never runs or creeps upon other plants, but merely forms a compact bush.

HEDGE, one of the most lasting and effectual of our fences. When hedges have been well made, and are kept in good order, nothing can surpass them, except well-built stone or brick walls, and even these are far less effectual in keeping out trespassers of every description.

Hedges are made of various kinds of shrubs and trees, trained so as to throw out numerous branches along the stem from the surface of the earth upwards; this is done by judicious pruning when they are young. The head being cut off and the side branches shortened, numerous smaller branches spring out, which are shortened in their turn, and form a very compact mass, consisting of the ends of stumps and branches pointing in every direction. Those shrubs which are of a thorny nature are best adapted for hedges. Holly, which bears prickles on the edges of the leaves, is on this account by far the best shrub to form a hedge. But it has a great inconvenience in its very slow growth, and, except in very old gardens, which have been surrounded by a high holly hedge before the present generation was born, it is very seldom that such a hedge is met with. The high price which the nurserymen charge for this plant is another reason why it is more seldom planted.

In forming a holly-hedge the ground should be prepared by trenching and abundant manuring: the plants should be most carefully planted after midsummer, or immediately before the usual rains which come at that season. There should also be a portion of virgin soil for the roots to spread in; and in planting they should be well divided, to give them the greatest possible extent from which to draw their nourishment. The earth should be well pressed to them by treading it down; and, in case of a continued want of rain, they may be occasionally watered, late in the evening, or early in the morning. By a little attention to them in the first year, they will form a good fence several years sooner than those which are comparatively neglected. The plants which are usually put in are three years old; but if they could be transplanted at once from the seed-bed, they would sooner come to perfection; and by being cut down and pruned earlier, would lay the foundation of a closer and better hedge. Next to holly, as forming a close and durable hedge, is the yew: it bears very close clipping, and forms a thick hedge and good shelter all through the year. For gardens and nursery-grounds, where shelter and occasional shading are required, the yew-hedge is preferred; but in all places where cattle are put to pasture, they should never be permitted to grow. Many valuable horses and cattle have been destroyed by grazing in places where yew-trees grew; and notwithstanding the instinct which leads animals to reject food which is hurtful, they greedily eat the yew leaves in spring. The same may be said of box.

The various kinds of thorns are peculiarly adapted to form hedges, and they are consequently by far the most common plants of which a live hedge is formed.

For high hedges and strong fences the hornbeam and a variety of the beech which throws many branches from the stem are extensively used in old gardens, where geometrical figures and numerous angles are admired.

Where it is desirable that the hedge should arrive very rapidly to such a size as to be a good defence against cattle, elder may be planted. Elder grows very rapidly, and throws out many long hollow branches, which soon become hard, and are admirably calculated for a fence, and cattle will not eat the leaves; but it is never very close or ornamental; and as it requires to be cut down frequently, it displays very unsightly knots and stumps when it has acquired a certain age.

Sweetbriar is ornamental, and forms a good fence against sheep. It is chiefly confined to flower-gardens and enclosures in pleasure-grounds.

Many other shrubs might be named, such as the *pyrus Japonica*, which is prickly, grows close, and bears a beautiful flower. It is as hardy as any native British plant, and will bear cutting and training as well as any of them. Hitherto no edges have been made of this shrub, except a few in the gardens of nurserymen; but there is no doubt that if many young plants were wanted for hedges, they would soon be produced at a reasonable price. The privet is a very common and quick-growing shrub, which is frequently planted as a hedge where cattle are not admitted; but of all shrubs, the most common and most useful for the purpose of hedges are the black and white thorn, and they almost universally form the quick hedges by which our fields are separated and enclosed.

In order to have a good hedge, the shrubs should be planted in a soil which is naturally strong, but well pulverised, and in which no shrub or tree has lately grown. The best soil is that which is produced by the decomposition of sods taken from commons or old pastures; and it is observed that in new enclosures, where the quick has been inserted between two sods, it always grows luxuriantly, and only requires to be protected, when young, against the cropping of cattle and sheep, which are fond of the young tender shoots. The usual mode is to insert, in the early part of the spring, two or three rows of quick in the side of the bank, on a level with the surface of the ground, where a sod has been turned over, and forms the base of the bank raised by the earth taken out of the ditch. This quick requires to be protected from cattle or sheep by some fence. [FENCE.] Sometimes the quick is planted in two or three parallel rows on the top of the bank, which in this case is made much wider, with a ditch on each side. A double fence in such case is necessary for its complete protection. When the quick is planted on the top of the bank, the surface sods are reserved to lay at the top; and after being broken and chopped to pieces, are dug into the bank. Stable-dung is frequently dug in at the same time, and is well bestowed: the quicks are then inserted, and well watered. They never fail to come up luxuriantly; and when properly pruned they form a close and impenetrable hedge.

Many think that it is advantageous to prune and cut down the young shoots every year, in order to excite them to throw out fresh ones in greater number. But this is an error by which the growth of the hedge is much retarded. The shoot should be allowed to grow to its full extent the first and second year; the root will then have struck deep into the ground; and in the third or fourth year the quicks may be cut down to a few inches. They will then send out several fresh and strong shoots, which may be cut and pruned to the height and width of the intended hedge.

In Holland and Flanders the hedges are often trained along stakes and rods placed for the purpose, and tied together with oziers. In this case every slender branch is tied to the rods, and they are laid so as to cross each other frequently, and the redundant shoots which cannot be conveniently tied in are cut off. These hedges, when in leaf, look very close and light, and take up very little room; and birds can scarcely harbour in them. It appears at first sight that much labour is required to train hedges in this way; but this is by no means the case. When they have once grown to the proper height they only require to be regularly clipped.

In forming a hedge it is necessary to take into consideration the quality of the soil, the aspect of the bank, and whether the land is porous, or very retentive of moisture. In the first case it will be advantageous to plant the quick in the side of the bank, raising the earth above it to keep in the moisture. A ledge may be made by setting the first sod at a couple of inches from the edge of the ditch. The water which may fall on the bank and run down the smooth side is arrested by the ledge and soaks into the roots. In the other case the top of the bank is the proper place, and a small concavity may be given to it to retain the water and keep the roots moist.

In a dry soil which does not require draining, ditches are unnecessary, and it is much better to plant a hedge on a little bank formed by a few sods about eighteen inches wide, with a small water-furrow on each side. The whole width need not be above two feet six inches, whereas a bank and ditch take up at least six feet, and the plough cannot go nearer than a foot from the edge of the ditch or the bank. Thus eight feet are taken up by the fence.

When a hedge has been left uncut for several years, it grows wide and high. It requires to be cut down once in seven or eight years; in this case much care is required in the cutting that the shoots may grow out again regularly. The common labourers often do this very carelessly by cutting the stems downwards with one or more cuts of their bill-hook. The consequence is that the stem is split and shivered, and the rain lodging in the ragged cut injures the wood and causes it to die down farther than it otherwise would. Hence the general maxim of 'cutting up,' so strongly recommended by all those who give directions about cutting hedges. Portions of the stems are often left of a greater length than the rest for the purpose of holding the bushes, which are generally laid over the cut stumps to protect them against cattle. But it is better to cut the hedge regularly, one row close to the ground, and one a few inches longer; this will strengthen the foot of the hedge, and prevent its being thin and hollow at bottom.

When a hedge has become old, and many of the plants are decayed, it is very difficult to renew it. If young quicks are planted on the same spot, they will scarcely ever succeed, unless very great precautions are taken. The soil is exhausted or deteriorated, and must be renewed: but manuring is not sufficient; fresh earth is required for the new quick. The simplest process is to level the old bank, spread the earth of which it was formed, which will be of great use to the ground where it is spread, and form a new bank in the same place from earth taken elsewhere; or, where it can be done without inconvenience, it is better to make an entirely new ditch and bank, and to fill up the old. This is perhaps the surest as well as the soonest way of having a new hedge which will be permanent.

What has been said of renewing a hedge is equally applicable to repairing gaps in an old one. It is of no use to put in young plants in the old bank. The earth must be removed, and fresh earth put in its place. The old hedge must be cut and trimmed, so that the young quick may not be shaded, and in that case the gap will shortly be filled up, and the hedge be restored as a continuous fence. Where the gaps are very small, and the hedge is not cut down altogether, it may sometimes be advisable to plant hollies or other plants, which will grow well and fill up the deficiency.

Well managed hedges are the most effective fences, the cheapest, and the most pleasing to the eye. It is to the hedge-rows that England owes much of its garden-like appearance; but the trees, which are their chief ornament, are very destructive of the hedge as a fence; and where trees are planted it would be much better if they stood within the bank, without interfering with the hedge. Whether trees can be allowed in hedge-rows, in a perfect system of agriculture, is a question which we will not attempt to answer.

There is a method of repairing hedges which is called *plashing*. It consists in cutting half through some of the stems near the ground, and then bending the upper parts down in a horizontal or oblique position, keeping them so by means of hooked sticks driven into the bank. Thus a live hedge is made, which fills up the gaps in the same manner as a dead hedge would have done, and the bent stems soon throw out shoots. If the stems are young, and not above the thickness of a finger, an excellent hedge may be thus formed, which, when clipped, will be close and perfectly impervious. But the work is generally done in a very injudicious manner. When a hedge is plashed which has been long neglected, the thick stems, which are hacked through, leaving only a small portion of the under bark uncut, have an unsightly appearance, and seldom throw out shoots near the bottom, where they are most wanted. To plash a young hedge by merely bending the twigs is an excellent practice: but when the stems are thick and old, the only remedy is to cut them down, or make an entirely new bank well planted with quick.

HEDGEHOG, *Hérisson* of the French. The Hedgehogs are placed by Cuvier at the head of the *Insectivorous Mammifers*; and M. F. Cuvier observes that in *Chrysochloris* the normal system of dentition of the *Insectivora* may be seen reduced to the narrowest dimensions; whilst in the Hedgehogs it appears to be brought to the greatest development.

Dental Formula.—Incisors $\frac{6}{2}$; Canines 0; Molars $\frac{7-7}{7-7}$ = 36.

Generic Character.—*Body* covered with spines, with the power of rolling itself up in a ball by means of appropriate muscles; *muzzle* pointed; *ears* more or less apparent; *tail* short; each *foot* five-toed and armed with robust claws.

Geographical Distribution of the Genus.—Species of Hedgehog have been recorded as inhabitants of Europe, Africa, and India.

We select as an example the *Common Hedgehog, Erinaceus Europæus.*

This is the *Riccio* of the Italians, *Erizo* of the Spanish, *Ourizo* of the Portuguese, *L'Hérisson* of the French, *Igel* of the Germans, *Eegel-varken* of the Dutch, *Pin-suin* of the Danes, *Draenog* and *Draen y coed* of the antient British, *Urchin* of the modern British, *Echinus terrestris* of Gesner, *Echinus (Erinaceus) terrestris* of Ray, and *Acanthion vulgaris* of Klein. There can be little doubt that it is the Echinus (Ἐχῖνος) of Aristotle.

This indigenous animal is too well known to need a lengthened description. The length is generally rather more than nine inches.

Food, Habits, Reproduction.—The food of the Hedgehog, which is a nocturnal animal, consists principally of insects, worms, slugs, and snails. That it will eat vegetables is shown by White of Selborne, who relates how it eats the root of the plantain, by boring beneath it, leaving the tuft of leaves untouched. In the *Zoological Journal* (vol. ii.) is an account by Mr. Broderip of an experiment made by Professor Buckland, proving that, in captivity at least, the Hedgehog will devour snakes: but there is no good reason for supposing that it will not do the same in a state of nature, for frogs, toads, and other reptiles, and mice, have been recorded as its prey. From its fondness for insects it is often placed in the London kitchens to keep down the swarms of cockroaches with which they are infested; and there are generally hedgehogs on sale in Covent Garden market for this purpose. It is hardly worth while to refute the idle story that this persecuted animal sucks the cows; but, according to Sir William Jardine, it is very fond of eggs, and is consequently mischievous in the game-preserve and hen-house. The Hedgehog hybernates regularly, and early in the summer brings forth from two to four young ones at a birth, which, at the time of their production, are blind, and have the spines white, soft, and flexible. The nest wherein they are cradled is said to be very artificially constructed, the roof being rain-proof.

Utility to Man.—The flesh of the Hedgehog, when it has been well fed, is sweet and well-flavoured, and is eaten on the Continent in many places. In Britain few besides the gipsies partake of it. The prickly skin appears to have been used by the Romans for hackling hemp.

We refer those who would pursue the history of the common Hedgehog still further to the interesting account in the 'History of British Quadrupeds,' by Thomas Bell, Esq., F.R.S., &c., 8vo. London.

Among the foreign *Erinaceadæ*, *Erinaceus spatangus* and *Erinaceus Grayi* will be found recorded in the *Proceedings of the Zoological Society* for 1832. Both came from the Himalayan Mountains, and the latter was considered by Mr. Gray to be identical with *Erinaceus collaris*, figured in the *Illustrations of Indian Zoology*. Mr. Bennett however regarded it as a new species, inasmuch as *Erinaceus Grayi* was destitute of a white collar, and differed in other particulars from the figure referred to. A species from the interior of South Africa, forming part of the collection brought from that country by Mr. A. Steedman, *Erinaceus frontalis*, is recorded in the same vol. of the *Proceedings*.

Mr. Gray places the subfamily *Erinacina* under the family *Talpidæ*. (*Annals of Philosophy*, 1825.)

HEDGEHOG, a name given in gardens to the round prickly pods of various species of Medicago.

HEDINGHAM. [ESSEX.]

HEDJAZ, or HEJAZ. [ARABIA.]

HEJIRA. [ÆRA.]

HEGEL, GEORGE WILLIAM FREDERICK, was born at Stuttgart on the 27th of August, 1770, and was educated at the gymnasium of his native city. At the age of eighteen he proceeded to Tübingen to join the classes of theology and philosophy, where he had for his class-fellow the illustrious Schelling. Dissatisfied with the prevailing system of metaphysics, Hegel sought to supply its deficiencies by the works of Plato, Spinosa, and Kant; and in the conviction that a truly philosophical comprehension can only be educed by an enlarged and diversified inquiry, he combined with a knowledge of philosophy a profound acquaintance with the natural and political sciences. Upon being admitted to the degree of doctor in philosophy, he accepted an engagement as private tutor, in which capacity he lived for some years first in Switzerland, and afterwards at Frankfort-on-the-Main, until, on the death of his father in 1800, he was enabled by the inheritance of a small patrimony to devote himself without restraint to the study of philosophy. He accordingly proceeded to Jena, where Schelling was teaching his system of *Absolute Identity*, and of which Hegel was at this period one of the warmest partisans. Here he composed as an academical exercise the essay 'De Orbitis Planetarum,' (Jenæ, 1801), and shortly afterwards his first philosophical work, entitled 'On the Difference of the Systems of Fichte and Schelling;' which treatise, notwithstanding the sincerity with which Hegel then advocated the views of the latter, contained the germ of that dissent which was afterwards expanded into a peculiar theory. He was also associated with Schelling in conducting the 'Critical Journal of Science;' and among the most important of the articles contributed by him is that 'On Faith and Science,' which contains a luminous review of the doctrines of Kant, Jacobi, and Fichte, whose several systems are represented as nothing more than so many forms of a purely subjective philosophy. In 1806, when Schelling went to Würzburg, Hegel was appointed to supply his place as lecturer. The duty of communicating his views to others necessarily imparted to them distinctness and precision; and now for the first time Hegel openly avowed his dissatisfaction with the system of Schelling. The difference between the ideas of the master and disciple was marked still more strongly in the 'Phenomenology of Mind,' which was published at Bamberg, whither Hegel had retired after the battle of Jena. This work he used to call his 'Voyage of Discovery,' as indicating the researches he had passed through in order to arrive at a clear knowledge of the truth. It contains an account of the several grades of development through which the 'self,' or 'ego,' proceeds: first of all from consciousness into self-consciousness; next into reflecting and active reason, from which it becomes philosophical reason, self-cognisant and self-analyzing, until at last, rising to the notion of God, it manifests itself in a religious form. The title 'Phenomenology' points out the limits of the work, which is confined to the phenomena of mind as displayed in the element of its immediate existence, *i.e.* in experience. It traces the course of mind up to the point where it recognises the identity of thought and substance, of reason and reality, and where the opposition of science and reality ceases. Henceforward mind develops itself as pure thought or simple science, and the several forms it successively assumes, which differ only in their subject-matter or contents, are the objects of logic, or *dialectic*.

During his retirement at Bamberg, Hegel conducted the political journal of that town with great ability, and with an honesty and candour rare in the journals of that period, until he was called, in 1808, to preside over the gymnasium of Nürnberg. The duties of this situation he discharged with as much energy as skill, and the benefit of the reforms he effected, both in the discipline and the studies of the school, are still gratefully noticed at the annual commemoration. In 1812 he published his 'Logic,' which was designed, with the 'Phenomenology,' to complete the whole body of science. Hegel employs the term logic in a very extended sense. He does not confine it, as is usually the case, to the account of the abstract forms of thought and the laws of the enchainment and development of ideas, but understands thereby the science of the self-sufficient and self-determining idea—the science of truth and of reality. From his fundamental principle, that thought and substance are one and identical, it followed that whatever is true of the former is true also of the latter, and consequently the laws of logic become ontological. From this point of view Hegel describes in this work the progress of reason; how, by virtue of a peculiar and inherent impulse, it passes constantly onwards, until at last it returns into itself. The general merits of this work were at once admitted, and the high powers of philosophical reflection which it evinced were acknowledged by the offer of a professorship at Heidelberg. His first course of lectures was attended by a numerous and distinguished class, attracted by the profoundness and originality of his views, notwithstanding the great obscurity of his style. By the publication of the 'Encyclopædia of Philosophical Sciences,' in 1817, his reputation as a philosopher was established, and Hegel was invited by the Prussian government to fill the chair at Berlin, which had remained vacant since the death of Fichte, in 1814. This work, being designed as a manual for his class, takes a general view of his whole system, and exhibits in the clearest manner the ultimate tendency of his views. Considering logic as the base of all ontology, and starting from the idea in itself or potentially, he considers it as the essence and primary substance. He then examines thought as at first existing in itself, then *in other* or in nature; next in the mind of the individual, in a purely subjective point of view; and then objectively, in its outward realisation; and lastly, as he terms it, absolutely, *i.e.* as manifesting itself in art, religion, and philosophy. From 1817 until death terminated his career there is nothing to relate in the life of Hegel beyond the constantly increasing celebrity of his lectures and the publication of several works. He successively published the 'Philosophy of Jurisprudence;' two new editions of the 'Encyclopædia;' the 1st vol. of the 2nd edition of his 'Logic;' and several articles in the 'Annals of Scientific Criticism,' which he had established as an organ of his system, and of its application to every branch of art and science. He fell a victim, on the 14th November, to the cholera which ravaged Berlin in 1831, and was, in compliance with his express desire, buried by the side of Fichte.

The history of philosophy from its earliest origin to its latest development forms so perfect and compact a whole, that no single part can be separately considered without losing something of its value and significancy. This difficulty is greatly increased in the case of a philosophy which gives itself out not only as the completion of its immediate forerunner, but as the sum and result of all anterior systems. Accordingly our general view of the Hegelian system will be unintelligible unless preceded by a rapid sketch of the states of philosophy out of which it grew. The transcendental idealism of Kant formed the transition from the *empiricism* of the eighteenth century, and effected, as it were, a compromise between the antient realism and the scepticism of Hume. To the system of Kant succeeded the pure and absolute idealism of Fichte, destined to be displaced in its turn by Schelling's system of absolute identity and intellectual intuition, which was itself to be further modified and developed by the *dialectical momentum* of Hegel. Essentially the systems of Hegel and Schelling are both founded on the same principle, viz. the absolute ideality of thought and being; for there is evidently but little difference between the doctrine of Schelling, which supposed that the human mind contains within it the fullness of reality and truth, the consciousness of which it may attain to simply by contemplating its own nature, and that of Hegel, according to whom the *concrete notion*, or the reason, comprises within itself all verity, and that in order to arrive at the science thereof it is only necessary to employ ogical thought, or dialectic. The difference is purely a difference of method. For the cold and narrow abstractions, the rigorous formalism, of Fichte, Schelling had substituted a sort of poetical enthusiasm, and banishing from philosophy the scientific form it had received from Wolff, had introduced into it the rapturous mysticism of the intellectual intuition. Hegel however, insisting that the scientific system is the only form under which truth can exist, re-established the rights and utility of method by his doctrine of the dialectical momentum, or development of the idea. Indeed with Hegel the method of philosophy is philosophy itself. This he defines to be the knowledge of *the evolution of the concrete*. The concrete is the idea, which, as a unity, is diversely determined, and has in itself the principle of its activity. The origin of the activity, the action itself, and the result, are one, and constitute the concrete. Its movement is the development by which that which exists merely potentially is realized. The concrete in itself, or virtually, must become actual; it is simple, yet different. This inherent contradiction of the concrete is the spring of its development. Hence arise differences, which however ultimately vanish into unity. There is both movement, and repose in the movement. The difference scarcely becomes apparent before it disappears, whereupon there issues from it a full and concrete unity. Of this he gives the following illustration:—the flower, notwithstanding its many qualities, is one; no single quality that belongs to it is wanting in the smallest of its leaves, and every portion of the leaf possesses the same properties as the entire leaf. He then observes, that although this union of qualities in sensible objects is readily admitted, it is denied in immaterial objects, and held to be irreconcilable. Thus it is said that man possesses liberty; but that freedom and necessity are mutually opposed; that the one excluding the other, they can never be united so as to become concrete. But according to Hegel, the mind is in reality concrete, and its qualities are liberty and necessity. It is by necessity that man is free, and it is only in necessity that he experiences liberty. The objects of nature are, it is true, subject exclusively to necessity; but liberty without necessity is an arbitrary abstraction, a purely formal liberty.

This concrete idea develops itself in obedience to certain laws which it determines of itself. Among these Hegel distinguishes three species of thought, or three productions of thought in general. 1. The *thought*, which he calls formal, as considered independent of its subject matter, or, in the Hegelian terminology, of all its *contents*. 2. The *notion*, which is thought more closely determined; and 3. The *idea*, or thought in its totality and fully determined. The truth, determined in itself, experiences a want of development. The idea, concrete and self-developing, is an organical system, a totality comprising in itself vast treasures of degrees and *momenta*, or germs of further development. Now philosophy is nothing else than the knowledge of this development, and, in so far as it is methodical and self-conscious thought, it is the development itself. With the progress of this evolution philosophy advances towards perfection. The more the idea develops itself the more precise and limited does it become, the wider its expansion and the deeper its intensity. All the partial results it gives rise to, as well as their systematization, proceed from the one identical *idea*. Particular systems are but so many diversified forms of the same *life*; they have no reality but in this unity, and their differences and their specific determinations taken collectively are but the expression of the forms contained in the idea. The idea is at once the centre and the circumference—the source of light, which in all its expansions does not pass out of itself; it is both the system of necessity and its own necessity, and yet nevertheless liberty.

In the history of philosophy we have, under the form of accidental succession, the actual development of philosophy itself. In the different systems which the history records there is one and the same philosophy at different degrees of its development, and the different principles which have been employed to support these systems are but branches of a single unity and of one whole. The philosophy therefore which is the last in time is the result of all preceding systems, and consequently must comprise the principles of all, and therefore it is the most perfectly developed, the richest, and the most *concrete*. The more concrete the idea becomes, the more widely extended is the domain of science. It reconciles the apparent inconsistencies of appearance and reason, and a true philosophy removes the contradiction in which the antient philosophy was involved with the natural and historical development of the human mind. Starting from and nourished by experience, the thought rises to the idea of the general and the absolute, and, being allowed its free course, passes beyond the moment of doubt and difficulty, to reproduce all that it has conceived in a rational order, and to impress upon it the stamp of a logical necessity. For all verity is virtually contained in thought, from which, being made fruitful by experience, it is the duty of philosophy to draw it, and to deduce the actual consciousness. Accordingly it is the high pretension of the Hegelian philosophy to reconcile philosophy with reflection, and positive religion with the state and with every political and religious establishment. It is, he observes, an evil prejudice to suppose that true philosophy is opposed to the sober results of experience, and with the rational enactments of actual laws.

Hegel divides philosophy into three parts:—1. Logic, or the science of the idea in and by itself, or in the abstract element of pure thought; 2. Philosophy of nature, or the science of the idea out of itself—or in nature, or as nature; 3. Philosophy of mind, or the science of the idea in its return into itself. Into the details of this division it would be idle to enter, as it would only lead to a dry and barren nomenclature. Each part is again divided into three parts; for this holy number determines throughout the divisions and subdivisions of the system. In this respect, as well as for his obscurity and neologism, Hegel well deserves the reproach of Wolfianism, which his master Schelling has urged against him. Schelling indeed disavowed him as his disciple, which honour however Hegel still loved to claim with a satisfaction mingled with regret.

A complete edition of the works of Hegel, in 17 vols., collected by Michelet and others of his disciples, is in course of publication.

HEIDELBERG, an antient city in the circle of the Lower Main, in the grand-duchy of Baden, is situated in one of the most beautiful parts of Germany, on the left bank of the Neckar, over which there is a covered stone bridge of nine arches, 702 feet long and 30 wide; in 49° 24′ N. lat. and 8° 41′ E. long. The town is between the river and the mountains. On the south is the Königstuhl, 2000 feet high (called the Kaiserstuhl since the emperor Francis ascended it in 1815), on the summit of which a lofty tower has been erected. The population, which is now about 12,000, and gradually increasing, is much inferior to what it formerly was. Various causes have contributed to this decay: and among them chiefly the desolation of the Palatinate by the French in 1689 and 1693, and then the removal of the court of the elector Palatine to Manheim in 1709. In 1689 the elector's splendid palace was most wantonly devastated, and in 1764 it was struck with lightning and rendered wholly uninhabitable. In the cellar of the palace is the celebrated Heidelberg tun, which contains 600 hogsheads. Heidelberg has three Lutheran, one Calvinist, and one Roman Catholic church, and a synagogue. It owes its chief renown to its university, which is the oldest in Germany except that at Prague. It was founded in 1386 by the elector Ruprecht II., and soon acquired a high reputation to which its valuable library greatly contributed; for it gradually became possessed of 1956 Latin, 431 Greek, 289 Hebrew, and 846 German manuscripts, in all 3522. The university continued to flourish till 1622, when the town was taken by Tilly, and the library sent by duke Maximilian of Bavaria to Rome, as a present to Gregory XV., who placed it in the Vatican by the name of Bibliotheca Palatina. In 1795 the French having compelled the pope to let them take 500 manuscripts from the Vatican, carried off 38 of the Heidelberg collection. In 1815, when France was obliged to restore all its plunder, the pope not only gave up those 38 manuscripts to Heidelberg, but, at the intervention of Austria and Prussia, ordered all the German manuscripts to be restored. Accordingly 847 antient German manuscripts, and also the celebrated Codex Palatinus of the monk Ottfried's poetical paraphrase of the Four Gospels, and four Latin manuscripts containing the history of the university, were delivered up to Heidelberg. A new æra for the university commenced in 1802, when it was assigned, together with the bailiwick, which has 80,000 inhabitants, besides the population of the town, to the grand-duke of Baden, who is of the Lutheran religion, and is himself the rector. The reputation of the university is increasing, but the number of the students has been much reduced, because Prussian subjects must have a special permission from their government to visit it. Its annual revenue is now 108,000 florins, of which 84,000 are contributed by the government; and its library, much increased by the purchase of the library of the Cistercian convent of Salmansweiler (or Salem), is said now to consist of 120,000 volumes. All the institutions and collections attached to the university have been much improved; and among the twenty professors are some of the most eminent men in Germany. The streets of the town are narrow and gloomy, and there are no manufactures except on a small scale. Its trade is however improving, and the great beauty of the country and its many other advantages have caused a great number of foreigners to settle here. There are numerous descriptions of Heidelberg; one of the latest is Engelmann, 'Heidelbergs alte und neue Zeit, Stadt, Universität, Schloss, und Umgebungen.'

HEIGHTS, MEASUREMENT OF. There are three very distinct ways by which heights may be measured. The first is by observation of the angles of elevation of objects, supposing their distances to be known, which is explained roughly in works of trigonometry and mensuration, and with more precision in those on geodesy. [MENSURATION.] The second serves for the measurement of heights in cases where not only the height of a summit is required, but also that of the slope which leads to it, at different distances from the summit; and this is done by means of the level. [LEVELLING.] The third, which we propose here to describe more particularly, is accomplished by means of the barometer. [BAROMETER.]

If we ascend with a barometer through any height, the weight of the column of air which presses on the instrument is diminished, and the counterpoise, namely, the column of mercury under the vacuum, must diminish likewise; that is, the mercury must fall. The amount of this fall depends upon the height in question: and when the relation between the two is perfectly well ascertained, may be made the means of determining it. If the temperature at the higher and lower station were the same in all places and at all times, and if the force of gravity were precisely the same at all heights, one formula would serve for all times and for different places, if the height of the barometer remained always the same at the same height above the sea. In such a case, one observation made in London a hundred years ago, combined with one made at Quito in the present time, would serve to determine the difference of level between those two places. And even as it is, the mean height of the barometer at the two places, when known, could be made to determine the point. But when only one or two observations can be made at each place, the differences of temperature, &c., must be noted and allowed for: and this necessity renders the numerical operations connected with the solution of the problem more intricate than they would otherwise be.

If the temperature were unaltered during the ascent, and the force of gravity also remained uniform, the *logarithms* of the atmospheric pressures corresponding to different altitudes would *decrease* in arithmetical proportion as the altitudes themselves *increase* in arithmetical proportion. Thus if at altitudes 0 and h the logarithms of the pressures were k and $k-l$, at an altitude $2h$ the logarithm of the pressure would be $k-2l$, and so on. And since the height of the barometer is proportional to the pressure for the time being, this would lead to an equation of the form

$$z = c\,(\log. h - \log. h');$$

where z is the difference of altitudes at two stations, and h and h' the heights of the mercury at the lower and upper stations. This is proved in every elementary work on pneumatics which professes to apply the differential calculus.

The constant c might be determined either from theory or actual measurement; for if h and h' were known in any one case, and also z by trigonometrical or other measurement, c might be determined, and being independent of z, h, and h', would then be known in all cases. But in truth c is not to be thus determined, for though independent of h and h', it varies with temperature, the force of gravity, &c.

1. If the temperature either of the higher or lower stations be not the same in different observations, the multiplier c will be of one value or another, depending on the temperatures.

2. If the mercury be not of the same temperature at all times, its specific gravity will vary, so that a given column of it will not represent the same atmospheric pressure at all times.

3. If the force of gravity be taken into account, the pressure taken off by the ascent will be a larger proportion of the whole pressure than was supposed in the investigation of the preceding formula, since it is taken from the part of the atmosphere where the force of gravity is greatest. This is independent of its greater weight as being taken from the densest part of the atmosphere. The latter circumstance has been already taken into account in the formula, and from it comes the law that the logarithms of the pressures diminish in arithmetical progression, since the pressures themselves would diminish in arithmetical progression if the density of the air were the same at all heights.

We now proceed to describe two formulæ made on slight differences of hypothesis as to the element of the problem about which we know least, namely, the law of variation of the temperature of the atmosphere. The first formula, which is nearly in the form given by Laplace, is taken from the second edition of Poisson's Mechanics, and supposes that the air intermediate between the higher and lower stations may be treated as if it had throughout the mean between the temperature of the two stations. The second, taken from Lindenau's Barometric Tables (Gotha, 1809), is on the supposition (which was also made by Euler and Oriani) that the temperature of the air diminishes in harmonic progression through a series of heights increasing in arithmetical progression.

Let h and h' be the heights of the barometer at the lower and upper stations; t and t' the temperatures of the air; T and T′ those of the mercury (ascertained by a thermometer whose bulb is in the cistern); r the radius of the earth, supposed to be 6366198 metres or 6962283 yards; and λ the latitude of the place. All the temperatures are in degrees of Fahrenheit. Let

$$k = h\left(1 + \frac{T - T'}{9990}\right)$$

$$c = \frac{20053\cdot95}{1 - \cdot002588\cos. 2\lambda}\left(1 + \frac{t + t' - 64}{900}\right)$$

$$z = c\,(\log. h - \log. k).$$

Then z itself is a near approximation to the number of yards in the difference of level between the two stations (for metres use 18337·46 instead of 20053·95); but if a more exact one be required, it may be found by calculating (using z itself as just found)

$$c\left(\log. h - \log. k + 2\log.\left(1 + \frac{z}{r}\right)\right)\left(1 + \frac{z}{r}\right).$$

When the lower station is at a great distance from the higher on the earth's surface, then five-eighths of $\frac{z}{r}$ should be used instead of $\frac{z}{r}$ in the last formula.

The preceding is the most accurate formula which the present state of science will allow to be given, and there is reason to suppose that the constant 20053·95 could not be altered by a single unit with any increase of correctness. The following formula however is sufficient for ordinary purposes:—

$$20115\left(1 + \frac{t + t' - 64}{900}\right)(\log. h - \log. h');$$

in which the constant 20115 is that determined by a considerable number of comparisons of theory with trigonometrical observation made by M. Ramond in the Pyrenees.

The second formula, by M. Lindenau, is as follows, the letters meaning the same things as before; but the degrees are those of Réaumur's thermometer, and the distances are expressed in toises. The toise is 2·1315308 English yards, and a reading of Réaumur is reduced to one of Fahrenheit by the following formula:—

$$\text{Fahr.} = 32 + \frac{9}{4}\ \text{Réaum.}$$

$$\text{Let } c = \left(1 + \frac{t + t'}{400} - \frac{(t - t')^2}{160000}\right) \times 9442;$$

$$H = h\left(1 - \frac{T - 10}{4329 \cdot 6}\right)$$

$$H' = h'\left(1 - \frac{T' - 10}{4329 \cdot 6}\right)$$

Then the number of toises in the difference of elevation of the stations is

$$c\ (\log. H - \log. H').$$

The formula which has been generally used is of the form

$$a\left(1 + \frac{t + t'}{b}\right)(\log. h - \log. h');$$

and the following are the constants a and b used by the observers whose names are mentioned, all reduced by M. Lindenau to those values which they should have when the thermometer is Réaumur's and the result in toises:—

Ramond	$a = 9437$	$b = 400$
Trembley	$a = 9401$	$b = 361$
Roy	$a = 9388$	$b = 362 \cdot 2$
Schuckburgh	$a = 9400$	$b = 366 \cdot 6$
Deluc	$a = 9220$	$b = 396 \cdot 4$

HEILBRONN, the capital of the circle of the Neckar in the kingdom of Würtemberg; in 49° 7′ N. lat. and 9° 8′ 45″ E. long. It has 8400 inhabitants, considerable manufactures, and an extensive trade, which, with the culture of the vine, give employment to the inhabitants. According to tradition, it was founded about the year 800, by Charlemagne, and named by him Heilbronn, or the 'spring of health,' from a medicinal spring in the vicinity. It was a free imperial city, till it was adjudged to Würtemberg in 1803. It had formerly a commandery of the Teutonic order. The house of that order has been converted into barracks, and the old orphan house into a handsome palace. The town-hall contains an antient collection of archives; and the gymnasium has a library of 12,000 volumes. There are three Lutheran and two Roman Catholic churches, and many respectable public institutions. A tower called Thieves' Tower, in which Götz von Berlichingen was confined in 1525, is shown as a curiosity.

HEINECCIUS, JOHN GOTTLIEB, born at Eisenberg, in Saxony, in 1681, was one of the most learned jurists that Germany has produced. He was appointed professor of philosophy at Halle in 1713, and was afterwards professor of law at Franeker in West Friesland, which place he left in 1727, on account of ill health. He was then appointed professor of law at Frankfort-on-the-Oder, and lastly ho filled the same chair at Halle, where he died in 1741. His principal works are:—1. 'Antiquitatum Romanarum Jurisprudentiam illustrantium Syntagma, secundum Ordinem Institutionum Justiniani digestum, in quo multa Juris Romani, atque Auctorum Veterum loca explicantur atque illustrantur,' 8vo., 1741; a very useful work, which has since been edited by Haubold, 1822. 2. 'Elementa Juris Civilis, secundum Ordinem Institutionum.' 3. 'Elementa Juris Civilis, secundum Ordinem Pandectarum, commoda Auditoribus Methodo adornata.' This work, which comprises a course of civil law, explains the origin, object, and application of the various laws. 4. 'Historia Juris Civilis Romani ac Germanici,' published with Ritter's notes, Leyden, 1748. 5. 'Elementa Juris Germanici, tum Veteris tum Hodierni,' 2 vols. 8vo., Halle, 1736. 6. 'Corpus Juris Germanici Antiqui,' 4to., 1738. 7. 'Prœlectiones Academicæ in H. Grotii de Jure Belli et Pacis libros.' 8. 'Elementa Juris Naturæ et Gentium,' translated into English under the title of 'A Methodical Sytem of Universal Law, or the Law of Nature and Nations, deduced from certain principles and applied to proper cases,' by G. Turnbull, 2 vols. 8vo., London, 1763. 9. 'Fundamenta Styli Cultioris.' 10. 'Elementa Philosophiæ Rationalis et Moralis;' besides academical dissertations, &c. The works of Heineccius were collected and published at Geneva, 'Opera omnia,' 9 vols. 4to., 1771, with additions and notes by his son John Christopher (Gottl.) Heineccius, who prefixed to tho first volume a Life of his father.

HEINECKEN, or **HEINECKE, CHRISTIAN HEINRICH**, born at Lübeck, the 6th February, 1721, was the son of the painter Paul Heinecken, and younger brother of Karl Heinrich Heinecken, also an artist, and a writer on the fine arts. Christian Heinrich was an extraordinarily precocious child. At the age of ten months he could speak and repeat every word which was said to him: when twelve months old he knew by heart the principal events narrated in the Pentateuch: in his second year he learned the greater part of the history of the Bible, both of the Old and New Testaments: in his third year he could reply to most questions on universal history and geography, and in the same year he learned to speak Latin and French: in his fourth year he employed himself with the study of religion and the history of the Church, and he was able not only to repeat what he had read, but also to reason upon it, and express his own judgment. The fame of this wonderful child spread widely, and many persons resorted to Lübeck on purpose to see and hear him. The king of Denmark wishing to see him, he was taken to Copenhagen, and there examined before the court, and pronounced to be a wonder. On his return home he learned to write, but his constitution being weak, he shortly after fell ill. Though he rallied for a time, he soon relapsed, and died on the 27th June, 1725, without, it is said, showing much uneasiness at the approach of death. His teacher, Christian Von Schöneich, published a narrative of his life, 8vo., Lübeck, 1726, and his account is confirmed by many respectable contemporary authorities; among others Hirsching, in his 'Historisch-literärisches Handbuch,' 3rd part, pp. 62-64; the 'Deutsche Bibliothek,' vol. 17; and by most of tho journals of the time. See also Jöcher, 'Gelehrtenlexicon,' vol. ii., p. 1454, and the 'Allgemeine Encyklopädie der Wissenschaften und Kunst,' Leipzig, 1829, art. 'Heinecken.' Martini published a dissertation at Lübeck, 1730, in which he endeavoured to account for the circumstances of the child's early development of intellect.

HEINSE, WILLIAM, the author of 'Ardinghello,' was born at Langewiesen, near Ilmenau in Thuringia, in 1749. After passing through a course of legal studies at the university of Jena, he took up his residence at Erfurt, where, being encouraged to apply himself to literature by Wieland, he commenced his career as an author by a translation of Petronius (1773), which was quickly followed by 'Laidion, or the Eleusinian Mysteries.' The choice ho had shown in selecting the first-mentioned work, together with the fidelity with which he adhered to the original, and also many parts of the other, scandalized not only the public, but Wieland himself. His next productions were less objectionable for their tendency, being a prose translation of Tasso's 'Jerusalem,' and another of Ariosto's 'Orlando,' both which he is said to have executed during his residence in Italy (1780-83); but these tasks did not prevent him from giving full scope to his unrestrained passion for enjoyment; and with what license he abandoned himself to the gratifications which Italy, long the object of his wishes, presented to him, may easily be inferred from his 'Ardinghello,which may ho considered in some degree as the record of his own feelings and opinions, and, while it gives us much eloquent and impassioned criticism on art, abounds not only with the most dissolute scenes, but with maxims immoral in the extreme. Fortunately the narrative and incidents are so interrupted by the dialogues and disquisitions on art, that the work can hardly be classed as a romance; for most of the scenes and characters which belong to it as such, are calculated only to corrupt. It is true, considered merely in regard to its ability as a production of the pen, that its dissolutoness is redeemed by the refinement with which the grossness of vice is veiled; yet this does not at all abate its moral turpitude. However, if we estimate the critic apart from the novelist, Heinse must be allowed to have here manifested an extraordinary sympathy for art; and although some of his views of it may be erroneous, he is always original, forcible, and enthusiastic. His 'Dialogues on Music' were not published till after his death, which happened June 22, 1803. Besides another romance, entitled 'Hildegard,' he contributed a variety of articles to the 'Deutsche Mercur,' and other periodicals; including a critical account of the principal pictures of the Düsseldorf Gallery, in a series of letters to Gleim. A complete edition of his works in 10 vols. 8vo., with a critical and biographical introduction by Laube, is now in course of publication.

HEINSIUS, DANIEL, was born at Ghent in the year 1580 or 1581. He was taken to England at an early age by his father, who was obliged to leave Holland in consequence of the part he took in the wars which then prevailed in his native country. His father returned to Holland after a short time, and sent his son, at the age of fourteen, to study law at Franeker. But Heinsius, contrary to the wish of his father, resolved to study antient literature; and accordingly, after remaining at Franeker only six months, he went to Leyden, where he prosecuted the study of the classics under Joseph Scaliger. At the age of eighteen he explained the Latin classics in the university, and seven years afterwards was appointed professor of history and politics. In 1607 he was made librarian and secretary to the university. Heinsius was considered one of the most learned men of his time, and was repeatedly solicited by many of the monarchs of Europe to settle in their dominions; but he refused to leave his native country, in which he died on the 23rd February, 1655, at the age of 75. He held the office of historian to the states of Holland, from which he received a handsome salary. He also took an active part in the theological warfare of the times, and was appointed secretary to the celebrated synod of Dort in 1618.

The name of Heinsius is principally known by his editions of the Greek and Roman classics. But his Latin poems, which are seldom read in the present day, were highly esteemed by his contemporaries: they were published at Leyden in 1602. He also wrote some poems in his native language, which were published by Petrus Scriverius in 1616.

The following is a list of the principal classical authors edited by Heinsius:—'Crepundia Siliana, sive notæ in Silium Italicum,' 1600; 'Theocritus,' 1603; 'Hesiod,' 1603; 'Paraphrasis Andronici Rhodii in Aristotelis Ethica,' 1607, 1617; 'Maximi Tyrii Dissertationes,' 1607, 1614; 'Dissertatio de Nonni Dionysiacis,' 1610; 'Senecæ Tragœdiæ,' 1611; 'Aristotelis Poetica,' 1611, 1643; 'Theophrastus Eresius,' 1611, 1613; 'Horatius et de Satira Horatiana,' 1612; 'Animadversiones et Notæ in Horatii Opera,' 1629; 'Notæ et Emendationes in Clementem Alexandrinum,' 1616; 'Terence,' 1618; 'Paraphrasis Perpetua in Politica Aristotelis,' 1621; Aristarchus sacer, sive Exercitationes ad Nonni Paraphrasin in Johannem,' 1627; 'Ovid,' 1630, 1653, 1661; 'Livy,' 1620, 1631, 1634; 'Aurelius Prudentius,' 1637; 'Exercitationes Sacræ ad Novum Testamentum,' 1639. Heinsius was also the author of 'Rerum ad Sylvam Ducis atque alibi in Belgia aut a Belgis anno 1629 Gestarum Historia,' Leyd., 1631, fol.; 'Orationes varii Argumenti,' Leyd., 1615, 1620, 12mo.

HEINSIUS, NICHOLAS, only son of Daniel Heinsius, was born at Leyden, 29th July, 1620. His education was carefully attended to by his father, and he enjoyed the advice and instruction of Gronovius, Grotius, and other learned men of the time. In 1642 he visited England, and afterwards went to France, Germany, and Italy, principally with the view of consulting MSS. of Ovid and Claudian. In 1649 he was invited by Christina, queen of Sweden, to settle at Stockholm, where he remained till the death of his father in 1655. He resided principally in Holland during the remainder of his life. He was sent on a public mission to Russia in 1667. He died on the 7th October, 1681.

Heinsius edited 'Claudian,' 1650, 1665; 'Ovid,' 1652, 1661; 'Virgil,' 1676; 'Valerius Flaccus,' 1680. His Latin poems were published at Amsterdam in 1666. He also left behind him many MSS. notes on the Latin poets, which have been published by Burmann, in his editions of Virgil, Valerius Flaccus, Silius Italicus, Phædrus, &c. (*Life of Heinsius* prefixed to Burmann's 'Adversaria,' 4to., 1742.)

HEIR, by the law of England, is he who succeeds by right of blood to the real property or lands, tenements, and hereditaments of the deceased owner, designated by the correlative term of ancestor, not given away from him by will. The English law which determines the succession to personal property, when uncontrolled by local custom, is contained in the statutes of distributions (22 and 23 Chas. II., c. 10; 29 Chas. II., c. 3; and 1 Jac. II., c. 17), which are founded upon the provisions of the civil law. The persons so entitled are not called heirs, but next of kin.

The several rules of descent which regulate the right to succeed to real property spring from the system of feudal tenures, but have been somewhat modified by the recent statute of 3 and 4 Wm. IV., c. 106. [DESCENT; ENTAIL; ESTATE; FEUDAL SYSTEM.]

Heir-at-law, or heir-general, is he who succeeds according to the rules explained in the article DESCENT, where there is no will of his ancestor and no instrument which determines a special course of descent. Heir-special is he who succeeds in the order pointed out by some instrument which determines such special course of descent. [ENTAIL.] Heir-apparent is he whose right of inheritance is indefeasible, provided he outlives his ancestor; as the eldest son. Heir-presumptive is he who, if his ancestor should die immediately, would in the present circumstances be his heir, but whose right of inheritance may be defeated by the birth of some nearer heir; the brother or nephew of a man who has no children is heir-presumptive. Heir by custom is he whose right as heir is determined by certain customary modes of descent, which are attached to the land. [DESCENT; COPYHOLD; GAVELKIND.]

The expression 'heirs by devise' has also been sometimes used, though such are not strictly heirs according to the English law; but have been so called inaccurately after the *heres factus* of the Roman law.

The rules of the civil law upon the subject long prevailed in Scotland, both in principle and practice. But various alterations have been made in the Scotch law of inheritance, and now the different descriptions of heirs are far more numerous than in either the English or the Roman law. Heirs-at-law are called heirs whatsomever. Heirs-in-tail, heirs of tailsie, and heirs of provision differ little in their nature. There are also heirs active, heirs by conquest, heirs of line, heirs passive, heirs male, and heirs portioners, the particular distinctions between each of whom it is not necessary here to describe. [See Bell's *Commentaries and Principles*, and Lord Kames's *Law Tracts*.)

The French law of descent has followed the Roman law, and the obligations and privileges of the heir are essentially the same as there prescribed.

In America the English law of descents has been in most instances rejected, and each state seems to have established rules for itself. There is no entire information upon this subject; indeed chief-justice Reeve in the preface to his 'Treatise on the Law of Descent in America,' has this strong passage, that the nation 'may be said to have no general law of descents, which probably has not fallen to the lot of any other civilized country.' (Kent's *Commentaries*, lect. 65.)

The term *heres* in the Roman law has a very different signification from the term *heir* in the English law. The Roman term *hereditas* denoted all the rights and obligations of a testator or intestate; and the *heres*, when his title as such was completed, represented the person of the testator or intestate, and as a consequence succeeded to all his rights and obligations. A man might by his will appoint one *heres* or more; and the property of an intestate might devolve on one *heres* or more, but this made no difference with respect to their character. Each person was *heres* in proportion to his share of the inheritance. The *heres* appointed by will was called *scriptus*, or *factus*, or *testamentarius;* the *heres* who succeeded in case of intestacy, *ex lege*, or *legitimus*, that is, appointed by the law, or *ab intestato*.

An important distinction between *heredes* as established by the old Roman law was this, and the distinction was the same (so far as it could be applicable) both in the case of testacy and intestacy. All persons who were in the power (*potestas*) of the testator, or intestate, during his lifetime, such as children not emancipated, and slaves, were obliged to accept the inheritance with all its burdens; the inheritance in fact devolved upon them by the will of the testator, and no act of assent on their part was necessary. Other persons, not in the power of the testator, were only bound to undertake the burden of the testator's debts in case they accepted the inheritance, for which purpose their express assent was necessary. But by the legislation of Justinian the *heres* in all cases was only answerable for the debts of the testator, or intestate, to the amount of the property which such testator or intestate left behind him, of which however the *heres* was required to make an inventory within a certain time. (*Cod.* vi., *Tit.* 30, l. 22; *Instit.*, ii. 19.)

The discussion of the various rights and duties of the Roman *heres scriptus* belongs to the subject of wills.

In the case of intestacy the distribution of the property was analogous to the distribution of an intestate's personal estate by the English law. The Roman law gave no preference to an eldest son over a younger, or to a brother over a sister. Emancipated sons, who, by the strict rule of the civil law, were excluded from the inheritance [EMANCIPATION], were placed by Justinian's legislation on the same footing as children not emancipated. It is unnecessary here to state more minutely the rules which regulated the distribution of an intestate's property. (*Instit.*, iii. 1; *Nov.* 118, c. 1, 2, 4.)

It is important to conceive clearly the fundamental notion of the difference between the Roman *heres* and the English *heir*. The Roman *heres*, when his title to the inheritance was completed, represented the person of the testator or intestate, and so far corresponded to our executor or administrator. His title to the property, as *heres*, was absolute and derived entirely from him to whose rights and obligations he succeeded. The English *heir*, according to the strict principles of tenure, derives his title to the land not from his immediate ancestor, as such, but by virtue of his relationship by blood to the person who acquired the land, deduced through his immediate ancestor. The consequences which flow from these two different notions of the Roman *heres* and English *heir* are numerous and important. They are well stated, in a general way, by Mr. Butler in his note on *Coke-Litt.*, 191 *a*. The stat. 4 Wm. IV., c. 104, which makes all a deceased person's estate in land liable to the payment of his debts, has materially affected the antient right of the English heir.

HEIR-LOOMS are such goods and personal chattels as, contrary to the nature of chattels, go to the heir by special custom along with the inheritance, and not to the executor of the last proprietor. [CHATTELS.] They are principally such things as cannot be removed without damage to the inheritance, as chimney-pieces, fixed tables, &c. Deer in an authorized park, fishes in a pond, deeds, charters, and court-rolls, together with the chests in which they are contained, are heir-looms. And so it seems are Journals of the House of Lords in the possession of a peer. By special custom in some places carriages also and household implements may be heir-looms.

The termination 'loom' is of Saxon origin, in which language it signifies a limb or member; so that an heir-loom is nothing else but a limb or member of the inheritance. (2 Bl. *Com.*) Chattels are sometimes directed by testators to go to the heir, together with the inheritance, as heir-looms, and though it is the duty of the executors to carry the intention into effect so far as they can, yet the direction does not affect the rights of creditors, neither can it effectually prevent the devolution of the chattels according to their real nature.

HE'LAMYS, a genus of Rodents nearly allied to the Jerboas. [PEDETES.]

HELARCTOS. [BEAR, vol. iv., p. 91.]

HELDER and HELDER CANAL. [HOLLAND.]

HE'LENA, daughter of Constantine the Great and of Fausta, was given in marriage by her brother Constantius to her cousin Julian, when he made him Cæsar, at Milan, A.D. 355. She followed her husband to his government of Gaul, and died in 359 at Vienne. The historian Ammianus Marcellinus (b. xvi., c. 10) reports that the Empress Eusebia bribed Helena's midwife, who occasioned the death of a son, the only child that Helena bore; and yet Eusebia had been the constant protectress of her husband Julian. The truth of the story is doubted by Gibbon, in his 'Decline and Fall' (ch. xix.).

HE'LENA, ST., the first wife of Constantius Chlorus, was born of obscure parents, in a village called Drepanum, in Bithynia, which was afterwards raised by her son Constantine to the rank of a city, under the name of Helenopolis. Her husband Constantius, on being made Cæsar by Diocletian and Maximianus (A.D. 292), repudiated Helena, and married Theodora, daughter of Maximianus. Helena withdrew into retirement, until her son Constantine, having become emperor and triumphed over his enemies, called his mother to his court, and gave her the title of Augusta. He also gave her large sums of money, which she employed in building and endowing churches, and in relieving the poor. About the year 325 she set out on a pilgrimage to Palestine, and having explored the site of Jerusalem, she thought that she had discovered the sepulchre of Jesus Christ, and also the cross on which he died. The identity of the cross which she found has been much doubted: she however built a church on the spot supposed to be that of the Sepulchre, which has continued to be venerated by that name to the present day. She also built a church at Bethlehem in honour of the nativity of our Saviour. From Palestine she rejoined her son at Nicomedia, in Bithynia, where she expired in the year 327, at a very advanced age. She is numbered by the Roman Church among the saints. (Eusobius, *Life of Constantine*; Hübner, *De Crucis Dominicæ per Helenam inventione*, Helmstädt, 1724.)

HELE'NA, ST., an island in the Atlantic Ocean, 1200 miles west of the coast of Benguela, in South Africa, and nearly in the latitude of Cape Negro, and about 1800 miles east of the coast of Brazil, in South America. Seen at a distance it appears like a lofty mass of barren rocks rising in a pyramidal form; on a nearer approach, rugged and almost perpendicular cliffs, from 600 to 1200 feet high, are seen encompassing the island all round, broken through in several places by deep chasms which open to the sea-shore, and which form so many narrow valleys winding up to the table-land in the centre of the island. One of the principal of these openings is called James' Valley, on the north-west coast of the island, and at the opening of it to the sea is James' Town, the only town and port of the island, which is defended by strong batteries, and is the residence of the authorities. James' Town is in 15° 55′ S. lat. and 5° 49′ W. long. Ascending James' Valley we arrive at the plain or table-land of Longwood, situated in the eastern part of the island, and consisting of 1500 acres of fine land, nearly 2000 feet above the sea, sloping gently towards the south-east. Longwood House was the place of Napoleon's confinement and death, and his tomb is at a short distance from it, situated under a willow-tree, and covered by a plain tombstone without inscription, and enclosed by an iron railing. In the centre of the island rises Diana's Peak, 2693 feet above the sea. A calcareous ridge, which runs across from east to west, sloping abruptly on the south, divides the island into two unequal parts, the larger and finer of which is on the north side of it, containing James' Valley, Rupert's Valley, Longwood Plain, the deep crater-like dell called the Devil's Punchbowl, the Briars, near which is a fine cascade, Plantation House, which is a country residence of the governor, &c. The whole circumference of the island is about 28 miles. The population, exclusive of the garrison, is about 5000, about one-third of which are Europeans, and the rest are blacks, men of colour, and Chinese. The climate of St. Helena is one of the healthiest under the tropics, and is found beneficial to invalids from India, and even from Europe. The range of the thermometer at Plantation House is from 61° to 73° within doors; it sometimes falls to 52° in the open air between June and September. In James' Town it is generally from 5 to 7 degrees higher than at Plantation House, and at Longwood it is somewhat lower. The summer rains fall in January or February, and the winter rains in July or August. Cloudy days are frequent and refreshing throughout the year. Viewed from the sea the island appears barren; but the interior is covered with a rich verdure, and is watered by abundant springs; the soil of the valleys is very rich, and produces all the fruits and flowers of Europe and Asia. Horned cattle, sheep, and goats feed on the rich pastures. Pretty cottages in picturesque situations are scattered about the island. (Major Beatson's *Tracts relative to the Island of St. Helena, written during a residence of five years*, 4to., London, 1816, with plates.) The base of the island appears to be basalt, and lava and scoriæ are found scattered about the surface.

The island of St. Helena was discovered by the Portuguese in 1502. It was afterwards taken possession of by the Dutch, who abandoned it in 1651 for the Cape of Good Hope. The English East India Company then took possession of it, and it became a resting-place for their ships between India and Europe. In our days it has become celebrated as the place of banishment of Napoleon, who resided there five years and a half. It is now still visited by ships returning from India, who take in fresh provisions and water, and on those occasions the place assumes the appearance of a bustling market-town.

HELGOLAND, or HELIGOLAND, a group of islands in the German Ocean, on the west coast of Schleswig, 25 miles from the mouths of the Elbe, Weser, and Eider. It consists of the principal island, so called, of the Sand Island, or Downs, and of several cliffs and reefs, the chief of which is that called the Monk. The main island is divided into the cliff and the low land. The cliff is a rock rising almost perpendicularly, and varying in elevation from 90 to 170 feet above the level of the sea. The ascent to it is by a flight of 191 steps. The summit is a tolerably level plain about 4200 paces in circumference. It is joined by a bottom of rock, 500 paces long, to the low land, which is an uninhabited down, with two good harbours, and to the east of the down is a road where vessels may anchor in 48 fathoms. The circumference of the whole island does not exceed three miles. In former ages it was of much greater extent; and is said to have been the residence of a chief of the Sicambri or North Frieslanders, and the seat of worship of a Saxon deity.

Of the rapid waste of this island, Mr. Lyell presents the following notice. Helgoland began in the year 800 to be much consumed by the waves. In the years 1300, 1500, and 1649, other parts were swept away, till at last a small portion only of the original island remained, consisting of a rock of red marl (of the *Keuper* formation of the Germans), about 200 feet high. Since 1770 a current has cut a passage no less than ten fathoms deep through this remaining portion, and has formed two islands, Helgoland and Sandy Island. (*Principles of Geology*, book ii., ch. 7.)

The inhabitants of the island, 2400 in number, live on the cliff. They are descended from the Frieslanders, and speak, besides the old Friesland language, the low German, retain their antient dress and customs, and subsist chiefly by fishing, and acting as pilots. They obtain turf, wood, vegetables, &c. from Cuxhaven and Hamburg in exchange for fish. The low land has now only some fishermen's huts; but when the English took possession of it in 1807, during the war with Denmark, and it became the depôt for goods which were smuggled into the Continental ports, the low land was covered with warehouses, and the population of the island increased to 4000. On the conclusion of peace in 1814 England retained possession of the island, probably for the sake of its double harbour, and for the advantages which it offers for defence, in having two wells of good water. The English have erected four batteries and a lighthouse on the cliff. They have a garrison and a governor, but levy no taxes and do not interfere with the internal government. The lighthouse is in 54° 11′ 84″ N. lat. and 7° 53′ 13″ E. long.

HELIACAL (ἥλιος, the sun), a term applied to the rising of a star, when it takes place just before that of the sun. If we suppose a star not very far from the sun's orbit, then as the sun approaches that star it will become for a season permanently invisible, for it will rise after the sun, and set after it also, the heavens remaining too light in the quarter of sunset to permit the star to be seen. But as soon as the orbital motion of the sun has carried it past the star, the latter will begin to rise first, and in process of time will rise so much before the sun as to become visible just before daylight. In this case it is said to rise heliacally: thus a star sets heliacally before its season of disappearance, and rises heliacally after its reappearance. The successive heliacal risings of stars thus form a continued warning of the seasons, and were used for this purpose among some antient nations. But since the precession of the equinoxes slowly changes the offices of different stars with respect to the seasons, an antient record of the time of the year when a given star rose heliacally would enable us to make a rough guess at the number of centuries elapsed since the time of the observation. Upon such a basis Newton rested a great part of his system of chronology, taking the descriptions of the heliacal risings of stars from Hesiod.

HELICA'RION. [Helicidæ.]

HELI'CIDÆ, HELIX FAMILY, the general name by which the land shell-snails are distinguished.

Mr. Gray, in his paper on *Streptaxis* (Loudon's *Magazine of Natural History*, vol. i., new series), observes that zoologists have divided land-shells into several genera; but that the late Baron Férussac united most of them into a single genus, as he wished to establish as a rule, that all the genera of Molluscans should be alone characterized by some peculiarity in the animal. 'The increased knowledge,' continues Mr. Gray, 'of the animal has shown that some of the species which he (Férussac) referred to the genus *Helix* have very different animals from the typical kinds; and it is probable that eventually several of the genera established before his time (which he attempted to set aside) will be found to be true genera, according to his own theory. The knowledge of the animal, and the history of several species which were unknown at the time he wrote his system, have shown that several of the characters which he considered as of generic importance are common to other species belonging to quite different groups. Thus we now know that some *Helices* (*Carocolla inversicolor*, *Balea Chemnitzii*, and some others) are viviparous, as well as the *Partulæ*; that the degree of development in the lower pair of tentacles is variable in the different species of *Pupa* and *Vertigo*; and that to separate the latter genus from the former, on account of the partial obliteration of these organs, has the effect of dividing very nearly allied species. I am inclined to think that these and numerous similar facts, which must be well known to every practical conchologist, show us that we are warranted in establishing genera from any peculiarity in the structure or form of a series of shells, as well as on a peculiarity in the animal alone; especially when we consider how very few of the animals of the different species which we are called upon to arrange are or ever can be known; and also as we constantly find by experience that every peculiarity in the form or structure of the shell is the indication of some peculiarity in the habit or organic structure of the animal which formed it, and warrants its separation from the rest of the species of the family.'

Having thus laid before the reader the difficulties with which the history of this very extensive family is surrounded, we shall first endeavour to give some account of the *general* organization of the *Helicidæ*, properly so called, as manifested in one of the most common forms.

Organization.*

Nutrient Organs.—In the museum of the Royal College of Surgeons, in London (*Physiological Series, Gallery*, No. 301), is a preparation of the large Shell-snail (*Helix Pomatia*, Linn.), showing the form of the mouth and the part which performs the office of teeth. This is a dentated horny substance, of a dark colour and arched form, situated transversely above the aperture of the mouth, and forming, as it were, the margin of the upper lip; the lower lip is divided by a vertical fissure. No. 302 of the same series shows in the head of another Shell-snail the same structure of mouth. No. 767 shows the soft parts of *Helix Pomatia*, and the alimentary canal has been injected with size and vermilion; so that the salivary glands, from their white colour, may be distinctly perceived upon the parietes of the stomach. These glands are of a flattened, elongated, and irregular form, and of a conglomerate structure: they may be seen diminishing in breadth as they extend upwards towards the pharynx, where their ducts terminate. Here also the semicircular, dentated, horny jaw, the course and termination of the alimentary canal, and the position and form of the liver, are well displayed. The next preparation (No. 768), which exhibits the mouth, œsophagus, and stomach of the same species, shows the junction of the two salivary glands at their lower extremities, and the termination of their ducts. The œsophagus and stomach being laid open, their internal structure is seen. (*Catal. Gal.*, vol. i.)

Circulating System.—In the Shell-snail, *Helix*, the heart is situated on the right side of the posterior third of the pulmonary sac; and in the Slug, *Limax*, it is situated at nearly the middle of the posterior surface of the pulmonary sac, and protected above by the rudimentary shell, so that this part of the structure in these animals is, as in other points, nearly allied. The preparation in the College Museum, No. 882 (*Gallery*), is a specimen of *Helix Pomatia* with the shell removed in order to show the heart, which is situated on the left side of the dorsal aspect of the body, near the posterior part of the branchial sac. The pericardium is laid open, and the heart being injected, the auricle, from its thinner parietes, is seen of a red colour; a bristle is passed behind the ventricle, and the aorta may be seen ramifying over the liver. No. 883 is a specimen of *Limax ater*, Linn. (Slug), to show the heart situated in the middle of the back. (*Catalogue, Gallery*, vol. ii.).

Respiratory System.—In the same series the soft parts of *Helix Pomatia* are prepared (No. 1081), to show the pulmonary sac, which receives the air by an anterior orifice on the right side of the neck. The sac is laid open from that orifice to the opposite extremity; and the roof of the cavity, upon which the pulmonary artery, or continuation of the veins of the body, ramifies, is turned back to exhibit the reticulation of the vascular and respiratory surface. The parts are injected with size and vermilion. No. 1082 is a similar specimen, with the left parietes of the pulmonary sac

* The reader should especially consult Swammerdam, in whose works he will find some excellent remarks on the anatomy of the Helicidæ.

removed, and the orifice by which the air is admitted and expelled left entire. No. 1083 is the portion of the vascular parietes of the pulmonary sac removed from the preceding preparation, and inverted to show the ramifications of the pulmonary vessels. These are continued from the veins of the body without the interposition of the propelling ventricle. No. 1084 is a similar preparation. No. 1085 shows the roof of the pulmonary sac of another *Helix Pomatia*, with the vessel injected; and in No. 1086 there is, in a similar specimen, a bristle inserted into the rectum, which terminates close to the orifice of the pulmonary sac. (*Catalogue, Gallery*, vol. ii.)

Brain, Nervous System, and Senses.—Not being able to refer to any preparation of the nervous system of a Shell-snail, we must call the reader's attention to this part of the organization in a slug, which so nearly corresponds with that of the Shell-snail as to afford a very sufficient illustration. In the same series of the same noble collection is a preparation of a slug (*Limax rufus*, Linn.)—No. 1304—laid open longitudinally along the back to show the nervous system. The viscera are removed. 'In this,' says Professor Owen, 'as in other Encephalous Mollusks, a well-developed ganglion is situated above the œsophagus; it is of a transverse shape, slightly enlarged at its extremities, and supplies the antennæ, or horns, and the eyes. The œsophageal nervous ring is completed by a larger ganglion below the tube, from which numerous nerves radiate to supply the body. The principal nerves are the two inferior ones, which extend on either side the mesial line of the ventral surface straight to the opposite end of the body, giving off nerves to the muscular disk or foot from their outer sides. A small unsymmetrical ganglion is formed on the nerve, which supplies the heart and respiratory apparatus.' No. 1305 is the same species of slug laid open along the ventral aspect, and the viscera removed, to show more especially the subœsophageal ganglion and its nerves. A bristle occupies the place of the œsophagus. No. 1306 exhibits the nervous system of a Black Slug removed from the body. (*Catalogue, Gallery*, vol. ii.)

Touch.—In the Shell-snails the sense of touch will be readily supposed, by any one who has observed the motions of a common garden-snail, to reside especially in the ventral disk, or foot, and the lower tentacles. In the Museum of the College we find, No. 1391, a specimen of *Helix Pomatia* prepared to show the different character of the surface of the skin in the exposed and protected parts of the body: in the latter it is thin and smooth; in the former, thick, vascular, and rugose. No. 1392 is a snail injected, slit down the back and eviscerated, to show the vascularity of the foot. No. 1393 is a snail injected, with one pair of tentacles, which serve as special instruments of touch, extended. Here too the pulmonary cavity is laid open. (*Catalogue, Gallery*, vol. ii.)

Sight.—In the gallery (*Physiological Series*) of the same rich museum is a preparation of a *Helix Pomatia* (No. 1756) with the posterior tentacles or horns extended, showing the eye-specks, or ocelli, situated at the side of the extremity of each horn. 'In this position, although destitute of appropriate muscles, the eyes have the advantage of all the mobility with which the tentacle itself is endowed; and by the admirable construction of the same part, they are defended from external injury by being retracted and inverted, together with the extremity on which they are supported within the cavity of the tentacle, as in a sheath*.' (Professor Owen, *Catalogue, Gallery*, vol. iii.)

Generative Functions.—In the common shell-snails (*Helix*), the male and female sexual organs are complete in one individual, but it requires a reciprocal junction of two individuals to produce a fruitful impregnation. The situation of these organs is at the anterior orifice of the neck; and at the time of congress a sharp horny or glass-like excitatory appendage is protruded, apparently for the purpose of stimulus. Some assert that these appendages are absolutely shot out from the body of one snail into the body of another, and engravings even exist where two snails are represented at a distance from each other reciprocally darting these *spicula amoris*, some of which are seen actually in the intervening space, and others on the ground. With all due submission, we do not believe that the *spiculum amoris* is ever thrown: we have had opportunities of examining the common garden shell-snails frequently when engaged in the reproduction of the species, and have never seen the hard excitatory appendage thrown from the body of the snail. Col. Montagu, it appears, is of the same opinion. He admits the existence of the *spicula* in the animal of *Helix aspersa*, as well as *Helix nemoralis* (or at least some of them); but 'that they are missile darts,' he continues, 'we have much reason to doubt, though it is natural to suppose the animals are furnished with them for the purpose of stimulating each other to love, because it is only at that season they are found to possess them. If such are ever discharged at each other, we have been extremely unfortunate in our observations, for in no one instance could we ever find the dart penetrated, though at the time the animals are close the point may irritate; but it is neither sufficiently strong nor sharp pointed to penetrate the tough skin with which these animals are furnished; and indeed the extremely viscid secretion with which they are so copiously provided adheres so strongly to these *spiculi* (spicula), when wholly projected from the body, that they are for a time held by it. Perhaps we may be told hereafter, that this tough excretory fluid is used as a cord to regain these darts after they have been discharged; but such we should hold equally fabulous with much of the accounts related by various authors. These celebrated love-darts are subpellucid, white, and very brittle, about one-fourth or three-eighths of an inch in length, and somewhat triangular like the blade of a small sword.' (*Testacea Britannica.*) Dr. Maton often observed these *spicula*, but never saw them actually projected from one to the other.

Where the reproduction is by means of eggs, as it is in the great majority of *Helicidæ*, these are either enveloped in a skin and round, as in the common garden snail, or provided with a hard calcareous shell, generally of a white or of a dirty white colour, as in *Achatina* and *Bulinus*. [BULINUS, vol. vi., p. 8.] These hard-shelled eggs are generally oval: in other instances they are round. Specimens of these eggs, some whole, some showing the young shell included, and others showing it breaking out of the egg-shell, are now in the British Museum (from Mr. Broderip's collection). In the museum of the College of Surgeons are several preparations, showing the organs of generation in the shell-snail, now numbered from 3000 to 3008, but these numbers will be changed when the catalogue of that part of the collection comes to be printed, and we have reason to believe that it will be printed in the course of a year.

Power of repairing Injuries.—The power which snails, in common with other testaceous mollusks, possess of repairing their shells, is known to most observers, and requires no comment; but the extent to which these animals will repair lesions of the soft parts, and even reproduce some of the principal ones after they have been deprived of them, is deserving of notice. The works of Schoeffer, Spallanzani, Bonnet, and others bear testimony to the wonderful *vis vitæ* in these animals, and its energy in replacing parts, the deprivation of some of which must, it might have been previously thought, have been followed by immediate death. Spallanzani cut off one of a snail's horns: it began to bud again in about 25 days, and continued to grow till it was equal in length to the other. He removed part of the head: in course of time the part was renewed. Not that this was always the case in those instances where the entire head had been taken off; but even in these instances the snail often recovered, and at the end of a few months appeared with a new head in all respects equal to the old one. The snails so treated retired into their shells the moment the operation was over, and there they concealed themselves for weeks and even months, covering the aperture with the parchment-like secretion so well known to those who have seen this temporary sort of operculum. When forced out for examination at the end of thirty or forty days, some appeared without any marks of renewal; but in others, especially in those cases which had the advantage of warm weather, there was a fleshy globule towards the middle of the trunk, soft, and whitish-ash in colour. At this period no organization was detected in the globule. But in eight or ten days the globule became larger, rudiments of lips were seen, and of the smaller horns, mouth, and tongue. A membrana-

* Swammerdam describes the eyes in detail; but some are of opinion that the organs above alluded to are not eyes. Sir Everard Home denied that they were visual organs; and so does M. Gaspard, who allows the snail no senses, save those of taste and touch, the latter of which he admits it to possess in an extreme degree of delicacy. See M. Gaspard's 'Memoir on the Physiology of *Helix Pomatia*.' (Majendie's *Journal de Physiol.*, tom. ii., p. 295, et seq.; and an abstract of the paper, with notes, by T. Bell, Esq., *Zool. Journ.*, vol. i.) See also Mr. Brayley's paper 'On Certain Organs of the *Helicidæ*, usually regarded as their Eyes, &c.' (*Zool. Journ.*, vol. ii.)

ceous substance was observed fixed in the upper jaw: this proved to be the new tooth. The parts then became further developed and more conspicuous, occupying a greater space, and in two or three months the injury was so completely repaired that the lighter colour only of the new head served to distinguish it from the old one. These experiments were confirmed by others, by Gerardi among the rest.

Hybernation.—M. Gaspard remarks that in our temperate climate, as soon as the first autumnal chills are felt, about the commencement of October, generally, *Helix Pomatia* becomes indolent, loses its appetite, and associates in considerable numbers on hillocks, the banks of ditches, in thickets, hedges, and such places. In a day or two the animals cease feeding, expel the last contents of the intestines, and then hide themselves under moss, grass, dead leaves, or the like rubbish. Here each forms for itself, with the anterior part of its muscular foot, a cavity sufficiently large to contain at least its shell: this cavity it enlarges and excavates by turning itself round on every side, then raising itself against the sides of the cavity, and at last against the roof formed of moss or leaves, or a small quantity of earth brought there by its motions. When it has succeeded in bringing the aperture of the sholl to nearly a horizontal position, it stops. The foot is soon contracted within the shell, the snail then expands, so as completely to cover it, the collar of the mantle, which is at this period very white; and then inspires a quantity of air, after which it closes the respiratory hole. When this is done, a fine transparent membrane is formed with its mucus, and interposed between the mantle and any extraneous substances lying above. The mantle then secretes a quantity of very white fluid over its whole surface, which sets uniformly, like plaster of Paris, and instantly forming a continuous covering about half a line thick. When this is hardened, the animal separates its mantle from it by another and stronger mucous secretion; and after a few hours, expelling a portion of the air it had previously inspired, it is enabled to shrink a little farther into the shell. It now forms another lamina of mucus, expires more air, and thus retires farther into the shell. In this way sometimes a fourth, fifth, and even sixth partition are formed, with intermediate cells filled with air. Such is M. Gaspard's account; but Mr. Bell remarks that it does not completely explain the manner in which the excavation is formed. 'It is not by the pressure of the foot,' says the last-named zoologist, 'and the turning round of the shell, that this is principally effected. A largo quantity of very viscid mucus is secreted on tho under surface of the foot, to which a layer of earth or dead leaves adheres; this is turned on one side, and a fresh secretion being thrown out, the layer of earth mixed with mucus is left. The animal then takes another layer of earth on the bottom of the foot, turns it also to the part where he intends to form the wall of his habitation, and leaves it in the same manner, repeating the process until the cavity is sufficiently large, and thus making the sides smooth, even, and compact. In forming tho dome or arch of the form, a similar method is used, the foot collecting on its under surface a quantity of earth; and the animal turning it upwards, leaves it by throwing out fresh mucus, and this is repeated until a perfect roof is formed. As I have very often watched this curious process, I am certain of the facts. On removing very carefully a portion of the roof soon after its completion, I was enabled to see the formation of the operculum. In about an hour, or even less, after the hybernaculum is covered in, the whole surface of the collar of the mantle instantaneously pours out the calcareous secretion in considerable quantity. This is at first as fluid as thick cream, but very soon acquires exactly the consistence of bird-lime, being excessively adhesivo and tenacious; and in about an hour after it is poured out it is perfectly solid.'

M. Gaspard states that the labour of each individual continues for about two or three days; but that the whole of the month of October is occupied by the general closing of the shells of the species. He adds that about the beginning of April the hybernation ceases. 'The mode by which their escape from confinement is effected is simple and easily comprehended. The air which is contained in the different cells, and which had been expired on the animal withdrawing itself farther and farther into the shell after the formation of the operculum, is again inspired, and each separate membranous partition broken by the pressure of the hinder parts of the foot projected through the mantle. When it arrives at the calcareous operculum, the animal, making a last effort, bursts and detaches its most obtuse angle. Then insinuating by little and little the edge of the foot between the shell and the operculum, it forces the latter off or breaks it away.' (See the Abstract of M. Gaspard's Memoir, with notes, by T. Bell, F.L.S., 'Zoological Journal,' vol. i., the whole of which is well worthy the perusal of the student in natural history and physiology.)

SYSTEMATICAL ARRANGEMENT AND NATURAL HISTORY.

We now proceed to give a sketch of the views of systematists with regard to this numerous tribe of animals.

The genus *Limax* (Slugs) is placed by Linnæus at the head of the *Mollusca* in his last edition of the 'Systema Naturæ,' and is numbered 282. The genus *Helix* is numbered 328, and consequently is widely separated by him from *Limax*. Both land and fresh-water testaceous gastropods were assembled under this genus, which stands between *Turbo* and *Nerita*.

Cuvier's *Pulmonés Terrestres*, or *Terrestrial Pulmoniferous Mollusks*, consisted of tho Slugs, *Limaces* (*Limax* of Linnæus, including *Vaginulus*, *Testacella*, and *Parmacella*), the *Escargots* (*Helix*), the *Nompareilles* (*Clausilia*, Drap.), and the *Agatines* (*Achatina*, Lam.).

Under *Helix*, Cuvier arranges *Helix*, *Vitrina* (Helicolimax), *Bulimus*, *Pupa*, *Chondrus*, and *Succinea*.

Then come the *Clausiliæ* (*Turbo perversus*, *Turbo bidens*, Linn., &c., &c.).

The *Achatinæ*, including *Liguus* and *Polyphemus* of De Montfort, follow.

Lamarck defines his *Colimacés* to be air-breathing Trachelipods (*Trachélipodes aëricoles*), provided with or deprived of an *operculum*, and baving cylindraceous tentacles. Their shell he characterizes as spirivalve, having no projecting parts on its exterior oxcopt the striæ and riblets (*costules*) of growth, and whose aporture is often recurved or reflected outwards. He divides this, the first family of his *Phytiphagous* (plant-eating) *Trachelipods*, into the following sections and genera:—

(*a*) Four Tentacles.

Helix, *Carocolla*, *Anostoma*, *Helicina*, *Pupa*, *Clausilia*, *Bulimus*, *Achatina*, *Succinea*.

(*b*) Two Tentacles.

Auricula and *Cyclostoma*.

M. de Férussac makes the fourth and fifth orders of Gastropods, consist of the Pulmoniferous Gastropods without an operculum (*Pulmonés sans opercule*), and the Pulmoniferous Gastropods with an operculum (*Pulmonés Operculés*).

The fourth order consists of the following suborders and genera:—

1st Suborder. Geophila.

The 1st family of this order consists of the different genera of *Slugs*, and of *Parmacella*, *Testacella*, &c.

The 2nd family embraces the following genera of *Snails*—*Helicarion*, *Helicolimax*, *Helix*, *Vertigo*, *Partula*.

2nd Suborder. Gehydrophila.

3rd Family (*Les Auricules*), *Carychium*, *Scarabus*, *Auricula*, *Pyramidella*, *Tornatella*, *Pedipes*.

3rd Suborder. Hygrophila.

This suborder consists of the *Limneans* or *Water-Snails*, such as *Limnæa*, *Planorbis*, &c.

The fifth order contains two families:—

1st. The Helicinians (*Helicina*).
2nd. The Turbicinians (*Cyclostoma*).

The *Pulmobranchiata* form the first order of M. de Blainville's *Paracephalophora Monoica*, the second subclass of the second class (*Parcephalophora*) of his *Malacozoa*.

M. de Blainville gives the following description of the *Pulmobranchiata*:—

Organs of respiration retiform or aërian, lining the roof and floor (plafond) of the cavity situated obliquely from left to right on the origin of the back of the animal, and communicating with the ambient fluid by a small rounded orifice, pierced on the right sido of the swollen (renflé) border of the mantle. All these animals are more or less framed for breathing air; tho greater part are terrestrial; some live on the banks of fresh waters, and others on the sea-banks (rivage des mers.) None bury themselves in the mud, with the exception of the Limnaceans, during the rigorous season; all are phytiphagous. Some of them are known in all lands.

M. de Blainville divides the *Pulmobranchiata* into the following families and genera:—

1st Family, the *Limnaceans*. (*Limnæa, Physa, Planorbis.*)

2nd Fam., the Auriculaceans. (*Pedipes, Auricula, Pyramidella.*)

3rd Fam., the Limacinians. (*Succinea, Bulimus, Achatina, Clausilia, Pupa, Tomogeres, Helix, Helicolimax:—Testacella, Parmacella, Limacella, Limax, Onchidium.*)

M. Latreille divides the *Pulmonés*, his fourth order of his *first* section of Gastropods (the Hermaphrodites), into tho following families and genera:—

1st Fam., Nudilimaces. (The Slugs, and *Parmacella, Testacella*, &c.)

2nd Fam., Géocochlides. (*Helicarion, Vitrine* (Helicolimax), *Succinea, Helix, Carocolla, Anostoma, Pupa, Chondrus* (Grenaille), *Clausilia, Bulimus, Achatina, Vertigo, Partula.*)

3rd Fam., Limnocochlides. (*Carychium, Scarabus, Auricula, Conovula, Cassidula, Limnæa, Physa, Planorbis, Ancylus.*)

The *second* section, the *Diœcious Gastropods*, consists of his fifth order (*Pneupomes*), and contains two families:—1st. The Helicinides (*Helicina*). 2nd. The Turbicines (*Cyclostoma*).

M. Rang in his 'Tableau Méthodique' makes the *Limaçons* of Férussac (*Trachélipodes colimacés* of Lamarck; *Limacinés* of De Blainville; *Géocochlides* of Latreille) the second family of the *Pulmonés inoperculés* of Férussac (*Pulmobranches* of De Blainville).

M. Rang, following De Férussac, thus, with some slight alterations, defines and arranges the family:—*Animal* elongated, having the body distinct from the foot, and forming a twisted spiral, rarely furnished with a cuirass, but always showing a fleshy collar which closes the shell. *Tentacula* to the number of four, rarely two, the upper ocellated. *Pulmonary cavity* placed forward, and opening in the thickness of the collar. *Organs of generation* united in front; vent near the respiratory orifice. *Shell* always spiral, very variable in form, receiving the animal more or less completely. Terrestrial.

† TETRACEROUS.

A. A cuirass and a collar.

Genera. *Vitrina*, Draparnaud (*Helicolimax* and *Helicarion* of Férussac).

B. A collar without a cuirass.

Genera. *Helix*, Muller (*Helix, Succinea, Amphibulimus, Acavus, Polydontes, Tomogeres, Anostoma, Carocolla, Bulimus, Achatina, Polyphemus, Pupa, Clausilia*, &c., &c., Fér.).

(†) Redundantes.

† *Volutatæ*:—*Helicoides.*

I. Subgenus. *Helicophanta*, Férussac.

Peristome simple.

1st Group. *Vitrinoides*, F. (*Helix brevipes*, &c.)

Peristome thickened and subreflected.

2nd Group. *Vesiculæ*, F. (*H. Cafra*, &c.)

†† *Evolutatæ*:—*Cochloides.*

II. Subgenus. *Cochlohydra*, F. (*Succinea*, Drap.; *Amphibulima*, Lam.; *Amphibulimus*, Montf.)

(††) *Inclusæ.*

† *Volutatæ*:—*Helicoides.*

III. Subgenus. *Helicogena*, Fér. (*Helix*, Linn.)

Columella solid and twisted.

1st Group. *Columellatæ.*

α. Peristome simple. (*Helix naticoides*, &c.)

β. Peristome reflected or thickened. (*Helix Jamaicensis*, &c.)

Shell perforated.

2nd Group. *Perforatæ*, F. (*Helix ligata*, &c.)

Shell umbilicated: umbilicus entirely covered.

a. Shell globulose or subtrochoid.

3rd Group. *Acavi* (*Helix aspersa*, &c.).

Shell imperforate.

β. Shell somewhat depressed (surbaissée).

4th Group, *Imperforatæ*, F.

. Mouth rounded; peristome open. (*Helix guttata*, &c.)

2. Mouth sinuous; peristome strongly reflected. (*Helix squamosa*, &c.)

3. Mouth turning over (versante); columellar border sinuous, flattened, and subdentated. (*Helix cognata*, &c.)

IV. Subgenus. *Helicodonta*, F. (*Tomogeres*, Montf.; *Anostoma*, Lam.)

1st Group. The *Grimaces, Personatæ*, F. (*Helix dentiens*, &c.)

Aperture defended by one or more elongated and internal laminæ.

2nd Group. *Lamellatæ*, F.

* Many laminæ. (*Helix carabinata*, &c.)

** A single lamina. (*Helix labyrinthica.*)

Peristome furnished with large teeth, one of which at the base of the columella forms a gutter.

3rd Group. *Maxillatæ, Polydontes*, Montf. (*Helix imperator*, &c.)

Mouth reversed, furnished with elevated folds, the impressions of which are visible outwards.

4th Group. *Anostomes*, F.; *Anostoma** (*Helix ringens*, &c.)

Interior border of the aperture furnished near the peristome, with elevated, longitudinal folds, the impressions of which are visible outwards.

5th Group. *Impressæ.* (*Helix cepa*, &c.)

V. Subgenus. *Helicigona*, F.

Umbilicus covered.

1st Group. *Carocolla*, Montf. (*Helix angistoma*, &c.)

Umbilicus masked or visible.

2nd Group. *Vortices*, Ok. (*Helix marginata*, &c.)

VI. Subgenus. *Helicella*, F.

Peristome reflected.

1st Group. *Lomastomes, Lomastoma*, F. (*Helix carascalensis*, &c.)

Peristome simple.

2nd Group. *Aplostomes, Aplostoma*, F.

* *Verticilli.* (*Helix lineata*, &c.)

** *Hyalinæ.* (*Helix olivetorum*, &c.)

*** *Fasciatæ.* (*Helix candida*, &c.)

Peristome bordered.

a. Shell horn-colour or brown, nearly unicoloured, rarely fasciated, often hairy; peristome rather spread; epidermis caducous.

3rd Group. *Hygromanes*, F. (*Helix cinctella*, &c.)

β. Shell white or reddish, very much ornamented with bands or small vivid-coloured lines; epidermis insensible, never hairy; sometimes carinated; peristome bordered but not spread.

4th Group. *Heliomanes*, F.

* Shell somewhat depressed or globulose. (*Helix groyana*, &c.)

* Here it is that the new genus *Streptaxis* should be inserted. Mr. Gray, who established it, states (Loudon's *Magazine of Natural History*, vol. i., *New Series*), that the Antique lamp (*Helix ringens*, Linn.), on which Lamarck established his genus *Anostoma*, had been long known and valued, on account of its rarity and strange form; the animal turning up the last whorl before it completes its growth, so that the mouth of the shell is even with the outer surface of the spire. A similar form, Mr. Gray remarks, has been lately observed among tho fossil shells, which on account of its resemblance to the *Cyclostomata* by the roundness and simplicity of its mouth, M. Deshayes has separated into a genus under the name of *Strophostoma*. (See Post, *Ferussina*, p. 109.) Mr. Gray in his paper on the structure of shells (*Phil. Trans.*, 1833) pointed out that some land shells, as *Helix contusa*, when they arrive at a certain period of their growth, throw their whorls out of tho regular series, as if the shell had been crushed, producing what may be considered as a natural distortion. Having since that time had the opportunity of observing several other species of a similar structure, and finding that they all agreed in the general form and position of their mouth, Mr. Gray was induced to consider them as forming a peculiar group, for which he has proposed the name of *Streptaxis*. One of the species, he states, forms, during the dry season, a hard, thin, calcareous epiphragma, differing considerably in structure from any that has hitherto been observed among the *Helicidæ*; but this, he observes, may be only a peculiarity of the species, though the *epiphragma* in this family often forms a good subsidiary character. The following is Mr. Gray's definition of *Streptaxis*:—

Animal like *Helix*?

Shell ovate or oblong; when young, sub-hemispherical, deeply umbilicated, with rapidly enlarging whorls. At length the penultimate whorl is bent towards the right and dorsal side of the axis, and the umbilicus becomes compressed and often nearly closed. The mouth lunate; the edge slightly thickened and reflexed, and often with a single tooth on the outer side of the inner or hinder lip.

Mr. Gray gives six species, which he subdivides into five sections, and says that these shells inhabit the tropical parts of Africa and South America; and that two of the species of these two distant countries appear to be very nearly allied. He further observes, that the animals of these shells, like the *Anostoma*, &c., must remain satisfied with the size of the shell after they have once formed its mouth, as they cannot alter it by reabsorption, as many of the *Helices* do, without removing the whole of the last whorl; for, if a new whorl were added to it, it would entirely alter the form of the shell.

** Shell trochoid and a little carinated. (*Helix pyramidata*, &c.)

VII. Subgenus. *Helicostyla*, F.

Columella strait; peristome simple; shell subdepressed.

1st Group. *Aplostomes, Aplostoma*, F. (*Helix misella*, &c.)
Columella twisted, truncated as it were at its base, or furnished with an internal spiral rib, forming a gutter and appearing under the form of a tooth or callosity.
2nd Group. *Canaliculatæ*, F. (*Helix delicatula*, &c.)
Columella flattened, without either tooth or lamina, forming a sort of gutter at its intersection with the penultimate whorl; peristome reflected.
3rd Group. *Marginatæ*, F. (*Helix studeriana*, &c.)
†† Evolutatæ. *Cochloides*.
* Mouth generally toothless.
1. Columella solid.
a. *En filet*, not truncated at its base.

VIII. Subgenus. *Cochlostyla*, F.

Peristome reflected.
1st Group. *Lomastomes*, F. (*Helix metaformis*, &c.)
Peristome simple.
2nd Group. *Aplostomes*, F. (*Helix Dufresnii*, &c.)
β. Columella solid, flattened, and truncated at its base.
† Shell conic or very ventricose; aperture enlarged.

IX. Subgenus. *Cochlitoma*, F.

Shell conical; mouth short; anterior border advanced.
1st Group. The *Rubans*, F. (*Helix exarata*, &c.)
Shell ventricose; mouth very large; external border in a vertical direction.
2nd Group. *Achatinæ*.
†† Shell ovoïd or turriculated; mouth elongated and narrow.

X. Subgenus. *Cochlicopa*, F.

Shell ovoïd; mouth long; exterior border in a vertical direction.
1st Group. The *Polyphemes*, Montf. (*Helix Priamus*, &c.)
Shell turriculated, mouth short, external border a little advanced.
2nd Group. *Styloides* F. (*Helix fulminea*, &c.)
2. Shell perforated or umbilicated; umbilicus masked or uncovered; peristome simple.
a. Whorls of the spire equalized; the last whorl shorter than the others united.

XI. Subgenus. *Cochlicella*, F.

Only group. *Turritæ*, F. (*Helix conoïdea*, &c.)
β. Last whorl of the spire generally larger and longer than the others united.

XII. Subgenus. *Cochlogena*, F.

† Peristome simple or thickened, but with sharp edges.
a. Shell umbilicated, columella straight.
1st Group. *Umbilicatæ*, F. (*Helix flammata*, &c.)
β. Shell perforated, columella twisted.

2nd Group. *Perforatæ*, F.
* Shell oblong. (*Helix fasciolata*, &c.)
** Shell ovoïd. (*Helix costulata*, &c.)
†† Peristome reflected or dentated.

Mouth crescent-shaped, without either teeth or folds; peristome reflected and regular; columella twisted, perforated; last whorl of the spire sometimes shorter than the others united.

3rd Group. *Lomastomes*, F.
* Last whorl of the spire larger and longer than the others united; shell ornamented with vivid colours. (*Helix Favannii*, &c.)
** Last whorl shorter and less than the others united; shell unicoloured. (*Helix Beticata*, &c.)

Mouth short, crescent-shaped; peristome simple or thickened and regular; columella twisted, more or less projecting and bent, or furnished with a plait which turns upon it and makes it appear subtruncated; umbilicus masked or exactly closed; last whorl of the spire sometimes shorter than the others united.

4th Group. *Helicteres*, F.; *Achatinella*, Sw.
* Shell coniform. (*Helix vulpina*, &c.)
** Shell turriculated. (*Helix turritella*, &c.)
*** Shell ovoïd. (*Helix tristis*, &c.)

Mouth angular at its extremities, or overlaid superiorly, often narrowed by the sinuosities of the external border; columella large, more or less spiral, and forming a plat more or less projecting in the aperture. Peristome thick and reflected; last whorl of the spire longer and more convex than the others united.

5th Group. *Stomotoides*, F. (*Helix Auris Leporis*, &c.)

Mouth crescent-shaped, rather angular at its extremities, most frequently furnished with short teeth at the peristome, which is bordered or a little opened out or reflected; never any laminæ; columella twisted, hollow, flattened at its base, or forming a protuberance; generally perforated.

6th Group. *Dontostomes*, F.
(*) Last whorl of the spire larger and longer than the others united. (*Helix Auris Bovis*, &c.)
(**) Whorls of the spire equalized, often pressed and narrow. (*Helix turgens*, &c.)
(**) Mouth generally furnished with teeth or laminæ.
1. Without gutters; peristome generally not continuous.

XIII. Subgenus. *Cochlodonta*, F.

Shell cylindrical.
1st Group. *Pupa*, F. (*Helix Uva*, &c.)
Shell fusiform.
2nd Group. *Cereales*, F. (*Helix Moricandi*, &c.)
2. One or two gutters; peristome generally continuous.

XIV. Subgenus. *Cochlodina*, F.

(*) Shell right-handed.
† Mouth without teeth or laminæ.
Peristome not continuous.
1st Group. *Pupoïdes*, F. (*Helix Carinula*, &c.)
Peristome continuous.
2nd Group. *Tracheloïdes*, F. (*Helix Sloanii*, &c.)
†† Mouth armed with great plaits or elongated teeth (*Helix Gargantua*.)
(**) Shell left-handed.
Mouth without any lamina. *Balea*, Gray.
3rd Group. *Anomales*, F. (*Helix perversa*, &c.
Mouth armed (with laminæ, one of which performs the part of an elastic operculum).
4th Group. *Clausilia*, Draparnaud. (*Helix torticollis*, &c.)

DICEROUS.

Genera. Vertigo. (Muller.)

Animal elongated, demi-cylindrical, with a rather large spiral body and a collar closing the shell; only two tentacles, long, obconical, retractile, rounded at their extremity; orifice of the pulmonary cavity upon the collar and to the right, approximated by that of the vent; organs of generation united and showing their orifice near the right tentacle, oviparous.

Shell cylindrical, very spiral; aperture straight, in the direction of the axis, short, often dentated; peristome often sinuous and reflected; right or left handed (dextral or sinistral).

Partula. (Férussac.)

Animal elongated, demi-cylindrical, with a rather large spiral body; a collar closing the shell and carrying the orifice of the pulmonary cavity on the right and at the external angle of the aperture; two tentacles only, cylindrical and retractile, ocellated on their summit; organs of generation united? showing their orifice near the right tentacle. Ovo-viviparous.

Shell oval, pointed; spire conical, last whorl convex and longer than the others united, whorls of the spire four to six; aperture straight in the direction of the axis, short, sometimes dentated or furnished with elevated laminæ; peristome commonly very much reflected, with the edge in the same vertical plane; columellar side or lip, callous at its base; dextral or sinistral.

M. Rang's 3rd family of inoperculate pulmoniferous mollusks consists of the *Auricules* of Férussac (*Auriculacea* of De Blainville; *Auriculidæ* of Gray; *Limnocochlides* (*à collier*) of Latreille). These are either terrestrial or marine; and one has been announced as fluviatile. They comprehend the genera *Carychium*, *Auricula* (*Auricula* and *Conovula*, Lam.; *Melampus*, Montf.), *Pedipes*, and *Scarabus*. To these may be added *Chilina*, Gray; *Acmea*, Hartmann; and *Marinula*, King. None of these can be considered to belong to the *Helicidæ*, properly so called.

The 4th family, the Limneans of Lamarck (*Limnæcea* of De Blainville; *Limnocochlides* (without a collar) of Latreille), is entirely fluviatile, consisting of the genera *Planorbis*, *Limnæa*, or, as Lamarck writes it, *Lymnæa*, and *Physa*, *Aplexus*, Flem., and *Amphipeplea*, Nils. This family cannot be considered as belonging to the *Helicidæ*, properly so called.

The order *Pulmonés Operculés* of Férussac (Trachélipodes *colimacés* of Lamarck; *Pectinibranches* of Cuvier; *Chismobranches cricostomes* of De Blainville; *Pneupomes* of Latreille) is thus defined by M. Rang:—

Animal furnished with a foot fitted for creeping, no branchiæ, but a pulmonary cavity receiving the ambient fluid by a large opening placed above the head; tentacles two in number; organs of generation on different individuals.

Shell external, complete, spiral, globulose or conical. *Operculum* calcareous or horny. All terrestrial.

M. Rang observes that this order was established by M. de Férussac at the expense of the *Pectinibranchiata* of M. Cuvier, and for the genus *Cyclostoma* only; but afterwards M. de Férussac added to it the genus *Helicina*, which was, at one time, confounded with the *Colimacés* of Lamarck. At present, continues M. Rang, the *Operculated Pulmonians* establish very well the passage from the *Pulmonians* to the *Pectinibranchians*, because they are related to the first with reference to the organs of respiration, and to the second with reference to the separation of the sexes.

1st Family.

Helicines of Férussac (*Helicinides* of Latreille).

Animal furnished with a collar, and two filiform tentacles carrying the eyes at their external base upon tubercles.

Shell more or less globulose, with a demi-oval aperture, and the columella transversal and delicate. *Operculum* horny, sometimes calcareous externally.

M. Rang observes that M. de Férussac established the two families of *Helicinians* and *Turbicinians* for two genera nearly approximated, and that it would be perhaps more convenient to unite them, the difference between them being really not very remarkable, except in their testaceous envelop; but Mr. Gray has pointed out that one has an annular, and the other a spiral operculum. See also the Rev. M. G. Berkeley's memoir hereinafter alluded to.

Genera. Helicina, Lam. (Oligyra, Say; Ampullina, De Blainville.)

Animal very spiral, furnished with a proboscidiform head and a bilabiated muzzle; tentacles filiform, carrying the eyes at their external base on tubercles; foot short, rounded, with a transverse anterior furrow; pulmonary cavity opening in front of the mantle by means of a large transversal slit.

Shell sub-globulose or conoïd, a little depressed, not umbilicated, with a low spire, an aperture demi-oval, or nearly oval, the peristome reflected into a border (bourrelet), the left lip enlarged upon the umbilicus, which it entirely covers; columella transversal and planulate. *Operculum* horny, sometimes slightly calcareous externally, lines of growth concentric.

Helicina was established by Lamarck, and placed by him among his *Colimacés*. M. Rang is of opinion that the genera *Ampullina* of De Blainville and *Oligyra* of Say ought to be referred to *Helicina*, an opinion which seems to be in unison with that of M. de Blainville himself, who has arranged both those genera under *Helicina* in his Manual. Mr. Gray has published a valuable monograph of the genus in the 1st vol. of the 'Zoological Journal;' and the late Rev. Lansdown Guilding has recorded some other species, with plates of the animal, in the same work, vol. iii.

The definition of M. de Férussac's second family, the *Turbicinians*, is—*Animal* without a collar, provided with two tentacles ocellated at their external base.

Shell conoïd, more or less elevated, with a roundish aperture and continuous borders. *Operculum* calcareous.

Cyclostoma. (Lamarck.)

Animal very spiral, furnished with a proboscidiform head, which bears two cylindraceous tentacles, convex, or swollen at their summit, contractile, and ocellated at their external base; foot elongated and oblong; pulmonary cavity communicating with the exterior by means of a large slit at the superior and anterior part of the mantle: position of the male organ indicated by a tentaculiform appendage situated at the right side.

Shell conoïd, discoïd, or turriculated, more or less elevated, with a sharp or mammillated summit, having all the whorls rounded; aperture round, with continuous and reflected borders. *Operculum* calcareous, with concentric lines, summit subcentral. (Rang.)

The species of *Cyclostoma* are very numerous, and many of them are very beautiful. Mr. G. B. Sowerby has added considerably to the catalogue. They are principally the inhabitants of temperate or warm climates; there is one English species, *Cyclostoma elegans*. The reader will find an excellent paper on the anatomy of this species, by the Rev. M. G. Berkeley, in the 4th vol. of the 'Zoological Journal.'

M. Rang adds to these pulmoniferous operculated mollusks, the fossil genus

Ferussina, Grateloup. (*Strophostoma*, Deshayes.)

Animal unknown.

Shell oval, subglobulose; aperture round, bordered, oblique, simple, toothless, turned over from the side of the spire; umbilicus more or less large. *Operculum?* (Rang.)

M. Rang remarks that M. Grateloup established this genus for a fossil shell from Dax, which seems at the first view very near to *Anostoma*, but which M. Grateloup, from the examination of its aperture, considers as more approximate to *Cyclostoma*. M. Rang states that he participates in this opinion, which the knowledge of the operculum can alone confirm; and he goes on to observe that M. Deshayes, doubtless not having seen the publication of this genus in the first number of the 'Bulletin of the Linnæan Society of Bordeaux,' had subsequently published it under the name of *Strophostoma*. Three or four species are known. (See above, *Streptaxis*, p. 107, note.)

Some may have doubts as to the propriety of placing these operculated pulmoniferous terrestrial mollusks under the family *Helicidæ*. But we believe, notwithstanding the difference of the operculum, that their general organization will warrant their being so placed; and that the terrestrial shell-snails may without violence be placed in one great family, which may be subdivided into the *Helicidæ* without opercula, and the *Helicidæ* with opercula.

Before we conclude this part of the subject, we must draw the reader's attention to the following arrangement proposed by Mr. Gray in the 'Annals of Philosophy' (August, 1824):—

Terrestrial.

Tentacles retractile. Eyes pedicillate.
Gasteropodous. *Limacidæ*.
Trachelipodous. *Helicidæ*.

Aquatic.

Tentacles contractile. Eyes sessile.
Trachelipodous (mantle thick-edged). *Auriculidæ*.
———— (mantle thin-edged). *Limnæadæ*.
Gasteropodous (mantle shield-like). *Onchidiadæ*.

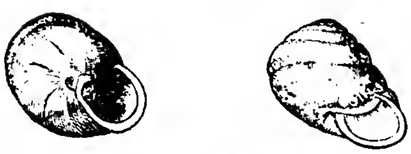
In the paper above alluded to, some interesting observations are made on the affinities of the family; and, with regard to the arrangement, Mr. Gray informs us that he has in his MS. corrected that of the first division, because the distinction between the two first families, though it is that used by Lamarck, Cuvier, and others, is, in his opinion, artificial and of little importance; and the knowledge which he has since acquired of the animals of several genera which were before unknown, have shown him that the character which De Férussac pointed out as the distinction between *Arion* and *Limax* (but which many succeeding naturalists have considered of little importance) is even of more importance than was accorded to it by De Férussac, affording a good character for dividing the Land Pulmonobranchous Mollusca into two families. Thus, he observes, the *Arionidæ* are characterized by having a gland on the end of the tail (which, in the gasteropodous genera, is produced beyond the mantle), and they have the orifices of the organs of generation on the right side immediately under the respiratory hole; whilst in *Helicidæ* there is no gland on the end of the tail, and the orifice above referred to is just behind the base of the upper right tentacle. There is also, he states, an important difference in the nervous system between the two families: in the first the under part of the infra-gular ganglion is 6-lobed, whilst it is only 4-lobed in the *Limacidæ*. Mr. Gray is further of opinion that, at present, only a few genera, as *Arion* and *Helicarion*, Fér., *Nanina*, Gray, and *Stenopus*, Guilding, can be referred with certainty to the *Arionidæ;* but he thinks it very probable that, when the animals of other shells are known, many of them may be found to belong to that family.

Geographical Distribution and Habits.—The *Helicidæ* are most widely diffused over the surface of the earth; scarcely any countries but those where the climate is surpassingly rigorous are without some species of the family. Many of the shells are strikingly beautiful in form and colour, and these are mostly the inhabitants of intertropical countries. Some of the genera (*Achatina*, for instance) attain a very large size, and lay eggs in proportion. *Helix aspersa*, the common garden-snail, is distributed over a large portion of the globe. It is found, for instance, at the foot of Chimboraço, in the forests of Guiana and Brazil, and on all the coasts of the Mediterranean in Europe, Asia, and Africa. *Helix Pomatia* has been naturalized with us, and is still found in some countries. The first importation is attributed by some to Sir Kenelm Digby. Merrett mentions it as a British inhabitant before his time. A moist and rather warm state of the atmosphere seems most congenial to this family. To avoid great dry heat they get under stones, under old trunks of trees, leaves, &c. &c., and some of the species will burrow into the earth for protection against it. A shower will bring them forth in such numbers sometimes, the smaller species especially, as to induce the belief in some cases that it has been raining snails. Most of the species hybernate.

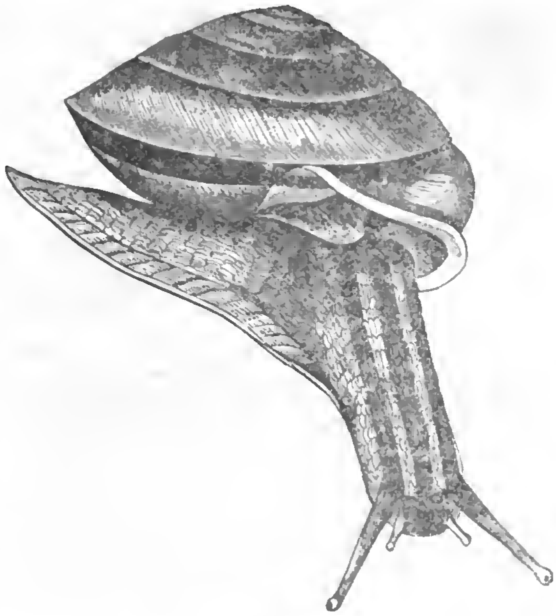
Utility to Man.—The *Helicidæ*, from their voracity, are very injurious to the agriculturist and horticulturist; but there can be no doubt that the larger species are good food. We know that they were a favourite dish with the Romans, who had their *cochlearia*, where they were regularly fattened with new wine boiled down and meal (*sapa et farre*, &c.). (Pliny, *Hist.*, lib. ix., c. 56.) *Helix Pomatia* is used as food in many parts of Europe during Lent, and the snails are kept in an *escargotoire* (snaillery), which is generally a large place boarded in, having the floor covered half a foot deep with herbs, where the animals fatten. Many are familiar with the passage in Pliny (*loc. cit.*), who, on the authority of Varro, relates the incredible size to which the art of fattening had brought the snails. There must, one should think, be some mistake in the text, which says, 'Cujus artis gloria in eam magnitudinem perducta sit, ut octoginta quadrantes caperent singularum calices.' Pennant, referring to this and to Varro (*De Re Rusticâ*), says, 'If we should credit Varro, they grew so large that the shells of some would hold ten quarts! People need not admire the temperance of the supper of the younger Pliny (*Epist.*, lib. i.; *Epist.* xv.), which consisted of only a lettuce a-piece, three snails, two eggs, a barley cake, sweet wine and snow, in case his snails bore any proportion to those of Hirpinus.'

The following cuts, and those given under Bulimulus and Bulinus, will afford the reader an idea of some of the forms of the *Helicidæ* :—Anostoma, Streptaxis, Carocolla, Balea, Partula, Vertigo, Clausilia, Cyclostoma.

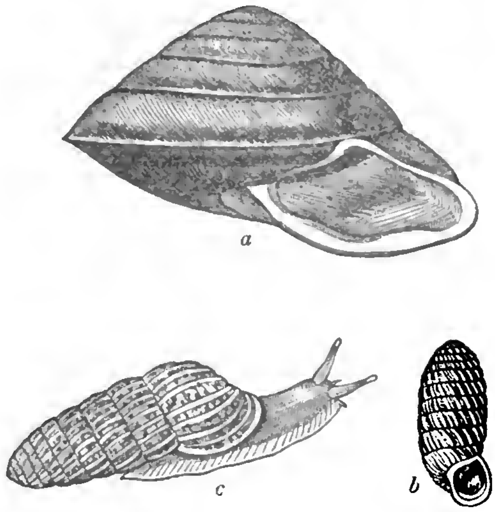
Anostoma depressum.



Streptaxis costatus.

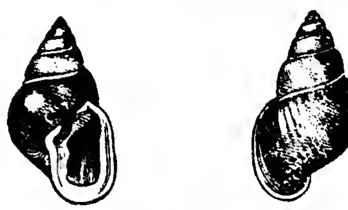


Carocolla Lamarckii.

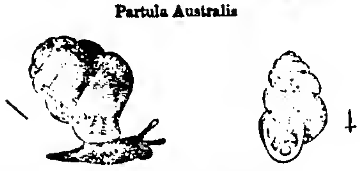


a, Carocolla albilabris.
b, Pupa Uva; c, Pupa Chrysalis, with the animal.

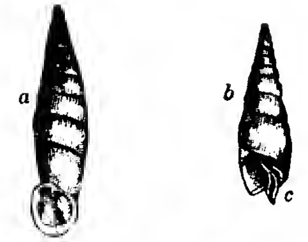
Balea fragilis, magnified.



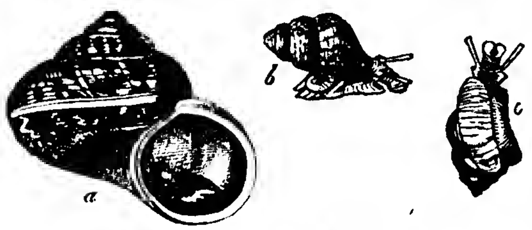
Partula Australis



a, Vertigo pusilla; b, another species of Vertigo, with the animal; both magnified.



a, Clausilia Macascarensis; b, the same, broken, to show the clausium, c.



a, Cyclostoma involvulus; b, Cyclostoma elegans, with the animal; c, Cyclostoma elegans; showing the alternate contraction of the two sides of the animal's foot.

Fossil Helicidæ.

Fossil species of *Helicidæ* are by no means rare. Thus M. Deshayes enumerates thirty-five species of *Helix*, two of *Anostoma*, one of *Helicina*, three of *Pupa*, two of *Clausilia*, three of *Bulimus*, three of *Achatina*, seven of *Pedipes*, and six of *Cyclostoma*, &c., as fossil (tertiary), mostly in the Pliocene period of Lyell, and many of them as both living and fossil.

The student should consult especially the great work of Férussac, and the writings of Cuvier, De Blainville, Deshayes, Draparnaud, Gray, Lamarck, Linnæus, De Montfort, Montagu, Rang, Sowerby, Swainson, &c. &c., and the works of Bonnet, Gaspard, Réaumur, Redi, Schœffer, Spallanzani, and Swammerdam. He will find many new species recorded in the 'Proceedings of the Zoological Society of London,' and in Müller's 'Synopsis Testaceorum' (Berlin, 1836). He should also consult M. Bouillet's 'Catalogue of the Terrestrial and Fluviatile Testacea of Auvergne, both recent and fossil;' among the latter are two species of *Vertigo*.

HELICI'NA. [Helicidæ.]

HELICOLI'MAX. [Helicidæ.]

HELICOSTE'GUES. [Foraminifera, vol. x., p. 348.]

HELICTIS, Mr. Gray's name for a genus of quadrupeds, which inhabits eastern Asia and has the general appearance and colouring of *Mydaüs*, combined with a dentition resembling that of *Gulo* or *Mustela*, but differing from both the latter genera in the large internal central lobe of the upper carnivorous tooth. The genus is thus characterized by Mr. Gray:—

Dental Formula:—Incisors (primores) $\frac{6}{6}$; Canines (laniarii) $\frac{1-1}{1-1}$; molars $\frac{5-6}{5-6}$.

Head elongated. *Feet* short; soles of the feet nearly naked to the heel; toes 5—5; claws strong, the anterior ones long and compressed. Tail cylindrical and moderate.

Mr. Gray exhibited to the Zoological Society one species, *Helictis moschata*, the entire length of which was 23½ inches, of which the tail measured 8. Inhabits China and smells strongly of musk. For further particulars see *Zool. Proc.*, 1831. [Gulo, vol. xi., p. 483.]

HELIER, ST. [Jersey.]

HELIOCENTRIC (having the sun as centre), a term applied to the place of a planet, as seen from the centre of the sun, in opposition to its *geocentric* place, as seen from the centre of the earth. [Parallax.]

HELIODO'RUS, was born at Emesa in Syria, in the fourth century of the Christian æra. He was bishop of Tricca in Thessaly, and is said to have introduced into his diocese the custom of deposing from their office all priests who lived with their wives after their ordination.

He wrote in his youth a romance in the Greek language entitled 'Æthiopica,' which contains an account of the wonderful adventures of two lovers, Chariclea, the daughter of Hydaspes, king of Ethiopia, and Theagenes, a noble Thessalian. It has been remarked that the work of Heliodorus served as a kind of model to the subsequent Greek writers of romance. Though not without merit in point of style and animated description, it belongs to that kind of works of fiction which deal in improbabilities and strange adventures, and in no respect approaches to that class which fix our attention and hold fast our sympathies by exhibiting a portrait of human life and its accidents. This work was published for the first time by Obsopoeus, 4to., Basel, 1534; afterwards by Commelinus, 8vo., 1596; Bourdelotius, 8vo., Paris, 1619; Pareus, 8vo., Frankf., 1631; Schmidius, 8vo., Leip., 1772; Mitscherlich, 2 vols. 8vo., Bipont edition; but the best edition is by Coray, 2 vols. 8vo., Paris, 1804. The 'Æthiopica' has been translated into most of the modern European languages:—into French by Amyot, Paris, 1549, 1559; anonymous, 8vo., Paris, 1623; anonymous, 8vo., Lond. (Paris), 1743, Paris, 1757; by Quenneville, 3 vols. 12mo., Paris, 1803:—into Spanish by Ferdinand de Mena, 12mo., 1616:—into Italian by Ghini, 1556, frequently reprinted:—into German by Meinhard, 2 vols. 8vo., Leip., 1767; and by Göttling, 8vo., 1822, said to be a good translation:—into English by Underdowne, 4to., 1587; Lisle, 4to., 1622; Tate, 8vo., 1686 and 1753; anonymous, 2 vols. 12mo., 1791:—into Dutch, 12mo., 1669; and into Polish, 8vo., 1606. At least half a dozen other Greek writers of the name of Heliodorus are mentioned.

HELIOGABA'LUS. [Elagabalus.]

HELIO'METER (ἥλιος, the 'sun,' and μέτρον, 'measure') is the name given by M. Bouguer to a micrometer invented by himself about 1745, by means of which the diameters of the heavenly bodies may be measured with considerable accuracy. In Bouguer's construction the tube was of a conical form, and provided with two object-glasses of equal focal length, which were so adjusted as to admit of being moved in a direction transverse to the axis of the tube. By this contrivance the two images which are formed in the focus of the eye-glass may be made to diverge, coincide or lap over each other, by merely varying the distance between the centres of the object-glasses, and this distance is indicated by a graduated scale attached to the tube. When the two images coincide, the angle subtended by the observed objects will be equal to that subtended by the centres of the object-glasses, which being known, the magnitude of the observed object may readily be computed when its distance is given, or the distance determined when its magnitude is given. As this instrument does not differ in principle from the divided object-glass micrometer, the reader is referred to the article Micrometer; and for further information relative to the invention, see the 'Mémoires de l'Académie Royale des Sciences,' 1748, p. 11. [Bouguer.]

HELIO'POLIS. [Baalbek; Egypt.]

HELIO'PORA, a genus of stony Polyparia, established by Blainville, from observations of MM. Quoy and Gaimard on a recent species called by Lamarck Pocillopora cærulea.

Generic Character.—Animals short and cylindrical, provided with a simple circle of thick tentacula, fifteen or sixteen in number, contained in vertical or diverging cylindrical cells; cells immersed, internally crenulated by imperfect radiating lamellæ, united into a calcareous mass, which is regularly porous in the intervals of the cells. The Coral is found attached to various bodies.

Three recent species are mentioned by Blainville, all from warm seas. One of the fossil species (Heliopora porosa, Bl.; H. interstincta, Bronn) abounds in strata of the Silurian system; others occur in the chalk and in tertiary deposits. (*Manuel d'Actinologie.*)

HELIORNIS, Bonaterre's name for a genus of water-birds (*Grèbifoulques* of Buffon) which have lobated feet like the Coots and Grebes, but with a greater development of tail and sharper claws. [Podoa.]

HELIOSCOPE (a Greek term signifying literally 'sun-observer') is a kind of telescope adapted for making observations upon the sun without the eye being injured by the intense brightness of the solar rays. Dr. Hooke wrote a treatise in 1742 expressly on the subject of helioscopes, wherein he recommends four reflecting-glasses to be so placed within the tube of the telescope that the solar rays may suffer four reflexions before they strike the eye; and thus, he observes, their intensity will be reduced to the 256th part of their original intensity. Hevelius and other philosophers preferred the use of coloured glasses, which is the common practice of the present day; while Huygens merely blackened the inner side of the eye-glass by holding it over the smoke of a lamp or candle. (Dr. Hooke's treatise, above mentioned.)

HELIOSTAT (ἥλιος, the 'sun,' and the root στα, *sta*, to 'put or place') is the name given to an instrument employed in optical experiments to fix the position of the solar ray. 'Experiments upon the physical properties of light are usually made in a room so darkened as only to admit the solar rays through a single aperture. The solar ray thus admitted is in two respects unfavourably circumstanced for being operated upon. In the first place, from the ordinary elevation of the sun, the ray enters the room obliquely, is immediately thrown upon the floor, and thereby that portion of its length which can be experimented upon is inconveniently limited; secondly, from the rotation of the earth the ray can only be admitted during a few hours in the day, and even during that time the position of the ray will be constantly changing, and will thus require a corresponding change in the position of the lens or other object employed in the experiment. To remedy these inconveniences is the object of the heliostat, invented by s'Gravesande, by means of which the solar ray may be fixed at pleasure in any desired position. It consists of a plane metallic mirror provided with a vertical and horizontal movement, and of a clock, the index of which moves in a plane parallel to that of the equinoctial. The extremity of the index is connected with the hinder part of the mirror by means of a long cylindrical rod adjusted perpendicularly to the plane of the mirror. The subordinate parts, which are numerous and complicated, are explained in Desaguliers's translation of s'Gravesande's 'Natural Philosophy,' vol. ii., p. 107, ed. 1747; and in Biot's 'Physique Experimentale,' tom. ii., cap. 4.

HELIX. [HELICIDÆ.]

HELIX. [SCREW.]

HELLA'NICUS, one of the early Greek prose writers, was born at Mitylene in the island of Lesbos, B.C. 496 (*Gell.*, xv. 23). According to Lucian (*Macrob.*, c. 22) he lived to the age of 85. Suidas says that he lived at the court of Amyntas, king of Macedon, together with Herodotus; but this statement is inaccurate, since there was no king of Macedon of the name of Amyntas during the lives of Hellanicus or Herodotus.

He wrote several works, which are frequently quoted by antient writers; of which the most important appear to have been, a 'History of Argos,' arranged in chronological order, according to the successive priestesses of the temple of Hera in that city; a 'History of Attica, Cyprus, Æolia, and Lesbos;' an account of Phœnicia, Persia, Scythia, and other Eastern nations; and some geographical pieces. Hellanicus is mentioned by Thucydides (i. 97).

The fragments which remain of the writings of Hellanicus were published by Sturz, 8vo., Leip. 1787; 2nd edition, 1826; and in the 'Museum Criticum,' vol. ii., p. 90-107, Camb. 1826.

HELLEBORE, WHITE. [VERATRUM ALBUM.]

HELLE'BORUS, a genus of exogenous plants belonging to the natural order Ranunculaceæ, among which it is known by its having eight to ten very short tubular petals, permanent sepals, and from three to ten leathery follicles. The most remarkable species is that which produced the 'Black Hellebore,' a dangerous acrid poison, much used by the antient Greek physicians in mania, epilepsy, and dropsy. This plant, the *Helleborus orientalis* of botanists, was found by Sibthorp abundantly in mountainous broken ground in Greece and the Levant, where it is still used medicinally under the name of *scarphe* (Σκαρφη). It has a thick black rhizoma, pedate leaves downy on the under side, and corymbose purple flowers. Except in the colour of the flowers and downy leaves, it resembles the *Helleborus niger*, or Christmas rose, an alpine plant now common in gardens, where it flowers about Christmas time, whence its common name. Other species are *H. viridis* and *fœtidus*, two herbaceous plants with green flowers; of these the properties are nearly the same as those of *H. orientalis*, but less energetic. Their leaves are emetic and purgative, and are recommended as an active vermifuge.

HELLE'BORUS OFFICINA'LIS (Salisbury), H. Orientalis (Dec.), has been substituted in the Pharmacopœia for the H. Niger, from a belief that it is more powerful. It is a perennial species, growing in mountainous places in the East, and used to be collected by the antients in Eubœa, Bœotia, on Helicon, Œta, and in the island of Anticyra; by the moderns it is gathered in Greece and the Levant, as mentioned in the previous article. The root, which is the part employed, is black, the caudex thick, the fibres cylindrical: it is extremely acrid.

The root of H. Niger will long continue to be employed as the officinal one, and it is to be regretted that many other roots, especially those of Actæa spicata and Adonis vernalis are often intentionally or accidentally sold in its stead. These may be discriminated by physical characters (particularly the internal structure) and by chemical tests. The activity of Hellebore seems to reside in its resinous matter, for which rectified (not proof) spirit is the proper menstruum.

Like most ranunculaceous plants hellebore can occasion rubefaction and inflammation of any surface with which it is brought in contact; when taken into the stomach in a moderate dose it gently stimulates it and the other viscera of the abdomen; but in large doses it is a fatal poison. It was celebrated in antient times as a cure for various forms of insanity, which it sometimes accomplished by its drastic action on the bowels; and it has been employed occasionally in this and some other diseases in modern times. It is however a dangerous medicine, and one which it is rarely necessary to have recourse to.

HELLE'NES. [GREECE.]

HELLESPONT. [DARDANELLES.]

HELMET, an antient armour of defence for the head, still worn by the officers and soldiers of some of our cavalry regiments. Its original name was Helm, possibly borrowed from the Latin (of the lower age) *helmus*. Skinner however derives it from the Anglo-Saxon verb *helar*, to hide. 'Helm' certainly occurs both in Cædmon's 'Paraphrase' and in the Saxon Gospels, as well as in Ælfric's 'Glossary.' *Helmet* was probably adopted, in the middle age, from the Italian *elmetto*.

As a part of defensive armour the helmet is of high antiquity: some sort of covering of this description for the head appears to have been worn by the warriors of every country. Helmets were found even among the inhabitants of the South Sea Islands when discovered by Captain Cook. Among the oldest specimens now remaining are probably the two helmets found on the field of Cannæ in 1752, preserved in Sir William Hamilton's collection in the British Museum. Another antient helmet, bearing an inscription, found at Olympia, was presented to the British Museum by King George IV.

The form of the Greek helmet and its general description may be collected from various passages of the Greek writers from Homer downwards, and more especially from the medals and marbles on which it is represented. [ATHENS, p. 13, and the *Library of Entertaining Knowledge* (*Elgin* and *Townley Marbles*), published by the Society for the Diffusion of Useful Knowledge.] It does not appear that the Greek or Roman helmet usually protected the face. Both the helmets found at Cannæ however protect the face, and have projecting nasals. Lipsius's treatise *De Militia Romana* (iii., c. 5) contains a full account of the Roman helmet, with which the reader may compare the plates and descriptions in the third volume of Count de Caylus's *Recueil d'Antiq.* For the helmets in more modern use Grose's *Treatise*, and Meyrick's *Critical Account, of Antient Armour* must be referred to. Among the varieties which had separate names we find the Chapelle de Fer, the Bacinet, the Burgonet, the Castle, the Hufken, the Morion, the Salade, and the Skull. These were almost invariably of steel. There was also the Justing Helmet, used in tournaments, which was sometimes of leather.

The *nasal*, the *ventaile* or moveable front, the *visor*, lifted up by pivots, and the *bevor*, to allow of drinking, were the names of parts of certain helmets introduced at different periods, and not always used.

As ornaments over the shield or coat of arms, helmets are still used in heraldry. The full-faced helmet with six bars, all of gold, damasked, is for the sovereign and princes of the blood; the full-faced helmet of steel for marquises and dukes; earls, viscounts, and barons have a profile or side-standing helmet of steel ornamented with bars; the full-faced helmet of steel, with the visor or bevor open, is for baronets and knights; the profile helmet, steel, with the visor closed, for an esquire.

HELMONT, VAN. [CHEMISTRY.]

HELMSTEDT, a town in the district of Schöningen in the duchy of Brunswick, 52° 13′ N. lat. and 11° E. long., has about 6300 inhabitants, who carry on a pretty considerable trade. Helmstedt was formerly the seat of a university, which was founded in 1575 by Duke Julius of Brunswick, and was supported at the joint expense of the principalities of Wolfenbüttel and Calenberg. It was one of the most flourishing universities in Germany, till the foundation of that of Göttingen in 1734. In 1735 the elector of Hanover, as sovereign of Calenberg, ceased to contribute his share towards its support, and in 1809 Jerome Bonaparte, king of Westphalia, suppressed it entirely. Besides the fine building formerly occupied by the university, and now appropriated to the district tribunal, there are the gymnasium, the church of the Holy Sepulchre, and the town-hall. The old town had a rampart, with four gates, now converted into a promenade with an avenue of lime-trees. In the neighbouring romantic forest of Marienberg are much frequented medicinal springs; and on the Corneliusberg are the Lübbensteine, or four enormous altars of Thor and Odin, surrounded with a circle of single stones. (Kunhard's *Beiträge zur Geschichte der Universität H.*; and Ludwig's *Geschichte und Beschreibung der Stadt H.* 1821.)

HELOISE. [ABELARD.]

HELO'NIAS. [CEVADILLA.]

HELO'PIDÆ (Leach), a family of Coleopterous insects of the section Heteromera and subsection Stenelytra. Distinguishing characters:—head short, obtusely terminated anteriorly; mandibles notched at the apex; antennæ placed near the eyes, generally filiform, or nearly so, or slightly thickened at the apex, where the joints are short; the basal joint of the antennæ hidden above by a projected margin of the head; the third joint long; terminal joint of the maxillary palpi large and securiform; eyes emarginated anteriorly; legs moderate; the penultimate joint of the tarsi generally simple or but slightly emarginated; claws simple; body usually convex, and of an oval form.

The larvæ of these insects live in rotten wood, upon which they feed; they are of a cylindrical form, hard to the touch, and have six small legs, attached, two to each of the thoracic segments. The perfect insects are, like the larva, also found in rotten wood, or under the bark of trees; they are rather slow in their movements, and generally adorned with metallic colours.

In the genus Helops, as it is now restricted, the joints of the antennæ are somewhat compressed; the two basal joints are short, the third is long; the two or three terminal joints are short and obconic, the last joint is the shortest; the intermediate joints are moderately long and nearly cylindrical. The thorax approaches to a square form, or is slightly attenuated behind, and is closely applied to the elytra: the body is of an oblong oval form.

Helops Caraboïdes, an insect very abundant in various parts of England, will afford an example of this genus. It is rather less than half an inch in length, of an oval form and deep brown colour, having a bronze gloss in certain lights; the upper surface of the body is finely punctured, and so are the striæ of the elytra. This insect is usually found under the bark of trees, near the root.

Helops Cæruleus is another species of this genus, which is common in many parts of England. This insect is nearly three-quarters of an inch in length, and of a violet-blue colour. It is generally found in old pollard willow-trees. The larva is cylindrical in form, of a yellowish-white colour, and has two recurved hooks on the terminal segment of the body.

Upwards of sixty species of the genus Helops are enumerated in catalogues, and these are chiefly confined to Europe and North America.

HELOTS. [SPARTA.]

HELSINGFORS, the capital of the Russian government of Finland, at the mouth of the Wanna, in 60° 10′ N. lat., and 25° 0′ 15″ E. long. It has now about 10,000 inhabitants, and a considerable export trade in corn, fish, iron, and deals; and important manufactures of sailcloth, sacking, and linen. The town was built by Gustavus I. of Sweden, and burnt in the Russian war in 1728. The fine harbour is defended by several forts, especially the strong fortress Sweaborg. Finland having been taken by the Russians in 1808, and ceded to them at the peace in 1809, no pains have been spared by them to render it an important naval station. Since 1815 a plan for enlarging the town has been carrying into effect. Masses of rock have been blown up and inequalities levelled in order to obtain a site for the new buildings. Among the public edifices the most remarkable are the palace of the governor and the barracks; and likewise the magnificent building for assemblies, on the Esplanade, which was finished in 1833. After the destructive fire at Abo, the university, called Alexander's University, was transferred by an ukase of 21st December, 1827, to Helsingfors. It is divided into four faculties, with 22 professors; and has a library and botanic garden. There are now above 400 students.

HELSTON. [CORNWALL.]

HELVELLYN. [CUMBERLAND.]

HELVETIUS, CLAUDE-ADRIEN, was born at Paris in January, 1715, and was educated at the Jesuits College of Louis-le-Grand, where his earlier years were far from betokening those talents of shrewdness and observation which his writings subsequently exhibited. Having passed through a course of legal study, Helvetius was sent to his maternal uncle d'Armancourt, *directeur des fermes* at Caen, in order to acquire a practical knowledge of finance, and he shortly afterwards obtained the lucrative appointment of *fermier-général*, through the influence of the queen Marie Leczinsky, to whom his father was physician. But disgusted with the oppressive nature of its duties, which however he discharged with singular lenity, he resigned this situation, and purchased that of chamberlain to the queen's household. At this period Helvetius led a disorderly life, without having any elevated or moral end in view, though his general conduct was relieved by occasional acts of the noblest generosity. Into these excesses he appears to have been led by an inordinate vanity athirst for universal admiration. Thus, in order to gain the applause of the theatre, he danced on the public stage in the mask of Javiller (for masks had not yet been exploded by Voverre), and his temporary study of mathematics was stimulated by the honours and attention which were lavished by the highest circles at Paris upon Maupertuis after his return from a scientific visit to Lapland. Aspiring to rival the dramatic fame of Voltaire he composed the tragedy 'La Conjuration de Fiesque,' and upon the appearance of Montesquieu's work, 'L'Esprit des Lois,' Helvetius declared that he too would raise a monument worthy to stand by the side of that of the philosophical legist. But Helvetius was as kind-hearted as he was vain, and an act of beneficence was as dear to him for its own sake as the applause which he courted so eagerly. When Saurin the academician married, Helvetius not only made him a free gift of 200*l.* but also settled upon him an annuity of 80*l.*, and when Marivaux, to whom he allowed a yearly pension of 120*l.*, forgot the decencies of gratitude, Helvetius mildly observed, 'How would I have answered him if he had not, by accepting my favours, laid me under an obligation to him!'

In 1751 Helvetius married the beautiful and accomplished daughter of the Comte de Ligneville and niece of Mad. de Graffigny, by whom she had been brought up. From this time he lived chiefly in retirement at a small estate at Voré, enjoying with his wife and children the pure pleasures of domestic life and ameliorating the condition of his tenants and vassals. He is said to have been very jealous of the game on his estates, and very severe against violators of the game-laws. In 1758 he published the treatise 'De l'Esprit,' which, while it was favourably received by the self-styled philosophical party, was denounced by the court and the Jesuits as dangerous to society and to religion, and as being nothing less than a summary of all the evil doctrines of the 'Encyclopédie.' A strong passion for praise is usually accompanied by a keen sensibility to censure: to regain the favour of the court Helvetius thought no concession too great, and he successively published three letters of apology which gradually advanced in humility and submission. Notwithstanding the confession which they contained of a Christian faith and his disclaimer of all opinions inconsistent with its spirit, the doctors of the Sorbonne drew up a formal condemnation of the work, which they declared to be a compendium of all the evil contained in all the bad books that had yet appeared. It was publicly burned, according to a decree of the parliament of Paris. As to the literary merits of this work, the style is vicious and declamatory, but the argument is well sustained throughout, and enforced by great felicity and copiousness of illustration. In 1764 Helvetius visited England, and in the following year Germany, where he was received by Frederick the Great with marks of the highest consideration and esteem. Helvetius died at Paris, 26th December, 1771, leaving behind him a work entitled 'De l'Homme, de ses Facultés et de son Education,' which was published the same year at London by Prince Gallitsin. This treatise, which may be considered as a continuation of and commentary upon his earlier philosophical work, is vastly superior to it in style and diction. Among the earliest works of Helvetius is his poem 'Sur le Bonheur,' which, however secondary as a poetical composition, evinces all that nice observation of men and manners which forms at once the truth and the charm of his philosophical essays. These may be considered to constitute the practical portion of the sensuous system which in this part was left incomplete by Condillac, who confined himself to the exposition and derivation of the cognitive faculties. By 'esprit' Helvetius understood as well the mental faculties as the ideas acquired by them. Both faculties and ideas he reduced to simple sensation, and he accounts for man's superiority over the brutes by the finer organism of his senses and the structure of his hands. Man, he considers, is the work of nature, but his intelligence and virtue are the fruits of education. The end of virtue is happiness, and utility determines the value of all actions, of which those are virtuous which are generally useful. Utility and inutility are however merely relative, and there is consequently nothing which is either absolutely good or absolutely evil. The happiness and enlightenment of the people he makes to be the true end of all human government; and, denying a Divine Providence in the government of the world, he declares all religion to be a cheat and a prejudice. (*Œuvres d'Helvetius*, 3 vols., Paris, 1818.)

HELVIN, a crystallized mineral of which the primary form is a cube. Cleavage parallel to the planes of the regular octohedron, indistinct; fracture uneven; hardness 6·0, 6·5; scratches glass; colour pale-wax and greenish-yellow; streak white; lustre resinous, vitreo-resinous; translucent; transparent on the edges; specific gravity 3·166.

It is found at Schwarzenberg in Saxony.

Before the blowpipe or charcoal it melts with effervescence into a globule of the same colour as the mineral; in the oxidizing flame the colour becomes deeper and the fusion is more difficult; with borax it yields a transparent glass often coloured by manganese.

Analysis by Gmelin—

Silica	35·272
Glucina	8·026
Alumina and Glucina	1·445
Protoxide of manganese	29·344
,, iron	7·990
Sulphuret of manganese	14·000
Loss by calcination	1·155
	97·232

HELVOETSLUYS. [HOLLAND.]

HEMATIN, the colouring matter of the *Hæmatoxylon campechianum*, or logwood, discovered by Chevreul. It is prepared by evaporating a watery infusion of logwood to dryness, treating the residue with alcohol, filtering the spirituous solution, and evaporating it to the consistence of a syrup. If a certain quantity of water be added to this, and evaporation be performed with a gentle heat, the hematin crystallizes, and requires only to be washed with a little alcohol and dried. Hematin crystallizes in small crystalline laminæ of a reddish colour. The taste of hematin is at first sweet and astringent, and afterwards bitter. It is decomposed by heat, and ammonia being one of the products, proves that it contains azote. Water dissolves hematin, and the solution is of an orange red, at 212° Fahr., but becomes yellow on cooling. Acids saturated with oxygen turn its colour first to yellow and afterwards to red; the alkalis in small quantity render hematin purple, and when in excess violet-blue, and eventually decomposing it, make it yellowish-brown.

This colouring principle is a constituent part of all the colours prepared with logwood, and the changes which it undergoes by the action of acids and alkalis render it useful as a re-agent to detect their presence.

HEMEL HEMPSTEAD. [HERTFORDSHIRE.]

HEMERALO'PIA, a word which is now used to signify 'night-blindness,' though in fact it means 'day-seeing,' being similarly formed to the genuine Greek word 'nyctalopia' (νυκταλωπία), which means 'night-seeing.' Much confusion has arisen in regard to the use of the two words, in consequence of an error committed either by Hippocrates or one of his early editors. In the 2nd book of his 'Prædicta,' he says, 'We call those nyctalopes who see by night;' but in the 4th and 6th books of his 'Epidemics,' the disease which he speaks of under a similar term appears to be that in which the patients are blind at night; and his translators, Paulus Ægineta, Ætius, and Galen, quote various authorities to show that those only are properly called nyctalopes who are affected with night-blindness. They have been followed by Bontius, Sir G. Blane, and many naval surgeons, who apply to the present disease the name of nyctalopia, or dysopia tenebrarum. Linnæus and Vogel however define nyctalopia to be night-vision, and call night-blindness, hemeralopia; and as their meanings have been since received by Scarpa, Lawrence, and all the chief writers on diseases of the eyes, they will be adopted here.

Night-blindness is a common disease amongst seamen in the East and West Indies, the Mediterranean, and in all hot countries, and affects in a slighter degree soldiers and the natives in the same parts of the globe. To persons affected by it, all objects appear at sunset as if covered with an ash-coloured veil, which becomes gradually denser, and at last involves them in complete darkness. In slight cases they can see by bright candle-light or by moon-light; but after the disease has lasted a few days, even the largest objects are invisible after sunset, and the patients have to grope their way even where the moon or candles are shining brightly. The disease will daily increase in severity if not judiciously treated, till the sight becomes weak by day-light, and so disordered that total blindness might be apprehended, though it very rarely follows. The pupils are generally dilated, and at night cannot be made to contract even by a brilliant light.

The most probable cause of this disease is the exhaustion of the retina, produced by the continued glare of a bright sun, either directly transmitted to it, or reflected from the clear waters of the tropical seas, or the bright sands of their shores; a condition of which one may form an idea from the inability to perceive objects in a dimly lighted room after leaving one where there was a glare of light. In many cases it is connected with a disordered condition of the digestive organs, and in others with scurvy.

The disease will generally get well, though it may exist for weeks or months. The most successful treatment is the repeated application of small blisters to the temples. Mr. Bampfield cured by this means upwards of 300 cases. This treatment never failed; but in some instances its effects were accelerated by the administration of purgatives and other medicines adapted for the coincident symptoms of scurvy or of disordered digestion. The best description of the disease is in Mr. Bampfield's 'Essay on Hemeralopia,' in the 5th vol. of the 'Medico-Chirurgical Transactions.'

Nyctalopia, night-vision, or day-blindness, probably never occurs as a separate disease. It is often a symptom of scrofulous ophthalmia and other diseases where the eye is so irritable that the stimulus of day-light cannot be borne, as well as of those conditions in which great dilatation of the pupil is requisite for vision, as in commencing cataract, or opacity of the centre of the lens or its capsule.

HEMICA'RDIUM. [CONCHACEA, vol. viii., p. 427.]

HEMICYCLO'STOMA, M. De Blainville's name for the fourth family of his order *Asiphonobranchiata*, the latter being the second order of the first subclass (*Paracephalophora Dioica*) of the class *Paracephalophora*, the second class of his *Malacozoa*. [NERITIDÆ.]

HEMIDA'CTYLUS. [GECKO, vol. xi., p. 103.]

HEMINGFORD, WALTER, sometimes called HEMINGBURGH, a canon regular of the Austin Priory of Giseburn, or Gisborough, in Yorkshire, where he died in 1347. His history, which begins from the Norman Conquest, continues to the reign of King Edward II. It was first published by Gale in his 'Scriptores V.,' fol., Oxford, 1687; and again by Hearne, in 2 vols. 8vo., Oxford, 1731.

HEMIO'PIA (from ἡμί, 'half,' and ὤψ, 'the eye') is a disease in which the patient sees only a part of the object he looks at; the middle of it, or its circumference, or its upper or lower part, or more commonly one lateral half, being completely obscured. In some cases it arises from a partial mechanical obstruction to vision, as when part of the transparent tissues of the eye become opaque, or when the upper eye-lid falls over half the pupil. But more frequently it is the result of a morbid and partial insensibility of the retina, produced by the excessive stimulus of a bright light, and will cease after a night's rest; sometimes it is a consequence of disordered digestion; and sometimes a symptom of commencing amaurosis, or gutta serena, and terminates in complete blindness.

A very interesting account of this disease is given in the 'Philosophical Transactions' for 1824, by Dr. Wollaston, who himself suffered from it on two occasions. He endeavoured to explain it by the semi-decussation of the optic nerves [EYE]; and it is remarkable that the appearances found in his brain after death were such as on that theory might have been anticipated. But in a large proportion of the cases the affection is too transient to admit of the supposition of any organic disease.

HEMIPLE'GIA. [APOPLEXY.]

HEMIPO'DIUS. [TETRAONIDÆ.]

HEMISPHERE, the half of a sphere. [SPHERE.]

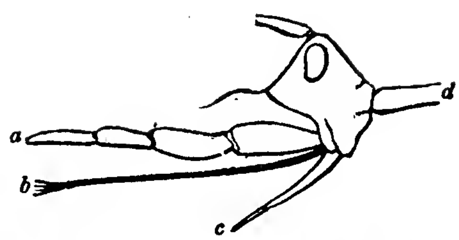
HEMI'PTERA (from ἡμί, *half*, and πτερόν, *a wing*), one of the orders of the class Insecta.

The order Hemiptera, according to the twelfth edition of the 'Systema Naturæ' of Linnæus, contains insects which agree in having incomplete metamorphoses (*i.e.* the larva and pupa both possess the power of locomotion, and bear a great resemblance to the perfect insect), and also in having the superior wings generally coriaceous, and the inferior membranous. Thus Linnæus included in this order the *Cockroaches, Locusts, Grasshoppers, Bugs, Cicadæ*, &c. The last-mentioned insects, the Bugs and Cicadæ, however differ very materially from the former, inasmuch as they possess a suctorial instead of a masticatory mouth; and as these latter characters have been considered of great importance by all the more modern entomologists, the term Hemiptera has been restricted to such insects as have *imperfect metamorphosis* and a *suctorial mouth*.

This definition will include the Linnæan genera *Fulgoria, Cicada, Notonecta, Nepa, Cimex, Aphis, Chermes, Coccus*, and *Thrips*, and these, with the addition of the genus *Pulex*, constitute the order to which Fabricius applies the name of *Ryngota*. Without the last-mentioned genus they constitute the order Hemiptera according to Latreille, Burmeister, and most of the foreign entomologists; and the orders Hemiptera and Homoptera according to Leach, Stephens, MacLeay, and several other British authors.

The Hemiptera are divided by Latreille into two sections; to the first he applies the name of *Heteroptera*, and to the second that of *Homoptera*. The *Heteroptera* are characterized by having the rostrum attached to the fore part of the head; the elytra coriaceous with the extremity membranous, folding one over the other when at rest, and the first segment of the trunk (or the prothorax) the largest, and forming the most conspicuous part of the thorax. The second section, *Homoptera* (which by many of the English entomologists is regarded as an order), is distinguished by the proboscis being attached to the lower portion of the head, near the chest; the elytra almost always of a uniform coriaceous texture, with their inner margin straight and contiguous: the three segments of the thorax are united in a mass, and the first is frequently shorter than the second. All the insects of this section feed exclusively on vegetable juices: their structure is more fully described in the article HOMOPTERA. We shall at present confine our remarks to the first section, or to the true Hemipterous insects.

In the greater number of the Heteropterous Hemiptera the head is small, situated on the same plane as the thorax, or nearly so; the fore part is somewhat produced; the eyes are of moderate size, very convex, and hence project rather suddenly from the sides of the head: between the eyes there are, in many species, two ocelli, or simple eyes; the antennæ are of moderate size, composed of long joints, few in number, and situated in front of the eyes: the part usually termed the thorax in descriptions, but which is in fact the prothorax, is of moderate size, often broader than long, and very frequently produced on each side, so as to form an angular projection; the scutellum is large, generally triangular; but in some (the Scutelleræ, for instance) it assumes the form of the body, and is so large that it completely covers that part; the body itself is often flat or concave above; convex and more or less distinctly keeled beneath: when the wings are closed, the upper part of these insects generally presents a flat or slightly convex surface, and is seldom very convex. The legs are of moderate size, or not unfrequently long. In certain groups (the *Coreidæ*) the posterior thighs of the males of many of the species are remarkably large, and many have the tibiæ also large, often broad and compressed.



The proboscis springs from the fore part of the head, and when not in use is suddenly curved downwards and backwards, and lies close to the under surface of the thorax and between the fore pair of legs. It consists of a jointed process (*a*), which is grooved upon the upper side, and in this groove there are four setæ (*b*), or bristle-like organs, which are covered above, at their base, by another appendage (*c*), which is supposed to be analogous to the upper lip or labrum of mandibulate insects; whilst the four setæ probably represent the mandibles and maxillæ, and the jointed process the labium. In the figure, the setæ (*b*) are represented as disengaged from their sheath (*a*), and the labrum is lifted up. When in the ordinary position these organs form together a tube, by means of which the juices of plants or animals are extracted and conveyed to the œsophagus.

The Heteroptera are divided by Latreille into two families; the first, or the Geocorisæ, are characterized as having the antennæ free, longer than the head, and inserted between the eyes and near their anterior margin. The tarsi are three-jointed, but the first joint is sometimes very short. The second family, to which the name of Hydrocorisæ is applied, have the antennæ enclosed and hidden in a groove beneath the eye; the tarsi have but two distinct joints,* and the eyes are generally very large.

The species of the family Geocorisæ are for the most part found on the leaves of trees or small plants; some there are which do not quit the ground, and there are others which live upon the surface of the water. The genera *Hydrometra, Gerris*, and *Velia*, afford examples of this mode of life. [HYDROMETRIDÆ.]

The insects belonging to the second family (*Hydrocorisæ*) live, as their name implies, in the water, and they prey upon other insects.

The two families which have just been characterized are by most entomologists regarded as sections or subsections rather than families; the latter is in fact an aberrant group, the former containing by far the greater portion of the species. Regarding them therefore as sections, they may be divided into the following families:

Geocorisæ.

Family 1.	Scutelleridæ.	Family 5.	Cimioidæ.
2.	Pentatomidæ.	6.	Reduviidæ.
3.	Coreidæ.	7.	Hydrometridæ.
4.	Acanthiidæ.		

Hydrocorisæ.

Family 1. Nepidæ. Family 2. Notonectidæ.

HEMITONE, an interval in antient music, the ratio of which is $\frac{243}{256}$.

HEMLOCK. [CONIUM.]

HEMP. [CANNABIS.]

HEMP. Our supplies of this article are almost wholly brought from Russia. Of 586,032 cwt. imported in 1836 into the United Kingdom, 556,458 cwt. were shipped at St. Petersburg and Riga. Some trifling shipments are made at ports in the north of Germany and the Netherlands, and a small supply is brought from India. The total quantity of hemp imported in each of the ten years from 1827 to 1836 was—

1827	573,393 cwt.	1832	593,564 cwt.
1828	504,120 „	1833	527,459 „
1829	374,932 „	1834	673,810 „
1830	506,770 „	1835	687,558 „
1831	530,820 „	1836	586,032 „

The price of hemp fluctuated exceedingly during the war. While the ports in the Baltic were closed against us it be-

* The third joint is to be found (at least in some of the species, if not all) within the apex of the tibiæ.

came exorbitantly dear. In the year 1792 the price was 25*l.* per ton, and in 1808 had risen to 118*l.*, under the restrictions imposed on the trade of this country by the Milan and Berlin decrees of Napoleon. By this advance the ingenuity of mercantile men was so stimulated, that the obstacles raised by the governments then subject to the dictation of France were overcome, and the importations, which in 1808 had been only 259,687 cwt., were increased to 858,875 cwt. in 1809, and 955,799 cwt. in 1810, when the price fell to 58*l.* per ton, which rate was below the cost, including the exorbitant freight to which it was subjected. Since the peace in 1815 the price has fluctuated between 24*l.* and 50*l.* per ton; during the last few years it has scarcely ever gone beyond 30*l.* per ton.

HEMSTERHUYS, TIBERIUS, son of a French physician, was born at Groningen, A.D. 1685. He entered the university of that town in his 14th year, and studied theology and philology under Braun, Oriental literature under Schultens, and mathematics and philosophy under Bernoulli. He afterwards went to Leyden to hear the lectures of Perizonius on antient history; where he was engaged to put in order the MSS. belonging to the university library. In his 19th year he was appointed professor of mathematics and philosophy at Amsterdam, and shortly afterwards undertook to complete an edition of Pollux which Lederlin had left unfinished. Bentley in two letters to Hemsterhuys pointed out the faults of this edition; which so much discouraged Hemsterhuys that he did not open a Greek book for two months afterwards. Conscious of his own deficiencies he resolved to acquire an accurate knowledge of the Greek language, and for that purpose read through all the Greek writers in chronological order. In 1720 he succeeded Lambert Bos at Franecker as professor of Greek; and in 1740 removed to Leyden, where he was also professor of the same language. He died 7th April, 1766.

Hemsterhuys did not write much; but he was an accurate and laborious scholar, and it was principally owing to his reputation and exertions that the study of the Greek language, which had been greatly neglected in Holland, again became general in that country. He introduced what has been called the analogical system, which prevailed in the universities of Holland for a long time, and which is fully developed in the writings of Lennep. Hemsterhuys was not only a good classical scholar, but he was acquainted with several of the Oriental languages, and had a considerable reputation for his knowledge of mathematics and philosophy.

The principal works of Hemsterhuys are: the latter part of the edition of 'Pollux' by Lederlin, 1706; 'Luciani Colloquia et Timon,' 1708; 'Plutus' of Aristophanes, 1744; 'Latin Orations,' published by Valckenaer, 1784; Latin Translation of the 'Birds' of Aristophanes, in the edition of Kuster; 'Notes and Emendations on Xenophon of Ephesus,' inserted in the 3rd volume of the 'Miscellanea Critica' of Amsterdam. He also edited the early part of the edition of Lucian, which was completed by Reitz.

The life of Hemsterhuys has been written by Ruhnken. This work has been reprinted at Leipzig, together with the life of Wyttenbach, edited by Lindemann, 8vo., 1822.

HE'NAULT, CHARLES JEAN, born at Paris in 1685, was the son of a fermier-général. He showed at an early age a taste for literature, and wrote several poems. Being made intendant-general of the queen's household, he became by his pleasing address and suavity of manners a great favourite with the high society of the capital. He was also appointed president of the Court of Enquêtes. In 1723 he was made a member of the French Academy. At the age of fifty he withdrew from the fashionable world, and gave himself up entirely to study and to practices of devotion; but his devotion was free from moroseness or superstition. He died at Paris in 1770. Not many years before his death he wrote to Voltaire, with whom he had been on intimate terms, a serious letter representing to him the impropriety and bad taste of his continual sarcasms and invectives against religion. (*Correspondance de Mad. du Deffand*, the 23rd letter of those addressed to Voltaire.). The work for which Henault is best known is his 'Abrégé Chronologique de l'Histoire de France,' which is a very good model of works of that kind. It has gone through numerous editions, and has been translated into several languages. In two small volumes the author has registered under each year every event of any importance in the annals of the French monarchy, from its first establishment to the death of Louis XIV.; with a happy conciseness of expression he has cleared up many doubtful or controverted points, and he has introduced many wise, moral, and political reflections on the character of men and times. The arrangement is clear, and the hand of a man deeply versed in the laws and the records of his country is visible throughout the work. At the beginning of every reign he exhibits in a tabular form the dates of the birth, accession to the throne, and death of the monarch, the names of his wife or wives, and children, those of the contemporary European sovereigns, and those of the ministers, generals, chancellors, and men of learning who lived during that period; and at the end of every dynasty he adds an interesting dissertation on the social, civil, and intellectual condition of France at the time. A good index completes the work. Hénault has had many imitators and continuators, one of whom is the compiler of the 'Revue Chronologique de l'Histoire de France de 1789 jusqu'au 1819,' 1 vol. 8vo., Paris, 1823, in which all the multifarious events of those thirty years are registered in due order. Hénault wrote also 'Histoire Critique de l'Etablissement des François dans les Gaules;' and several dramatic works collected under the title of 'Pièces de Théâtre,' 1 vol. 8vo. 1770.

HENLEY on Thames. [OXFORDSHIRE.]

HENLEY in Arden. [ARDEN; WARWICKSHIRE.]

HENNA. [LAWSONIA.]

HENNEBON. [MORBIHAN.]

HENRI I. of France, son of king Robert, and grandson of Hugues Capet, succeeded his father in July, 1031, being then about twenty-seven years of age. His mother, Constance of Provence, who wished to favour her younger son Robert, excited a civil war, in which Eudes, count of Champagne, and Baldwin, count of Flanders, took her part, while the duke of Normandy assisted Henri. Peace was made by Henri giving to his brother Robert the duchy of Burgundy, which was the beginning of the first ducal house of Burgundy. In the year 1035, Robert le Diable, duke of Normandy, died; and his son William the Bastard, who succeeded him, was assisted by Henri in defeating several rivals who claimed the dukedom. A new pretender however arose some time after in the person of William of Arques, cousin to the late duke; and Henri of France, who had now become jealous of the power of William the Bastard, assisted his competitor, who however was in the end defeated by the Bastard about the year 1047. Henri married, in 1044, Anna, daughter of Jaroslav, duke of Russia, by whom he had several sons, the eldest of whom, Philip, was crowned at Rheims in 1059, at seven years of age, by order of his father, who died in the following year, leaving Philip I. under the guardianship of Baldwin, earl of Flanders. [BALDWIN IV.]

HENRI II., born in 1518, succeeded his father Francis I. in 1547. In 1550 he concluded the war which was then pending with England, which gave up to him Boulogne for the sum of 400,000 crowns. About this time Mary Stuart, the queen of Scotland, then a minor, came to France, under the guardianship of her uncles of Guise, and was betrothed to Francis, son of Henri. In 1552 Henri assisted Maurice, elector of Saxony, and Albert, marquis of Brandenburg, who had united for the defence of the religious and civil liberties of Germany against Charles V. Henri invaded Lorraine and took Metz, Toul, and Verdun, which were from that time annexed to France. It is curious to see the French government, which persecuted Protestantism at home, taking up arms for the professed purpose of supporting the Protestants of Germany. After the abdication of Charles V. the war continued between his successor Philip II. and Henri, whose troops, under the command of the Constable Montmorency, were defeated by the Spaniards at the battle of St Quentin in 1557; the French arms were likewise unsuccessful on the side of Italy, where the duke of Alba commanded the Spaniards. The war ended in 1559, by the peace of Château Cambresis, by which Calais, which had been taken the year before by the duke of Guise, remained in the hands of the French. At the same time a double marriage was concluded between Elizabeth, Henri's daughter, and Philip II. of Spain; and between Margaret, Henri's sister, and the duke of Savoy. The festivals given on this occasion had a tragical end. Henri was accidentally wounded at a tournament by the count of Montgomery, with the shaft of his broken spear, which struck the king on the right eye. Henri died shortly after, July 10, 1559. By his wife Catherine de' Medici he had four sons, of whom three reigned in succession after him, beginning with the eldest, Francis II. He also left several natural children by various mistresses. He had none however by his principal female favourite Diana de Poitiers, whom he made Duchess of Valentinois, and who survived him. The great influence of the Guises began under his reign. [GUISE, DUKES OF.]

HENRI III., born at Fontainebleau in 1551, was the third son of Henri II. Under the reign of his brother Charles IX., when he was called the Duke of Anjou, he fought courageously at the battles of Jarnac and Moncontour against the Huguenots. In 1573 he was elected king of Poland and the successor of Sigismund Augustus. Henri was crowned at Cracow; but a few months after, upon hearing of the death of his brother Charles IX., he suddenly quitted Poland and returned to France, where he assumed the title of Henri III. His reign was a reign of unworthy favourites. A mixture of bigotry and debauchery, of vice and folly, characterized his court. Under his weak administration factions and civil and religious wars desolated France; and instead of checking party spirit he was himself the leader of a party, and that party not the strongest. The king's party stood between the other two parties, that of the Ligueurs under Henri of Guise, and that of the Huguenots under Henri of Navarre, and the war which ensued was appropriately called the war of the three Henris. At last Paris revolted in favour of the Guises, and Henri had recourse to assassination, by causing the Duke of Guise and his brother the cardinal to be murdered. Most of the towns of France, indignant at this base act, rebelled; the parliament of Paris instituted his trial; and the pope excommunicated him. In this emergency Henri felt for a moment his old spirit revive; he applied for assistance to his generous enemy Henri of Navarre, who joined him with his army, repulsed the Duke of Mayenne, the leader of the League, and the two kings laid siege to Paris. During this siege a fanatical Dominican monk, named Jacques Clément, excited by the declamations of the Ligueurs, assassinated Henri III. at St. Cloud. Henri died on the 2nd of August, 1589. He left no issue, and in him terminated the dynasty of Valois, which had reigned in France since the accession of Philip VI., in 1328.

HENRI IV., king of France and of Navarre, born at Pau in the Béarn, the 15th December, 1553, was descended in a direct line from Robert, count of Clermont, sixth son of Louis IX., who married, in 1272, Beatrix of Burgundy, heiress of Bourbon, and assumed the arms and the name of Bourbon. [BOURBON.] Henri's father, Antoine de Bourbon, married Jeanne d'Albret, only daughter and heiress of Henri d'Albret, king of Navarre, after whose death, in 1535, Antoine became king of Navarre in right of his wife. Henri IV., during his youthful years, was trained up to hardiness and privations in his native mountains, after which he was sent to the French court till 1566, when his mother Jeanne d'Albert recalled him to Pau and had him instructed in the Calvinist communion. In 1569 he was acknowledged at La Rochelle as the leader of the Calvinists, and fought at the battles of Jarnac and Moncontour in the same year. After the peace of 1570 he was invited to the French court, and two years after he married Margaret, sister of Charles IX. By the death of his mother, June, 1572, he became king of Navarre. At the massacre of the St. Barthélemi, which followed close upon his marriage, Henri's life was spared on condition of his becoming a Roman Catholic; but as the court did not trust a conversion which was extorted by fear, he was kept under watch as a state prisoner for about three years. Having escaped in 1576, he put himself again at the head of the Calvinists, and began a series of hazardous and hard-fought campaigns, interrupted by short cessations of arms whenever Henri III. of France made promises of peace and toleration to his Calvinist subjects,—promises which he or the Guise never failed to break. Henri won the battle of Coutras in Guyenne, October, 1587, in which his antagonist the Duke of Joyeuse was killed. In 1589 he made his peace with Henri III. and joined him against the League. Henri III. before he expired named the king of Navarre as his successor, telling him at the same time that he wished him a quieter reign than his own had been. Henri however was opposed by one half of the kingdom, which obeyed the Duke of Mayenne, whom the parliament of Paris had appointed Lieutenant-General, and he was obliged to raise the siege of the capital.

He soon after gained the battles of Arques and Ivry, received some reinforcements from Elizabeth of England, and pursued the war with renewed vigour. At last in 1593 Henri began negotiations with several of the leaders of the League, and as a preliminary condition of their submission he was induced to make a public profession of the Catholic faith at St. Denis on the 25th of July of that year. In March 1594 Paris opened its gates to him, and Rouen and other cities followed the example of the capital. Charles, duke of Guise, likewise made his submission. In the following year the Pope acknowledged Henri, and in 1596 the Duke of Mayenne submitted. It was not however till 1598 that all France acknowledged Henri, nine years after his assumption of the crown. The peace of Vervins, concluded in that year, put an end to the interference of Spain in the affairs of France. From that time till his death Henri enjoyed peace, with the exception of a short campaign against the Duke of Savoy in the year 1600, which terminated in favour of the French arms.

The king applied himself to reform the administration of justice, to restore order in the finances, and to promote industry and commerce. He established new manufactories; he introduced plantations of mulberry-trees and the rearing of silkworms, and he began the botanical garden of Montpellier. He embellished Paris, and founded the hospital of La Charité Chrétienne for invalid officers and soldiers; he added to the collection in the royal library, and encouraged and rewarded men of learning, among others Grotius, Isaac Casaubon, Joseph Scaliger, De Thou, Malherbe, &c. In his foreign politics he was the ally of England; he supported the independence of Holland, and took the part of the Protestants of Germany against the encroachments of Rudolf II. Henri was censured for his change of religion, and by none more earnestly than by his faithful friend and counsellor Duplessis Mornay. On the other hand, many of the Catholics never believed his conversion to be sincere. But the truth probably was that Henri, accustomed from his infancy to the life of camps and the hurry of dissipation, was not capable of serious religious meditation, and that he knew as little of the religion which he forsook as of that which he embraced. In his long conference at Chartres in September, 1593, with Duplessis Mornay, which took place after his abjuration, he told his friend that the step he had taken was one not only of prudence, but of absolute necessity; that his affections remained the same towards his friends and subjects of the Reformed communion, and he expressed a hope that he should one day be able to bring about a union between the two religions, which, he observed, differed less in essentials than was supposed. To which Duplessis replied, that no such union could ever be effected in France unless the Pope's power were first entirely abolished. (*Mémoires et Correspondance de Duplessis Mornay depuis l'an* 1571 *jusqu'en* 1623, Paris, 1824-34.)

By the Edit de Nantes, promulgated in 1598, Henri gave what he thought a full redress of the grievances under which his Protestant subjects had so long laboured, and such it would have proved, had the provisions of the edict been honestly and fully carried into effect, and had not the king's intentions been frustrated in great measure by the intolerance of the different parliaments and courts of justice. Henri found the finances of the kingdom in a most wretched condition; of 150 millions of livres taken from the people only 30 millions reached the king's coffers. His able minister Sully had the task of restoring order in this financial chaos. He adopted the method of letting the taxes by public auction; he entered into a rigorous examination of the accounts of former receivers-general and other agents, and introduced forms of accounts which were to be filled up and accompanied with the necessary vouchers, so that no pretence was left for obscurity or omission. During a ministry of fifteen years he reduced the taille five millions of livres, and other imposts one half: he redeemed 135 millions of debt, while he added four millions to the king's revenue, and left 35 millions in the treasury, besides a value of 12 millions in arms and ammunition, five millions expended in fortifications, and above 26 millions on public works and royal gratuities. (Bresson, *Histoire Financière de la France*, Paris, 1829.) The sympathy which Henri felt and showed for the humbler classes of his subjects, whom his predecessors had looked upon as an inferior race of beings, would alone be sufficient to account for his popularity with the French people, a popularity which has survived all the eventful changes in that country. He is the only king of the old monarchy whose memory is still popular in France. His brilliant qualities, his tastes, even his failings, such as his excessive gallantry, were national, and they flattered the self-love and the vanity of the people. 'He was,' says the President Hénault, 'his own general and his own minister. He united to a blunt frankness the most dexterous policy, to the most elevated sentiments a delightful simplicity of manners, and to an undaunted courage a most touching feeling of humanity and benevolence.' He often forgave, and when forced to punish, as in the case of Biron, he did it with extreme regret. His life was repeatedly attempted by assassins who were stimulated by the old fanaticism of the League; and at last he was stabbed to death in his carriage, by Ravaillac, on the 14th May, 1610. He was succeeded by his son Louis XIII. under the guardianship of his consort Maria de' Medici. The grief for his death was deeply felt all over France. (*Mémoires de Sully;* Hénault and the other French historians; Thomas, *Essai sur les Eloges;* and a collection of Henri's most remarkable sayings and doings, entitled *L'Esprit de Henri IV.*, Paris, 1769.) Lenglet du Fresnoy, in the 4th vol. of his *Journal de Henri III.*, has published many letters of Henri IV. When the royal tombs at St. Denis were ransacked in the time of the Revolution, 1793, the body of Henri IV. was found in very good preservation: his features appeared hardly changed.

HENRY I., King of England, surnamed Beauclerc, or the Scholar, was the fourth and youngest son of William the Conqueror, by his queen Matilda of Flanders, and was born in 1068 at Selby in Yorkshire, being the only one of the sons of the Conqueror who was an Englishman by birth. His surname attests that he had received a more literary education than was then usually given either to the sons of kings or to laymen of any rank; and this advantage was seconded by natural abilities of a superior order. From an early age he and his next brother, William, appear to have monopolized the favour of their father to the exclusion of his eldest son, Robert Richard, the second son, died in his youth); and Robert's first recourse to arms is even attributed to his indignation at having one day had a pitcher of water thrown down upon his head, in mockery or sport, at the town of L'Aigle in Normandy, by his two younger brothers, and at his father's refusal to punish them for the insult. If this incident took place at all it must have been when Henry was a mere child, not beyond his eighth or ninth year:—his brother William was about twelve years his senior. In the last days of their father's reign jealousies arose between these two brothers; and in this new family quarrel the father seems to have attached himself to the one who was on the whole most like himself in character. At his death in 1087, the Conqueror expressed his wish that William should be his successor in the crown of England, and only left Henry a legacy of 5000*l.* of silver. With 3000*l.* of this however Henry soon after obtained, from the facility of his brother Robert, the whole of the district of Cotentin, comprehending nearly a third of Normandy. Although in the first instance a quarrel between the two arose out of this bargain, they were afterwards reconciled; and in 1090, when the intrigues of William, now king of England, had excited a revolt of the Norman barons against Robert, Henry came to the assistance of the latter, and was chiefly instrumental in putting down the insurrection. Upon this occasion Henry gave a striking proof of the relentless determination of his character. Conan, a rich burgess of Rouen, one of the most active and powerful of those who had taken part in the treason, having fallen into the hands of his enemies, Duke Robert thought it punishment enough to condemn him to perpetual imprisonment; but Henry, deeming it expedient to have better security against his future attempts, led the unfortunate man, on pretence of giving him a view of the surrounding country, to the highest tower of the castle in which he was confined, and threw him over the battlements. When Robert and William made peace the following year, they turned their united arms against Henry, who was soon compelled to evacuate even his last stronghold, the fortress built on the lofty rock of St. Michael, after which he wandered about for some two years in a state of nearly complete destitution. At length, on the invitation of the inhabitants of the town of Domfront, he assumed the government of that place; and it would appear that from this *point d'appui* he gradually raised himself to the repossession of nearly all the territory that he had lost. He also became reconciled to Rufus, and was in England and in the New Forest with that king when he came by his death (2nd August, A.D. 1100). That sudden and mysterious event (which very possibly his hand or his contrivance may have caused, and into which at least he never instituted any inquiry), made Henry king of England. His reign is reckoned from Sunday the 3rd of August, on which day he was crowned in Westminster Abbey by Maurice, bishop of London. The next day he published a charter confirming the rights and liberties both of the church and of the nation, and promising the restoration of the laws of the Confessor, with only such alterations as had been made in them by his father. All the circumstances of Henry's accession furnish strong evidence of the great importance which the Saxon population had already recovered since the Conquest. Henry from the first put forward his English birth as one of his chief claims to acceptance with his subjects; and he hastened to strengthen this title by an act which almost amounted to a tacit admission that the rights of the old Saxon line were not yet extinct, his marriage with Maud, or Matilda, daughter of Malcolm, king of Scotland, and niece of Edgar Atheling, which, after a delay occasioned by the reluctance of the princess to unite herself to the supplanter of her house, and by the circumstance of her having been at least designed to pass her days as the inmate of a nunnery, if she had not actually taken the veil, was at last celebrated on Sunday the 11th of November. As soon as he assumed the crown Henry affected a complete change of manners, laying aside the open licentiousness in which he had heretofore indulged, and with much apparent zeal clearing the court of the mistresses and profligate minions of the late king; but this show of reformation, like most of his other professions, was soon found to be merely an expedient adopted for the purposes of the moment.

The history of the reign opens with the contest between Henry and his elder brother for the crown. At the moment of the death of Rufus the gallant and thoughtless Duke Robert, after a brilliant career of arms in the Holy Land, was lingering on his return home in the south of Italy, detained there by the fascinations of the beautiful Sibylla, daughter of the count of Conversano, whom he eventually married and brought with him to Normandy. After his arrival in his own territories he threw away more time in a succession of festive displays; but at last he prepared to make a descent upon England. He landed with a considerable force at Portsmouth, soon after Whitsuntide, A.D. 1101. But this effort ended in nothing: Henry, having an army assembled at Pevensey, marched forward, and overtook his brother before he could reach Winchester, of which it was his object to obtain possession. After some negotiation the two princes met in a vacant space between the armies, and in a few minutes agreed to make up their differences on the terms of Henry retaining England, and Robert Normandy, with the proviso that, if either died without legitimate issue, the survivor should be his heir. The easy temper of the one brother and the craft of the other are equally conspicuous in this treaty, by which Henry extricated himself, at little or no cost, from all the inconveniences and hazards of his present position, while Robert at once relinquished the whole object in dispute, bating only what part of it he may have conceived was made over to him in his qualified and precarious reversionary right. It was by no means Henry's intention however that he should escape even at this sacrifice. Several of the English barons who possessed estates in Normandy, anxious for their own interests to secure the union of the two countries, had taken part in Robert's attempt: it was one of the stipulations of the treaty that a full pardon should be extended to all the subjects of either brother who might thus have gone over to the other; but no sooner was the duke returned to Normandy than Henry proceeded to take systematic measures for effecting the ruin of the leading barons who had deserted him. In this way he soon provoked a series of petty insurrections in England, which he easily crushed, extinguishing thereby, one after another, all the persons that were most obnoxious to him, and acquiring their estates to distribute among new men that were his devoted adherents. These proceedings could not fail to rouse the indignation of Robert; and Henry was not slow in taking advantage of the courses into which his irritated feelings drove him, to declare that the peace between them was for ever at an end. Circumstances were now in every way much more favourable for the English king than when he formerly contrived to avoid a contest of arms with his brother: on the one hand, some years of possession had established him more firmly on his throne; on the other, the strength of Duke Robert was broken and wasted, and his extravagance and misgovernment had both dissipated his means of every description and loosened the very tenure of his sovereignty. Henry, in the first instance, called upon him to cede the duchy for a sum of money or an annual pension: he then (A.D. 1105), on this demand being scornfully rejected, crossed over to Normandy at the head of an army, and speedily made himself master of many of the chief places of strength.

The following year the English king, who had returned home, again crossed the seas with a more numerous force than before. About the end of July he commenced the siege of the castle of Tenchebrai; Robert, after some time, advanced to its relief; and on the 28th September a long and sanguinary battle was fought between the two brothers before the walls of that fortress, the result of which was the utter ruin of Robert and his cause. He himself, after a last splendid display of the heroic valour which he had always shown, was taken prisoner, with 400 of his knights. He was condemned by his brother to confinement for life. According to Matthew Paris, an unsuccessful attempt which he soon after made to effect his escape was diabolically punished, on the order of his merciless brother, by the extinction of his sight: a basin of iron made red-hot was held before his eyes, which were kept open by force, until they were burned blind; and in this state the miserable prince survived for twenty-eight years, dying in Cardiff Castle, at the age of eighty, in February, 1135, not quite twelve months before Henry. Immediately after the victory of Tenchebrai Henry was, without opposition, acknowledged their duke by the Norman barons. About the same time also was terminated by a compromise, for the present, the dispute with Anselm, the archbishop of Canterbury, on the subject of investitures, which had been proceeding ever since the commencement of the reign. [ANSELM.]

The next six or seven years passed without any events of much moment. In 1113 however Henry was attacked in Normandy by Louis VI. of France, and Fulk, earl of Anjou, acting in confederacy in support of the interests of William, styled Fitz-Robert, the son of Duke Robert, who had escaped the vengeance of his uncle, and became from this time a rallying-point for the friends of his father's house and the enemies of the English king. The war lasted for about two years, and was on the whole adverse to Henry; but he then managed, with his usual dexterity, to bring it to a close by a treaty, which restored to him all that he had lost, and for the present wholly detached the earl of Anjou from the cause of his young protégé. It had been agreed that a marriage should take place between William and the earl's daughter Sibylla. That project was now given up, and it was arranged instead that Matilda, another daughter of the earl, should be united to Henry's only son, Prince William of England. But Henry seems to have made this engagement with no intention of ever fulfilling it: as soon as it had served its immediate purpose, he showed in the most open manner his disregard of every stipulation of the treaty. The consequence was the formation against him of a second Continental confederacy, in which the earl and the king of France received the active and zealous co-operation of Baldwin, earl of Flanders. Another war of about two years followed, in which success inclined sometimes to the one side, sometimes to the other; but the death of the earl of Flanders of a wound received at the siege of Eu, the secession of the earl of Anjou, again drawn off by a renewal of the proposal for the marriage of his daughter, the intrigues of Henry with the disaffected Norman barons, and, finally, the mediation of the pope, brought it also, in 1120, to a termination entirely favourable to the English king.

Immediately after this peace Henry's brightest hopes were turned to sudden night by the frightful calamity of the loss, on Friday, the 25th November, of the ship in which his son had embarked at Barfleur for England: with the exception of one individual, a butcher of Rouen, all on board perished, to the number of nearly 300 persons, including the prince, his half-brother Richard, his half-sister Marie, and the earl of Chester, with his wife and her brother, who were the niece and nephew of the king, among 140 of the members of the most noble houses of England and Normandy, of whom eighteen were females. Henry is said never to have been known to smile after this blow. It did not however extinguish his spirit of ambition. Two years before this he had lost his consort, the good Queen Maud; and a daughter, Matilda, married in 1114 to the Emperor Henry V., was now his only legitimate progeny. In the hope of male offspring, he now (2nd February, 1121) espoused the young and beautiful Adelais, or Alice, daughter of Geoffrey, duke of Louvaine. Scarcely had he entered into this alliance when he found himself called to meet a new revolt in Normandy, excited by the restless Fulk, earl of Anjou, who now having lost all hope of the English marriage, had renewed his connection with Fitz-Robert, and again affianced to him his younger daughter Sibylla, putting him in the mean time in possession of the earldom of Mons. But this movement was very soon put down by Henry, who also contrived once more to gain over the fickle and venal earl of Anjou, and so to deprive the Norman prince of the hand of the fair Sibylla, when he had it almost in his grasp.

When four or five years of his second marriage had passed without producing any issue, Henry determined upon the bold enterprise of endeavouring to secure the succession to his dominions for his daughter, the empress Matilda, who had become a widow by the death of her husband in 1125. On Christmas-day, 1126, she was unanimously declared his heir, in a great council of the lords spiritual and temporal assembled at Windsor Castle. The following year, in the octaves of Whitsuntide, she was married to Geoffrey, surnamed Plantagenet, the son of Fulk, earl of Anjou, to whom, although only a boy of sixteen, his father had renounced that earldom on his departure for the Holy Land, where he was a few years afterwards elected king of Jerusalem. Soon after this settlement of his daughter, Henry was relieved of a source of perpetual annoyance and apprehension by the death of his nephew William Fitz-Robert, which took place 27th July, 1128, in the twenty-sixth year of his age. This prince had not been abandoned by King Louis of France, who, after giving him in marriage Joan of Morienne, the sister of his queen, had first put him in possession of the countries of Pontoise, Chaumont, and the Vexin, and then, on the murder of Charles the Good, had invested him with the earldom of Flanders. The intrigues and the money of Henry however speedily stirred up against him a revolt of a party of his Flemish subjects, who putting Thiodric, or Thierry, landgrave of Alsace, at their head, endeavoured to drive him from the country; and it was in a battle with Thierry, under the walls of Alost, that, in the moment of victory, he received the wound of which he soon after died in the monastery of St. Omer. It was not however till March, 1133, that Henry's longings for a grandchild were gratified by the birth of Matilda's first child, Henry, styled Fitz-Empress, afterwards Henry II. Two other sons, Geoffrey and William, were born in the course of the next two years. These events had been preceded by such dissensions between the ex-empress and her husband as at one time occasioned their separation; and now that they were again living together, Henry and his son-in-law quarrelled about the Norman duchy, of which the latter wished to be put in immediate possession, according to a promise which he said had been given on his marriage. From these family broils Henry was only delivered by his death, which took place at Rouen on Sunday, the 1st December, 1135, being the seventh day of an illness brought on by eating to excess of lampreys, after a day spent in hunting. He had completed the 67th year of his age and the 35th of his reign.

Besides the son and daughter born in wedlock that have already been mentioned, the genealogists assign to Henry I. the following natural children:—1. Robert, earl of Gloucester, who died, after a distinguished career, in 1146, by Nesta, daughter of Rhees-ap-Tudor, prince of South Wales,; 2. Richard, drowned in 1120 with Prince William, by the widow of Anskil, a nobleman of Berkshire; 3. Reginald, earl of Cornwall, who died in 1176, by Sibylla, daughter of Sir Robert Corbet, and wife of Henry Fitzherbert; 4. Robert, by Editha, daughter of Sigewolf, a Saxon nobleman; 5. Gilbert; 6. William, surnamed de Tracy; 7. Henry Fitz-Herbert, who was killed in battle in 1197, also, according to one account, by Nesta; 8. Marie (otherwise called Maud, or Adela), countess of Perche, another of those who perished in the shipwreck of 1120; 9. Maud, married to Conan the Gross, earl of Brittany; 10. Juliana, married to Eustace of Breteuil, earl of Pacie in

Normandy; 11. Constance, married to Roscelin, Viscount Beaumont in France; 12. another daughter, married to William Goet, a Norman; 13. another, married to Matthew Montmorency, the founder of the illustrious French family of that surname; and 14. Sibylla (otherwise called Elizabeth), who was married in 1107 to Alexander I. of Scotland, and died in 1122, by Elizabeth, wife of Gilbert de Clare, earl of Pembroke, and father by her of the famous Strongbow. (See accounts of these personages and their descendants in Fisher's *Companion and Key to the History of England*, 8vo., London, 1832.)

The character of Henry is sufficiently indicated by the facts that have been detailed. In a moral point of view it was detestable, but in the line of policy and craft it evinced superlative ability. In the midst of all his profligacy and unscrupulous ambition however he cherished a love of letters, and in his hours of leisure was fond of the society of learned men. It must be admitted also that his government, though still arbitrary and tyrannical in a high degree, appears to have been on the whole a considerable improvement on that of his father and his elder brother. He may be said to have led the way in the reformation of the law and the constitution by his re-establishment, partial as it was, of the Saxon laws, and by his charter, the example of that series of subsequent royal concessions, the same in form though much more extended in amount, which lie at the foundation of the national liberties. There can be no doubt that the country made considerable social progress in his reign, undisturbed as it was by any internal commotion, and enjoying, notwithstanding much oppression on the part of the crown, probably a more regular dispensation of justice between man and man, and more security from disorder and violence, than it had known since the coming over of the Normans. Henry I. was succeeded on the throne of England by Stephen.

HENRY II., surnamed Fitz-Empress, was the eldest son of Geoffrey Plantagenet (so named from a sprig of broom—in Latin, *planta genista*—in French, *plante genêt*—which he used to wear in his cap), earl of Anjou, and of Matilda, daughter of Henry I. king of England, whose first husband had been the Emperor Henry V. [HENRY I.] He was born at Le Mans, the capital of his father's dominions, in March, 1133. In the struggle between Stephen and Matilda for the English crown [STEPHEN], Matilda's husband Geoffrey had, by the year 1141, reduced nearly the whole of Normandy, and his infant son Henry had been acknowledged by the majority of the nobility of that country as their legitimate duke. In June of the following year Matilda's great supporter, her bastard half-brother Robert, earl of Gloucester, passed over to Normandy, and returned to England in December, bringing Prince Henry along with him, together with a small body of troops, obtained from the earl his father. Here the boy remained for nearly five years shut up for safety in the strong castle of Bristol, where his education was superintended by his excellent uncle Gloucester, who was distinguished for his scholarship and love of letters. He returned to his father in Normandy about Whitsuntide, 1147. In 1149 however, being now sixteen years of age, he recrossed the seas, and, at an interview held on Whitsuntide in Carlisle with his uncle David I. of Scotland, received from that prince the honour of knighthood, and concerted measures with him and his other friends for recovering his grandfather's throne. He returned to Normandy in the beginning of the following year, and was a few months afterwards, with the consent of his father, formally invested with that dukedom by Louis VII. of France, the portion of the country called the Vexin being ceded to Louis as the price of his consent to such arrangement. By the death of his father, 10th September, 1151, Henry became earl of Anjou, Touraine, and Maine. On Whitsunday of the year following, within six weeks after she had been divorced from her first husband, King Louis of France, he married Eleanor, in her own right countess of Poitou and duchess of Guienne or Aquitaine, an alliance which made him master of all the western coast of France, with the exception only of Brittany, from the Somme to the Pyrenees. Soon after this Henry sailed for England at the head of a small but well-appointed force. He and Stephen, having advanced, the one from the west, the other from the east, came in sight of each other at Wallingford, and in an interview which they had there, standing on opposite sides of the Thames, agreed to a truce. The death of Eustace, Stephen's eldest son, having removed the chief obstacle to a permanent arrangement between the two competitors, a peace was finally adjusted in a great council held at Winchester, 7th November, 1153, in which Stephen, adopting Henry for his son, appointed him his successor and gave the kingdom of England, after his own death, to him and his heirs for ever. The death of Stephen, 25th October, 1154, made Henry, in conformity with this agreement, king of England without opposition.

The commencement of the reign of Henry II. is reckoned from his coronation at Westminster along with his queen, 19th December, 1154. His first proceedings were strikingly indicative of the system of combined energy and policy which continued to characterize his government. He dismissed the foreign troops which Stephen had brought into the kingdom; razed to the ground nearly all the numerous castles that had been erected throughout the country by the barons in the preceding twenty years of anarchy; and resumed with remorseless determination all the lands that had been alienated from the crown since the death of Henry I., the grants only excepted that had been made to the church and to William, the second son of Stephen. This last act o rigour, the most daring upon which he adventured, was undertaken with the express concurrence of the great council or assembly of the immediate tenants of the crown. He next proceeded to settle the succession, and for that purpose a great council was assembled at Wallingford, soon after Easter, 1155, which ordained that after his death the crown should descend to his eldest son William, now in his third year, and in case of the death of William (which in fact took place the following year), to his younger brother Henry, who was as yet only a few months old. Oaths of fealty were at the same time taken to both the young princes; 'and we may undeniably infer from this,' observes Lord Lyttleton, 'as well as many other facts, that no right of birth, how indisputable soever, was thought in those days a sufficient title to convey the succession, without a parliamentary acknowledgment of it, followed and confirmed by feudal engagements.' Such ratifications were at least regarded as an important security, if not as essential. It was in another council, or parliament, as some writers call it, held at London after these arrangements had been made, that Henry, in conformity with the now established practice, granted a short charter, confirming, for himself and his heirs, to the clergy, the nobility, and the commonalty, all the rights, liberties, and customs (*consuetudines*) which had been conceded by his grandfather Henry I.

His presence was now called for across the seas by the attempt of his younger brother Geoffrey to wrest from him his paternal inheritance of Anjou, Touraine, and Maine, on the pretence, as stated by some authorities, that the will of their father had directed that Henry should resign these earldoms as soon as he should have obtained possession of the English crown. After a very short contest Geoffrey was forced to give up his claim in exchange for a pension of 1000 English and 2000 Angevin crowns, which he enjoyed little more than a year. He died in 1158 at Nantes, the inhabitants of which city had chosen him for their governor, in consequence of which circumstance the place was immediately claimed by Henry, as having devolved to him as his brother's heir. Partly by force, partly by management, Henry succeeded in acquiring through this claim first the virtual and eventually the actual possession of the whole of Brittany; the only portion of territory that was wanting to complete his sovereignty over all the western coast of France, and indeed over nearly the entire half of that kingdom. Conan, the hereditary count or duke of Brittany, who was also earl of Richmond in England, was now in the first instance induced, or compelled, to sign a treaty by which he bequeathed the country after his death to his daughter Constantia, an infant, whom he affianced to Henry's youngest son Geoffrey. At the same time the neutrality of Louis of France was secured by another arrangement, according to which it was agreed that Henry's eldest son, William, should marry that king's infant daughter Margaret (her mother was Constance of Castile, whom Louis had married after his separation from Eleanor), three castles in the Vexin being made over along with the princess as her dower. Henry had already recovered from the young Malcolm IV. of Scotland the northern counties which had been taken possession of by his predecessor David I., and the cession of which in perpetuity had been one of Henry's engagements with his uncle in 1149; he had also driven back the Welsh from those parts of the English territory which they had seized during the reign of Stephen, and even, as it would appear, compelled the princes of North and South Wales to acknowledge him as their feudal superior. His next attempt was upon the great French earldom of Toulouse, which he claimed in right of his wife Eleanor, whose grandfather William, duke of Aquitaine, had married Philippa, the only child of William, the fourth earl of Toulouse. He was here opposed both by Raymond de St. Gilles, the descendant of a brother of earl William, in whose line the principality had descended for nearly a hundred years, and by Louis of France, whose sister had married Raymond, and to whom, besides, the progressive aggrandizement of his ambitious vassal was every day becoming a subject of more serious alarm. Henry's expedition to France in support of this claim is memorable for the introduction of the practice of commuting the military service of the vassals of the crown for a payment in money, an innovation the credit of which is attributed to Thomas à Becket, recently elevated to the place of chancellor of the kingdom. [ESCUAGE.] The contest which ensued was suspended by a peace in May, 1160, by which Henry was allowed to retain a few places he had conquered in Toulouse; and although it soon broke out anew, it was after a few months put an end to by a second peace, concluded in 1162 by the mediation of pope Alexander III.

The history of the reign of Henry II. for the next eight years is principally that of his contest with the haughty and intrepid churchman, who, from an obscure origin having advanced through the degrees of royal favourite, prime minister, and chancellor, to the ecclesiastical sovereignty of archbishop of Canterbury, forthwith proceeded to assume the bearing of a rival monarch, and made his former master feel that he was only half king in the dominions he called his own. [BECKET.] This struggle for supremacy between the church and the state was not even terminated by the murder of Becket, 29th December, 1170: the blood of the martyr crying from the ground was found to be still more powerful than had been his living voice. In 1174 Henry performed an abject penance at his tomb for having been the unintentional instigator of his slaughter; and two years after, the famous constitutions of Clarendon, passed in 1164, by which the clergy had been made amenable to the civil courts, and the church in other respects subjected to the royal authority, were, after having been long practically disregarded, at last formally repealed in a great council held at Northampton.

Meanwhile two formidable insurrections of the Welsh in 1163 and 1165 had been repressed with great devastation of their country, and, in the second instance especially, with unusual cruelty. In 1166 a revolt of the people of Brittany against their duke Conan afforded Henry, after putting it down with his customary promptitude and vigour, a pretext for taking the government of the country out of the hands of that feeble dependent, and assuming to himself the direct administration of affairs in the name of his son Geoffrey and Conan's daughter Constantia, between whom, young as they both still were, the marriage ceremony was now solemnized for the sake of this arrangement. On the 10th of September, 1167, Henry's mother, the ex-empress Matilda, died at Rouen. Some further hostilities in which he now became involved with the French king were, before producing any important result, terminated by a new peace concluded at Montmirail, 6th January, 1169. By this treaty it was arranged that Henry, the king of England's eldest son, should do homage to Louis for the earldoms of Anjou and Maine, and that his second son Richard should in like manner hold the duchy of Aquitaine of the French king, and espouse Adelais, or Alice, the youngest daughter of Louis. But the greatest event which divided the manifold activity of king Henry with the affairs of Becket was the conquest of Ireland, which was begun in 1169 by a body of private adventurers, headed by Richard de Clare, earl of Pembroke, the celebrated Strongbow, and completed by Henry in person, who crossed over from Milford to Waterford with a powerful armament, 18th October, 1171, and after making an unresisted progress through the country, during which he received the submission of the princes of all parts of it except Ulster, and holding his court or assembling councils at Dublin, Cashel, and elsewhere, sailed back from Wexford to Portfinan in Wales, on Easter Monday, the 17th of April, 1172. The national spirit however recovered itself after this first prostration, and a protracted struggle ensued between the people and their invaders; but the acquisition of Ireland was finally sealed by a formal treaty concluded in 1175 with Roderick O'Connor, considered the head king of the country, in which he consented to become Henry's liegeman, to pay an annual tribute, and, although he was still to retain his nominal royalty for his life, to hold his crown in subjection to the English king.

Much of the remaining portion of Henry's life and reign presents an involved and deplorable scene of family discord and contention; sons against their father, wife against husband, brother against brother. His eldest son Henry had not only been invested, as mentioned above, with the earldoms of Maine and Anjou, but, being then sixteen years of age, had, after the custom which prevailed in the French monarchy, been, as heir apparent, solemnly crowned in Westminster Abbey on Sunday, 15th of June, 1170. On this account that prince is in old writings sometimes styled Henry III., and his common title during his life was from this date the junior or younger king; that of the senior or elder king being given to his father. In 1172 the ceremony of his coronation was repeated, his wife Margaret of France being this time crowned along with him. Soon after this, at the instigation, it is said, of his father-in-law king Louis, the prince advanced the extraordinary pretension that he had become entitled actually to share the royal power with his father, and he demanded that Henry should resign to him either England or Normandy. His refusal was speedily followed (in March, 1173) by the flight first of the prince, then of his younger brothers Richard and Geoffrey, to the French court. Richard professed to consider himself entitled to Aquitaine in virtue of the homage he had performed to Louis for that duchy after the peace of Montmirail, and Geoffrey founded on his marriage and his investiture some years before with the principality of Brittany a similar claim to the immediate possession of that territory. About the same time queen Eleanor also left her husband to associate herself openly with the rebellion of her sons, of which she had in fact been the prime mover, for Henry's infidelities and neglect—the appropriate retribution of the indecent precipitancy with which she had thrown herself into his arms—had long changed this woman's love into bitter hatred and thirst of revenge. She was also making her way for the French court, nothing perplexed, as it would seem, by the awkwardness of seeking the protection of her former husband, when she was caught dressed in man's clothes and brought back to Henry, during the rest of whose life she remained in confinement. Her capture however did not break up the unnatural confederacy of her sons. We can only notice the leading incidents of the confused and revolting drama that ensued. The cause of young Henry was supported not only by Louis, but also by William of Scotland, and by some of the most powerful both of the Norman and the English barons. With his characteristic energy and activity however the English king made ready to meet his various enemies at every point. Hostilities commenced both on the Continent, whither Henry proceeded in person, and on the Scottish borders, in the summer of this same year. Occasionally suspended, and again renewed, the war continued for about two years, during which the most important event that happened was the capture of king William of Scotland at Alnwick Castle, by the famous chief-justiciary Glanville, 12th July, 1174, which appears to have been the Saturday following the Thursday on which Henry did penance before the tomb of Becket at Canterbury. Soon after this Henry, who had throughout decidedly the best of the contest, assented to the petition of his sons for a peace; he and king Louis restored whatever they had taken from each other, and young Henry, Richard, and Geoffrey were gratified with the possession of one or two castles each, and liberal allowances from the revenues of the provinces to which they had severally laid claim. A new quarrel broke out between Henry and his eldest son the following year, but they were reconciled before they had time to betake themselves to arms. Meanwhile in December, 1174, a treaty with Scotland had been signed at the castle of Falaise, in Normandy, by which the Scots agreed to make acknowledgment of the feudal dependence of their crown on that of England, in return for the liberation of king William. The period of seven or eight years that followed was the most tranquil of Henry's reign, and that in which his greatness stood at the highest. With his ancestral dominions of England, Normandy, and

Anjou undisturbed by any rival claimant, his matrimonial acquisitions of Aquitaine and Poitou bound in the subjection of fear, if not of attachment, his conquest of Ireland secure, the Welsh and the Scotch reduced to submission and to the acknowledgment of his supremacy, he was undoubtedly at this time the most powerful of the European sovereigns. In 1183 however another outbreak of the fierce and turbulent spirit of the princes led the way to a new succession of family wars. This time Richard took up arms against Henry and Geoffrey, because his father called upon him to do homage to Henry for Aquitaine. A reconcilement between the brothers, effected by their father's interference, only suspended hostilities for a few months; the old king and his son Richard were then compelled to take the field against the other two. After deserting his father and his youngest brother alternately about half a dozen times, Prince Henry was suddenly taken ill, and died at Château-Martel, 11th June, 1183, in the twenty-seventh year of his age. Geoffrey still held out, supported by the chief nobility of Aquitaine, where there was a strong feeling of the people against the English king for his treatment of their hereditary chieftainess Eleanor; but he too in a short time made his submission and implored his father's pardon. A solemn family reconciliation then took place, at which even Eleanor was released from her prison and allowed to be present. But it did not last for more than a few months; Geoffrey then, in consequence of his father refusing to surrender to him the earldom of Anjou, fled to the court of France, where Philip II. was now king, and prepared for a new war; but before he could carry his design into execution he was, in August, 1186, thrown from his horse at a tournament, and so severely injured that he died in a few days after. No sooner was Geoffrey thus removed than his brother Richard hastened to the French court to take his place; but after unsuccessfully attempting to excite a new revolt in Aquitaine, he was compelled to throw himself upon his father's clemency. A project of a new crusade, at the call of pope Clement III., in the beginning of 1188, for a moment united Henry and Philip; the impetuous Richard actually took the cross, carried away by the feeling which thrilled all Europe on the arrival of the news of the capture of Jerusalem by Saladin in the preceding September; but before the end of the same year the unhappy father saw his son again bearing arms against him in alliance with the French king. The pretext on the part of Philip and of Richard for this new war was Henry's refusal to deliver up the princess Alice, the sister of the former, and the affianced bride of the latter, whose person as well as part of her dowry he had for many years had in his possession. Richard pretended to believe that his father wished to marry the princess himself, and even asserted or insinuated that her honour had already fallen a sacrifice to Henry's passion; it appears to be certain however that her restitution was only made a demand of the two confederates for popular effect, and was a very small part of their real object. Richard, having first done homage to Philip for all his father's Continental possessions, immediately proceeded to wrest them from the old man by the sword. Henry's spirit seems now to have given way at last, and the resistance he offered to his son was feeble and ineffective. The pope made an attempt to bring about a reconciliation, which failed; in the end Henry was compelled to sue for peace, on which he and Philip met on a plain between Tours and Azay-sur-Cher, when it was agreed, among other humiliating conditions, that all Henry's vassals, both Continental and English, should do homage to Richard, in acknowledgment of his rights as heir apparent, and that all those persons who had taken his side should from that time be considered as his liegemen, unless they should of their own accord return to his father. Henry was stretched on a sick-bed when this treaty was read to him; but when he found in the list of those that had deserted him to join Richard, his youngest and favourite son John, whose fidelity till now he had never had cause to suspect, the discovery appears to have broken his heart; he turned himself to the wall, saying that all his interest in the world was over. He was soon after removed to Chinon, on the Loire; and there, after a few days more of suffering, he died, 6th July, 1189, in the fifty-seventh year of his age and thirty-fifth of his reign. He was buried in the choir of the abbey of Fontevraud, in the presence of his son Richard, who succeeded him on the throne.

The character of this great king is a mixture of all the qualities, good and bad, naturally arising out of a strong intellect, a strong will, and strong passions. His faculties had in early life received a learned training, and to the end of his days he preserved an attachment to literature and to the conversation of scholars. The age was distinguished throughout Western Europe, both from that which preceded and from that which followed it, by a revival of elegant letters, which, from its speedy evanescence, appears to have been premature; and Henry drew around him many of the chief lights of the time, both natives of England and of other countries. Among these two of the most conspicuous names were John of Salisbury and Peter of Blois, both of whom have left us ample testimony, in their writings, how greatly they were dazzled by his brilliant and commanding genius. And if on the one hand he was ambitious, unscrupulous, licentious, and easily kindled to frantic excesses of rage, it must be admitted on the other that he was neither a cruel nor a vindictive or unforgiving enemy, and that he was far from incapable of generous and kindly emotions. He has that hold upon our sympathies which springs from the feeling that his enemies were worse men than himself, and from the pity excited by the tragic close as contrasted with the earlier course of his history, which taken altogether is one of the saddest and most affecting of those which preach to us the instability of fortune and the vanity of human ambition.

The government of England during this reign was still nearly as despotic in principle as in the days of the Conqueror and his sons, but the more advanced social condition of the country and the firmer establishment of the new dynasty combined with the temper of the king to render it considerably less oppressive in practice. The augmented security and strength of the crown, and the measures which Henry took to depress or curb the aristocracy, had the effect of relieving the people to some extent of one, and that perhaps the most severe, of the two tyrannies under which they suffered, without adding to the weight of the other. While the power of the barons was curtailed or restrained, that of the throne was certainly not exercised with more, but rather with less, insolence and rapacity than formerly. The laws were also administered with greater regularity during this reign than they had been since the Conquest; if the original *curia regis*, or royal court, was not already separated into the subdivisions out of which have sprung the present Courts of King's Bench and Common Pleas (which is doubtful), the important institution of justices itinerant, or justices in eyre, as they were styled, that is, judges making periodical circuits through the kingdom for the trial of causes, was now made a permanent part of the judicial establishment of the country. [Eyre.] Another important legal improvement now introduced was the substitution in the trial of the species of action called a writ of right of the grand assize, for the old ordeal of battle. [Assize.] The earliest of the English law-writers, Ranulf de Glanville, the supposed author of the Latin treatise entitled 'Tractatus de Legibus et Consuetudinibus Angliæ,' held the office of chief-justiciary in the time of Henry II. To this reign also belong the 'Dialogus de Scaccario,' and the two collections of charters, &c., known as the 'Liber Niger' and the 'Liber Ruber.'

Henry's children by his queen Eleanor were: 1, William, born 1152, died 1156; 2, Henry, born 28th February, 1155, died 11th June, 1183; 3, Maud, born 1156, married to Henry V., duke of Saxony, died 1189, a few days after her father; 4, Richard, who succeeded him on the throne; 5, Geoffrey, born 23th September, 1158, died 19th August, 1186; 6, Eleanor, born 13th October, 1162, married to Alphonso VIII., king of Castile, died 1214; 7, Joan, born October, 1164, married to William II., king of Sicily, died 4th September, 1195; and 8, John, who succeeded Richard as king. His illegitimate children were: 1, by the famous Rosamund, daughter of Walter, lord Clifford, William, surnamed De Longespee, who became earl of Salisbury in right of his wife Ela, daughter and heiress of William Devereux, died 1226; 2, by the same, Geoffrey, who became bishop of Lincoln, lord chancellor, and afterwards archbishop of York, and died 18th December, 1212; and 3, by the wife of Rodolph Blewit, Morgan, a churchman, who held the office of provost of Beverley.

HENRY III., surnamed of Winchester, from the place of his birth, was the eldest son of King John by his queen, Isabella of Angoulême, and was born 1st October, 1206. His father having died 18th October, 1216, the boy was, chiefly through the influence of the earl of Pembroke, lord marshal, acknowledged heir to the throne by those of the barons who were opposed to the French party; and on the 28th he was solemnly crowned in the abbey-church of St. Peter, at Gloucester, by the papal legate Gualo. His reign is reckoned from that day.

On the 11th November following, at a great council held at Bristol, Pembroke was appointed protector or governor of the king and kingdom (Rector Regis et Regni); and this able and excellent nobleman continued at the head of affairs till his death in May, 1219; long before which event the dauphin Louis and the French had been compelled to quit the country, their evacuation having been finally arranged in a conference held at Kingston 11th September, 1217. After the death of Pembroke the administration of the government fell into the hands of Hubert de Burgh, who had greatly distinguished himself in the expulsion of the foreigners, and Peter des Roches, bishop of Winchester. De Burgh however and the bishop, who was not an Englishman, but a native of Poitou, from coadjutors soon became rivals, and their attempts to throw each other down at length led, in 1224, to the resignation of Des Roches and his retirement from the kingdom. Meanwhile, on the 17th May, 1220, Henry, in consequence of some doubts being entertained about the efficacy of the former ceremony, had been crowned a second time at Westminster by Langton, archbishop of Canterbury. In 1221 the relations of peace and alliance with Scotland, which had subsisted ever since the departure of the French, were made closer and firmer by the marriages of Alexander II., the king of that country, with Jane, Henry's eldest sister, and of De Burgh with the Princess Margaret, the eldest sister of Alexander. About the same time Pandulf, who had succeeded Gualo as papal legate, left the country, which was thus practically freed from the domination of Rome, although that power still persisted in asserting theoretically the vassalage of the crown which had been originally conceded by John, and which had also been acknowledged at his accession by the present king.

In 1222 Henry had been declared of age to exercise at least certain of the functions of government; but his feeble character was already become sufficiently apparent, and this formality gave him no real power. It only served to enable De Burgh the more easily to get rid of his colleague. That minister, now left alone at the head of affairs, conducted the government with ability and success on the whole, though in a spirit of severity, which, whether necessary or not, could not fail to make him many enemies. A war broke out with France in 1225, which however was carried on with little spirit on either side, and produced no events of note, although Henry, in May, 1230, conducted in person an expedition to the Continent, from which great things were expected by himself and his subjects; but he returned home in the following October, without having done anything. At this time France was suffering under the usual weakness and distraction of a regal minority, Louis IX., afterwards designated St. Louis, having, while yet only in his twelfth year, succeeded his father in 1226. A growing opposition to De Burgh was at length headed by Richard, earl of Cornwall, the king's brother, who possessed very great influence, not only from his nearness to to the throne, but from his immense wealth; and the consequence was the sudden expulsion of that minister from all his offices, and his consignment to prison, with the loss of all his honours and estates, in the latter part of the year 1132. Des Roches, the bishop of Winchester, who had returned to the country some time before this crisis, was now placed at the head of affairs; but his administration, a course of insulting preference for his countrymen and other foreigners, and of open hostility to the great charter and the whole body of the national liberties, speedily proved unbearably distasteful to both barons and commons; and a confederacy of the laity and the clergy, with Edmund, archbishop of Canterbury, at its head, compelled his dismissal within little more than a year after his restoration to power. The archbishop now became chief minister. In 1236 Henry, being now in his thirtieth year, married Eleanor, the daughter of Raymond, count of Provence; and this connection soon gave new and great umbrage to the nation, in consequence of the numbers of her relations and countrymen who came over with or followed the queen, and with whom she surrounded her weak husband, besides inducing him to gratify their rapacity with pensions estates honours, and the most lucrative offices in the kingdom. In the midst of the contests thus occasioned between the crown and the nobility, whose meetings for deliberation on national affairs were now commonly called parliaments, a renewal of active hostilities with France was brought about through a private resentment of Henry's mother Isabella, who, after the death of John, had returned and been remarried to Hugh, count of La Marche, to whom she had been espoused before she gave her hand to John: she had instigated La Marche to insult and defy Alphonse, count of Poitou, the brother of the French king, after doing homage to him, and had then prevailed upon her son, the king of England, to take her part in the war with France that ensued. Henry again sailed for the Continent; but this expedition was still more unfortunate and disgraceful than the former: after being beaten by Louis in a succession of actions, he was glad to get home again, with the loss of army, money, baggage, and everything. A new truce for five years was then agreed to between the two countries.

These events of course did not tend to put the nation in better humour with the king, or to dispose the parliament to greater liberality. The contest with the crown however ended for the present in an attempt on the part of Henry to govern by the prerogative, which was so far successful that no effective resistance was made to it for many years. In the pressure of his embarrassments he several times reassembled the legislative body, but no accommodation was effected by these advances; the parliament was found as impracticable as ever, and the king resumed his arbitrary courses. In 1253 he succeeded in obtaining a grant of money by consenting to a solemn ratification of the great charters; a ceremony which had already been repeatedly performed in the course of the reign; and this enabled him to proceed at the head of a military force to Guienne, where a revolt against the English dominion had been excited by Alphonso, king of Castile. The dispute was soon settled by the arrangement of a marriage between Henry's eldest son Prince Edward, and Eleanor, the sister of Alphonso. [EDWARD I.] After this Henry engaged in a project which speedily involved him in a complication of difficulties—the acceptance of the nominal crown of Sicily for his second son Edmund from pope Innocent IV., who pretended to have it at his disposal in consequence of Frederick II., the late king, having died (A.D. 1250) in a state of excommunication, and who had ever since been hawking about the empty title among the princes of Europe, without finding any one simple enough to close with his proposals till he applied to the king of England. The exorbitant extent to which Henry was forced to carry his exactions in order to meet his engagements with the pontiff raised a spirit of resistance, which grew stronger and stronger, till it broke out into an open revolt against the supremacy of the crown. What is called by most of the old chroniclers 'the mad parliament' assembled at Oxford, 11th June, 1258, by adjournment from Westminster, where it had met on the 2nd of May previous; and placed the whole authority of the state in the hands of a committee of government, consisting of twelve persons appointed by the barons and as many by the king. The leader of the barons on this occasion was the famous Simon de Montfort, who was a Frenchman by birth, being the youngest son of the Count de Montfort, but who, in right of his mother, had succeeded to the English earldom of Leicester, and had so long ago as the year 1238 married Eleanor, countess-dowager of Pembroke, a sister of king Henry. After the enjoyment however of a long course of court favour he had quarrelled with and been insulted by his royal brother-in-law in 1252, and although they had been apparently reconciled, it is probable that the feelings then excited had never been extinguished in either. From the imperfect accounts and the partial temper of the annalists of the time, it is difficult to obtain a clear view of De Montfort's character and objects; but if his position may be reasonably suspected to have acted upon him with its natural temptations, and led him to form designs more ambitious than he could venture openly to profess, it must be admitted that he stands remarkably free from any well-established or even probable imputation affecting his actual conduct, and that he was undoubtedly a person both of eminent ability and of many excellent as well as popular moral qualities. His cause was also undoubtedly in the main that of the national liberties, and he appears to have had throughout the national voice and heart with him. He and his friends soon contrived to monopolize the whole power of the committee of government, and compelled the principal nominees of the king not only to relinquish their functions, but to fly from the kingdom. Dissensions now however broke out in the dominant party, and De Montfort found a rival aspirant to the supreme power in another of the great barons, Richard de Clare, earl of Gloucester. The quarrels of the adverse factions enabled Henry, in the beginning of the year 1261, altogether to throw off the authority of the committee of government; and although the parliamentary party was on this occasion joined by Prince Edward, it was for the present effectually put down, De Montfort himself being obliged to take refuge in France. He returned however in April, 1263, and being now supported by Gilbert, earl of Gloucester, the son of his late rival, proceeded to prosecute his quarrel with the crown by force of arms. Henry had now his son Edward on his side; but the success of the insurgents nevertheless was such as to threaten the complete overthrow of the royal power, when an accommodation was effected through the interference of the king's younger brother, Richard, earl of Cornwall, called King of the Romans, to which dignity he had been elected a few years before. The result was to place De Montfort and his friends once more at the head of affairs, the king being reduced to a cipher, or a mere puppet in their hands. In the course of a few months however we find the war between the two parties renewed. The contest of arms was suspended for a short time in the beginning of the following year (1264) by an appeal on the part of a number of the most influential barons and bishops to the arbitration of Louis IX. of France; but his award, which was upon the whole favourable to Henry, was very soon disregarded. On the 14th of May the forces of the barons, led by De Montfort, and those of the royalists, commanded by the king in person, and by his son Edward, met at Lewes, in Sussex, where the former gained a complete victory, both Henry and his son being taken prisoners. This success of course once more placed all the power of the kingdom at the feet of the great baronial leader. His arrogance and assumption of superiority however, it is said, had already alienated from him some of his most powerful adherents, and disposed them to take measures for the restoration of the royal authority, when, on the Thursday of Whitsun-week, 1265, Prince Edward contrived to make his escape from Dover Castle, and to join the earl of Gloucester, who had now deserted the interest of De Montfort, and waited to receive him with an army at Ludlow in Shropshire. This event immediately led to the renewal of the war. On the 4th of August the two parties again encountered at Evesham; Edward here gave brilliant proof of the military talent which distinguished his future career; and the result was the defeat of the baronial forces with immense slaughter, De Montfort himself and his son Henry being both in the number of the slain. In this battle the king is said to have had a narrow escape; the earl, in whose camp he was, had compelled him to put on armour and mount a war-horse, from which he was thrown down in one of the charges, and would probably have been put to the sword or trampled to death had he not called out that he was 'Harry of Winchester,' when his voice was heard by his son, who came up and rescued him.

The victory of Evesham however, although it liberated Henry and re-established the royal government, did not completely put down the defeated party. The adherents of De Montfort maintained themselves, notwithstanding all the efforts of Prince Edward, in various parts of the kingdom, for more than two years longer. Even after the parliament, in October, 1267, had passed an Act of Concord, known by the name of the 'Dictum de Kenilworth,' by which easy terms of pardon were offered to all who would submit themselves, the insurrection was renewed by the people of London, with the earl of Gloucester at their head; but that rash and fickle personage almost immediately threw himself upon the king's mercy without drawing the sword, and was glad to obtain pardon through the mediation of the King of the Romans, leaving his followers to their fate. A final arrangement was at last effected in a parliament which met at Marlborough on the 18th of November. The short remainder of the reign of Henry after this date passed without disturbance, or any remarkable events. His son Edward, leaving everything tranquil, set out for the Holy Land in July, 1270, from which he had not returned when Henry died at Westminster on the Feast of St. Edmund, being the 16th of November, 1272, in the sixty-seventh year of his age, and the fifty-seventh of his reign.

The children of Henry III., by his wife, Eleanor of Provence, were,—1, Edward, who succeeded him; 2, Margaret, born in October, 1240, married to Alexander III. of Scotland, at York, 26th December, 1251, died 26th February, 1275; 3, Beatrice, born at Bordeaux, 25th June, 1242, married to John de Dreux, duke of Brittany and earl of Richmond, at London in 1260, died 1273; 4, Edmund, surnamed Crouchback (probably from the crouch or cross which he wore upon his back, as having made the voyage to Jerusalem), born 16th January, 1245, created earl of Chester 1253, earl of Leicester 1264, earl of Lancaster 1267, died 1295; 5, Catherine, born 25th November, 1253, died in 1258; and four sons, Richard, John, William, and Henry, who died in infancy.

The reign of Henry III. is especially memorable in the history of the constitution as affording us the first distinct example of a parliament constituted as at present, of representatives from the counties, cities, and boroughs, as well as of the barons and higher clergy, or great tenants of the crown, lay and ecclesiastical. The assembly in question met at London, 22nd January, 1265, having been summoned in the name of king Henry, while he was in the hands of De Montfort, a few weeks before. Hence this great leader of the barons has been regarded as the introducer of the principle of popular representation into the English constitution, and the founder of the House of Commons. The fact simply is however that the writs for his parliament of 1265 are the earliest extant directing the return of knights of the shire, and representatives of cities and boroughs. There is nothing either in the writs themselves, or, what is more important, in the notices of any of the contemporary historians, from which it could be gathered that what took place was an innovation. Moreover, county representation, as at least an occasional usage, may certainly be distinctly traced to a date half a century earlier than this.

Our statute law also begins with this reign—the earliest enactment on the statute-book being that entitled the 'Provisions of Merton,' passed in the 20th year of Henry III., A.D. 1235-6. Only two of the statutes passed in this reign however are extant on the rolls in the Tower, namely, 'Magna Charta' and the 'Charta de Foresta,' and even these are only found in charters of inspeximus, or confirmation, of the next reign. The 'Charta de Foresta' was first made a distinct charter in the 2nd of Henry III., A.D. 1217 (not in his 9th year, as stated by mistake in the article FOREST LAWS). For an enumeration of the repeated confirmations both of that and of the great charter which were obtained in this reign, and which form the principal legislation of the period, the reader is referred to the account by Blackstone in the Fourth of his *Law Tracts*, or to the *Introduction* to the *Statutes at Large* in the edition of the Record Commissioners. Bracton's law treatise entitled *De Consuetudinibus et Legibus Anglicanis* is assigned to the reign of Henry III.

HENRY IV., surnamed Bolingbroke, was the eldest son of John of Gaunt, duke of Lancaster, the fourth son of king Edward III. His mother was the Lady Blanch, younger daughter and eventually heiress of Henry Plantagenet, duke of Lancaster, who was grandson of Edmund, second son of King Henry III. He was born at Bolingbroke in Lincolnshire in 1366, and as early as 1380 is styled earl of Derby, which was one of his father's titles. In 1397 he was created duke of Hereford, having married Mary, daughter and coheir of Humphrey de Bohun, the last earl of Hereford. He became duke of Lancaster on the death of his father, February 3, 1399.

The first occasion on which the earl of Derby appears in English history is as one of the lords associated with Thomas, duke of Gloucester, the uncle of Richard II., in the insurrection of 1387. It appears however that whatever may have been the designs of the duke, the earl contemplated nothing more than the temporary control of the royal authority. Accordingly, in May, 1389, when the king recovered his authority, his cousin Derby was one of the persons whom he immediately took into his confidence. Some of the years immediately following these events, the earl is supposed to have spent on the Continent. We find him again in England in 1397 at the time of the seizure of Gloucester, which act, Richard, in a proclamation which he issued on the occasion, stated to have been done with his approbation. Within a few months, after being raised to the rank of duke of Hereford, he and the duke of Norfolk, formerly the earl of Nottingham, who had also participated in Gloucester's rebellion ten years before, were involved in the same ruin with their former associates, in circumstances leading to a strong suspicion that, notwithstanding the forgiveness and even favour which he had apparently shown them, the insidious king had never forgotten their offence, but had still cherished a secret determination of revenge. It appears that while Hereford was riding from Brentford to London he was overtaken by Norfolk, who, entering into conversation with him, expressed his conviction, on grounds which he stated, that the king was preparing to destroy them. In some way or other, but how is doubtful, a report of this conversation reached the ears of the king. The consequence was that Hereford in obedience to a royal order appeared before Richard and the parliament at Shrewsbury, January 30, 1398, and there formally accused Norfolk of having spoken to him in the terms that have been mentioned. Apparently he had been induced to take this course as affording his only chance of escape from destruction; but it did not save him, although it perfectly answered the ond the king probably had in view. The charge against Norfolk was in the first instance roferred to a committee of twelve peers and six commoners, and eventually it was determined that it should be brought before a high court of chivalry. That court assemhled at Windsor on the 29th of April, and awarded that wager of battle should be joined between the two dukes at Coventry on the 16th of September. When the day arrived and the combatants had entered the lists, and were on the point of advancing to the encounter, tho king, who presided, suddenly threw down his warder, and so arrested both where they stood. Norfolk was ordered to go on a pilgrimage to the Holy Land, and banished from England for life; Hereford was also senteneed to quit the kingdom within four months, and to remain abroad for the next ten years. He retired to Paris, and while he was resident in that city his father the duke of Lancaster died, February 3, 1399, on which Richard immediately seized his estates, on the pretence that tho banishment of the son disqualified him from inheriting. This injury determined the latter immediately to return home, with the avowed object of maintaining his rights as duke of Lancaster, but doubtless with a real design of a higher pitch. He landed with a few attendants at Ravenspurn in Yorkshire on the 4th of July, while Richard was in Ireland. The events that followed belong to the history of the reign of that king; it is sufficient to state here that Henry, who was immediately joined by tho two powerful earls of Northumberland and Westmoreland, carried everything before him, and, the deposition of Richard having been pronounced by the parliament, was on the 30th of September solemnly acknowledged as king by the estates of the realm assembled in Westminster Hall. The commencement of his reign is reckoned from that day.

This change was undoubtedly in tho highest degree acceptable to the great body of the peoplo, among whom the vices and misgovernment of Richard had made him an object of hatred or contempt, while Henry of Lancaster had long been the idol of their affections and hopes. The new settlement was first disturbed by a plot of a few of the nobility, the lords who had appealed the duke of Gloucester, and who for that act had now been deprived of the titles and estates they had received as the reward of their services from Richard. Their scheme to assassinate the new king however was detected in time, and when they afterwards flew to arms they were everywhere fallen upon and easily overpowered hy tho spontaneous loyalty of the people. A war with France, of which some apprehension was for a moment entertained, from the feelings naturally excited in the king and people of that country by the treatment of Richard II., who had lately married Isabella, the young daughter of Charles VI., was averted by the restoration of that princess. Military operations however speedily commenced on the side both of Wales and Scotland, in the former of which countries an insurrection, headed by the famous Owen Glendower, baffled all Henry's efforts during several successive campaigns to put it down; while two Scottish armies, that marched across the horders pretending that they came to restore king Richard, who, it was said, was still alive and resident at the northern court, were defeated, the first on the 22nd of June, 1402, at Neshet Moor, the second on the 14th of September, in the same year, in the much more destructive fight of Homildon Hill. The victorious commander in this last affair was Harry Percy, the renowned Hotspur, eldest son of the earl of Northumberland, the nobleman to whom more than to any other individual Henry owed his throne. That great house, conscious of its power and its services, now broke with the king of its own making, on his refusal to permit the ransoming of Henry Percy's wife's brother, Sir Edmund Mortimer, who had been taken prisoner by Glendower, and whom, as the uncle and natural guardian of the young earl of March, the legitimate heir by lineal descent to the crown, Henry had his own reasons for wishing out of the way.* A most formidable rebellion followed, in which the Percies were joined hy Hotspur's uncle the earl of Worcester, and Scroop, archbishop of York, and leagued both with Owen Glendower, who now gave his daughter in marriage to his prisoner Mortimer, and with the Scottish Earl Douglas, whom Percy liberated without ransom, on condition of his aiding them, with all his power. The mighty confederacy however was annihilated, 21st July, 1403, by the battle of Shrewsbury, in which Henry Percy, the commander of the rebel force, was himself slain. This decisive victory established the throne of Henry of Lancaster. Some further hostilities with the Scots and tho Welsh, the latter being assisted by a force from France, continued to give him occupation for two or three years longer; but before the end of 1405 Owen Glendower was effectually put down, prinoipally by the activity and military skill of Henry, Prince of Wales, the eldest son of the English king, and a truce with Scotland had restored quiet for the present in that quarter. It was in the time of this truce that on the 30th of March, 1405, an English cruiser captured the ship in which James, the eldest son of king Robert of Scotland, was proceeding to France, on which Henry rotained possession of the young prince, who, becoming king tho following year by the death of his father, remained a prisoner in England till 1424. About the same time Henry detected a conspiracy against his life, one of the principal persons engaged in which was his cousin Edward, duke of York, whose estates were immediately forfeited to the crown, and quelled another insurrectionary attempt of the Percies, headed by Scroop, archbishop of York, who expiated his treason by a death on tho scaffold. A third northern insurrection, the last effort of the crafty old earl of Northumberland, who had some years before been deprivod of his estates and outlawed, was put down, 28th February, 1408, at the battle of Branham Moor, near Tadcaster, in which the earl himself fell.

Meanwhile an irregular war with France, which had at first been carried on principally at sea, had led at last to some military operations in Guienne, where the English possessions were attacked hy the French; and this involved Henry to a slight degree in the contest between the two great factions that then distracted France, the Bourguignons and the Orleanists, or Armagnacs. Having first sent a small body of troops to the assistance of the former in 1411, the next year he changed sides and entered into alliance with the latter, his principal object apparently being to keep up the anarchy which their quarrel occasioned; but these transactions led to no important national results during this reign.

In his latter years Henry, whose character tho more it hecame known developed a harsher and more unamiable aspect, lost all the popular favour that had greeted his accession; and he had the unhappiness of seeing not only his chief friends transformed into enemies, but the affections of his subjects generally transferred to his son. To ill health of body is also said to have been added remorse for many of the actions of his unscrupulous career, and especially for the means by which he had acquired a crown that sat so heavy on his hrow, and which he superstitiously dreaded heaven would not permit to be long worn by his descendants. He had endeavoured to soothe his conscience with the project of a crusade to the Holy Land, hut death took him off before he could execute that design. He breathed his last on the 20th of March, 1413, in the forty-seventh year of his age and the fourteenth of his reign.

By his first wife, Mary de Bohun, Henry IV. had the following children:—1, Henry, who succeeded him; 2, Thomas, born 1389, created earl of Alhemarle and duke of Clarence,

* For the respective positions in relation to the throne of the families of March (afterwards York) and Lancaster, see the genealogical table in EDWARD IV., in which however the line drawn from Lionel, duke of Clarence, ought to descend upon his daughter Philippa, and not, as it has been printed by mistake, upon her husband Edmund Mortimer.

1411, died 1421; 3, John, created earl of Kendal and duke of Bedford, 1414, afterwards regent of France, died 1435; 4, Humphrey, created earl of Pembroke and duke of Gloucester, 1414, died 1446; 5, Blanch, married successively to Lewis Barbatus, elector palatine and duke of Bavaria, to the king of Aragon, and to the duke of Bar; and 6, Philippa, married to Eric X., king of Denmark and Norway. By a second wife, Joanna, daughter of Charles II., king of Navarre, and widow of John V., duke of Brittany, whom he married in 1403, he had no issue.

Of the laws made in this reign the most memorable is the statute against the Lollards (the 2 Henry IV., c. 15), one of the enactments of which was that persons guilty of heresy, and refusing to abjure, or relapsing after abjuration, should be publicly burned. It is commonly supposed however that the writ 'De Hæretico Comburendo' was a common-law process before the passing of this statute. Several executions took place upon the new law in the course of the reign. In Henry's first parliament also the law of treason was brought back (by the 1st Henry IV., c. 10) to the state in which it had been placed by the act of the 25th of Edward III., certain new treasons created in the 21st year of the preceding reign being all repealed. The defects of Henry's title to the crown, and the repeated applications he was obliged to make to parliament for the means of putting down the insurrections by which the new settlement was assailed, had the effect of greatly enhancing the importance and power of the House of Commons under this king and the other Lancastrian princes.

HENRY V., surnamed of Monmouth, from the place of his birth, was the eldest son of king Henry IV., by his first wife, Mary de Bohun, and was born in the year 1388. He was educated at Queen's College, Oxford, under the superintendence of his half-uncle, the great cardinal Henry Beaufort. When his father was in exile in 1399, he and a son of the late Duke of Gloucester were carried by king Richard to Ireland, and placed in custody in the castle of Trim, where they remained till the deposition of Richard. On his father's accession he was created prince of Wales, duke of Guienne, Lancaster, and Cornwall, and earl of Chester, and declared by act of parliament heir-apparent to the throne. He was introduced to arms, while yet only in his sixteenth year, at the battle of Shrewsbury, where, though severely wounded in the face, he fought gallantly to the close of the bloody day. Immediately after this he was sent to Wales in command of the army employed against Glendower, and for some years he was occupied in the contest with that able and active leader, in the course of which he evinced extraordinary military genius, defeating his adversary in a succession of engagements,—in one of which, fought at Grosmont in Monmouthshire, in March, 1405, he took his son Griffith prisoner,—and driving him from fastness to fastness, till all Wales, except a small part of the north, was reduced to submission. It is said that the renown and popularity the prince acquired by these successes so inflamed the jealousy of his father as to occasion his recal from the army, and that after this, allowing the energies of his ardent mind to run to waste in riotous intemperance and debaucheries, he drew upon himself as much reprobation and odium by his wild and dissipated life, as he had gained glory and favour among his countrymen by his previous conduct. The story of his being sent to prison by the lord-chief-justice Sir William Gascoigne, for striking him in open court, and other accounts of his disorderly and reckless courses, are familiar to every reader. These anecdotes however are not recorded by the more antient chroniclers, and do not appear to have found their way into our written history before the middle of the sixteenth century, though they may have floated among the people as traditions from a considerably earlier date. It is likely that they had some general foundation, though many or most of the details are probably fictitious.

Henry V. was proclaimed king on the 21st of April, 1413, the day after his father's death, amidst universal and enthusiastic joy. He began his reign with several acts of a generous stamp—transferring the remains of Richard II. to Westminster Abbey—releasing the young earl of March from the captivity in which he had been held all the preceding reign—and recalling the son of Hotspur from his exile in Scotland to be reinstated in his hereditary lands and honours. He had been seated on the throne little more than a year when, warmly supported by the church, the parliament, both Lords and Commons, and by the nation generally, he entered upon the enterprise of the conquest of France, which forms nearly the whole history of his reign. The claim which he advanced to the French crown was the same that had been put forward in the preceding century by Edward III., to whose rights he seems to have regarded himself as the legitimate successor in virtue of his possession of the throne, although he was certainly not the heir of that king by lineal descent, and this particular pretension was one that stood wholly upon descent by blood. After some time spent in negotiations with the French court, which led to no result, Henry, having appointed his brother, the Duke of Bedford, regent of the kingdom during his absence, set sail from Southampton, 13th August, 1415, with a force of 24,000 foot and about 6500 cavalry, in a fleet of from 1200 to 1400 vessels, and reached the mouth of the Seine, about three miles from Harfleur, on the second day following. Three days were spent in disembarking the troops. Henry immediately proceeded to lay siege to the strong and well garrisoned fortress of Harfleur. It capitulated after a siege of six weeks, in the course of which time however a dysentery that broke out in their camp made a frightful devastation among the English.

On the 6th of October Henry set out on his march through Normandy, with a force which at the utmost could not have exceeded 9000 men. On the 19th he succeeded in crossing the Somme by an unguarded ford between Betencourt and Voyenne; on the 24th he crossed the Ternois at Blangi, and then came in sight of a French army, commanded by the constable of France and the dukes of Orleans and Bourbon, the strength of which has been variously estimated at from 50,000 to 150,000 men. The great battle of Azincourt was fought on the next day, in which the English gained one of the most complete as well as wonderful victories on record. [AGINCOURT.] Henry then marched to Calais, and embarked for England. From his landing-place at Dover, where they rushed into the sea to meet him, all the way to London, which he entered on the 23rd of November, his progress was through a confluence of the people intoxicated with tumultuous joy. All seemed to feel that the victory of Azincourt was the conquest of France. But although no nation ever received so great a blow in a single field as France did on that fatal day—when a hundred and twenty of her greatest nobles fell, besides many more that were taken prisoners, including the dukes of Orleans and Bourbon, the commanders-in-chief in conjunction with the constable d'Albret, who was among the killed—it was not till after some years that, torn as she was by the most lamentable civil dissensions, and left nearly without a government, that unfortunate country at last consented to receive the yoke of her invader. Harfleur was attacked by the French the following August; but the attempt was put an end to by a great naval victory gained by the duke of Bedford. In September Henry passed over to Calais, and there had a secret conference with the head of one of the great French factions, John, surnamed Sans-peur, duke of Burgundy, with whom there is no doubt that he came to some understanding about the employment of their united efforts for the destruction of the Orleanists, who now had the government in their hands. It was by thus politically taking advantage of the dissensions of his enemies, rather than by any further very brilliant military operations, that Henry at last achieved the conquest of France. He returned to that country in August, 1417, having under his command a magnificent army of about 35,000 men. With this force he soon reduced the whole of Lower Normandy. He then laid siege to Rouen, 30th July, 1418, and was detained before this town till after a brave resistance it capitulated on the 16th of January in the following year. By this time the duke of Burgundy had obtained the ascendancy in Paris and at the court of the incapable Charles and his profligate queen; and he was not now so much disposed as he had probably been two years before to aid the ambitious project of the English king. From Rouen Henry advanced upon Paris, on which Burgundy and the queen, taking the king with them, left that city, and went, first to Lagny, and afterwards to Provins. It was at last agreed however that a truce should be concluded between the English and the Bourguignons, and that Henry should meet the duke and the king and queen of France on the 30th of May. On that day the conference took place on the right bank of the Seine, near the town of Meulan. But after being protracted for above a month, the negotiation was suddenly broken off by the French party; and then it was discovered that the duke had concluded a treaty with the Dauphin and the faction of the Armagnacs. On this Henry immediately resumed his advance upon Paris. Meanwhile the hollowness of the apparent reconciliation that had been hastily patched up between the two rival factions became abundantly manifest; the formal alliance of the chiefs had no effect in uniting their followers. At length, on the 10th of September, Burgundy having been induced to meet the Dauphin on the bridge of Montereau, was there foully fallen upon and murdered by the attendants, and in the presence, of the treacherous prince. From this time the Bourguignons, and even the people of Paris, who were attached to that party, looked upon the English as their natural allies against the Dauphin and his faction. Philip, the young duke of Burgundy, and the queen in the name of her husband, immediately assented to all Henry's demands, which were—the hand of Charles's eldest daughter, the Princess Catherine, the present regency of the kingdom, and the succession to the throne of France on the death of Charles. It was also arranged that one of Henry's brothers should marry a sister of duke Philip. Several months were spent in the settlement of certain minor points; but at last the treaty of 'Perpetual Peace,' as it was styled, was completed and signed at Troyes by Queen Isabella and Duke Philip, as the commissioners of King Charles, on the 20th of May, 1420; and on the following day the oath to observe it was taken without murmur or hesitation by the parliament, the nobility, and deputies from such of the commonalties as acknowledged the royal authority.

Henry's marriage with Catherine was solemnized on the 2nd June. On the second day after he resumed his military operations, and some months were spent in reducing successively the towns of Sens, Montereau, Villeneuve-le-Roi, and Melun. On the 18th November Henry and Charles entered Paris together in triumph, and here the treaty of Troyes was unanimously confirmed (10th December) in an assembly of the three estates of the kingdom. Henry soon after set out with his queen for England, and on the 2nd February, 1421, entered London amidst such pageants and popular rejoicings as that capital had never before witnessed.

He did not however remain long at home. On the 22nd March his brother the duke of Clarence, whom he had left governor of Normandy, was defeated in a battle fought at Baugé, in Anjou, by a force chiefly composed of a body of Scottish auxiliaries under the earl of Buchan, who slew Clarence with his own hand, an exploit for which the Dauphin conferred upon the Scottish earl the office of constable of France. This victory appears to have produced a wonderful effect in reanimating the almost broken spirits and extinguished hopes of the Dauphin's party. Feeling that his presence was wanted in France, Henry again set sail for Calais in the beginning of June, taking with him a Scottish force commanded by Archibald, earl of Douglas, and also his prisoner, the Scottish king, to whom he promised his liberty as soon as they should have returned to England. His wonted success attended him in this new expedition; and he drove the Dauphin before him, from one place after another, till he forced him to retire to Bourges, in Berry. He then, after taking the strong town of Meaux, which cost him a siege of seven months, proceeded to Paris, which he entered with great pomp, 30th May, 1422, accompanied by his queen, who had come over to join him, after having given birth to a son at Windsor Castle on the 6th of the preceding December. But the end of Henry's triumphant career was now at hand. The Dauphin and the constable Buchan having again advanced from the south, and laid siege to the town of Cosne, Henry, though ill at the time, set out to relieve that place, but was unable to proceed farther than Corbeil, about twenty miles from Paris, when, resigning the command to his brother the duke of Bedford, he was carried back in a litter to the Bois de Vincennes, in the vicinity of the capital, and there, after an illness of about a month, he breathed his last, on the 31st of August, in the 34th year of his age, and the 10th of his reign.

It is unnecessary in the present day to waste a word on either the injustice or the folly of the enterprise on which Henry thus threw away the whole of his reign. In estimating his character it is of more importance to remember that the folly and injustice, which are now so evident, were as little perceived at that day by his subjects in general as by himself, and that there can be no doubt whatever that both he and they thought he was, in the assertion of his fancied rights to the crown of France, pursuing both a most important and a most legitimate object. That motives of personal ambition mingled their influence in his views and proceedings must no doubt be admitted; but that is perfectly consistent with honesty of purpose, and a thorough belief in the rightness both of the object sought and the means employed to secure it. In following the bright though misleading *idea* that had captivated him, he certainly displayed many endowments of the loftiest and most admirable kind—energy, both of body and mind, which no fatigue could quell; the most heroic gallantry; patience and endurance, watchfulness and activity, steadiness, determination, policy, and other moral constituents, as they may be called, of genius, as well as mere military skill and resources. Nor does any weighty imputation dim the lustre of these virtues. His slaughter of his prisoners at the battle of Azincourt, almost the only stigma that rests upon his memory, was an act of self-preservation justified by what appeared to be the circumstances in which he was placed. No monarch ever occupied a throne who was more the idol of his subjects than Henry V.; nor is any trace to be found of popular dissatisfaction with any part of his government, from the beginning to the end of his reign.

HENRY VI., surnamed of Windsor, was born there 6th December, 1421, being the only issue of Henry V. by his queen the Princess Catherine of France. He was consequently not quite nine months old when the death of his father left him king of England. His reign is reckoned from the 1st of September, 1422, the day following his father's death.

In the settlement of the government which took place upon the accession of the infant king, the actual administration of affairs in England was entrusted to the younger of his two uncles, Humphrey, popularly called 'The Good,' duke of Gloucester, as substitute for the elder, John, duke of Bedford, who was appointed president of the council, but who remained in France, taking his late brother's place as regent of that kingdom. Gloucester's title was 'Protector of the Realm and Church of England.' The care of the person and education of the king was some time after committed to Richard De Beauchamp, earl of Warwick, and to the king's great-uncle bishop (afterwards cardinal) Henry Beaufort.

The history of the earlier and longer portion of this reign is the history of the gradual decay and final subversion of the English dominion in France. The death of Henry V. was followed in a few weeks (22nd October) by that of his father-in-law, the imbecile Charles VI. Immediately on this event the Dauphin was acknowledged by his adherents as Charles VII.; and Henry VI. was also proclaimed in Paris, and wherever the English power prevailed, as king of France. The next events of importance that occurred were the two great victories of Crevant and Verneuil obtained by the English over the French and their Scottish allies, the former on the 31st of July, 1423, the latter on the 17th of August, 1424. In the interim king James of Scotland, after his detention of nearly twenty years, had been released by the English council, and had returned to his native country after marrying a near connexion of the royal family, the Lady Jane Beaufort, daughter of the duke of Somerset. One of the engagements made by James on his liberation was that he should not permit any more of his subjects to enter into the service of France: the Scots who were already there were for the most part destroyed a few months afterwards in the slaughter of Verneuil.

This however was the last great success obtained by the English in France. From this time their dominion began to loosen and shake, and then to crumble faster and faster away, until it fell wholly to ruin. The first thing which materially contributed to unsettle it was the disgust given to the duke of Burgundy by the marriage of the duke of Gloucester with Jacqueline of Hainault, and their subsequent invasion and seizure of her hereditary states, then held by her former husband John, duke of Brabant, who was the cousin of the duke of Burgundy. Although Burgundy, on being left to pursue his quarrel with Jacqueline, whom he soon succeeded in crushing, after she had been abandoned by Gloucester, did not go the length of openly breaking with the English on account of this matter, his attachment was never afterwards to be much relied upon, and he merely waited for a favourable occasion to change sides. Meanwhile another of the most powerful of the English allies, the duke of Brittany, openly declared for Charles VII. Other embarrassments also arose about the same time out of the mutual jealousies and opposition of Gloucester and Bishop Beaufort, which at last blazed up into open and violent hostility. It required all the moderating prudence and steadiness of the duke of Bedford to break as much as possible the shock of these various adverse occurrences. For some years accordingly he had enough to do in merely maintaining his actual position. It was not till the close of 1428 that he proceeded to attempt the extension of the English authority beyond the Loire. With this view the siege of Orleans was commenced on the 12th of October in that year, by the earl of Salisbury, and, on his death from a wound received a few weeks after, carried on by the earl of Suffolk. The extraordinary succession of events that followed—the appearance of Joan of Arc on the scene; her arrival in the besieged city (29th April, 1429); the raising of the siege (8th May); the defeat of the English at the battle of Patay (18th June); the coronation of king Charles at Rheims (15th July); the attack on Paris (12th September); the capture of Joan at Compiegne (25th May, 1430); her trial and execution at Rouen (30th May, 1431) —all belong to the singular story of the heroic maid. [Arc, Joan of.]

The young king of England, now in his ninth year, had in the meantime been brought to Rouen (May, 1430), and was about a year and a half afterwards solemnly crowned at Paris (17th December, 1431). The death of the duchess of Bedford, the sister of the duke of Burgundy, in November, 1432, and the marriage of Bedford in May of the following year with Jacquetta of Luxembourg, aided materially in still further detaching Burgundy from the English connection, till, his remaining scruples gradually giving way under his resentment, in September, 1435, he concluded a peace with king Charles. This important transaction was managed at a great congress of representatives from all the sovereign powers of Europe assembled at Arras, with the view of effecting a general peace under the mediation of the pope. On the 14th of September, a few days after the treaty between Charles and Burgundy had been signed, but before it was proclaimed, died the great duke of Bedford. This event gave the finishing blow to the dominion of the English in France. In April, 1436, the English garrison in Paris was compelled to capitulate. The struggle lingered on for about fifteen years more; but although some partial successes, and especially the brilliant exertions of the famous Talbot (afterwards earl of Shrewsbury), in Normandy and elsewhere, gave a check from time to time to the progressive dissolution of the English power, the prevailing current of events ran decidedly in the contrary direction. In 1444 a truce was agreed upon, to last till 1st April, 1446; and in this interval a marriage was arranged between king Henry and Margaret, the beautiful daughter of René, king of Sicily and Jerusalem, and duke of Anjou, Maine, and Bar. These lofty dignities however were all merely titular; with all his kingdoms and dukedoms, René was at this time nearly destitute both of land and revenue. Thus circumstanced, in return for the hand of his daughter, he demanded the restoration of his hereditary states of Maine and Anjou, which were in the possession of the English, and the proposal was at length assented to. Nor was this cession of territory the only thing that tended from the first to excite popular feeling in England against the marriage. Margaret was a near relation of the French king, and had been in great part brought up at the court of Charles. The connexion therefore seemed to be one thoroughly French in spirit, and it is no wonder that the earl of Suffolk, by whom it had been negotiated, became from this time the object of much general odium and suspicion, the more especially when it was found that Margaret, who soon evinced both commanding talent and a most imperious temper, distinguished him by every mark of her favour, and made him almost exclusively her confidential adviser and assistant in winding to her purposes her feeble and pliant husband. The marriage was solemnized in the abbey of Tichfield, 22nd April, 1445, Suffolk having a few months before, on the conclusion of the negotiations, been created a marquess. The truce with France was now prolonged till the 1st of April, 1449. The first remarkable event that followed was the destruction of the duke of Gloucester, who, although he appears not to have openly opposed the marriage, was certainly the most formidable obstacle in the way of the complete ascendancy of Suffolk and the queen. Having been arrested on a charge of high treason, 11th February, 1447, he was on the seventeenth day thereafter found dead in his bed. In the popular feeling, which however may very possibly have been mistaken, his death was generally attributed to the agency of Suffolk, who now, raised to the dignity of duke, became, ostensibly as well as really, prime, or rather sole minister.

Soon after hostilities were renewed in France, and a numerous force having been poured by king Charles into Normandy, through the adjacent country of Maine, no longer a hostile frontier, town after town was speedily reduced, till at last Rouen, the capital, surrendered, 4th November, 1449. Early in the next year another heavy reverse was sustained in the defeat of Sir Thomas Kyriel at Fourmigny; and at last the fall of Cherbourg, 12th August, 1450, completed the loss of the duchy. Before this catastrophe however the public indignation in England had swept away the unhappy minister on whose head all this accumulation of disasters and disgraces was laid; the duke of Suffolk, after having been committed to the Tower, on the impeachment of the House of Commons, and banished from the kingdom by the judgment of his peers, was seized as he was sailing across from Dover to Calais, and being carried on board one of the king's ships, was there detained for a few days, and at last had his head struck off by an executioner who came alongside in a boat from the shore, May 2nd, 1450. The murder of Suffolk was immediately followed by a popular insurrection, unparaleled in its extent and violence since the rebellion of Wat Tyler, seventy years before. [Cade, John.] Before the close of the following year the French, in addition to Normandy, had recovered all Guienne; and with the exception of Calais, not a foot of ground remained to England of all her recent Continental possessions. Bordeaux, which had been subject to the English government for three centuries and a half, revolted the following year; and the brave Talbot, now eighty years of age, was sent to Guienne to take advantage of that movement; but both he and his son fell in battle, 20th July, 1453; and on the 10th of October following Bordeaux surrendered to Charles.

The remainder of the history of the reign of Henry VI. is made up of the events that arose out of the contest for the crown which eventually placed another family on the throne. [Edward IV.] It is only necessary here to enumerate in their chronological order the leading facts in the story of Henry's personal fortunes. On the 13th of October, 1453, Queen Margaret was delivered at Westminster of a son, who was named Edward, and early in the next year, according to custom, created prince of Wales and earl of Chester. About the same time the king sunk into a state of mind amounting to absolute incapacity. By the beginning of the year 1455 however he had recovered such use of his faculties as he had formerly had, and again took upon him the nominal administration of the government, which during his malady had been committed to the duke of York. In the contest of arms that soon ensued, he was taken prisoner by the earl of Warwick at St. Albans, 23rd May, 1455, and towards the end of that year he was again declared to be in a state of incapacity, and the duke of York resumed the management of affairs with the title of protector. Again however in a few months Henry recovered his health, and the government was conducted in his name till his second capture by the young earl of March (afterwards Edward IV.) at Northampton, 10th July, 1460. On this occasion the queen escaped with her son, and eventually made her way to Scotland. The victory obtained by Margaret over the earl of Warwick at Barnet Heath, 17th February, 1461, again liberated her husband; after which, and the issue of the battle of Towton, 29th March, which established Edward on the throne, he retired with the queen and Prince Edward to Scotland. Here he fixed his residence in the first instance at Kirkcudbright; but it appears that he afterwards, as well as his queen, proceeded to Edinburgh. (See Note by Sir W. Scott, on the fifth canto of *Marmion.*) When Margaret again took up arms and invaded England in 1462, Henry was placed for security in the Castle of Hardlough in Merionethshire; and here he remained till the spring of 1464, when he was brought from Wales to join a new insurrection of his adherents in the north of England. After the two final defeats of the Lancastrians at Hedgley Moor, 25th April, and at Hexham, 15th May, the deposed king lurked for more than a year among the moors of Lancashire and Westmorland, till he was at last betrayed by a monk of Addington, and seized as he sat at dinner in Waddington Hall in Yorkshire, in June, 1465. He was immediately conducted to London and consigned to the Tower, where he remained in close confinement, till the extraordinary revolution of October, 1470, again restored him, for a few months, to both his liberty and his crown. He was carried from London to the battle of Barnet, fought 14th April, 1471, and there fell into the hands of Edward, who immediately remanded him to his cell in the Tower. The old man survived the final defeat of his adherents, and the murder of his son at Tewkesbury, 4th May; and a few days after an attempt, which had nearly succeeded, was made by Thomas Nevil, called the Bastard of Falconberg, to break into his prison and carry him off by force. This probably determined Edward to take effectual means for the prevention of further disturbance from the same quarter. All that is further known is that on Wednesday the 22nd the dead body of Henry was exposed to public view in St. Paul's. It was generally believed however that he had been murdered, and that his murderer was the king's brother, the Duke of Gloucester, afterwards Richard III. Henry VI. was after his death revered as a martyr by the Lancastrians, and many miracles were reported to have been wrought at his tomb. An attempt was made in the next century by his successor Henry VII. to prevail upon Pope Julius II. to canonize him; the pope referred the matter to the examination of the archbishop of Canterbury and the bishops of London, Winchester, and Durham; but it came to nothing. 'The general opinion was,' says Bacon (*Life of Henry VII.*), 'that Pope Julius was too dear, and that the king would not come to his rates. But it is more probable that that pope, who was extremely jealous of the dignity of the see of Rome, and of the acts thereof, knowing that King Henry VI. was reputed in the world abroad but for a simple man, was afraid it would but diminish the estimation of that kind of honour, if there were not a distance kept between innocents and saints.'

HENRY VII. was born at Pembroke Castle, 21st January, 1456. His father was Edmund Tudor (or rather Tydor, pronounced Tuddor, that is, Theodore), surnamed of Hadham, who had been created earl of Richmond in 1452, being the son of Sir Owen Tudor and Queen Catherine, widow of Henry V. He was thus paternally descended both from the royal house of France and also, it is said, from the antient sovereigns of Wales, for such is the derivation assigned by the genealogists to the Tudors—if indeed, as Camden remarks (in his 'Remains') that can with any propriety be considered as the family name which was really merely the Christian name of Owen Tudor's grandfather, from whom he and his father assumed it as their patronymic. But it was his maternal extraction that gave Henry Tudor his political importance. His mother was Margaret, the only child of John Beaufort, duke of Somerset, whose father of the same name was the eldest of the sons of John of Gaunt, duke of Lancaster, the root of the Lancastrian house, by his third wife, Catherine Swynford. The Beauforts, as the children of Gaunt by this wife were named, having been born before marriage, and only subsequently legitimated by a patent entered on the rolls of parliament, which appears (though there is some doubt as to that point) not to have opened to them the succession to the crown, were not at first looked upon as in themselves or their descendants forming strictly a branch of the House of Lancaster; their name itself distinguished them as another family. But towards the close of the reign of Henry VI. their royal descent and proximity to the throne began to be spoken of as giving them important pretensions. After the termination of the wars of the roses the Somerset family remained the only representatives of the House of Lancaster, in England: there were indeed in Portugal, Spain, Germany, and Denmark, nearly a dozen descendants of the daughters of John of Gaunt by his two earlier marriages, some of whom at least, namely, those sprung from Henry IV., had clearly a prior place in the line of succession to the Beauforts, had the legitimation of the latter been ever so perfect; but the circumstances of the time were not such as to allow any validity to these foreign titles. After Richard III. obtained the throne, only two really formidable members of the House of Lancaster survived, namely, this Henry, earl of Richmond, and Henry, duke of Buckingham, whose mother was also a Margaret Beaufort, a great-grand-daughter of John of Gaunt. But her father was a younger brother of the father of the Countess of Richmond, whose son therefore undoubtedly stood first in the line of the family succession.

The following anecdotes are related by Bacon at the close of his History of Henry VII.: 'When the Lady Margaret, his mother, had divers grand suitors for marriage, she dreamed one night that one in the likeness of a bishop in pontifical habit did tender her Edmund, earl of Richmond, the king's father, for her husband; neither had she ever any child but the king, though she had three husbands. One day when King Henry VI., whose innocency gave him holiness, was washing his hands at a great feast, and cast his eye upon King Henry, then a young youth, he said, "This is the lad that shall possess quietly that that we now strive for."' Edmund Tudor, earl of Richmond, died in 1456, the same year in which his son Henry was born. Throughout the stormy period that followed the child found a protector in his uncle Jasper Tudor, earl of Pembroke, till on the accession of Edward IV. in 1461, the earl was attainted and obliged to fly the country. Henry appears to have been then consigned by the new king to the charge of Sir William Herbert, Baron Herbert (afterwards created earl of Pembroke), and to have been carried by that nobleman to his residence of Ragland Castle in Monmouthshire. Long afterwards he told the French historian Comines that he had been either in prison or under strict surveillance from the time he was five years of age. He is said however to have been brought to court on the restoration of Henry VI. in 1470, and it is to this date that the story is assigned of his having been prophetically pointed out by Henry as the person that was to bring to a close the contest between the two Houses. It must have been at this time also that he was sent to Eton, if he ever really studied, as is reported by some, at that school. After the battle of Tewkesbury he seems to have been sent back to Ragland Castle, and to have remained there till his uncle, who had fled to France, returned secretly, and found means to carry him off to his own castle of Pembroke. Upon this Edward immediately took measures to recover possession of the boy, but his uncle at last contrived to embark with him at Tenby, with the intention of proceeding to France. They were forced however by stress of weather to put into a port of Bretagne, and there they were detained by the duke, Francis II. But although this prince would not suffer them to pursue their journey, he allowed them an honourable maintenance, and as much liberty as was consistent with his design that they should not pass out of his dominions, nor although repeatedly importuned by King Edward to deliver them up would he ever listen to the proposal. Henry continued resident in these circumstances in the town of Vannes in Bretagne till after the accession of Richard III.

As soon as it came to be known that Edward V. and his brother no longer existed, a fact which Richard III. himself took pains to publish, without any attempt to make it appear that they had not been taken off by violence, the minds of men turned to the young earl of Richmond as the most eligible opponent to set up against the actual possessor of the crown. Morton, bishop of Ely, afterwards archbishop of Canterbury and cardinal, has the credit of having first suggested to the heads of his party, that the crown should be offered to Henry on condition of his engaging to espouse the princess Elizabeth, daughter of Edward IV., and since the death of her brothers the undoubted heiress of the rights of the House of York. The scheme received the assent of the leaders of the various interests already confederated against Richard—of the queen dowager, of her son the marquis of Dorset, and of the duke of Buckingham, whatever were the motives that had induced the last-mentioned nobleman to make his sudden change from the one side to the other. Communications were immediately entered into with Henry's mother the countess of Richmond, and she also entered cordially into the design, although her present husband Lord Stanley had all along steadily adhered to Richard, with whom he at present was. A messenger was now despatched to Henry in Bretagne, September 24, 1483, and he was informed that the general rising in his favour would take place on the 18th of October. The issue of this first attempt was eminently disastrous to the confederacy of the earl's friends. Henry sailed from St. Malo with a fleet of forty sail, which he had been enabled to provide partly by the assistance of the duke of Bretagne; but a storm dispersed his ships as he crossed the Channel, and when he reached the English coast near Poole he deemed it prudent, with the insufficient force that he had remaining, not to land. Meanwhile the hasty, ill-combined revolt of Buckingham and his associates fell to pieces without the striking of a blow. Buckingham himself was taken and executed as a traitor; of the other chief persons engaged in the attempt, several underwent the same fate; others escaped death by flight; many were attainted, among the rest the countess of Richmond, whose life was only spared at the intercession of her husband Lord Stanley. Henry himself returned to Bretagne, and here at Christmas, in the presence of a meeting of the English exiles to the number of five hundred, held in the cathedral of Rhedon, he solemnly swore to marry Elizabeth as soon as he should have triumphed over the usurper, and in return the assembly promised him fealty on that condition, and did him homage as their sovereign. A few months after this however Henry and his friends found it expedient to withdraw from Bretagne to avoid the machinations of the duke's minister Landois, who had been gained over by Richard, and had prevailed upon the duke to take measures for betraying them to the English king. They succeeded in making their escape to the territory of the French king, where they spent another year in making preparations for a new expedition under the countenance and with the assistance of king Charles VIII. At length, on the 1st of August, 1485, Henry sailed with his fleet from Harfleur, and on the 7th landed at Milford-Haven in Wales. The two rivals encountered at Bosworth in Leicestershire, on the 22nd, when the result was that Henry obtained a complete victory, which, with the death of Richard, who fell in the battle, at once placed the crown on his head. This was afterwards reckoned the first day of his reign, an arrangement by which only those who had actually drawn their swords against him at Bosworth were made to be guilty of treason, and whatever acts had been done in the service of the usurper (as Richard was considered) up to the eve of that battle were overlooked. [BOSWORTH; RICHARD III.]

Henry's marriage with Elizabeth was not solemnized till the 18th of January, 1486, before which time it had been enacted by the parliament that 'the inheritance of the crown should be, rest, remain, and abide in the most royal person of the then sovereign lord King Henry VII., and the heirs of his body lawfully coming, perpetually with the grace of God so to endure, and in none other;' the only security taken for the marriage being a request subsequently presented to the king by the Commons along with the grant of tonnage and poundage for life, that he would be pleased 'to take to wife and consort the princess Elizabeth,' with which, after it had been formally concurred in by the lords spiritual and temporal, Henry intimated that he was willing to comply. It has been usually asserted that Henry throughout their union treated his queen with marked coldness and neglect. He must have felt indeed that he owed nothing to any preference that had been shown for him by a woman who was equally ready to give her hand to his deadliest enemy, had the fortune of the contest been different; but it would appear that, from policy, if not from affection, he latterly behaved to her with more attention than he had at first shown; and there is even some evidence that their domestic intercourse came at length to breathe more cordiality and tenderness than has been generally supposed.

It was not to be expected that a reign commencing in such circumstances should be undisturbed by insurrectionary attempts. A succession of such movements kept Henry in disquietude for many years. The first that occurred was that headed by Francis, viscount Lovel, in April, 1486, which was speedily and effectually put down. Before the end of the same year however a new and more formidable commotion was excited by the imposture of the boy Lambert Simnel, the son of a joiner at Oxford, who was put forward as Edward Plantagenet, earl of Warwick, the son and heir of the late duke of Clarence, brother of Richard III. The young prince in question had, in fact, been lodged in the Tower by Henry among the first acts of his reign, and he remained immured in that fortress while the person who had assumed his name was receiving royal honours in Ireland as Edward VI. Simnel was soon joined both by Lord Lovel, who had made his escape from the recent disturbance, and by John de la Pole, earl of Lincoln, whose mother was a sister of Edward IV., and who had been at one time declared heir to the crown by the late king after the death of his own son. The duchess of Burgundy, another sister of Edward IV., also gave her countenance and effective aid to the enterprise of the pretender, whom probably the friends of the House of York merely intended to make use of for effecting their first object, the ejection of the present king. The brief royalty of Simnel however was terminated, June 16th, 1487, by the defeat of his adherents in the battle of Stoke, in which Lincoln himself was slain. The imposture of Simnel was followed after some years by the appearance of the more celebrated pretender Perkin Warbeck, who was asserted by his adherents to be Richard, duke of York, the younger brother of Edward V., and generally supposed to have been murdered along with him in the Tower. Warbeck arrived in Ireland from Lisbon in the beginning of May, 1492, and was afterwards acknowledged as duke of York, or rather as Richard, king of England, not only by the duchess of Burgundy, but by the governments both of France and Scotland. This affair occupied Henry for the next five or six years; for it was not till the end of 1497 that the adventurer was finally put down. Another pretended earl of Warwick next arose, one Ralph Wulford, or Wilford, the son of a shoemaker, whose attempt however was immediately nipped in the bud by his apprehension and execution, in March, 1499. The restless succession of these conspiracies seems at last to have convinced Henry that his throne would never be secure, nor the kingdom at peace, until the persons who were made rallying-points by his enemies were put out of existence. The same year in which Wulford was put to death witnessed the executions of both Perkin Warbeck and the earl of Warwick. From this time Henry's reign was one of complete internal tranquillity, of which he chiefly took advantage to augment his revenue and his hoarded treasures—extracting money from his subjects on all sorts of pretences, which were not the less oppressive for being generally legal in their form and colour. The English law at this time, if only stretched as far as it would go, was abundantly sufficient for the purposes of the most exorbitant tyranny. The chief instruments of Henry's rapacity were two lawyers, Sir Richard Empson and Edmund Dudley, names immortalized by the detestation of their country.

Henry was early in his reign involved in the politics of the Continent by the quarrel which arose between Francis duke of Bretagne and Charles VIII. of France, with both of whom he had been connected before he came to the throne, and each of whom applied to him for his assistance. This quarrel, by the death of Francis, soon after it broke out, leaving only two daughters, one of whom also soon afterwards died, became in fact a contest for the possession of Bretagne on the part of France. [BRETAGNE, v. 401.] This was an object to which the public mind in England was strongly opposed; but although Henry was forced to appear to go along with the national feeling, he deferred taking any steps to prevent the subjugation of the Bretons till it was too late. The money that was eagerly voted by parliament to fit out an expedition, he collected very carefully; but instead of fighting, he endeavoured to manage the matter by the cheaper method of negotiation. Afterwards indeed, in the spring of 1489, he found himself compelled to equip a small force, which proceeded to Bretagne; but he had previously assured the French government that if the troops were sent they should act only on the defensive, an engagement which was faithfully kept. Charles eventually compelled the duchess of Bretagne to marry him, after she had been affianced to Maximilian, the King of the Romans; and the duchy was thus finally annexed to the French crown. The indignation in England at this result forced Henry to conduct an army to France in person, in the beginning of October, 1492; but he had already secretly arranged a peace with Charles, and before there was any fighting the treaty was published in the beginning of November. By this treaty, called the Treaty of Estaples, Charles bound himself to pay Henry the sum of 149,000*l.* sterling, in half-yearly instalments of 25,000 francs. In 1496, notwithstanding this peace, Henry joined the league of the pope, the King of the Romans, the king of Castile, the duke of Milan, and the republic of Venice, which, after Charles had overrun the kingdom of Naples in 1494, had in a few months expelled him from his sudden conquest; but when Charles died, in 1498, the treaty of Estaples was renewed with his successor Louis XII., and continued to regulate the relations of the two kingdoms to the end of the reign

By successive truces with James III. and James IV., the peace with Scotland was preserved till 1495, when, on the recommendation of the French king and the duchess of Burgundy, Perkin Warbeck was received in that kingdom as the rightful heir of the English crown. King James not only assisted the adventurer with money and troops, but gave him in marriage the Lady Catherine Gordon, a relation of his own. After Warbeck's final discomfiture however in 1497, a new truce was concluded between the two countries, to last till the expiration of a year after both kings should be dead; and this led in 1502 to a treaty of perpetual peace, cemented by the marriage of James with Henry's eldest daughter, the princess Margaret. This marriage, from which flowed, after the lapse of a century, the important political result of the union of the two crowns, was solemnized at Edinburgh on the 8th of August, 1503. It was reported, Bacon informs us, that when the project of the marriage was discussed in the council of the English king, an objection was raised on the ground that it might possibly lead to the kingdom of England falling to the king of Scotland. 'Whereunto,' continues the historian, 'the king himself replied, that if that should be, Scotland would be but an accession to England, and not England to Scotland, for that the greater would draw the less; and that it was a safer union for England than that of France. This passed as an oracle, and silenced those that moved the question.'

Nearly two years before this, namely, 14th November, 1501, a marriage, long contemplated and agreed upon, had been solemnized between Henry's eldest son Arthur, prince of Wales, and Catherine, the fourth daughter of Ferdinand, king of Castile. Arthur however, who was a prince of the highest promise, died within six months after this time; and then it was arranged that Catherine should be married to his surviving brother Henry. The marriage of Catherine and Arthur proved still more momentous in its consequences than that of Margaret and James.

Queen Elizabeth died 11th February, 1503, a few days after giving birth to a daughter, on which Henry lost no time in proceeding to turn his widowhood to account in the acquirement of some political advantage, or in the augmentation of his riches, now his ruling passion, by means of a new matrimonial alliance. One disappointment after another however met him in this pursuit; and after having first made application to the widow of the king of Naples; then concluded a treaty with the archduke Philip, husband of Joanna, queen of Castile, for the band of his sister Margaret, widow of the duke of Savoy; and finally, on the death of Philip, in September, 1506, once more changed his ground, and proposed himself as the husband of Philip's widow, the queen Joanna, who was insane,—he died before he could accomplish his object. His death took place at Richmond, as the royal palace at Sheen was now called, 22nd April, 1509, in the twenty-fourth year of his reign, and the fifty-third of his age.

The children of Henry VII. by his queen Elizabeth of York were—1. Arthur, born 20th September, 1486, created prince of Wales 1489, married to Catherine of Spain (to whom he had been contracted eleven years before), 14th November, 1501, died at Ludlow Castle, 2nd April, 1502; 2. Margaret, born 29th November, 1489, married to king James IV. of Scotland, 8th August, 1503, died 1539; 3. Henry, who succeeded his father as Henry VIII.; 4. Elizabeth, born 2nd July, 1492, died 14th September, 1495; 5. Mary, born 1498, married to Louis XII. of France, 5th November, 1514, and secondly, in 1515, to Charles Brandon, duke of Suffolk, died 25th June, 1533; 6. Edmund, born 21st February, 1499, soon after created duke of Somerset, died in infancy; 7. Edward, born February, 1500, died young; and 8. Catherine, born 2nd February, 1503, died a few days after her mother.

Bacon, in his striking and masterly 'History of the Reign of Henry VII.,' has drawn this king as a hero of policy and craft, who may almost compete with the 'Principe' of Macchiavel, if we make allowance for the greater ruthlessness and more sanguinary spirit natural to the Italian blood. It may be admitted that this great writer, in the elaboration of his design, has been drawn into some degree of exaggeration or over-refinement; and he has probably also softened the more repulsive features in Henry's moral character, as much as he has unduly exalted his intellectual endowments. But the difficult position which he occupied, and the success with which he maintained himself in it, vindicate the title of this sovereign to be regarded as at least one of the greatest masters of king-craft that figure in history. Bacon compares him, justly enough, to Louis XI. of France and Ferdinand of Spain, designating the three as 'the *tres magi* of kings of those ages.' The age in which Henry lived was that of the birth of modern policy, and that in which the foundations were laid of the still enduring system of the European states. Nothing that was then established has been greatly shaken since; all the changes that have since taken place have been little more than the growth and development of the arrangements that were then made and the principles that were called into action. This reign therefore may be considered as the beginning of the modern history of England.

HENRY VIII., the second son of Henry VII., by his queen Elizabeth of York, was born at Greenwich, 28th June, 1491. On the 1st of November following he was created duke of York, and in 1494 his father conferred upon him the honorary title of lord-lieutenant of Ireland, Sir Edward Poynings being appointed his deputy. The government of Sir Edward is famous for the enactment of the statute, or rather series of statutes, declaring the dependence of the Irish parliament upon that of England, which passes under his name. Henry's nominal lord-lieutenancy appears to have lasted only till the next year, when he exchanged that dignity for the office of president of the Northern Marches. The king's design in these appointments seems to have been to oppose his son's name to the pretensions of Perkin Warbeck, and the efforts of the supporters of that adventurer, first in Ireland and afterwards from the side of Scotland. Although thus early distinguished by these and other civil titles and appointments, it is stated by Paolo Sarpi, in his 'History of the Council of Trent,' that Henry was from the first destined to the archbishopric of Canterbury; 'that prudent king his father,' observes Lord Herbert (in the 'History of his Life and Reign') 'choosing this as the most cheap and glorious way for disposing of a younger son.' He received accordingly a learned education; 'so that,' continues this writer, 'besides his being an able Latinist, philosopher, and divine, he was (which one might wonder at in a king) a curious musician, as two entire masses composed by him, and often sung in his chapel, did abundantly witness.' As the death of his elder brother Arthur, however, 2nd April, 1502, made him heir to the crown before he had completed his eleventh year, it is evident that his clerical education could not have proceeded very far, and that what he knew either of divinity or of the learned tongues must have been for the most part acquired without any view to the church. There is a contradiction in the statements as to the time when he was created prince of Wales. Bacon says, first, that 'it was half a year's time between the creation of Henry, prince of Wales, and Prince Arthur's death, which was construed to be, for to expect a full time, whereby it might appear whether the Lady Catherine was with child by Prince Arthur or no.' A few lines farther down in the same page, he says, 'the February following, Henry, duke of York, was created prince of Wales and earl of Chester and Flint; for the dukedom of Cornwall devolved to him by statute.' (*History of King Henry VII.*, in Bacon's Works, by Montague, iii. 377.) This last account makes the interval, not half a year, but eleven months. Sir Harris Nicolas (*Synopsis of the Peerage*, i. 7) also, we do not know on what authority, dates Henry's creation as prince of Wales, 18th February, 1503. But there is a patent in Rymer (vol. xiii., p. 11) appointing him warden of the forest of Gualtres in Yorkshire, by this title, 22nd June, 1502, within three months after his brother's death. This is consistent with what we are told by Holinshed, who, after relating the death of Arthur, says, 'his brother, the Duke of York, was stayed from the title of Prince by the space of a month, till to women it might appear whether the Lady Catherine, wife to the said Prince Arthur, was conceived with child or not.'

Very soon after Arthur's death the singular project was started of marrying Henry to his brother's widow. The proposition appears to have originally come from Ferdinand and Isabella, the parents of the princess, who were anxious to retain the connexion with England; and to have been assented to by King Henry in great part from his wish to avoid the repayment of the dower of the princess. The final agreement between the two kings was signed 23rd June, 1503, and, according to the chroniclers, the parties were affianced on Sunday the 25th of the same month, at the bishop of Salisbury's house in Fleet Street, although the dispensation was certainly not obtained from Pope Julius II. till the 26th of December following. This bull however contains a clause legitimatizing the marriage, although it should have been already contracted, or even consummated. It may be observed that nobody at this time seems to have doubted that Catherine's preceding marriage with Arthur had been followed by consummation.

Henry became king 22nd April, 1509, being then in his 19th year. On a memorial being presented by the Spanish ambassador, it was, notwithstanding the opposition of Warham, archbishop of Canterbury, resolved in the council that the marriage with Catherine should be completed; Fox, bishop of Winchester, strongly urging, among other reasons, 'that there was no room to doubt that the princess was still a virgin, since she herself affirmed it, offering even to be tried by matrons, to show that she spoke the truth.' The marriage was accordingly solemnized in the beginning of June, though not so early as the 3rd of that month, the date assigned both by Lord Herbert and by Holinshed and the other chroniclers, as appears from the act of resignation of her dowry by Catherine, signed at Greenwich on the 7th, in which she still styles herself Princess of Wales. (Rymer, xiii., 251.)

Henry was indebted for the warm and general gratulation with which his accession was hailed by his subjects, partly to his distinguished personal advantages and accomplishments, and to some points of manner and character adapted to take the popular taste; partly to the sense of relief produced by the termination of the austere and oppressive rule of his predecessor. One of the earliest proceedings of the new reign was the trial and punishment of his father's ministers, Dudley and Empson. They were indicted for a conspiracy to take possession of London with an armed force during the last illness of the late king, and being convicted on this charge, and afterwards attainted by parliament, were, after lying in gaol for about a year, beheaded together on Tower Hill, 17th August, 1510.

Henry had not been long upon the throne when he was induced to join what was called the Holy League, formed against France by the pope, the emperor, and the king of Spain. A force of 10,000 men was sent to Biscay under the Earl of Dorset in the spring of 1512, to co-operate with an army promised by Ferdinand for the conquest of Guienne; but the Spanish king, after dexterously availing himself of the presence of the English troops to enable him to overrun and take possession of Navarre, showed plainly that he had no intention of assisting his ally in his object; and after having had his ranks thinned, not by the sword, but by disease, Dorset was compelled by discontents in his camp, which rose at last to actual mutiny, to return to England before the end of the year, without having done anything. The next year Henry passed over in person to France with a new army, and having been joined by the Emperor Maximilian, defeated the French, 4th August, at Guinegaste, in what was called the Battle of the Spurs, from the unusual energy the beaten party are said to have shown in riding off the ground, and took the two towns of Terouenne and Tournay. On the 9th of September also the Scottish king James IV., who as the ally of France had invaded England, was defeated by the earl of Surrey in the great battle of Flodden, he himself with many of his principal nobility being left dead on the field. This war with France however was ended the following year by a treaty, the principal condition of which was that Louis XII., who had just lost his queen, Ann of Bretagne, the same who had been in the first instance married to his predecessor Charles VIII. [HENRY VII.], should wed Henry's sister, the Princess Mary. The marriage between Louis, who was in his fifty-third, and the English princess, as yet only in her sixteenth year, was solemnized 9th October, 1514; but Louis died within three months, and scarcely was she again her own mistress when his young widow gave her hand to Charles Brandon, duke of Suffolk, an alliance out of which afterwards sprung a claim to the crown. [GREY, LADY JANE.]

The members of Henry's council, when he came to the throne, had been selected, according to Lord Herbert, 'out of those his father most trusted,' by his grandmother the countess of Richmond, 'noted to be a virtuous and prudent lady.' A rivalry however and contest for the chief power soon broke out between Richard Fox, bishop of Winchester, secretary and lord privy seal, and Thomas Howard, earl of Surrey (afterwards duke of Norfolk), who held the office of lord treasurer. This led to the introduction at court of the famous Thomas Wolsey, who, being then dean of Lincoln, was brought forward by Fox to counteract the growing ascendancy of Surrey, and who speedily made good for himself a place in the royal favour that reduced all the rest of the king's ministers to insignificance, and left in his hands for a long course of years nearly the whole power of the state. [WOLSEY, CARDINAL.] The reign of Wolsey may be considered as having begun after the return of Henry from his expedition to France, towards the close of the year 1513; and henceforth the affairs of the kingdom for fourteen or fifteen years were directed principally by the interests of his ambition, which governed and made subservient to its purposes even the vanity and other passions of his master.

The history of the greater part of this period consists of Henry's transactions with his two celebrated contemporaries, Francis I. of France, the successor of Louis XII., and Charles, originally archduke of Austria, but who became king of Spain as Charles I. by the death of his mother's father, Ferdinand, in 1516, and three years after was elected to succeed his paternal grandfather Maximilian I. as emperor of Germany. [CHARLES V.; FRANCIS I.] His position might have enabled the English king in some degree to hold the balance between these two irreconcileable rivals, who both accordingly made it a principal point of policy to endeavour to secure his friendship and alliance; but his influence on their long contention was in reality very inconsiderable, directed as it was for the most part either by mere caprice, or by nothing higher than the private resentments, ambitions, and vanities of himself or his minister. The foreign policy of this reign had nothing national about it, either in reality or even in semblance; it was neither regulated by a view to the true interests of the country, nor even by any real, however mistaken, popular sentiment. Henry had himself been a candidate for the imperial dignity when the prize was obtained by Charles; but he never had for a moment the least chance of success. For a short time he remained at peace, both with Charles and Francis; the former of whom paid him a visit at Dover in the end of May, 1520; and with the latter of whom he had a few days after a seemingly most amicable interview, celebrated under the name of the 'Field of the Cloth of Gold,' in the neighbourhood of Calais. Wolsey's object at this time however was to detach his master from the interests of the French king; and a visit which Henry paid to the emperor at Gravelines, on his way home, showed Francis how little he was to count upon any lasting effect of their recent cordialities. Before the close of the following year Henry was formally joined in league with the emperor and the pope; and in March, 1522, he declared war against France. In the summer of the same year the emperor flattered him by paying him a visit at London; his vanity having also been a short time before gratified in another way by the title of 'Defender of the Faith' bestowed upon him by pope Leo X. (recently succeeded by Adrian VI.) for a Latin treatise which he had published 'On the Seven Sacraments,' in confutation of Luther. Henry continued to attach himself to the interest of the emperor,—even sending an army to France, in August, 1523, under the duke of Suffolk, which succeeded in taking several towns, though only to give them up again in a few months, —until the disappointment, for the second time, of Wolsey's hope of being made pope through the influence of Charles, on the death of Adrian in September of the last-mentioned year, is supposed to have determined that minister upon a change of politics. Before the memorable defeat and capture of Francis at the battle of Pavia, 24th February, 1525, the English king had made every preparation to break with the emperor; having actually commenced negotiations for a peace with Francis's ally, James V., the young king of Scotland, on condition of giving James in marriage his daughter the princess Mary (afterwards queen), who had been already promised to the emperor. In August he concluded a treaty of peace and alliance with France; and after the release of Francis, in March, 1526, Henry was declared protector of the league styled 'Most Clement and Most Holy,' which was formed under the auspices of the pope for the renewal of the war against Charles.

Before this date two domestic occurrences took place that especially deserve to be noted. The first of these was the execution, in 1513, immediately before Henry proceeded on his expedition to France, of Edmund de la Pole, duke of

Suffolk, whose mother was Elizabeth Plantagenet, sister of Edward IV.; he had lain a prisoner in the Tower ever since a short time before the death of the late king, who had contrived to obtain possession of his person after he had fled to the Continent, and, it is said, had in his last hours recommended that he should not be suffered to live. He was now put to death without any form of trial or other legal proceeding, his crime, there can be no doubt, being merely his connexion with the House of York. Lord Herbert tells us that Henry's going to the Continent at this time was deemed dangerous and inexpedient, on the ground 'that if the king should die without issue, however the succession were undoubted in his sister Margaret, yet the people were so affected to the House of York, as they might take Edmund de la Pole out of the Tower and set him up.' Wolsey was perhaps as yet too new in office to be fairly made answerable for this act of bloodshed; in the next case the unfortunate victim is generally believed to have been sacrificed to his resentment and thirst of vengeance. In 1521 Edward Stafford, duke of Buckingham, son of the duke beheaded by Richard III. [HENRY VII.], was apprehended on some information furnished to Wolsey by a discarded servant, and being brought to trial was found guilty and executed as a traitor. The acts with which he was charged did not according to law amount to treason, even if they had been proved; but the duke is said by certain indiscretions of speech and demeanor to have wounded the pride of the all-powerful minister; and, besides, he was also of dangerous pedigree, being not only maternally of the stock of John of Gaunt, but likewise a Plantagenet by his descent from Anne, the daughter of Edward the Third's youngest son Thomas, duke of Gloucester. With this nobleman came to an end the great office of hereditary lord high constable.*

What may be called the second part of Henry's reign begins in the year 1527, from which date our attention is called to a busy scene of domestic transactions beside which the foreign politics of the kingdom become of little interest or importance. It is no longer the ambition and intrigue of the minister, but the wilfulness and furious passions of the king himself, that move all things. In 1527 Henry cast his eyes upon Anne Boleyn, and appears to have very soon formed the design of ridding himself of Catherine, and making the object of this new attachment his queen. [BOLEYN, ANNE.] Anne was understood to be favourably disposed towards those new views on the subject of religion and ecclesiastical affairs which had been agitating all Europe ever since Luther had begun his intrepid career by publicly opposing indulgences at Wittemberg ten years before. Queen Catherine on the other hand was a good Catholic; and, besides, the circumstances in which she was placed made it her interest to take her stand by the church, as on the other hand her adversaries were driven in like manner by their interests and the course of events into dissent and opposition. This one consideration sufficiently explains all that followed. The friends of the old religion generally considered Catherine's cause as their own; the reformers as naturally arrayed themselves on the side of her rival. Henry himself again, though he had been till now resolutely opposed to the new opinions, was carried over by his passion towards the same side; the consequence of which was the loss of the royal favour by those who had hitherto monopolized it, and its transference in great part to other men, to be employed by them in the promotion of entirely opposite purposes and politics. The proceedings for the divorce were commenced by an application to the court of Rome, in August, 1527. For two years the affair lingered on through a succession of legal proceedings, but without any decisive result. From the autumn of 1529 are to be dated both the fall of Wolsey and the rise of Cranmer. [CRANMER, THOMAS.] The death of the great cardinal took place 29th November, 1530. In January following the first blow was struck at the church by an indictment being brought into the King's Bench against all the clergy of the kingdom for supporting Wolsey in the exercise of his legatine powers without the royal licence, as required by the old statutes of *provisors* and *premunire;* and it was in an act passed immediately after by the Convocation of the province of Canterbury, for granting to the king a sum of money to exempt them from the penalties of their conviction on this indictment, that the first movement was made towards a revolt against the see of Rome, by the titles given to Henry of 'the one protector of the English church, its only and supreme lord, and, as far as might be by the law of Christ, its supreme head.' Shortly after, the convocation declared the king's marriage with Catherine to be contrary to the law of God. The same year Henry went the length of openly countenancing Protestantism abroad by remitting a subsidy to the confederacy of the Elector of Brandenburg and other German princes, called the League of Smalcald. In August, 1532, Cranmer was appointed to the archbishopric of Canterbury. In the beginning of the year 1533 Henry was privately married to Anne Boleyn; and on the 23rd of May following archbishop Cranmer pronounced the former marriage with Catherine void. In the meantime the parliament had passed an act forbidding all appeals to the see of Rome. Pope Clement VII. met this by annulling the sentence of Cranmer in the matter of the marriage; on which the separation from Rome became complete. Acts were passed by the parliament the next year declaring that the clergy should in future be assembled in convocation only by the king's writ, that no constitutions enacted by them should be of force without the king's assent, and that no first-fruits, or Peter's pence, or money for dispensations, should be any longer paid to the pope. [ANNATES.] The clergy of the province of York themselves in convocation declared that the pope had no more power in England than any other bishop. A new and most efficient supporter of the Reformation now also becomes conspicuous on the scene, Thomas Cromwell (afterwards lord Cromwell and earl of Essex), who was this year made first secretary of state, and then master of the rolls. [CROMWELL, THOMAS.] In the next session, the parliament, which re-assembled in the end of this same year, passed acts declaring the king's highness to be supreme head of the church of England, and to have authority to redress all errors, heresies, and abuses in the church; and ordering first-fruits and tenths of all spiritual benefices to be paid to the king. After this various persons were executed for refusing to acknowledge the king's supremacy; among others, two illustrious victims, the learned Fisher, bishop of Rochester, and the admirable Sir Thomas More. [FISHER, JOHN; MORE, THOMAS.] In 1535 began the dissolution of the monasteries, under the zealous superintendance of Cromwell, constituted for that purpose visitor-general of these establishments. Latimer and other friends of Cranmer and the Reformation were now also promoted to bishoprics; so that not only in matters of discipline and polity, but even of doctrine, the church might be said to have separated itself from Rome. One of the last acts of the parliament under which all these great innovations had been made was to petition the king that a new translation of the Scriptures might be made by authority and set up in churches. It was dissolved on the 18th of July, 1536, after having sat for the then unprecedented period of six years.

Events now set in a new current. The month of May of this year witnessed the trial and execution of Queen Anne—in less than six months after the death of her predecessor, Catherine of Aragon—and the marriage of the brutal king, the very next morning, to Jane Seymour, the new beauty, his passion for whom must be regarded as the true motive that had impelled him to the deed of blood. Queen Jane dying on the 14th of October, 1537, a few days after giving birth to a son, was succeeded by Anne, sister of the duke of Cleves, whom Henry married in January, 1540, and put away in six months after—the subservient parliament, and the not less subservient convocation of the clergy, on his mere request, pronouncing the marriage to be null, and the former body making it high treason 'by word or deed to accept, take, judge, or believe the said marriage to be good.'

Meanwhile the ecclesiastical changes continued to proceed at as rapid a rate as ever. In 1536 Cromwell was constituted a sort of lord-lieutenant over the church, by the title of vicar-general, which was held to invest him with all the king's authority over the spiritualty. The dissolution of the monasteries in this and the following year, as carried forward under the direction of this energetic minister, produced a succession of popular insurrections in different parts of the kingdom, which were not put down without great destruction of life, both in the field and afterwards by the executioner. In 1538 all incumbents were ordered to set up in their churches copies of the newly-published English translation of the Bible, and to teach the people the Creed, the Lord's Prayer, and the Ten Commandments, in English; the famous image of our Lady at Walsingham,

* See vol. vii., p. 467, where the duke is by a misprint called Edward Stanley.

and other similar objects of the popular veneration, were also under Cromwell's order removed from their shrines and burnt. In 1539 the parliament, after enacting (by tho 31 Henry VIII., c. 8) that the proclamation of the king in council should henceforth have the same authority as a statute, passed the famous act (the 31 Henry VIII., c. 14) known by the name of the Six Articles, or the Bloody Statute, by which burning or hanging was made the punishment of all who should deny that the bread and wine of the sacrament was the natural body and blood of the Saviour—or that communion in both kinds was not necessary to salvation—or that priests may not marry—or that vows of chastity ought to be observed—or that the mass was agreeable to God's law—or that auricular confession is expedient and necessary. This statute, the cause of numerous executions, proceeded from a new influence which had now gained an ascendancy over the fickle king, that of Gardiner, bishop of Winchester, the able leader of the party in church and state opposed to Cranmer and Cromwell. [GARDINER, STEPHEN.] This new favourite was not long in effecting the ruin of the rival that was most in his way; Cromwell, who had just been created earl of Essex, and made lord chamberlain of England, was in the beginning of June, 1540, committed to the Tower on a charge of treason, and beheaded in a few weeks after.

On the 8th of August this year Henry married his fifth wife, the Lady Catherine Howard, whom he beheaded, 13th February, 1542. During this interval he also rid himself by the axe of the executioner of a noble lady whom he had attainted and consigned to a prison two years before on a charge of treason, Margaret, countess dowager of Salisbury, the daughter of tho late duke of Clarence, and the last of the York Plantagenets. Her real crime was that she was the mother of cardinal Pole, who had offended the tyraut, and who was himself beyond his reach.

In the latter part of the year 1542 war was declared by Henry against Scotland, with a revival of the old claim to the sovereignty of that kingdom. An incursion made by the duke of Norfolk into Scotland, in October, was followed the next month by the advance of a Scottish army into England; but this force was completely defeated and dispersed at Solway Moss, a disaster which is believed to have killed King James, who died a few weeks after, leaving his crown to a daughter, the unfortunate Mary Stuart, then only an infant seven days old. The failure of the efforts of the English king to obtain possession of the government and of the young queen, owing to the successful resistance of cardinal Beaton and the Catholic party, led to a renewal of hostilities in the spring of 1544, when Scotland was invaded by a great army under the earl of Hertford, which penetrated as far as Edinburgh, and burned that capital with many other towns and villages. In the preceding year also Henry had concluded a new alliance with the emperor against the French king; and in July, 1544, he passed over with an army to France, with which he succeeded in taking the town of Boulogne. On this however tho emperor made a separate peace with Francis; and on the 7th of June, 1546, Henry also signed a treaty with that king, in which he agreed to restore Boulogne and its dependencies in consideration of a payment of two millions of crowns.

He had some years before found a sixth wife, Catherine Parr, the widow of the Lord Latimer, whom he married 10th July, 1543. As the infirmities of age and disease grew upon him, the suspiciousness and impetuosity of his temper acquired additional violence, and the closing years of his reign were as deeply stained with blood as any that had preceded them. One of his last butcheries was that of the amiable and accomplished Henry Howard, earl of Surrey, who, being convicted, after the usual process, of treason, was executed on the 19th (other accounts say the 21st) of January, 1547. Already Henry, says Holinshed, 'was lying in the agonies of death.' Surrey's father, the duke of Norfolk, was also to have suffered on the 28th; but was saved by the death of the king at two o'clock on the morning of that day.

The children of Henry VIII. were: 1. and 2. by Catherine of Aragon, two sons who died in infancy; 3. Mary, afterwards queen of England; 4. by Anne Boleyn, Elizabeth, afterwards queen; 5. a son still-born, 29th February, 1535; 6. by Jane Seymour, Edward, by whom he was succeeded on the throne.

The most important changes made in the law during this reign were those affecting ecclesiastical affairs, of which the principal have been already noticed. Along with these may be mentioned the statute defining the degrees within which marriage should be lawful (25 Henry VIII., c. 22), which, in regard to that point, is still the law of the land. The law of real property was also materially altered by the statute of Uses (27 Henry VIII., c. 10), and by various statutes permitting the devise, which was not before allowed, except by the custom of particular places, of real estates by will. [RECOVERIES, COMMON; FINES; USES; WILL.] To this reign is also to be assigned the origin of the Bankrupt Laws. [BANKRUPT.] Wales was first incorporated with England, and the laws and liberties of the latter country granted to the inhabitants of the former, in the 27th year of Henry VIII.; and Ireland, which before was styled only a lordship, was in 1542 erected into a kingdom.

HENRY (Kings of Germany). [GERMANY, *History*.]

HENRY IV. of Germany. [GREGORY VII.]

HENRY (Kings of Spain and Portugal). [SPAIN; PORTUGAL.]

HENRY OF HUNTINGDON, an antient English historian, the son of Nicholas, a married priest (see Tanner, *De Script.*, from Cave), was born about the end of the eleventh century; and, according to Warton (*Hist Engl. Poet.*, diss. ii., p. 125), was educated under Alcuinc of Anjou, a canon of Lincoln cathedral. Aldwin and Reginald, both Normans and abbots of Ramsey, were his patrons. He was made archdeacon of Huntingdon (whence he took his name), by Robert Bloet, bishop of Lincoln, some time before 1123. In his youth he discovered a taste for poetry, but in more advanced years applied himself to the study of history; and at the request of another friend and patron, Alexander, bishop of Lincoln, composed a general history of England, from the earliest accounts to the death of Stephen, A.D. 1154, in eight books, published by Sir Henry Savile among the 'Scriptores post Bedam,' fol., London, 1596, and Francof., 1601. The early part of this history was a compilation from older writers; the sequel, from what he had heard and seen. Wharton, in his 'Anglia Sacra,' vol. ii., p. 694, has published a letter of Henry of Huntingdon to his friend Walter, who was also abbot of Ramsey, 'De Mundi Contemptu,' which contains many curious anecdotes of tho kings, nobles, prelates, and other great men who were his contemporaries. Warton (*Hist. Engl. Poet.*, ut supr.) says, in the Bodleian Library there is a manuscript Latin poem by Henry of Huntingdon on the death of King Stephen and the arrival of Henry II. in England, which is by no means contemptible. The exact time of his death is not known.

HENRY, MATTHEW, an eminent nonconformist divine, was born at Broad Oak, a farm-house in the township of Iscoyd in Flintshire, October 18, A.D. 1662. His father, Philip Henry, who was highly esteemed for his talents and piety, was one of the 2000 clergymen who left the church of England in 1662, in consequence of their refusal to comply with the regulations of tho 'Act of Uniformity.' Matthew Henry received the principal part of his education under Mr. Doolittle of London. In 1685 he commenced the study of the law in Gray's Inn; but he soon relinquished this profession; and after being ordained in 1687, settled at Chester in the same year as minister of a Dissenting congregation. In 1712 he left Chester, and became the minister of another congregation at Hackney. He died on the 22nd of June, 1714, of apoplexy, while he was travelling from Chester to London.

The work by which Matthew Henry is principally known is his 'Exposition of the Old and New Testament,' which originally appeared in 5 vols. fol.; and has since been frequently reprinted. This work has been greatly admired by many persons, on account of the piety of the author and the lively style in which it is written; and perhaps it is the best Commentary on the Bible for the use of those persona who are more anxious to obtain a devout sentiment from a text than to understand the real meaning of the passage. Matthew Henry did not live to complete the 'Exposition.' The remarks on the latter books of the New Testament, from *Romans* to *Revelations*, were written by the ministers whose names are printed in the 'Exposition.' Matthew Henry was also the author of many other works; of which the principal are, 'Inquiry into the Nature of Schism;' 'Life of Philip Henry;' 'Scripture Catechism;' 'Communicants' Companion;' 'Discourses against Vice and Profaneness;' 'Method of Prayer;' and numerous Sermons on separate subjects. These works have been little read of late years; but Mr. Williams, who is well acquainted with them, remarks (*Preface to the Miscellaneous Works of Henry*, p. iii.), 'that it will be found on examination that the same commanding excellences, which have rendered Mr. Henry so celebrated as an expositor, distinguished him as a preacher, and have imparted to his sermons and treatises and tracts a charm not less fascinating than that which pervades the Commentary. There is throughout the same soundness of diction, the same facility of illustration, and the same unvarying attention to usefulness.' The miscellaneous works were republished in 8vo., Lond. 1830.

The life of Matthew Henry has been written by Tong, 8vo., 1716; but a fuller and more accurate account of his life and writings is given by Williams in his *Memoirs of the Life, Character, and Writings of the Rev. M. Henry*, prefixed to the edition of the *Exposition*, published in 3 vols. 8vo., Lond. 1828.

HENRY, ROBERT, D.D., was the son of a farmer in the parish of St. Ninians, Stirlingshire, where he was born in 1718. Having completed the usual course of education for the Scottish church at the university of Edinburgh, he was licensed as a preacher in 1746, being then master of the burgh or grammar school of Annan, in Dumfriesshire. In 1748 he was elected minister of a Presbyterian congregation at Carlisle, with which he remained till August, 1760, when he removed to a similar situation in the town of Berwick-upon-Tweed. It is supposed to have been about this time that he conceived the project of his 'History of Great Britain, written on a new plan,' on which his literary reputation rests. The same year that he established himself in Berwick he married a Miss Balderston, whose sister afterwards married Gilbert Laurie, Esq., lord provost of Edinburgh; and this connexion eventually led, in 1768, to Mr. Henry's removal to that city. His first appointment was as minister of the church of the New Grey Friars, which he retained till 1776, and then exchanged for the easier charge of one of the ministers of the Old Church, in which he continued till his death. His access to the libraries at Edinburgh encouraged him to proceed with the design of his History, which want of the necessary books had before almost induced him to relinquish. The first volume, in 4to., appeared in 1771, the second in 1774, the third in 1777, the fourth in 1781, and the fifth, bringing down the narrative to the accession of Henry VII., in 1785. The author, upon whom the degree of D.D. had been conferred by the university of Edinburgh in 1770, died in 1790; but before his death he had completed the greater part of another volume of his History, extending to the accession of Edward VI., which was published in 1793 under the superintendence of Malcolm Laing, Esq., who supplied the chapters that were wanting, and added an Appendix. A continuation of the work, but on a less extended scale, to the accession of James I., was published in one volume 4to., and in two volumes 8vo., in 1796, by James Pettit Andrews, Esq., who is also the author of a 'History of Great Britain connected with the Chronology of Europe,' coming down to the accession of Edward VI., and compiled in great part from Dr. Henry's work (though there are also many other sources used, especially for the foreign history), which appeared in two volumes 4to. in 1794 and 1795. Dr. Henry's History has, since its completion, been repeatedly reprinted in twelve volumes 8vo. The author had published the successive quarto volumes on his own account; but when the first octavo edition was proposed in 1786, he sold the property of the work to a publishing house for 1000*l.*, besides which the profits it had already yielded him amounted to 2300*l.* In 1781, on the unsolicited application of Lord Mansfield, a pension of 100*l.* a year was granted to Dr. Henry by the king.

These facts are extracted from a biographical memoir of some length which appeared with the posthumous volume of the History, and in which may be also found a diffuse account of Dr. Henry as a private member of society, in which character he appears to much advantage. His only other publication was a Sermon preached before the (Scottish) Society for propagating Christian Knowledge, in 1773. The early volumes of his History were assailed with unusual virulence as they successively appeared by Dr. Gilbert Stuart, well known as the author of various able and learned historical works. An interesting account may be found in Mr. D'Israeli's 'Calamities of Authors' of the persecution, as he represents it, of Dr. Henry, by Stuart, first in the Edinburgh Magazine and Review, and afterwards in the English Review, which he set up in London. Stuart was a man of bad temper and little principle, and he was probably actuated in this affair by feelings of personal animosity to Dr. Henry or some of his friends; but he was a person of genuine learning and original research, as well as of great acuteness, and in many of his objections to the History there was much force and justice. Henry's cause, on the other hand, was taken up by his friends, and there is printed in the Memoir of his Life a very encomiastic character of his work (so far as it had proceeded), which is said to be 'by one of the most eminent historians of the present age, whose history of the same period justly possesses the highest reputation,' and 'who died before the publication of the third volume,'—words which we suppose describe Mr. Hume. The work had certainly considerable merit as the first attempt to write a History of England upon so extended a plan, combining the history of society and the general civilization of the country with that of public events; and the author has collected a great mass of very curious matter, a large portion of which is not to be found in any of our common histories; but it has no pretensions to be considered as executed either classically or critically. It abounds in statements derived from sources of no authority, and in other negligences and inaccuracies, partly arising from the character of the author's mind and acquirements, partly the consequence of his provincial situation and want of acquaintance with or access to the best sources of information. In almost every one of the departments into which it is divided it is now far behind the state to which historical and archæological knowledge has advanced.

HENRY, WILLIAM, was the son of Mr. Thomas Henry, of Manchester, who was a zealous cultivator of chemical science. Dr. Henry was born on the 12th of December, 1775. His earliest instructor was the Rev. Ralph Harrison, who, on the establishment of an academy in Manchester, which has since been removed to York, was chosen to fill the chair of classical literature. Immediately after leaving the academy he became an inmate in the house of Dr. Percival, whose character as an able and enlightened physician is well known. Here he remained for some years, and in 1795 he studied at Edinburgh, where the chair of chemistry was occupied by the venerable Dr. Black. After remaining there only one year however, he was obliged, from prudential motives, to quit the university. On visiting Edinburgh again in 1807 he received the diploma of Doctor in Medicine; and although he subsequently and successfully practised as a physician in Manchester, he was compelled to retire from it on account of the state of his health, which from an accident in early life had always been delicate.

Though the period between his two academical residences was passed in the engrossing occupations of his profession, and the superintendence of a chemical business established by his father, he nevertheless both zealously and successfully attended to the science of chemistry, and from that period until 1836, the year in which he died, he contributed a great number of important papers to the Royal Society, the Philosophical Society of Manchester, and to various philosophical journals. In 1797 he communicated to the Royal Society an experimental memoir, the design of which was to re-establish, in opposition to the conclusions drawn by Dr. Austin, and sanctioned by the approval of Dr. Beddoes and other eminent chemists, the title of carbon to be ranked among elementary bodies, although his proofs indeed contained a fallacy, which in a subsequent paper he himself corrected. In 1800 he published in the 'Philosophical Transactions' researches on muriatic acid gas. These experiments were undertaken in the hopes of detaching the imaginary element, which, in accordance with the prevailing theory, was supposed with oxygen to constitute the acid in question. It was not till many years afterwards that the true nature of this acid was ascertained by Davy, and to the new doctrine Dr. Henry was an early convert.

In 1803 Dr. Henry made known to the Royal Society his elaborate experiments on the quantity of gases absorbed by water at different temperatures, and he arrived at the simple law, 'that water takes up of gas condensed by one, two, or more additional atmospheres, a quantity which ordinarily compressed would be equal to twice, thrice, &c., the volume absorbed under the common pressure of the atmosphere.' In 1808 he published in the same work a form of apparatus adapted to the combustion of larger quantities of gas than could be fired in eudiometric tubes. In the same year he was elected a Fellow of the Royal Society, and in the year following he received, by the award of the president and council, Sir Godfrey Copley's donation, as a mark of their approbation of his valuable communications to the Society. He published various other papers, both in the 'Manchester Memoirs' and in the 'Philosophical Transactions.' His latest communication to the Royal Society was a paper in 1824, in which he succeeded in overcoming the only difficulty he had not before conquered, that of ascertaining by chemical means the exact proportions which the gases left after the action of chlorine on oil and coal gas bear to each other. This he effected by availing himself of the property which had been recently discovered by Döbereiner in finely-divided platina, of determining gaseous combination.

Alluding to his analysis of coal-gas, other compounds of carbon and hydrogen, and various other subjects, it has been truly remarked by his friend and townsman Mr. John Davies, that his papers 'present a fine specimen of inductive research. His investigations on the combinations of gases by volume, the absorption of different gases by water, the application of Döbereiner's spongy platina to gaseous analysis, and a great number of other interesting subjects, have exhibited great philosophical acumen and unequalled precision in manipulating. Never was there a more careful, a more impartial, a more accurate experimenter. It may be mentioned, as an instructive illustration, that on one occasion, when a young friend was assisting him in his operations, the former proceeded, before the termination of an experiment, to calculate the result. "Stop," said the doctor emphatically; "don't try what the result should be, or there will be danger of *coaxing the experiment* so as to make it correspond with the estimate."'

Dr. Henry was the author of a most valuable and useful work, entitled 'Elements of Experimental Chemistry,' which has reached the eleventh edition.

'As a literary character,' it is most truly stated by the gentleman above named, 'Dr. Henry deserves a much higher reputation than he has in this respect yet obtained. His characters of Priestley, of Davy, and of Wollaston, are some of the finest specimens of that species of composition in the English language. The discrimination which they manifest, and elegance and accuracy of the style in which they are written, will render them models of the highest value to those who may be required to exercise their powers upon such topics.'

With respect to the personal character of Dr. Henry, it is said of it, with great justice (as the writer of this memoir can testify), by his son Dr. C. Henry (*Biographical Memoir of the late Dr. Henry*), that in the general intercourse of society he was distinguished by a polished courtesy, by an intuitive propriety, and by a considerate forethought and respect for the feelings and opinions of others; qualities issuing out of the same highly-toned sensibility that guided his tastes in letters, and that softened and elevated his whole moral frame and bearing. His comprehensive range of thought and knowledge, his proneness to general speculation in contradistinction to detail, his ready command of the refinements of language, and the liveliness of his feelings and imagination, rendered him a most instructive and engaging companion. To the young, and more especially to such as gave evidence of a taste for liberal studies, his manner was peculiarly kind and encouraging. He was most anxious to promote, as far as was in his power, their progress in knowledge.'

His frame, originally delicate, worn out by illness and distracted by loss of sleep, at last gave way, and he died on the 2nd of September, 1836, in his 61st year.

HENSLOVIA'CEÆ, a very small and little known natural order of Exogens, supposed to be related either to Stilaginaceæ or Combretaceæ. Its fruit is unknown, and there is no possibility of forming a fixed opinion upon the subject until more species and genera shall have been discovered. Only three or four species, all natives of the hot and damp parts of Europe, have yet been seen. They are all trees, with opposite entire exstipulate leaves, and minute racemose, apetalous flowers, with as many anthers sessile in the sinus of the calyx as there are lobes of that organ; a two-celled, many-seeded ovary, and a single style.

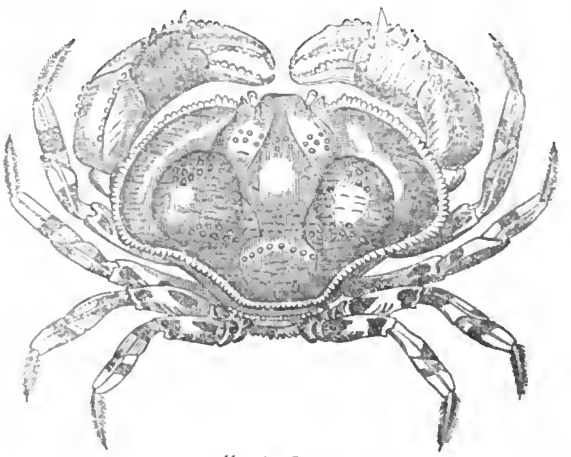
Henslovia pubescens.
1, A flower magnified; 2, a vertical section of the ovary.

HEPA'TICÆ, a name formerly applied to a class of cryptogamic plants, part of which are popularly called liverworts. It is now subdivided into several natural orders. [JUNGERMANNIACEÆ; MARCHANTIACEÆ.]

HEPATI'TIS. [LIVER.]

HE'PATUS, Latreille's name for a genus of brachyurous crustaceans, placed by M. Milne Edwards under the tribe of *Calappians*, and, in the opinion of the latter, establishing the passage between the *Cancerians*, which they approach in their general form; the *Calappæ*, which they resemble in the disposition of their *Chelæ* (*manus*); and the *Leucosians*, from which they differ but little with reference to the method of the organization of the mouth. The *Carapace* is large, convex, regularly arched anteriorly, strongly narrowed posteriorly; the *hepatic regions* are very large, and the branchial regions very small. The *front* is narrow, straight, rather projecting, and placed a good deal above the level of the lateral border of the carapace, which prolongs itself under the orbits to reach the sides of the buccal frame. The *orbits* are small, circular, and placed on the same level with the front. The *internal antennæ* are somewhat apart, and are bent back very obliquely under the front. The *external antennæ* occupy the internal angle of the orbits, which they separate from the antennary pits; their basilary joint is narrow, but rather long; the second is, on the contrary, small, and their terminal stem is nearly rudimentary. The *buccal frame*, which is very narrow forwards, and nearly regularly triangular, prolongs itself beyond the level of the lower border of the orbits, and is entirely occupied by the *external jaw-feet*, the third joint of which is triangular and terminated internally by a straight edge, under which are concealed the remaining joints. The *sternal plastron* is oval, and presents nothing remarkable. The *anterior feet* are strong, without being large, and are capable of a close and exact application against the lower surface of the body, where they are entirely concealed: the *hand* is surmounted by a crest, and the *claws* are rather inclined downwards and inwards. The remaining feet are of moderate length, and the abdomen is divided into seven joints in both sexes.

Geographical Distribution of the genus.—The only species known, viz. *Hepatus fasciatus* (*Calappa angustata* of Fabricius; *Cancer princeps* of Herbst; and *Calappa angustata* of Bosc), and *Hepatus Chiliensis*, are inhabitants of the coasts of America: the first having been found in the north and at the Antilles; the second on the coast of Valparaiso. (M. Edwards.)



Hepatus fasciatus.

HEPHÆ'STION, a grammarian of Alexandria, lived about the middle of the second century of the Christian era. He is said to have instructed the emperor Verus. (Julius Capitolinus, c. 2.) He wrote a treatise on Greek metres (Ἐγχειρίδιον περὶ Μέτρων), which was printed for the first time at Florence in 1526. This work has also been edited by Turnchus, 4to., Paris, 1553; by Pauw, 4to., Utrecht, 1726; but the best edition is by Gaisford, 8vo., Oxford, 1810, with the 'Chrestomathia' of Proclus, reprinted at Leipzig, 1832.

HEPHÆSTION. [ALEXANDER III.]

HEPIA'LIDÆ, a family of Lepidopterous insects of the section *Lepidoptera Nocturna* of Latreille. The moths belonging to this family are distinguished by the want of tongue, the wings being deflexed, long and narrow, and the thorax devoid of crest. Their larvæ live in the interior of vegetables, on which they feed, or in some instances they live in the ground, and feed upon the roots of plants; they are fleshy, naked, and have six thoracic, eight abdominal, and two anal feet. The pupæ have the segments of the body denticulated.

The principal genera contained in this family are *Hepialus*, *Cossus*, *Stygia*, and *Zeuzera*.

In the genus *Hepialus* (Fabricius) the antennæ are much shorter than the thorax, the wings are long and narrow, the posterior pair nearly equal to the anterior. The larvæ live in the ground and upon the roots of plants.

Hepialus Humuli, an insect commonly known by the name of ghost-moth, will afford an example of this genus. This moth measures from one and a half to two inches in width when the wings are expanded, and a large female is sometimes three inches in width. The male is of an immaculate silvery white colour above, and brown beneath. When on the wing, which is usually in the evening about twilight, it is seen with tolerable distinctness if below the eye, on account of its white colour; but upon a slight change in its position, when the darker colour of the underside of the wings is opposed to the eye, it suddenly disappears; hence probably arises the name which has been applied to it.

Mr. Stephens, in his 'British Entomology,' however accounts for the name in another manner; he says it is 'very common in grassy places in the middle of June, and not unfrequently met with in church-yards, whence its name of ghost-moth.' The female ghost-moth is very dissimilar in colour to the male; indeed such is the case in all the species of Hepialus. The anterior wings are of a buff yellow colour above, with spots of a deeper hue; the under wings are palish brown, having a faint pink tint.

Five or six other species of this genus inhabit this country, for descriptions of which see Stephens, *Illustrations of British Entomology—Haustellata*, vol. ii.

HEPTAGON, a figure of seven sides. For the regular heptagon, see REGULAR FIGURES.

HEPTARCHY. [ENGLAND.]

HERACLE'A. [CALABRIA.]

HERACLI'DÆ, the descendants of Hercules. According to tradition, after the death of Hercules his children took refuge in Attica, in order to escape the persecution of Eurystheus. They were hospitably received by Theseus, and with the assistance of the Athenians defeated Eurystheus. After the battle the Heraclidæ are said to have obtained possession of the whole of Peloponnesus; but they had not remained in the country long before a pestilence again drove them back to Attica. They attempted soon afterwards to march again into Peloponnesus, but were met at the Isthmus by an army consisting of Arcadians, Ionians, and Achæans. In a single battle with Echemus, king of Tegea, Hyllus, the eldest son of Hercules, was slain, and the Heraclidæ promised not to invade Peloponnesus for a hundred years from that time. (Herod., ix. 26; Pausan., i. 41.) They did not however observe their engagement, for both Cleodæus, son of Hyllus, and his grandson Aristomachus, renewed the attempt, but without success. The Heraclidæ retreated to Doris, where they obtained a considerable army to assist them in the recovery of their dominions. With the aid of an Ætolian chief named Oxylus, they crossed from Naupactus to the southern side of the Corinthian gulf eighty years after the Trojan war. (Thucyd., i. 12.) A battle took place between the Dorians under the command of the sons of Aristomachus and the Peloponnesians under that of Tisamenus, the grandson of Agamemnon, in which the latter were defeated, and all Peloponnesus, except Arcadia and Achæa, fell into the hands of the Heraclidæ. Elis was assigned to Oxylus, and the rest of the Peloponnesus was divided between the three sons of Aristomachus; Temenus obtained possession of Argos, Cresphontes of Messenia, and Aristodemus, or his sons Eurysthenes and Procles (for according to the general tradition Aristodemus did not live to enter Peloponnesus) of Lacedæmon. The land of the conquered country was divided among the Dorians, and the old inhabitants were obliged to emigrate, or were reduced to an inferior caste. (Pausan., ii. 18; iii. 1; iv. 3.)

Such is the traditional account of that important event in Grecian history, usually called 'the return of the Heraclidæ,' by which the Dorians obtained possession of the greater part of the Peloponnesus. It is asserted by the universal tradition of antiquity that the Dorians were led to this conquest by Achæan chiefs; but this fact has been doubted by many modern writers, who have considered it improbable that the Dorians should have been commanded by foreign chiefs. It has been supposed that the Heraclidæ were the hereditary princes of the Doric race, who were descended from a Dorian Hercules; and that the story of the Heraclidæ being descended from the Argive Hercules, who performed the commands of Eurystheus, was not invented till after the conquest of the Peloponnesus. (Müller's *Dorians*, vol. i., p. 57, Eng. Transl.) Though the general tradition assigned the complete conquest of Peloponnesus to the sons of Aristomachus, it appears probable from other traditions that the greater part of the Peloponnesus was not reduced by the Dorians till long afterwards. (Thirlwall's *Hist. of Greece*, vol. i., pp. 262—273.)

HERACLI'TUS of Ephesus, surnamed the Naturalist (φυσικός), belongs to the dynamical school of the Ionian philosophy. He is said to have been born about B.C. 500, and, according to Aristotle, died in the sixtieth year of his age. The title he assumed of '*self-taught*' refutes at once the claims of the various masters whom he is said to have had, and the distinguished position that he held in political life attests the wealth and lustre of his descent. The gloomy haughtiness and melancholy of his temperament led him to despise all human pursuits, and he expressed unqualified contempt as well for the political sagacity of his fellow-citizens as for the speculations of all other philosophers, as having merē learning and not wisdom for their object. Of his work 'On Nature' (περὶ φύσεως), the difficulty of which obtained for him the surname of 'the obscure' (σκοτεινός), many fragments are still extant, and exhibit a broken and concise style, hinting rather than explaining his opinions, which are often conveyed in mythical and half-oracular images. On this account he well compares himself to the Sibyl, 'who,' he says, 'speaking with inspired mouth, smileless, inornate, and unperfumed, pierces though centuries by the power of the god.'

According to Heraclitus, the end of wisdom is to discover the ground and principle of all things. This principle, which is an eternal everliving unity, and pervades and is in all phenomena, he called *fire*. By this term Heraclitus understood, not the elemental fire or flame, which he held to be the excess of fire, but a warm and dry vapour; which therefore, as air, is not distinct from the soul or vital energy, and which, as guiding and directing the mundane development, is endued with wisdom and intelligence. This supreme and perfect force of life is obviously without limit to its activity; consequently nothing that it forms can remain fixed; all is constantly in a process of formation. This he has thus figuratively expressed: 'No one has ever been twice on the same stream.' Nay, the passenger himself is without identity: 'On the same stream we do and we do not embark; for we are and we are not.'

The vitality of the rational fire has in it a tendency to contraries, whereby it is made to pass from gratification to want, and from want to gratification, and in fixed periods it alternates between a swifter and a slower flux. Now these opposite tendencies meet together in determinate order, and by the inequality or equality of the forces occasion the phenomena of life and death. The quietude of death however is a mere semblance which exists only for the senses of man. For man in his folly forms a truth of his own, whereas it is only the universal reason that is really cognisant of the truth. Lastly, the rational principle which governs the whole moral and physical world is also the law of the individual; whatever therefore is, is the wisest and the best; and 'it is not for man's welfare that his wishes should be fulfilled; sickness makes health pleasant, as hunger does gratification, and labour rest.'

The physical doctrines of Heraclitus formed no inconsiderable portion of the eclectical system of the later Stoics, and in times still more recent there is much in the theories of Schelling and Hegel that presents a striking though general resemblance thereto.

The fragments of Heraclitus have been collected from Plutarch, Stobæus, Clemens of Alexandria, and Sextus Empiricus, and explained by Schleiermacher in Wolf and Buttman's 'Museum der Alterthumswissenschaft,' vol. i. See also Brandis's 'Handbuch der Geschichte der Griechisch-Röm. Philos.,' Berlin, 1835; and Ritter's 'History of Antient Philosophy,' Oxford, 1837.

HERA'CLIUS, the son of the patrician Heraclius who was governor of Africa under the emperor Phocas, assisted in dethroning the latter A.D. 610, and was proclaimed emperor in his place. He applied himself to reform the discipline of the army; he renewed the truce with the Longobards of Italy, and turned his arms against the Avari who had invaded Thrace, and had advanced to the gates of Constantinople. Those barbarians soon after retired across the Danube loaded with their spoils. The Persians meantime invaded Syria, devastated Jerusalem, and made an irruption into Egypt, in consequence of which the usual supplies of corn which that country used to send to Constantinople were stopped, and the capital was afflicted by a severe famine. Another Persian army had advanced through Asia Minor to Chalcedon, but Heraclius induced the commander to withdraw, and sent ambassadors to treat of peace with Khosru, the Persian king, who spurned his offers, and summoned Heraclius and his subjects to abjure Christ and pay worship to the sun. Heraclius, roused by this insult, collected an army, and marched against the Persians, whom he defeated in a succession of brilliant campaigns, and pursued them as far as the Tigris, A.D. 622—27. The first year of the expedition of Heraclius against the Persians was the same in which Mohammed openly assumed the character of prophet and legislator, after his flight to Medina. Khosru was at last dethroned by his son Siroes, who concluded peace with Heraclius. The latter years of the reign of this emperor were passed amidst theological controversies. Heraclius supported the doctrine of the Monothelites, who taught that the human nature in Jesus Christ was entirely passive under the will of his divine nature. [EUTYCHIANS.] Pope John IV. assembled a council at Rome A.D. 640, which condemned the Monothelites. Meantime the Arabians, after the death of Mohammed, and under the caliphate of Abu Bekr, invaded Syria, Palestine, and Mesopotamia, and under the following caliphate of Omar they conquered Egypt and Cyrenaica. Heraclius was unable to oppose the torrent of Arabian courage and fanaticism; he sunk into inactivity and sloth, and died of the dropsy in February, 1641, after a reign of thirty years. From that epoch the decided though gradual decline of the Eastern empire may be dated. Heraclius was succeeded by Heraclius Constantine, his son by his first wife Eudocia, who in the fourth month of his reign was poisoned by his step-mother Martina, who had her own son Heracleonas proclaimed in his stead. An insurrection however soon after broke out at Constantinople against the new emperor, who was mutilated and banished together with his mother, and Constans II., son of Heraclius Constantine, was raised to the imperial throne. (Theophanes and other Byzantine historians; Gibbon.)

Coin of Heraclius.

British Museum. Actual Size. Gold. Weight, 69 grains.

HERALD, an officer whose duty, during the middle ages, was to carry challenges or peaceful messages from one sovereign or nobleman to another, to proclaim peace or war, to lay out the lists in jousts or tournaments, to be the witness of all combats whether general or particular, and to record in writing the names of those who behaved most valiantly, to number the dead after battle, and specially to supervise all matters connected with the bearing of coat-armour, the marshalling of processions, and other state ceremonies. His functions were something like those of the Greek *kerux* (κῆρυξ), and the Roman *Fecialis*; but the origin of the name is much disputed, and the actual date of the institution uncertain. The word *Heraldus* occurs in the imperial constitutions of Frederick Barbarossa, A.D. 1152, about the same time to which the origin of heraldry is with most reason assigned. The earliest mention of a herald in England is in a pell-roll of the 12th Edward III.; but there is little doubt that the office existed as early at least as the dawn of hereditary coat-armour. The English heralds were first incorporated by Richard III. [HERALDS' COLLEGE.] There are three orders or grades of heralds, namely, kings of or at arms, heralds, and pursuivants. They were antiently created with much ceremony, and the mode is curiously detailed by Gerard Legh apud Upton. 'It is necessary,' says he, 'that all estates should have couriers as their messengers for the expedition of their business, whose office it is to pass and repass on foot, being clad in their prince's colours "parted upright;" that is to say, half of one colour and half of another, with the arms of their sovereigns painted on the boxes in which they carried their dispatches, and which were fixed to their girdle on the left side. It was not permitted to them to bear the arms of their lord in any other manner.' 'They were knights,' he adds, 'in their offices, but not nobles, and were called knights-caligate of arms, because they wore "startuppes" (a sort of boot or gaiter) "to the middle leg." When they had conducted themselves properly in this situation for seven years, they were made chevaliers of arms, and rode on horseback to deliver their sovereign's messages, clad in one colour, their garments being only guarded or trimmed with the colour of their sovereign, and bearing their boxes aforesaid, with the arms painted on them, on the left shoulder, "and not elsewhere."' From these runners and riders the three orders of heralds were supplied, the chevalier of arms, having served another seven years, being created a pursuivant in the following manner:—The herald of the province, to whom he was to be pursuivant, wearing his coat of arms, took the candidate by his left hand, holding in his right a cup of silver, filled with wine and water, and leading him to his sovereign, in the presence of many witnesses duly summoned for this purpose, inquired by what name the pursuivant was to be created; and upon the sovereign's answer proclaimed his style accordingly, pouring some of the wine and water upon his bare head. He then invested him with the tabard, or herald's coat, emblazoned with the arms of the sovereign, but so that the sleeves hung upon his breast and back, and the front and hind parts of the tabard over his arms, in which curious fashion he was to wear it till he became a herald. Strutt has given a representation of the pursuivant so attired from the Harleian MS. 2278, without being aware of the distinction. The oath of office was then administered to him, and lastly the sovereign presented him with the silver cup aforesaid. Having once been made pursuivant, he might be created a herald, 'even the next day,' which was done by the principal herald or king of arms leading him in like manner before the sovereign, but bearing a gilt instead of a silver cup, and turning the tabard so that the sleeves hung in their proper place over the arms. A collar of SS was then put about his neck, one S being argent, or silver, the other sable, or black, alternately, and when he was named, the prince himself poured the wine and water on his head, and after the oath was administered gave him the cup as before; whereupon the herald cried, 'A largess.' The kings of arms were created and solemnly crowned by the sovereigns themselves, and distinguished from the heralds by richer tabards, the embroidery being on velvet instead of satin, gilt collars of SS, and coronets composed of a plain circle of gold surmounted by sixteen strawberry leaves, eight of which are higher than the rest.

Modern heralds of all classes are now made and appointed by the earl marshal, and their functions and privileges are much abridged and disregarded. The present number in England is fourteen, viz.: four kings of arms—Garter, Clarencieux, Norroy, and Bath; the second and third being provincial kings, Clarencieux having power over all parts of England south of the Trent, and Norroy over all parts north of it. Six heralds—Somerset, Chester, Windsor, Richmond, Lancaster, and York; and four pursuivants—Rouge Dragon, Portcullis, Blue Mantle, and Rouge Croix. In Scotland there is one king at arms, named Lyon; and in Ireland one, named Ulster. To these regular officers are sometimes added, by command of the king to the earl marshal, a herald or pursuivant extraordinary. Such were the heralds Arundel, Norfolk, and Mowbray; and on the occasion of the funeral of the late King William IV., Mr. Albert Woods, son of Sir W. Woods, Clarencieux king of arms, was created Fitzalan pursuivant extraordinary.

HERALDS' COLLEGE, or COLLEGE OF ARMS, a corporation founded by Richard III. in the first year of his reign by a charter dated the 2nd of March, 1483, in which he gives to the principal officers of the corporation a house called Colde Arbor, in the parish of All Hallows the Less, London. In the first year of the reign of Henry VII. this house was seized into the king's hands under the Act of Resumption as the personal property of John Writhe, then garter king at arms; and during the reign of that king and of his successor Henry VIII. the heralds made several unsuccessful attempts by petition to obtain a restoration of it, or the grant of some other building for their general use. King Edward VI., in the third year of his reign, by a charter dated June 4th, confirmed to them all their antient privileges; and Philip and Mary, by charter of the 18th of July, 1554, re-incorporated them, and granted to them Derby House, then occupying the site of the present college on St. Benet's Hill, near St. Paul's Church-yard. The old building was destroyed in the great fire of London, but all the books, papers, &c., were fortunately saved, and removed to the palace in Westminster, where the heralds held their chapters, &c., until the college was rebuilt. The corporation consists of the three kings at arms—Garter, Clarencieux, and Norroy (Bath not being a member); six heralds, and four pursuivants. [HERALD.] The arms of the college are—argent, a cross gules between four doves rising azure. Crest, on a ducal coronet, Or, a dove rising azure. Supporters, two lions rampant gardant argent, ducally gorged Or. There is a heralds' college in Scotland, composed of Lyon king at arms, six heralds, and six pursuivants.

HERALDRY, the art of arranging and explaining in proper terms all that appertains to the bearing of coats of arms, badges, and other hereditary or assumed marks of honour; also the science of marshalling processions and conducting the ceremonies of coronations, instalments, creations of peers, funerals, marriages, and all other public solemnities.

The origin of heraldry, in the first and most commonly understood sense, has been attributed, by the general consent of all rational writers on the subject, to the necessity for distinguishing by some outward sign, amidst the confusion of battle, the principal leaders during the expeditions for the recovery of the Holy Land. But nothing is absolutely known concerning it beyond the fact that the middle of the 12th century is the earliest period to which the bearing of heraldic devices, properly so called, can be traced; and the commencement of the 13th, the time about which they became hereditary.

The earliest roll of arms of which we have any notice is of the reign of Henry III.; and the reign of Edward I. presents us with the earliest heraldic document extant. The famous roll of Caerlaveroch, a poem in old Norman French, rehearses the names and armorial ensigns of all the barons, knights, &c., who attended Edward I. at the siege of Caerlaveroch castle, A.D. 1300. [BANNER, p. 408.] Heraldry is therein first presented to us as a science. The principal rules and terms of the art were then in existence, and from about that time the latter are continually found in the fabliaux and romances of France and England.

The oldest writer on heraldry whose work has descended to us is Nicholas Upton, whose treatise 'De Militari Officio' was composed in the reign of Henry V., and translated in that of his successor by Juliana Barnes [BERNERS], in the work known as the 'Boke of St. Albans.' As Upton quotes no earlier authorities, his definitions and explanations can only be looked upon as assertions made nearly three hundred years after the origin of the practice, and consequently to be believed, or not, according to the discretion of the reader. In the reign of Richard III. the English heralds were incorporated and the College of Arms founded, and in the following century a swarm of writers arose both in France and England, each contradicting the other, and wasting a world of learning and research in the most absurd and idle controversies.

On the decline of chivalry the study of heraldry became gradually neglected, and the art, which had formed for centuries a portion of the education of princes, and occupied the attention of some of the most learned men in Europe, was abandoned to the coach-painter and the undertaker, while kings of arms and pursuivants were looked upon as mere appendages of state pageantry, their office ridiculed, and their authority defied.

That the pedantic nonsense of such writers as Morgan, Ferne, Mackenzie, &c., contributed to these results, there can be little doubt. A taste for the critical study of antiquities generally is now however reviving throughout Europe, and the use of heraldry as a key to history and biography is daily becoming more and more acknowledged.

The rules of heraldry as now practised at the College of Arms are, as we have before remarked, comparatively modern, and vary in some points from those observed in France and Germany.

According to the received authorities there are ten classes of arms, viz.:—

1. Arms of *Dominion*, being those which sovereigns bear as annexed to the territories they govern.

2. Of *Pretension*, those borne by sovereigns who are not in possession of the dominions to which such arms belong, but who claim or pretend to have a right to such possession, as for instance the kings of England from Edward III. to George III. quartered the arms of France.

3. Arms of *Community*, being those of bishoprics, cities, universities, academies, and other bodies corporate.

4. Of *Assumption*, such as are assumed by a man of his proper right without the grant of his sovereign, or of a king at arms. As for instance when a man of any degree whatsoever has taken prisoner in lawful war any gentleman, nobleman, or prince, he may bear the arms of that prisoner, and transmit them to his heirs for ever.

5. Arms of *Patronage*, such as governors of provinces, lords of manors, patrons of benefices, &c., add to their family arms, as a token of their superiority, rights, and jurisdiction.

6. Arms of *Succession*, borne by those who inherit certain estates, manors, &c., either by will, entail, or donation.

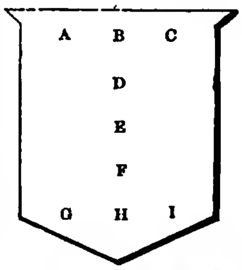
7. Arms of *Alliance*, such as the issue of heiresses take up to show their maternal descent.

8. Arms of *Adoption*, borne by a stranger in blood, with the special permission of the sovereign, applied for in order to fulfil the will of the testator who may bequeath certain monies or estates on condition of the party's assuming his name and arms.

9. Arms of *Concession*, augmentations granted by the sovereign of part of his own ensigns or regalia to such persons as he pleases to honour therewith.

10. Arms *Paternal* and *Hereditary*, such as are transmitted from the first possessor to his son, grandson, great-grandson, &c.; thereby forming complete and perfect nobility. The son being a gentleman of second coat-armour the grandson a gentleman of blood, and the great-grandson a gentleman of ancestry.

These several sorts of arms are displayed on shields, or escutcheons, and on banners, the ground of either being called the field, and the figures borne upon it the ordinaries and charges.



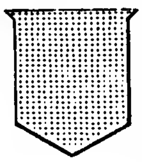
The shield, or escutcheon, contains certain points or locations, viz. A, B, C, the chief A being tho dexter or right-hand chief, B the precise middle chief, and C the sinister or left-hand chief. D is the honour point; E tho fess point, being the exact middle of the shield; F the nombril or navel point; G, H, I, the dexter, middle, and sinister base points.

The colours of the escutcheon, or of its ordinaries and charges, are five:—

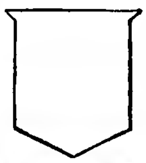
Red	(the heraldic name of which is)	Gules
Blue	"	Azure
Black	"	Sable
Green	"	Vert
Purple	"	Purpure.

To which must added, or rather prefixed, *yellow* and *white*, which being ordinarily represented by gold and silver, are called *metals*, and named by heralds, after tho French, *Or* and *Argent*.

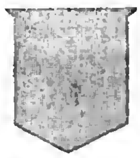
There are also two other colours recognised by heralds, but rarely seen in English coats of arms, viz. orange, called *Tenne*, and a dark blood-red inclining to purple, called *Sanguine*, or *Murrey*, from mulberry. These colours and metals have been since the sixteenth century expressed in engravings by lines and points or dots, the ingenious idea of which is attributed to an Italian named Petrasancta. Thus *Or*, or *gold*, is known by the escutcheon being filled with small points or dots.



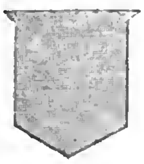
Argent, or *silver*, by the shield being left perfectly plain.



Gules, or *red*, by perpendicular lines from the top to the bottom of the escutcheon.

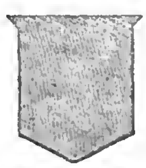


Azure, or *blue*, by horizontal lines.

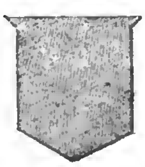


Sable, or *black*, by the two former crossing each other.

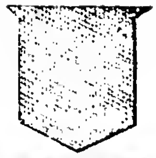
Vert, or *green*, by diagonal lines from right to left.



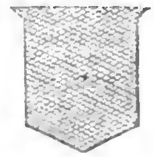
Purpure, or *purple*, by similar lines from left to right.



Tenne, or *orange*, by perpendicular lines crossing lines from right to left.



Sanguine, or *murrey*, by transverse lines from each side of the shield.

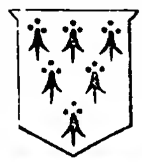


The metals and colours above mentioned are also distinguished by some heralds by the names of planets and precious stones; and there are besides, according to Sir John Ferne (*Glory of Generosity*), twelve other fantastical sorts of blazoning (by which word is meant, describing in proper heraldic terms, the bearings, &c., of a shield or banner); but as all these are now obsolete, we shall only allude to the fact without encumbering our columns by rehearsing them.

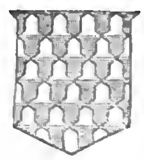
There are nine roundlets, or balls, also used in heraldry, the names of which are sufficient to denote their colour, without particularizing the same, viz.:—

Bezants .	Or	Hurts .	Azure	Pellets .	Sable
Plates .	Argent	Pommes	Vert	Oranges	Tenne
Torteaux	Gules	Golpes .	Purple	Guzes .	Sanguine.

To metals and colours must be added Furs, which, according to some heralds, are of ten different sorts. Those most commonly met with are however comprised under the names of Ermine and Vair, the rest being variations of colour and disposition. The first is represented in heraldry thus, the field being *white*, or *argent*, the spots and tails *black*, or *sable*.



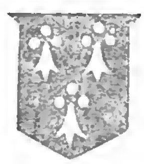
The second is represented by figures like little cups or bells reversed and ranged in lines, thus. The colours being, of the field *Argent*, of the cups *Azure*, or vice versâ; but where the matter is doubtful, the metal to possess the field by pre-eminence.



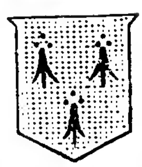
N.B. If the same figures are found in other colours, they are no longer to be blazoned or described as *Vair*; but '*Vairy, Or*, and *Gules*,' or whatever else it may be.

The principal variations above mentioned are:—

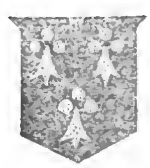
1. *Ermines*, the field of which is *Sable*, and the spots and tails *Argent*.



2. *Erminois*, the field *Or*, the spots and tails *Sable*.

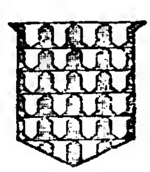


3. Pean, the field *Sable*, the spots and tails *Or*.

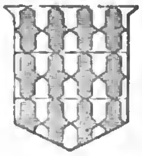


4. *Erminites*, the same as Ermine, with the addition of a *red* hair on each side the *black* tails.

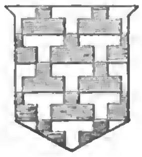
5. *Vair en point* is when the point of a cup or bell is opposite to the baso of another.



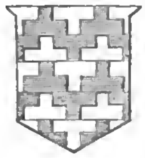
6. *Counter Vair*, when bells of the same colour are placed base to base and point to point.



7. *Potent* is classed as a fur, but the word signifies a crutch or a gibbet (Potence, Fr.) It is represented thus—



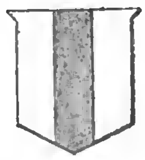
8. *Potent-counter-potent*, sometimes called *Vairy cuppy*, is when the crutches are counter placed; thus—



The principal charges or figures expressed on the shield are called the *Ordinaries;* they are nine in number, and styled *honourable.* They consist of the *Chief*, the *Pale*, the *Bend*, the *Bend Sinister*, the *Fess*, the *Bar*, the *Chevron*, the *Cross*, and the *Saltier*.

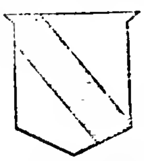
The *Chief* is the upper third of the escutcheon, determined by a horizontal line; thus—

The *Pale* is the middle third of the field when divided perpendicularly.



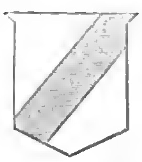
This ordinary has two diminutives; the *Pallet* being half the width of the *Pale*, and the *Endorse* half that of the *Pallet*.

The *Bend* is formed by two diagonal lines drawn from the right or dexter chief to the left or sinister base; thus—

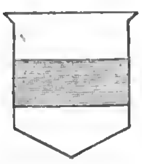


The *Bend* has four diminutives; the *Bendlet*, the *Garter*, the *Cost*, and the *Ribbon*.

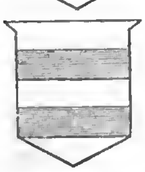
The *Bend Sinister* passes from the left to the right of the shield, and has two diminutives, the *Scarp* and the *Baton*.



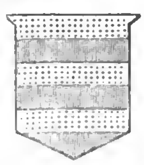
The *Fess* occupies the middle third of the shield divided horizontally.



The *Bar* is similarly formed, but occupies only a fifth of the shield, and is never borne single.



When the number exceeds five, it is blazoned Barry of so many pieces, expressing the number and colour, as Barry of Six, Or, and Gules.



The *Bar* has two diminutives; the *Barrulet*, half the width of the *Bar;* and the *Closet*, half that of the *Barrulet*.

The Chevron is a figure formed like the rafters which support the roof of a house, and is therefore sometimes called *a Spar*, and in German *Sparren*. It has two diminutives, the *Chevronel* and the *Couple-close*.

The Cross, as an ordinary, is drawn thus. All other sorts of crosses should, in our opinion, come under the head of common charges, as they must be specially described.

The Saltier is *the figure generally* known in England as St. Andrew's Cross, and is indeed always so called by the German heralds, and frequently by the Scotch.

Eight of these nine honourable ordinaries give their names to the various single lines used in dividing the field of the escutcheon, where more than one metal or colour is required, such escutcheon being described as *parted per pale*, when divided perpendicularly; *per fess*, when divided horizontally; *per cross*, when in four squares; *per saltier*, when in four triangles; *per bend*, when diagonally, from right to left; *per bend sinister*, when in the contrary direction; and *per chevron*, when in the shape of that figure. The Chief being itself formed by a single line, they do not say *parted per chief;* but when the partition-line is not straight or even, its peculiarity must be specified in every instance: and of crooked lines there are eight recognised by English heralds, namely:—

1. Engrailed . . 
2. Invected . . . 
3. Wavy . . .
4. Embattled . . 
5. Nebuly . . . 6. Raguly . . . 7. Indented . .
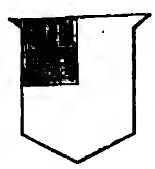
8. Dancette, limited to three indentations . 

It is therefore necessary to say 'a Chief engrailed,' or 'a Cross invected,' or 'Parted per fess, indented,' and so forth.

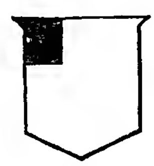
In addition to the nine honourable ordinaries are to be mentioned the subordinate ordinaries, the Gyron, the Quarter, the Canton, the Fret, the Pile, the Orle, the Tressure, the Flanches, the Flasques, the Voiders, and, according to some authorities, the Lozenge, the Fusil, the Mascle, and the Rustre.

The Gyron is formed thus: and when the shield is divided per cross and per saltier into eight similar divisions, it is called Gyronny.

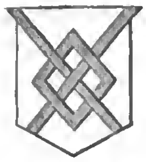
The Quarter is, as its name imports, the fourth part of the shield, and is always placed in chief.



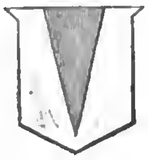
The Canton is a square figure like the quarter, but smaller, occupying only a third part of the chief itself.



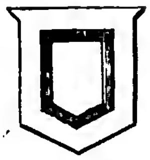
The Fret is formed thus: when composed of more pieces similarly interlaced, the field is said to be *fretty*.



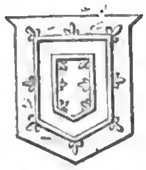
The Pile is formed like a wedge, thus: it is sometimes borne *in bend*, but must then be so described.



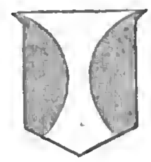
The Orle is a sort of border or frame within the shield.



The Tressure is commonly supposed to be half the breadth of the Orle, and is generally borne double, and what is called flowry and counter-flowry, as in the royal achievement of Scotland.

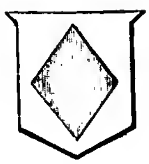


The Flanches are formed by two curved lines nearly meeting in the centre, thus:

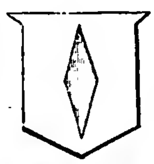


The Flasques may be called the diminutives of the Flanches, and the Voiders the diminutives of the Flasques, as the only difference is in the quantity of the shield which they occupy.

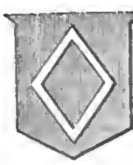
The Lozenge is of the shape of the Diamond in a playing-card. A shield so divided by diagonal lines as to form several of such figures is called Lozengy.



The Fusil, called also a Spindle, is longer and narrower than the Lozenge. A shield so divided by lines as to form several of such figures is called Fusily; and if parted per pale and per bend, would be either Lozengy-bendy, or Fusily-bendy, according to the width of the space between the lines.



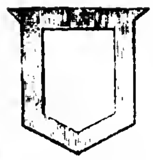
The Mascle is of the same form as the lozenge; but hollowed out, or, in heraldic term, *Voided*, so as to form a mere frame of that shape.



The Rustre is a similar figure, but pierced or voided round, instead of square, thus:

To these some heralds add the Inescutcheon, which is a small shield placed in the centre or top point of the escutcheon; but this, except when borne by an heiress as an escutcheon of pretence, may, in our opinion, be ranked amongst the common charges, as may also the lozenge, the fusil, the mascle, and the rustre.

We have next to speak of *differences*, so called from their being particular marks borne to distinguish persons of the same family from one another. While heraldry was arbitary, the son frequently assumed arms perfectly different from those of his father; but in the time of Edward I. we find two marks generally considered as family differences or signs of cadency,—the *Border* and the *Label*.



The Border is, as its name denotes, a guard or edging to the shield, and by the French heralds is accounted an ordinary. The border should always be in width one-fifth of the breadth of the shield itself, and stops when it encounters a chief, a quarter, or a canton, but passes over all other ordinaries. If the interior line is not plain or even, it must be described as *engrailed, invected*, &c. When divided into four equal parts, it is called a *border quarterly*. When divided into small squares of different colours, it is called a border *gobonated*, or *gobony*, or *compony*. When into *two* rows of squares, it is called a *border counter-compony*. When into *three* rows of squares, it is called *checky*.

The Label, or File, as it is sometimes called, is a sort of filet from which depend generally three or five lambeaux, or points, thus,—

It is sometimes however said to have been borne as a common charge, and is to be found only with one point and with as many as nine: other authorities consider it always as a *difference*. The label of three points is now always used as the difference of the heir or eldest son of the first house.

For the second son the difference is a crescent 

For the third, a mullet, or star of fine points 

For the fourth, a martlet . . . 

For the fifth, an annulet . . . 

For the sixth, a fleur-de-lys . . 

For the seventh, a rose . . . . 
For the eighth, a cross moline . . . 
For the ninth, a double quaterfoil . . 

These are called the differences of the first house; and by the six first, the six sons of Thomas Beauchamp, earl of Warwick (temp. Edward III.) are distinguished in a window of St. Mary's Church at Warwick.

The children of the second house are distinguished by the first son bearing a crescent charged with a label: the second, a crescent charged with a crescent; the third, a crescent charged with a martlet, and so on.

The junior branches of the royal family are however distinguished by the label only, the Prince of Wales bearing it simply argent, and the rest differenced by various charges, a practice as antient as the reign of Richard II.

In the general term *charges* we comprise all descriptions of figures borne in coat-armour, whether things animate or inanimate, real or imaginary, everything in short contained in or placed upon the shield; but those we have above-mentioned are to be distinguished from the *common charges*, by which expression are understood all other.

Many of these, such as crosses and crosslets in all their variety, escalop shells, bezants (the golden coins of Byzantium, or Constantinople), Saracens' heads, &c., were assumed during the Crusades, or after the return of the Crusaders, by themselves or their families, in commemoration of those expeditions. Others, such as beasts, birds, fishes, reptiles, trees, flowers, the sun, moon, stars, &c., were borne either as types of the peculiar dispositions or qualities, or as denoting by some similarity of sound in the pronunciation the names of the bearers. Such have been called with us *canting* or *punning* arms, and by the French *armes parlantes*. It has been the fashion with modern heralds to decry this species of bearing; to account it of rare occurrence in antient heraldry, and less honourable where it did occur: but recent investigations prove it to have been one of the most frequent as well as most antient descriptions of charges, and as worthy of respect as any other. It has indeed been suggested that the bearing frequently gave rise to the surname itself. This is however a mere conjecture; but the grants of arms which have been handed down to us prove incontestably that when sovereigns desired to express their approbation of noble or useful deeds by such distinctions, the name of the person to be honoured was frequently expressed by the charge, instead of the act he had performed, which would never have been the case had it been considered in those days as an inferior bearing. An acquaintance also with the language of the nation and time in which the arms were first granted or assumed, as also of its pronunciation, is of the greatest importance to this question, and such researches may yet shed much light upon the origin and history of heraldry. The Cornish family of Godolphin bear a white eagle; but those who are unacquainted with the antient Cornish language would be far from guessing that a white eagle was so called in it. A third species of allusive bearings is that which designates the place or office of the individual; and many charges appear in the arms of our nobility derived from ancestors who have held situations of high honour or great trust under our early monarchs; and lastly, a fourth portion have been assumed, as Camden has exemplified, in honour of the feudal lord, or most powerful neighbouring chief, or been conceded to the bearer by such nobleman as a mark of respect or affection.

The crest is the next object in point of antiquity to the shield. It was the ornament worn upon the helmet, and consequently the helmet itself was generally represented with it upon the seal of the knight or nobleman. The crest from Richard II.'s time was rarely worn, except upon the tilting helmet, and then upon a wreath which was generally a twisted roll of silk of two colours, being those of the family of the wearer. Beneath this wreath was frequently worn, as a sort of hood to the helmet, a piece of silk or velvet lined with ermine, which floated with jagged ends on the shoulders: these are by the French called *hachemens*, and by us *mantlings* or *lambrequins*. *Supporters* are of later origin, and are supposed to have taken their rise from the fanciful devices of the early seal-engravers, who filled up the space not occupied by the shield with all sorts of monsters or natural animals, by way of ornament. They did not become common till the close of the fourteenth century, and Henry VIII. was the first monarch who formally granted supporters to peers of the realm and knights of the garter and of the bath. No person under the rank of a knight of the bath has a right to supporters, unless by special grant of the sovereign.

Mottos had their origin probably in the war-cries of the different knights. There are several instances however of a motto being borne in addition to the *cri de guerre*.

The badge or device is frequently confounded with the crest; but it was altogether independent of the armorial bearings of the family, although in many instances it became hereditary. It is frequently, but very incorrectly, placed upon a wreath.

The arrangement and description of all the above insignia in proper heraldic order and terms are styled the *marshalling* and *blazoning* of arms.

We shall speak first of *blazoning*. The verb 'to blazon' is generally derived from the German *blasen*, to blow or sound a horn or trumpet, such being usually the practice before proclaiming the style or arms of any personage on his arrival in the camp, the lists, or the banqueting hall. The term however was soon applied to the proclamation itself, and finally used as synonymous with description generally: thus we find in the old book on hunting written by Jacques de Fouilloux, and presented to Charles IX. of France, the description of the hare entitled 'Le Blason du Lièvre.' To spread the fame or the disgrace of any person was also to blazon it. Favine, in his 'Théâtre d'Honneur,' says, 'Les habitans disent pour blasonner leur ville;' and in the Chronicle of Louis I., duke of Bourbon, the knights of the order of the crown are commanded not to suffer any person to defame (blazonner et medire) the ladies.

The principal rules of blazoning are as follows:—

1. In blazoning a coat the herald begins with the field, noticing the lines, if any, by which it is divided, the difference of those lines, and then the colours, next the charges, beginning with the *immediate* charge, that is, the one which lieth nearest the field, such as any ordinary, and nearest the centre of the field if a common charge, and lastly, the more remote or inferior charges.

Thus the accompanying coat would be blazoned: *Party per pale, indented, azure and gules; on a fess argent, a crescent of the first between two mullets sable.*

2. All tautology is to be strictly avoided, and the repetition particularly of such words as *of*, or, and *with*, is considered a great fault. In the above blazon, 'a crescent of the *first*' is said, in order to avoid the repetition of the word *azure;* so, if it were gules, we should say 'a crescent of *the second*.' For the same reason, when the field is undivided, and the charges, though of more than one description, of only one colour or metal, it would be blazoned in this way: 'Argent, a chevron between three mullets sable,' by which the chevron is understood to be sable as well as the mullets.

3. It is accounted by English heralds false heraldry to put metal upon metal, or colour upon colour; but instances of such blazoning frequently occur in foreign arms, particularly in those of German families. The objection is notwithstanding a sound one, as the charges should be rendered as distinct as possible, which can only be done by adhering to the English rule.

4. When a charge is represented of its *natural* colour, it is to be blazoned *proper*.

5. In blazoning animals, the teeth and claws, or talons, of the ravenous beasts are called their arms; and when they are to be represented of a different colour or metal from that of their bodies, they must be blazoned as '*armed*, Or,' or 'Gules,' as the case may be. If the tongue is shown the beast is said to be langued of such or such a colour, as 'a Lion, argent, *armed* and *langued*, azure.' More docile animals, the stag and deer, for instance, are said to be 'attired,' and not 'armed.' Beasts of prey are, according to their attitude, blazoned, *Rampant*, *Rampant-guardant*, *Rampant-regardant*, *statant*, *passant*, *salient*, *sejant*, *couchant*, *dormant*, *naissant*, *issuant*, *combattant*, *endorsed*, *erased*, &c. Stags are said to be *trippant*, *at gaze*, &c.

Birds of prey are also blazoned as 'armed' of such a colour, but such as have no talons are described as 'beaked and membered' *The Cock* is said to be *armed*, *crested*, and *jelloped*, the latter term referring to the wattles, or gills.

Birds, according to their attitudes, are blazoned *Volant*, *Displayed*, *Preying*, &c.

Fish, when placed horizontally, are termed '*naiant*; when perpendicularly, '*hauriant;*' when *bent* (as the dolphin is generally represented), '*embowed;*' if face to face, '*respecting each other;*' if back to back, '*endorsed*.'

The sun must be blazoned according to his condition, full, or in his eclipse. The moon, defined as crescent, *in*crescent, or *de*crescent: the first being, when represented with the horns upwards; the second, when the horns point to the dexter or right side of the shield; and the third, when to the left or sinister side. If downwards, it is called a *crescent reversed*.

The human figure is blazoned either *vested* or *naked*. Parts of the human figure, if cut off, are said to be *coupé;* if ragged or torn off, *erased*. Heads are also blazoned *wreathed* or *banded*, as the case may be.

Flowers are blazoned *jessant*, *slipped*, *seeded*, &c.

When the field of an escutcheon is covered with flowers of the same colour or metal, or any other pattern with flowers, or scroll work intermixed, it is said to be *diapered;* but when it is filled with flowers, crosses, or any other device of another colour or metal, repeated, as the French say, *sans nombre*, it is then blazoned as *semée*. An animal so covered with flowers or crosses should be blazoned as *powdered*. When the field, charge, or supporter is covered with *goutes*, or *drops*, it is called *gutty;* and if of gold or yellow, *gutty d'or;* of argent, *gutty d'eau;* of gules, *gutty de sang;* of azure, *gutty de larmes;* of vert, *gutty de vert;* and of sable, *gutty de poix*. When a bend, fess, or any other ordinary passes over an animal, it is said to be *debruised*. When the charge is divided by any of the partition lines, and the colours of the field are reversed upon it, it is said to be *counterchanged*.

By *marshalling* of arms we understand the orderly disposition of sundry coats, belonging to distinct families, in their proper places within one shield, by impaling or quartering;

and the joining of ensigns of honour and dominion with the paternal arms of the bearer, &c.

When a man marries he impales his wife's paternal arms, by placing them upright on the left side of his own in the same escutcheon, such impalement being also called *arms en baron et femme.* If that wife should be or become an heiress, the husband may bear her arms on an escutcheon of pretence over his own; Legh says however that this should not be done till he has begotten an heir of that heiress. In Scotland the husband frequently quarters the arms of his wife with his own when she is an heiress. In England this is only done by the children of such a marriage. If the mother be no heiress, the children cannot quarter her coat.

Another mode of impalement was by taking only half of each coat, and joining them in one escutcheon. This was called *dimidiation;* but the practice has long fallen into disuse.

The complete escutcheon of a family should never, according to some authorities, consist of more than six or eight quarterings; others admit of sixteen; and the Germans marshal sometimes twenty and thirty coats in one shield.

The best mode of marshalling so many is to begin by placing the arms of the first heiress who married into the family next to the paternal coat, and next to them the several coats which that heiress brought in; then the arms of the second heiress, followed by those which she brought in, and so on in rotation. When the royal arms are brought in by any match, it is usual however to give that match the second quarter next to the paternal coat, and some say it should even take precedence of that.

The arms of a widow are composed of her husband's and her father's impaled within a lozenge.

Those of a maid are her father's only, borne in a lozenge also, without any difference, except she be of the royal family, in which case a distinction is expressly furnished by the heralds for the individual coat by the command of the sovereign.

If the widow be an heiress, she may wear her paternal coat in an escutcheon of pretence over that of her husband, the latter however being in a lozenge, and her daughter, while unmarried, may quarter her mother's arms with her father's in a lozenge; but if the mother be no heiress, then, says Legh, the daughter has no further right to the arms of her mother's family, except to set them up pale-ways in her house to show her descent.

If the husband be a knight of the garter, or of any other order, the arms of the wife must not be impaled, but placed in a separate shield.

Such are the principal rules and terms of the science of heraldry: for further detail we must refer our readers to the works of Edmonson, Nisbett, Berry, &c., cautioning them, at the same time, against the Scylla and Charybdis of the heraldic inquirer, the absurd and misdirected enthusiasm of the champions of the art, and the undeserved contempt of its depreciators. By the latter it has been stigmatized as 'the science of fools with long memories.' It should rather be designated as a science which, properly directed, would make fools wise. It is, we repeat, a key to history which may yet unlock stores of information; at present its most learned professors have studied the art itself more than the use which may be made of it. They have wasted their time and their learning upon idle controversies, and still more idle speculations. A mysterious signification has been given to nearly every charge and tincture known in armoury, and a different one by nearly every writer upon the subject. The names of the ordinaries and colours have been derived from every sort of object and through every known language, without one fact having been elucidated on which we can depend. Even the word *blazon*, the only one we have ventured to hint the origin of, has been hotly claimed as Arabic by some disputants, and we will certainly not extend this article one line by an attempt to disprove it.

HERAT. [Khorassan.]

HE'RAULT, a department in France, on the coast of the Mediterranean, which derives its name from the river Hérault. The department approximates in form to a parallelogram, having its greatest extension N.E. and S.W.: it is bounded on the N.E. by the department of Gard; on the S.E. by the Mediterranean; on the S.W. by the department of Aude; and on the N.W. by the departments of Tarn, Aveyron, and Gard. The greatest length from north-east to south-west is nearly 80 miles. Its greatest breadth at right angles to the length 44 miles. The area of the department is estimated at 2417 square miles; the population in 1836 was 357,846, being about 148 to a square mile, somewhat below the average density of the population of France. The area rather exceeds that of the two English counties of Chester and Salop, but it has less than two-thirds of their population. Montpellier, the capital of the department, is in 43° 36′ N. lat. and in 3° 52′ or 3° 53′ E. long.: 366 miles from Paris in a straight line south by east.

The coast of the Mediterranean is low, and is lined by étangs, or pools; the chief of these are the Etang de Vendres, near the mouth of the Aude; and the Etangs de Thau and Mauguio, which, with the intermediate waters, form one long pool, extending 35 to 40 miles from the mouth of the Hérault to that of the Vidourle.

The north-western side of the department is occupied by the Espinouse mountains, part of the chain of the Cévennes, and their branches: nearly one-third of the department is of a mountainous or hilly character. Towards the Mediterranean the surface becomes more level. Many streams flow from the mountains to the sea. The Vidourle rather belongs to the department of Gard, in which it rises; but in the lower part of its course it separates the departments of Gard and Hérault. The Salazon and the Les, with its feeder, the Mosson (which receives the Caulazon), are small streams, none of them so much as 25 miles long. The Hérault is larger: it is generally considered to rise near Villeraugue in the department of Gard, but the head of its feeder, the Trevezet, which should be regarded as its true source, rises more to the west, near the border of the departments of Gard and Aveyron. It flows about 27 miles first eastward, then southward, before entering the department of Hérault, through which it flows about 53 miles in a direction nearly south by west into the Mediterranean, near Agde: its whole course is about 80 miles, for 7 or 8 of which, viz. from the town of Bessan, it is navigable. Its feeders are the Vis (chiefly belonging to the department of Gard), the Lergue, and the Boyne, on the right bank, and the Landou on the left. The Livron flows 25 miles from the lower slopes of the Cévennes into the sea. The Orb rises on the north-western boundary of the department, and flows about 65 miles in a very winding channel to the Mediterranean: it is navigable for about 3 miles. Its tributaries are the Bauson, the Vialas, the Jean or Jeau, and the Bernasobres, all on the right bank. The Aude forms for a short distance the south-western boundary of the department, and the Ceysse and the Brian, which belong to the system of the Aude, with the Agout and the Larn, which belong to the system of the Garonne, water the western part.

The navigable canals of the department are numerous, and some of considerable extent. The Canal du Midi, or Canal du Languedoc, enters the department on the southwest, and runs nearly 40 miles to its termination in the Mediterranean, near the town of Cette. The Canal des Etangs extends about 17 miles along the line of the coast-waters from the nearest part of the Etang de Mauguio to the town of Cette. The canal which skirts the Etang de Mauguio is about 6 or 7 miles long; and that of Lunel, from the town of Lunel to the Etang de Mauguio, about 8 miles. The Canal de Graves (or the navigation of the Les) with that of the Grau du Les is about 7 miles. That portion of the Canal Radelle (extending from Aigues Mortes to the Etang de Mauguio) which belongs to this department, is about 4 miles long: the canals of Robine de Vic and Peyrade are under 2 miles each. A canal has been projected from Montpellier to the Canal des Etangs: its length is estimated at about 5 miles. The whole length of the canal navigation of the department is about 87 miles.

There are seven 'routes royales,' or government roads, with an aggregate length of 232 miles; but of these about 55 miles were (at the commencement of 1837) out of repair, and above 36 miles unfinished. The principal government road is that from Paris into Spain by Perpignan; it enters the department between La Cavalerie, in the department of Aveyron, and Lodève; and passes by Lodève, Clermont de Lodève, Pézénas, and Béziers to Narbonne in the department of Aude: the other roads lead in various directions from Montpellier and Béziers. There are seventeen 'routes départmentales,' with an aggregate length of 300 miles; but not much more than half this extent is in repair. The 'chemins vicinaux,' or bye-roads and paths, have an aggregate length of more than 3000 miles. There is a railroad from Montpellier to Frontignan and Cette, 17 miles long, which is much used for passengers.

The greater part of the department is occupied by the strata between the chalk and the new or saliferous red sandstone. About the upper waters of the Orb are found the formations which intervene between these and the primitive rocks; and in the western extremity of the department, amid the Cévennes, the primitive rocks occur. The mineral wealth of the department is not great: it consists chiefly of coal, some iron, copper, and lead, some varieties of marble much valued for ornamental purposes, and a species of lignite which is used, under the name of 'fossil ashes,' for manure. There are mineral waters at Montpellier, Balaruc, and other places. There are some important salt-pans along the coast. The climate of the department is mild in winter; in summer it is frequently very hot, but on the whole healthy.

More than a third part of the surface of the department is waste, about one-fourth is arable, one-sixth is devoted to the cultivation of the vine, an eighth is woodland (the forests are chiefly of oaks, cork-trees and pines), and the remainder is devoted to various culture, or is occupied by the étangs, rivers, ponds, and other waters. The quantity of grass-land is very small. Wheat is the grain chiefly cultivated, then rye and oats; of barley and pulse, maize, and maslin or mixed corn, the quantity is unimportant: nor are potatoes much grown. The quantity of grain raised is not beyond what is required for home consumption; the produce of the vineyards, both wine and brandy, the dried fruits, perfumes, liqueurs, and wood, furnish the chief articles of export. The olive, fig, and mulberry are cultivated, and some plants used for dyeing are produced. Horned cattle are not numerous, but sheep are; and also mules. The manufactures of the department are considerable; they consist chiefly of cloth, especially for clothing the troops, and other woollen fabrics, cotton yarn and cotton goods, and silk hose: above 17,000 workmen are engaged in these various branches. The fishery on the coast is busily carried on, especially that of sardines.

The department is subdivided into four arrondissements, of which Montpellier, Béziers, Lodève, and St. Pons, are respectively the chief towns: the area and population of the department are thus distributed:—

Arrondissement.	Area.	Population.
Montpellier	780 sq. miles.	123,656
Béziers	696 „	128,149
Lodève	474 „	57,730
St. Pons	467 „	48,311
	2417	357,846

The chief towns of each arrondissement are as follows:—

In the arrondissement of Montpellier are Montpellier near the Lez, population in 1836, 35,506 [MONTPELLIER]; Cette on the Mediterranean, pop. in 1831, 10,638 [CETTE]; Lunel la Ville, so called to distinguish it from Vieux Lunel, near the Vidourle, pop. 6050 for the town, or 6260 for the whole commune; Mèze on the Etang de Thau, pop. 4258 for the town, or 4400 for the whole commune; Ganges on the Hérault, pop. 4173 for the town, 4193 for the whole commune; Marsillargues or Massillargues on the Vidourle, pop. 3233 for the town, 3292 for the whole commune; Aniane, near the Hérault, pop. 2408 for the town, 2480 for the whole commune; Poussan, near the Etang de Thau, pop. 1850 for the town, 1916 for the whole commune; Pignan, near Montpellier, pop. 1877 for the town, 1889 for the whole commune; Frontignan, on the line of the étangs near Cette, pop. 1656 for the town, 1877 for the whole commune; and St. Bauzille do Putois on the Hérault, pop. 1622: beside the smaller towns of Lansargues, Mauguio, Boisseron, Castries, Les Matelles, Celleneuve, Miravaux, and Villeneuve, near Montpellier.

Lunel and Frontignan are well known for the wines produced in their neighbourhood; the former is a place of considerable trade: brandy is sent to the north of France; and at the weekly market much corn is sold for the supply of the mountainous parts of the department. Ganges, a town of considerable business, preserves the remains of an old castle; and at Aniane are the remains of the first monastery built by St. Benedict.

In the arrondissement of Béziers, are Béziers on the Orb, population in 1836, 16,233 [BEZIERS]; Bedarrieux on the Orb, pop. 5781 for the town, 5998 for the whole commune [BEDARRIEUX]; Pézénas on the Hérault, pop. 7481 for the town, 7847 for the whole commune; Agde on the Hérault, near the Mediterranean, pop. 7965 for the town, 8202 for the whole commune; Marseillan on the Etang de Thau, pop. 3625 for the town, 3687 for the whole commune; Montagnac, near the Hérault, pop. 3260 for the town, 3440 for the whole commune; Florensac, near Marseillan, pop. 3512; Bessan on the Hérault, where the navigation begins, pop. 2210 for the town, 2228 for the whole commune; Serignan on the Orb, pop. 1997; Villeneuve, near Béziers, pop. 1966 for the town, 1996 for the whole commune; Servian, a few miles north-east of Béziers, pop. 1918 for the town, 2174 for the whole commune; and Vias, near Agde, pop. 1684 for the town, 1761 for the whole commune: besides the smaller towns of St. Gervais, Nissan, Capestan, Mauroilhan, and Quarante.

Pézénas is on the road from Paris to Narbonne, and into Spain through Moulins, Clermont, Mende, and Lodève, not far from the right bank of the river Hérault. Pézénas was known to the Romans by the name Piscenæ. Pliny notices the excellence of the woollen cloths made there. Pézénas was in the middle ages a chatellanie, which was successively held by the houses of Montmorency and Conti, the latter a younger branch of the house of Bourbon Condé. The town is neatly built, and is adorned with two fountains, a good quay, and handsome promenades. There are manufactures of woollens, which are in good repute, linens, cotton handkerchiefs, leather, soap, verdigris, silk-stockings, and hats. Wool-washing, for which the waters of the Pein are considered to be well adapted, and distilling, are carried on. The wines of the neighbourhood are considered excellent. Trade is carried on in the manufactured articles above mentioned, and in wine, brandy, almonds, olive-oil, dried fruits and capers, alum and copperas. There is a good market on Saturday, and three yearly fairs. There are a theatre and a college founded by Henri IV. Near this town is an old castle, built by Constable Montmorency.

Agde is a town of great antiquity. It is thought to have been a colony of the Greeks of Massilia: it bore the Greek name Agatha. A bishopric was established here, probably in the fifth century, which continued to the time of the Revolution; the bishop was a suffragan of the archbishop of Narbonne: there was also a celebrated abbey, which had at one period 300 monks. In the middle ages Agde was the capital of a county. The harbour is accessible to small vessels, of which 120 belong to the port: the chief trade is carried on coastwise. There are considerable salt-pans near the town.

In the arrondissement of Lodève, are Lodève on the Lergue, a feeder of the Hérault, population in 1836, 11,208 [LODEVE]; Clermont de Lodève, near the Lergue, pop. 5905 for the town, 6199 for the whole commune [CLERMONT]; Gignac, near the Hérault, pop. 2594 for the town, 2779 for the whole commune; St. André, between Gignac and Clermont de Lodève, pop. 2131; and Montpeyroux, near Gignac, pop. 1675 for the town, 1713 for the whole commune: besides the smaller towns of Joncels and Ceilhes.

In the arrondissement of St. Pons, are St. Pons on the Jean or Jeau, population in 1836, 6995; La Salvetat on the Agout, pop. 3986 for the whole commune; and St. Chinian, between St. Pons and Béziers, pop. 2375 for the town, or 3270 for the whole commune: besides the smaller towns of Orlargues and Olonzac.

St. Pons is situated in a valley amid the Cevennes, on a road leading across the mountains from Béziors to Castres and Alby. The town, which is pleasant, probably derives its origin from a religious house of the Benedictine order founded in the tenth century by Pons, count of Toulouse, who transported hither the relics of St. Pons, his patron Saint, martyred at Nice. In A.D. 1317 Pope John XXII. elevated the abbot of this house to episcopal rank, and detached thirty-nine parishes from the diocese of Narbonne to form a new diocese for him. The bishopric was abolished at the Revolution. Woollen cloth, hosiery, leather, and cotton-yarn are manufactured. Marble is quarried in the neighbourhood.

The population of the towns, except the chief towns of arrondissements, is taken from the census of 1831.

The department of Hérault constitutes the diocese of Montpellier, the bishop of which is a suffragan of the archbishop of Avignon. It is in the jurisdiction of the cour royale, or high court of justice, of Montpellier, and in the circuit of the university of the same city. It is included in the ninth military division, the head-quarters of which are at Montpellier. It sends six members to the Chamber of Deputies. There are four Protestant consistorial churches.

The proportion of those who could read and write among the young men enrolled in the military census of 1828-29 was forty-five in every hundred, being above the average of France.

The department is composed of the former dioceses of Montpellier, Lodève, and Béziors, part of the diocese of Narbonne, and part of the diocese of St. Pons, if not all: these were all in Languedoc.

HERBELOT, BARTHE'LEMI D', was born at Paris, on the 14th of December, 1625. He commenced the study of the Oriental languages in early life, and acquired an accurate knowledge of the Arabic, Hebrew, Syriac, Persian, and Turkish languages. During his residence in Italy, whither he went with the hope of obtaining instruction from natives of the East, he enjoyed the friendship and patronage of the Cardinals Barberini and Grimaldi; and on his return to France he received a pension from Fouquet of 1500 livres, which he afterwards lost on the disgrace of that minister. He was subsequently appointed Oriental secretary and interpreter to the king. During a second visit which he made to Italy he was received in the most distinguished manner by Ferdinand II., grand-duke of Tuscany, who presented him with a great number of valuable Oriental MSS., and wished to retain him at his court. But D'Herbelot was prevailed upon by the solicitations of the minister Colbert to return to Paris, where he was appointed professor of Syriac on the death of Auvergne. He also received a pension from the king. He died 8th of December, 1695.

The work by which D'Herbelot is known to posterity is entitled 'Bibliothèque Orientale, ou Dictionnaire Universel, contenant généralement tout ce qui regarde la connoissance des peuples de l'Orient,' fol., Paris, 1697. This work, which he commenced in Italy, and upon which he employed the labour of many years, was published after his death by Galand. The 'Bibliothèque Orientale' was founded upon the Arabic dictionary of Haji Khalfa, and has been deservedly considered by scholars as a most extraordinary work for the time in which it appeared. D'Herbelot also drew his materials from numerous other works in Arabic, Persian, and Turkish, which are enumerated by Galand in his preface to the 'Bibliothèque.' On many subjects connected with Oriental history and antiquities the 'Bibliothèque Orientale' supplies the only information which is available at the present day to a person unacquainted with the Oriental languages. But its statements must be received with great caution; for while the learned author appears to have had a most extensive knowledge on all subjects connected with the East, he certainly did not pay sufficient attention to accuracy. It should however be recollected that he did not live to complete the work, and that his plan embraced too great a number of subjects to allow any one individual to do justice to them all.

The 'Bibliothèque Orientale' was reprinted at Maestricht, fol., 1776, and also at the Hague, 4 vols. 4to., 1777—1799. The latter edition contains many valuable additions by Schultens and Reiske, and also a supplement by Visdelou and Galand. An abridgement of the original work was published at Paris, 6 vols. 8vo., 1782, by Désessarts. A German translation of the 'Bibliothèque Orientale' was published at Halle, by Schulz, 4 vols. 8vo., 1785—90.

D'Herbelot also wrote several other works, which have never been published. Amongst these Galand mentions a Turkish and Persian Dictionary, in three volumes folio.

HERBERT, EDWARD, LORD HERBERT OF CHERBURY, a profound and original thinker, but of a temperament somewhat fanciful and eccentric, was born in the year 1581, at Montgomery, in the principality of Wales. After going through the usual course of studies at Oxford, where he was a member of University College, Herbert visited London in 1600, and shortly afterwards proceeded to the Continent with the design of seeing foreign parts, but was induced by an inherent love of enterprise and danger to join the English auxiliaries then serving in the Netherlands, where he soon distinguished himself by his reckless daring and intrepidity. Having returned to England, he was upon the accession of James I. created a knight of the bath, and was distinguished at the court of that pedantic monarch by his gallantry and his learning. In 1816 Sir Edward was sent ambassador to France: in this situation the bold independence with which he answered a haughty remark of the Connétable De Luynes brought upon him the displeasure of the French monarch, at whose request he was recalled. The conduct of Herbert met however with the approbation of James, who, upon the death of De Luynes, sent him in a similar capacity to Paris, where he published his first work, entitled 'Tractatus de Veritate, prout distinguitur à Revelatione, à Verisimili, à Possibili, et à Falso,' 4to., Paris, 1624. The year following he returned to England, and was created a baron of the kingdom of Ireland. From this date Lord Herbert does not appear to have held any public office, and his time was divided between the gaieties of the court and the pursuits of literature. In 1631 he was elevated to an English peerage, and two years after published an enlarged edition of the 'Tractatus,' of which another appeared in 1645, accompanied with the treatise 'De Religione Gentilium, Errorumque apud eos Caussis.' Upon the outbreak of the political troubles under Charles I., Lord Herbert at first took the side of the parliament, which however he subsequently abandoned at a great sacrifice of personal interests and fortune. He died in the year 1648. After his death two posthumous works were published, the 'Expeditio Buckinghami Ducis in Ream Insulam,' and the 'Life and Reign of King Henry VIII.,' with a dedication to the first Charles. It is by the latter work that Lord Herbert is best known to posterity. His Memoirs, which are the earliest instance of autobiography in our language, remained in manuscript until they were printed, in 1764, by Horace Walpole, at his private press at Strawberry Hill.

Herbert of Cherbury was the contemporary of Hobbes of Malmesbury, to whose principles of philosophising he was directly opposed, notwithstanding the striking coincidence of many of the results at which they respectively arrived. He maintained the theory of innate ideas, and made a certain instinct of the reason (rationalis instinctus) to be the primary source of all human knowledge. Accordingly he did not, with Aristotle and the Stoics, compare the mind to a pure tablet (γραμματεῖον ἐν ᾧ μηθὲν ὑπάρχει ἐντελεχείᾳ γεγραμμένον), or to the tabula rasa of the schoolmen, but to a closed volume which opens itself at the solicitation of outward nature acting upon the senses. Thus acted upon the mind produces out of itself certain general or universal principles (communes notiones), by reference to which all debateable questions in theology and philosophy may be determined, since upon these principles at least all men are unanimous. Consistently with these views, he does not, with Hobbes, make religion to be founded on revelation or historical tradition, but upon an immediate consciousness of God and of divine things. The religion of reason therefore, resting on such grounds, is, he rightly argues, the criterion of every positive religion which claims a foundation in revelation. No man can appeal to revelation as an immediate evidence of the reasonableness of his faith, except those to whom that revelation has been directly given; for all others, the fact of revelation is a matter of mere tradition or testimony. Even the recipient of a revelation may himself be easily deceived, since he possesses no means of convincing himself of the reality or authenticity of his admitted revelation.

Herbert made his own religion of reason to rest upon the following grounds:—There is a God whom man ought to honour and reverence: a life of holiness is the most acceptable worship that can be offered him: sinners must repent them of their sins, and strive to become better; and after death every one must expect the rewards or penalties befitting the acts of this life.

Lord Herbert is one of the numerous instances on record of the little influence which speculative opinions exercise upon the conduct of life. Maintaining that no revelation is credible which is imparted to a portion only of mankind, he nevertheless claims the belief of his hearers when he tells them that his doubts as to the publication of his work were removed by a direct manifestation of the divine will. Notwithstanding the little favour which has been shown to his works, which is partly indeed attributable to the obscurity both of his style and diction, but chiefly to the predominant inclination for the empirical philosophy of Bacon and Hobbes, the skill and sagacity with which he has pursued his researches on a purely rational method are alone sufficient, even had we not a Glanvil and a few others to boast of, to refute the objection which has been urged against us of a total absence in the national mind of all pure and reflex reasoning. The doctrine that outward objects are but the occasions of educing all general knowledge is the foundation of the fame of Kant; and there is much also in the writings of Jacobi which reminds the reader of the principles and method of the philosopher of Cherbury.

The view of Lord Herbert on innate ideas is opposed generally by Locke ('On the Human Understanding,' b. i., c. 2), and some special points are called into question by Gassendi, in his 'Epistolæ ad Librum Ed. Herberti Angli,' in the third volume of his works.

HERBERT, GEORGE, born April 3, 1593, was the fifth brother of Lord Herbert of Cherbury. He was educated at Westminster, and elected thence to Trinity College, Cambridge, about the year 1608. In 1615 he became Fellow of the college, and in 1619 was elected to the office of public orator, a post in those times of considerably more importance than at present. While at Cambridge he made the acquaintance of Lord Bacon, but the pleasures of the court and some hopes of preferment led him to spend much of his time away from that seat of learning. His expectations however failing on the death of James I., he turned his attention to divinity, of which he had before been a laborious student, and took holy orders. He was made prebendary of Leighton Bromswold, or Layton Ecclesia, in 1626. He married in 1630, and in the same year accepted the rectory of Bemerton; but the effects of a quotidian ague, which had attacked him the year before, soon made themselves again apparent, and he died in 1632. His poetical works are well and deservedly known. They belong to the same school with those of Donne, Quarles, and Herrick, and remind us forcibly of certain poems which have lately appeared at Oxford under the title of 'The Christian Year,' and the same analogy may be traced between that school of divines to whom these poems are owing and our author; there is the same zeal and energy in pastoral duties, the same love of paradox in language, the same reverence for antiquity and for the ceremonies of the church.

Herbert's chief prose work is 'The Priest to the Temple,' a sequel to his work called 'The Temple; Sacred Poems and Private Ejaculations.' It lays down rules, and very good rules for the life which a country clergyman ought to lead. He also wrote a translation of Cornaro on Temperance, and some Latin poems.

(Izaak Walton's *Life of Herbert*; Chalmers' *Biog. Dict.*)

HERBERT, SIR THOMAS, was born at York about 1606, and entered Jesus College, Oxford, in 1621, whence he removed to Trinity College, Cambridge. In 1626 he went abroad in the suite of Sir Dodmore Cotton, ambassador from Charles I. to the Shah of Persia, through the interest and at the expense of his kinsman William Herbert, earl of Pembroke, a man of cultivated and elegant talents, and a generous encourager of learning. He sailed to Surat, thence to Ormus, traversed Persia northwards to the Caspian Sea, and returned by Ispahan and Bagdad, down the Tigris; thon proceeded to the coast of India, near Surat; visited (or at least described) the straits of Malacca, Java, Pegu, the Molucca islands, &c; and returned to England after four years' absence. In 1634 he published his 'Some Yeares Travels into Africa and Asia the Great,' &c. (revised and enlarged by the author in 1638), which is an accurate and trustworthy work, and the best account of Persia anterior to that of Chardin. It contains a great many curious facts which the reader will hardly find anywhere else. The work was translated into Dutch by Van Vliet, and re-translated into French by Wicquefort. The English edition is ornamented with a great many cuts. [CHARDIN, SIR JOHN.] Herbert espoused the cause of the parliament, and in 1647 was one of the commissioners appointed to receive the king from the Scots at Newcastle. In that capacity he attended the king to Holdenly Castle, and was selected by him, on the dismissal of his former attendants, to be about his person. Though, being a Presbyterian, he was opposed in religion, as well as politics, to the opinions of Charles, still the respectful propriety of his behaviour won the regard of the royal prisoner, towards whom Herbert in his turn appears to have conceived a strong veneration and affection. He attended him to the last; and after the Restoration his faithful service was rewarded by Charles II. with the title of baronet. In 1678 he published 'Threnodia Carolina,' an historical account of the two last years of the life of King Charles I., by Sir Thomas Herbert and others, reprinted by Nicol in 1813. He died at York in 1682. (*Athenæ Oxonienses*, where there is an original account of the last days and burial of Charles I., communicated to Wood by Herbert himself.)

HE'RBSTIUM. [THALASSINA.]

HERCULA'NEUM, or *Herculanum* (Cic. *ad Att.* 7, iii.), a very antient Italian city, situated on the coast of Campania, near Naples. It is said to have been of Pelasgian origin, but its history is obscure, and it seems never to have attained any importance. In the time of Titus, A.D. 79, it was overwhelmed by that memorable eruption of Vesuvius which also ruined Pompeii. [VESUVIUS.] It appears to have been buried under showers of ashes, subsequently overflowed by streams of lava, and is stated to be 70 feet below the present surface of the ground. It was re-discovered by the sinking of a well in 1713, when several antiquities were found. This led to further investigation; and after several years, in which little was done, the Neapolitan government undertook the work of excavation. The theatre, a chalcidicum, and two temples, are the chief buildings explored: the private houses are chiefly small, and of one story, like those of Pompeii. The whole excavation is said to have been about 600 yards long by 300; but it being impossible to remove the incumbent soil, in consequence of its thickness, as fast as one part was thoroughly searched, it was filled up with rubbish from another. A small part of the theatre is all that is now accessible. The chief advantage as yet derived from Herculaneum is the magnificent collection, not only of statues and paintings, and vases, but of domestic implements of every use and description, deposited in the Royal Museum at Portici. These are figured and described in the magnificent work, 'L'Antichita d'Ercolano,' Nap., 1757, 10 vols. fol. The collection has been abundantly increased from Pompeii.

Great expectations were raised by the discovery of a large number of manuscripts, written on rolls of papyrus. The attempts to unroll them hitherto have had but imperfect success; and those of which the subjects have been ascertained are of little interest. There seems to be very little hope of recovering any of the lost treasures of antiquity in this quarter. The work entitled 'Herculanensium Voluminum quæ supersunt,' Naples, 3 vols., 1788, 1809, 1827, contains, we believe, all that has yet been deciphered. The University of Oxford published, in 1824-5, two volumes, 8vo., of fragments lithographed from fac-similes (apographa) presented to them by George IV.; these have been also published in the Neapolitan work. The bulk of those which have been examined contain the works of Greek philosophers and sophists, and treat of natural and moral philosophy, medicine, criticism, the arts, &c. The papyri have uniformly been found in a state resembling charcoal, dry, and crumbling, the laminæ, for the most part, strongly adhering to each other. There is an elaborate account of the several methods which have been tried to unroll them in the last edition of the 'Encycl. Britann.,' art. 'Herculaneum.'

HE'RCULES (in Greek, Heracles), a celebrated hero of Greek mythology, the offspring of Zeus by Alcmena, daughter of Electryon, a son of Perseus, and king of Mycenæ. His reputed father was Amphitryon (son of Alcæus, another of the children of Perseus), who having accidentally killed his father-in-law Electryon, was compelled to leave Mycenæ, and take refuge in Thebes. Here Hercules was born and educated, and here his early feats of strength and valour were done; such as slaying the lion of Cithæron, delivering Thebes from the tribute to Erginus, king of Orchomenos, and taking in marriage the daughter of Creon.

Being fated to serve Eurystheus, king of Mycenæ, he performed what are called his labours, in obedience to the commands of his master. They are so well known that we need only enumerate them:—the first was, to bring the skin of the Nemean lion; the second, to destroy the Hydra; the third, to catch the hind of Artemis; the fourth, to bring to Eurystheus the Erymanthian boar alive; the fifth, to cleanse the stables of Augeas; the sixth, to drive away the water-fowl of lake Stymphalis; the seventh, to fetch the Cretan bull; the eighth, to bring to Mycenæ the mares of Diomedes; the ninth, to obtain the girdle of Hippolyta, queen of the Amazons; the tenth, to bring the oxen of Geryon from the island of Erythia; the eleventh, to bring the apples of the Hesperides; the twelfth, to conduct Cerberus from the under world. Many other exploits did he perform, such as the taking of Troy, which are all related by the mythologists, Apollodorus, and others. But we have already gone into somewhat unnecessary detail, as our object will rather be to point out the classes to which these traditions belong, than to give our readers information with which they can supply themselves elsewhere.

There are then three distinct kinds of tradition relating to Hercules; the first consisting of stories drawn from some Eastern or other religion, and applied to the Theban hero. Such are his wanderings round the coasts of Greece, which exhibit in a mythical form the establishment of the worship of a wandering god of the Phœnicians. Such also is his voluntary death on Mount Œta; and, according to Müller (*Dorians*, i. 444), his murdering his children. Another, and the second class of traditions, are those which represent him performing labours such as would naturally be those of a young community. (Pausan., viii. 14.) A third class exhibits him in the light of a conqueror and destroyer of tyrants, and here the awkwardness of ascribing the deeds of the Peloponnesian hero to the Theban Hercules is most striking; for while on the one hand he is serving Eurystheus as a slave, on the other he appears as one who forms alliances and disposes of kingdoms.

The legends of Hercules perhaps afford a better instance than those of any other hero or god, except Apollo, of the various sources from which mythical accounts spring.

Hercules is represented as a half-naked man, with broad shoulders and brawny limbs, resting on a club, and covered round his loins with the skin of the Nemean lion. He appears however to have originally borne a spear and buckler, or a bow and sword, the later representation having been substituted about the time of Stesichorus.

(Müller's *Dorians*, and the authors whom he quotes; Thirlwall's *History of Greece*; Müller's *Prolegomena*; Buttmann's *Mythologus*, i. xi.)

HERCULES, one of the old constellations, called ἐνγονασιν by Aratus, Hyginus, and Ptolemy, and described by the first as 'a figure like that of a man in sorrow' while the second offers various fabular significations from the stories of Hercules, Orpheus, Cetheus, Theseus, Thamyris, Ixion, Prometheus, &c. The club, lion's skin, and character of Hercules, are not so old as Aratus, who describes this figure as stretching his hands to different quarters, and makes an allusion to the neighbouring dragon, which shows that he was not painting a hero.

The constellation is situated between Draco, Bootes, Lyra, and Ophiuchus; but as there is no star in it larger than of the third magnitude, there is nothing very remarkable about it. The principal stars α and β lie between the bright stars in the head of Ophiuchus and in Corona Borealis.

HERCULES, PILLARS OF. [GIBRALTAR, STRAITS.]

HERDER, JOHANN GOTTFRIED Von, was born in 1744, at Morungen in East Prussia, where his father kept a little girls'-school. The only books he was allowed to read were a Bible and Hymn-book, though he secretly turned his attention to other works. A preacher named Trescho engaged him as a writer, and as he observed in him germs of talent, he allowed him to remain with his sons, while he gave them instruction in Latin and Greek. A complaint in the eyes, with which he was afflicted, was the means of his becoming acquainted with a Russian surgeon, who was so pleased with him, that he offered to take him to Königsberg and thence to Petersburg, designing to instruct him in surgery gratis. Herder accepted the offer, but at Königsberg fainted away at the first dissection which he attended, and thereupon resolved to study theology. He fortunately gained the acquaintance of persons who appreciated him, and procured him a place as instructor in the Frederick's College at Königsberg. With the most indefatigable industry he studied philosophy, natural science, history, and languages, and in 1764 became assistant at the cathedral school at Riga, to which office that also of preacher was attached. Though his sermons were greatly admired, he soon left the situation, as he desired to study the world at large. He accordingly went to France, and was there chosen by the Prince of Holstein-Oldenburg as his travelling companion. He would have gone from France to Italy had he not been arrested by the complaint in his eyes at Strasburg, where he first became acquainted with Göthe. In 1775 he became theological professor at Göttingen, where he was enabled to pursue his favourite studies under the benign influence of the Duke of Saxe-Weimar and his wife He died in 1803.

The writings of Herder fill about sixty volumes, and are on the greatest variety of subjects. As a theologian he has gained celebrity by his 'Spirit of Hebrew Poetry;' as a philosopher, he is known as the author of the 'Philosophy of the History of Man,' a work which has been translated into English. He was not so much a metaphysician as an observer. He strove to discover a point of union where science, religion, history, poetry, and art should meet; and in order to take one comprehensive view of all the tendencies of man, he made himself acquainted with the literature of a variety of countries, Oriental as well as European, antient as well as modern. His collection of popular ballads of all nations has a high reputation; and a poem by him called the 'Cid' has been declared by the Spaniards themselves to be truly Spanish. The great influence which he exercised on German literature, by introducing his countrymen to the knowledge of an infinite variety of subjects, was undoubtedly great; and his name is never mentioned among them but in terms of high respect and admiration.

HERDERITE, a mineral which occurs in crystals embedded in fluor at Ehrenfriedersdorf in Saxony. Primary form a right rhombic prism; cleavage parallel to the lateral planes, and in the long diagonal of the prism; fracture small, conchoidal; hardness 5; colour greyish and yellowish-white; streak white; lustre vitreo-resinous; nearly transparent; specific gravity 2·985.

HEREFORD, an antient city, and parliamentary and municipal borough, situated upon the left bank of the Wye, about 115 miles in a direct line west-north-west of London. The name is probably derived from the British Hên-fford, signifying the 'old road.' The city or liberties (these words are used indiscriminately) extend far beyond the mass of the town, and their boundaries are perfectly well ascertained. The liberties comprise the parish of All Saints; part of the parish of St. John the Baptist; part of the parish of St. Martin; part of the parish of St. Nicholas; part of the parish of St. Owen; part of the parish of St. Peter;

the township of Huntington in the parish of Holmer; another part of the parish of Holmer; part of the township of Tupsley in the parish of Hampton Bishop; and small portions of the parishes of Bullingham and Breinton. The city contains 2320 statute acres, and a population of 10,280. The borough council consists of the mayor, six aldermen, and eighteen councillors. The following courts are or may be held within its limits:—the Quarter-Sessions; the Petty Sessions; the Mayor's Court; View of Frankpledge; and Court of Pie Poudre. The income of the corporation arises from real property, tolls, and fees: in 1832 it amounted to 1176*l.*

History and Antiquities.—In early times this city was important as a garrison to restrain the Welsh. The principal events of its history are its pillage by the Welsh in 1055; its capture by King Stephen in 1141; the execution of Owen Tudor, who was beheaded here in 1461; the surrender of the city during the rebellion, in 1643, to the parliamentary troops, headed by Sir Wm. Waller; and the siege of Hereford by the Scotch under Lord Leven.

A house of Grey Friars stood at the southern extremity of the city: a house formerly belonging to the Black Friars, the picturesque arms of which have been engraved in the book of Mr. Grose and other antiquaries, may be seen in the suburb of Widemarsh St.; and adjoining it was a chapel and building belonging to the Knights Hospitallers of Jerusalem. There was also a Benedictine cell, belonging to the abbey of St. Peter, at Gloucester. The castle consisted of two wards of different dimensions, having a keep within the smaller: the Wye formed its defence on the south side; on other points it was defended by moats. It was taken possession of by Sir William Waller in 1643, and was garrisoned till 1652; but at that time the parliamentary commissioners returned it as 'ruinous,' and its materials worth no more than 85*l.*

Hereford is situated in a broad, fertile, and well-cultivated valley, and at sufficient elevation above the river Wye to be free from fogs and damp. It has always been esteemed a healthy town. The principal streets are broad and straight, and have all been macadamized. The private houses, with few exceptions, are built of red brick, and the public buildings of stone. The shire-hall was built after a plan of Sir Robert Smirke, and is remarkable for the unassuming beauty of its exterior, as well as the good general arrangement of the interior. Besides the courts and rooms necessary for the transaction of assize and magisterial business, it contains a large room, which is used at elections and other public meetings, and occasionally as an assembly-room. The town-hall, a large wood and plaster building supported by oaken pillars, stands in the High Town, and the fruit and vegetable market is held underneath and around it: additional markets have also been built between this site and the guildhall, a brick building in a remote situation. The Union workhouse, first inhabited in 1838, stands just beyond the north-east limits of the city. In the county gaols, which are in the same neighbourhood, the silent system is in force, the regulations rigid, and the superintence of the visiting magistrates is vigilant and discreet. One of the gateways of the ancient walls has been fitted up as a city prison. There are several hospitals or almshouses. A large infirmary, supported by contributions and benefactions, stands south-east of the city, near the Castle-green. The principal churches are those of All Saints, St. Peter, St. Nicholas, and St. John. All Saints Church faces Broad-street on the north; the steeple is tall and well-proportioned, but its external architecture is generally uninteresting. A parapet of brickwork on the south side, which has been added to the original stone wall, greatly disfigures the elevation. The vicarage of St. Martin's and All Saints, which is in the gift of the dean and canons of Windsor, is returned of the annual value of 380*l.* St. Peter's Church, founded by Walter de Lacy in 1085, is a plain building, with a spire. The annual value of the vicarage, as returned in 1835, is 366*l.* The rectory of St. Nicholas is valued at 188*l.* a year.

The church dedicated to St. Owen, and destroyed during the civil wars, was consolidated with St. Peter's in the reign of Charles II.: that of St. John the Baptist has probably been at all times an appendage to the cathedral. The latter is a vicarage, of which the dean and chapter are patrons.

Hereford Cathedral stands upon the south side of the city, not very far from the Wye. It is probable that this situation was occupied in very early times by a church of considerable importance. Polydore Virgil mentions that there was a large church (templum magnificum) at Hereford, in the reign of Offa, king of Mercia. Ethelbert, who was murdered at the instigation of Offa [Herefordshire], was buried in this cathedral, and gifts were offered at his shrine, where it was asserted that miraculous appearances had been shown. Milfrid, the governor of the province in the time of Egbert, was attracted to the spot, and he determined to erect in honour of St. Ethelbert a new church, which is referred to as 'lapidea structura,' a distinction which makes it probable that the former was a wooden building. The date of the building is fixed at 825. We are ignorant what were the causes of the rapid decay of this edifice; the whole however, says Grose, was rebuilt by Bishop Athelstan about the year 1030. This cathedral was entirely demolished in 1055. No renewal was attempted until the latter years of William the Conqueror's reign, when Bishop Lozing and others commenced the present building in the Saxon style. In 1786 the western portion of the cathedral fell, and alterations were subsequently made, the spire was removed, and a new western end added by Wyatt: either from want of funds or want of taste the architect has sadly marred the beauty of the original structure. The cathedral contains many monuments of great antiquity, some of which are highly ornamented. For a minute description of this cathedral, see Duncomb's 'Hist. of Herefordshire,' and Britton's 'Cathedrals.'

In the chapter-room there is a curious map of the world, probably one of the oldest original maps in existence; a copy of it was made, a few years ago, for the London Geographical Society. At the east end of the church is the library, which contains many valuable books and manuscripts. The 'college' is a quadrangle, which contains the residences of the vicars of the cathedral. At the west end there formerly stood two chapels, the one above the other, and a cloister communicating with the bishop's palace. The elevation of these chapels, destroyed long since, may be seen in Gough's edition of Camden. Part of the cloister which remains has lately been rendered more visible by the removal of a school-house which obscured it. Triennial music-meetings have for many years been held in the cathedral, in rotation with those of Gloucester and Worcester.

The members of the cathedral are the bishop; the dean, who holds a canonry, and is appointed by the crown; two archdeacons; one golden prebendary, whose office appears to have been that of confessor to the bishop; five other residentiary canons (including the dean); also a lecturer; these are all chosen from the prebendaries by the chapter, the bishop having the casting vote. Besides other dignitaries, there are twenty-eight prebendaries appointed by the bishop, and twelve vicars choral nominated by the dean and chapter. The vicars have rooms allotted to them in the 'college,' a gloomy building at the east end of the cathedral, which was built for their accommodation in the time of Edward IV.

In addition to the churches belonging to the establishment, there are places of worship for the principal denominations of dissenters. A Roman Catholic chapel of considerable dimensions is now (1838) erecting in Broad Street.

No manufacture or important wholesale trade is carried on here, unless it is the manufacture of gloves, of which a considerable quantity are made. The establishment of an iron-foundry has been consequent upon the reduction of the price of coal caused by the Abergavenny railroad. Before this project was completed, coal was sold here at from 30*s.* to 40*s.* a ton; the price now varies from 17*s.* to 22*s.* Gas-works have also been established, so that the streets and shops are well lighted. A literary and scientific society holds its meetings periodically, papers are read, and a collection for a museum is in progress; this useful institution is well attended, and if sufficient funds can be raised, it is intended to build a museum, library, and suitable apartments. A bill is now (1838) before parliament for enabling the citizens to dispose of certain lands belonging to them, and for the curtailing to two days St. Ethelbert's fair, which has heretofore been held on nine days in May. The principal fairs here are held on the first Tuesday after February 2, for cattle, &c.; the Wednesday in Easter week, for cattle; May 19—28, for diversions; July 1, October 20, horned cattle, cheese, &c. The February and October fairs are the most largely frequented; the latter is one of the most considerable cattle fairs in England. The market-days are Wednesday and Saturday; the 'Great Market' is on the Wednesday after St. Andrew's day.

HEREFORDSHIRE, an inland county, situated in that part of the west of England which is bordered by South Wales. The counties of Worcester and Gloucester form its boundaries on the east; Shropshire, with a portion of Worcestershire, on the north; Radnorshire, Brecknockshire, and a part of Monmouthshire, on the west; Monmouthshire and Gloucestershire on the south.

There are four detached portions of this county; the first belonging to Wolphy hundred, situated about 9 miles east-north-east of Ludlow; the second, also belonging to Wolphy, lies south of the river Teme, about 2 miles west of Tenbury; both these are separated by Shropshire from the main body of the county: the third, a portion of Huntington hundred, which is surrounded by Radnorshire, is about 3 miles west of Presteign; the fourth, a part of Ewyas Lacy, is on the borders of Brecknockshire and Monmouthshire, immediately west of Llanthony and the Hatterel range of the Black Mountain.

Its greatest length from the north side of Mocktree Hill to the southern portion of the Lord's Wood is about 40 miles. Its greatest breadth from the western side of the parish of Brilley, adjoining Clyro Hill, to the foot of the Malvern Hills, in the east of the parish of Cradley, is 34 miles. Its area is 860 square miles, or 550,400 acres. In 1831 the gross population amounted to 111,211 persons; and the average number of inhabitants to each square mile was 122. This distribution of population, compared with that of the neighbouring counties, gives the following results as to the average number of persons to a square mile:—Gloucester, 307; Hereford, 129; Monmouth, 198; Shropshire, 165; Brecknock, 63; Radnor, 58.

In extent of surface Herefordshire is exceeded by 24 English and Welsh counties, in amount of population by 44 counties in England and one in Wales. Hereford, the county town, is 132 miles distant from London by way of Wycombe, Oxford, Cheltenham, Tewkesbury, and Ledbury. A more direct line from Cheltenham to Ledbury, avoiding Tewkesbury and crossing the Severn at the Haw Bridge, saves three miles, and is frequently travelled by private carriages, but avoided by the public coaches on account of the absence of towns. The mail line is from Cheltenham through Tewkesbury; that of the coaches from Cheltenham through Gloucester and Ross.

Surface, &c.—The surface of this county is generally hilly, but the valleys occasionally expand into open plains. The Hatterel range of the Black Mountain, which forms its border on the west-south-west, is the highest land within its limits. Parallel to this range the chain which commences with the Vagar Hill and terminates in Mynydd Ferddin forms an important feature in the country: there is likewise a third and lower line of hills extending in the same direction from Middlewood to Wormbridge. In the south-west the Saddlebow and Garway are conspicuous; and in the south the hills near Walford and Penyard, with the long chain extending from the Lea northward towards Woolhope and Stoke Edith. The Malvern Hills, and the range stretching northward from Stamford Bishop to Wolferlow, comprising Bromyard Downs, are the principal heights upon the eastern boundary. On the north are the hills of Downton and Leintwardine, together with the range running in a south-west direction from Ludlow towards Kington, and continuing towards Huntington and Brilley Mountain. Near the centre of the county, Dinmore, Westhope, and Badnage Hills, with the line on which the circle of firs called Lady Lift stands conspicuous, form the most prominent features.

Rivers.—No large rivers have their source in these hills; the principal streams which water Herefordshire rise in the higher counties of South Wales. They are, the Wye, the Lugg, the Teme, the Arrow, the Fromie, the Leddon, the Dover, and the Munnow.

The *Wye*, which rises in Cardiganshire, enters Herefordshire on its western side, and running at first in a northerly direction, becomes for a short distance its boundary from Radnorshire: near Clifford the bearings of its course are changed, and the river flows east-south-east with many windings through a broad and fertile valley until it reaches the city of Hereford. Between that city and the town of Ross its general course is south, but its windings are numerous: two loops which surround King's Capel and Foy are from their length of great inconvenience to the inhabitants of that neighbourhood. From Ross the Wye runs a general south and then a south-west course, and again forming the boundary of Herefordshire for a few miles, finally leaves it near the Leys. It is imperfectly navigable throughout the whole of this county. when the depth of water has been moderately increased by rains, barges are worked up as far as the borders of Brecknockshire, but the numerous shoals and rapids, the frequent and sudden bends, form great impediments to their course. The immediate vicinity of mountains, and the very large surface of country which it drains, cause sudden and frequently destructive floods. After northerly or westerly rains the water sometimes rises eight or even ten feet in the course of 24 hours. For picturesque beauty this river is justly celebrated. In the upper part of its course through Herefordshire, there is a want of that boldness which characterizes the features of the country through which it afterwards flows, nevertheless there are some very striking prospects in the neighbourhood of its banks. This will be acknowledged by those who are acquainted with the following places—the Rhyd Spence Hill, Myrbidge Hill, Brobury Scar, and Lynda. To the majority of tourists these localities are unknown, not because they are not beautiful, but on account of the still greater beauty and accessibility of the scenery below Ross, the views of Goderich, the neighbourhood of the New Weir, and the vicinity of the Wye below Monmouth. The number of bridges by which this river is crossed is inconveniently small: fords indeed are frequent, but they are rough, and often rendered impracticable by floods. Trout, greyling, laspring, and salmon, are taken; since the destruction of a weir in the lower part of the river the number of salmon has increased, and it appears probable that it would receive further additions, but for the killing of the fish when they are not in season. From a deficiency in the protecting laws relating to this river, persons are permitted to destroy the old fish, whilst in the summer months, when the fish are in the best season, they are legally prohibited from taking them. Nearly the whole of the county of Hereford lies within the basin of the Wye.

The *Lugg*, rising in Radnorshire, enters Herefordshire near the Combe, flows in an easterly direction to Leominster, and after passing that town takes a more southerly course through Lugwardine, a village about three miles from Hereford, to Mordiford, near which place it falls into the Wye. Barges are sometimes navigated for the short space between Mordiford and Lugwardine Bridge. The river is not broad, and its banks are generally steep. Trout are plentiful, but salmon are rarely taken in this stream.

The *Teme*, which likewise rises in Radnorshire, enters Herefordshire near Brampton Bryan, and flowing under the beautiful woods and castle at Downton crosses the border into Shropshire. At Ludlow it again enters Herefordshire, which it finally quits near Burford, and falls into the Severn a few miles from Worcester. It is abundantly stocked with excellent trout and greyling.

The *Arrow* rises in the Radnorshire hills to the west of Kington, and passing through that town takes an easterly direction, until it falls into the Lugg, not far below Leominster. In this little stream there is excellent sport for fishermen.

The *Fromie* rises near Wolfrelow in the hundred of Broxash and falls into the Lugg at Hampton Bishop: the stream is small, but liable to be greatly swollen by floods.

The *Leddon*, also a small stream, rises in Radlow hundred above Bosbury, passes through Ledbury and becomes tributary to the Severn.

The *Doyer* rises above Dorstone, drains the fertile valley called the Golden Valley, and falls into the Munnow near Pontrilas.

The *Munnow* rises in the Hatterel Hills, and after receiving several tributary brooks falls into the Wye near Monmouth. Trout abound in all these streams, but are seldom of very great weight.

Canals.—In addition to the navigation of the Wye two canals have been formed through portions of this county for the conveyance of coal and other heavy goods. At the end of the last century acts of parliament were obtained for making a canal from Hereford to the Severn near Gloucester, also from Stourport in Worcestershire to the town of Kington. Want of funds has prevented the completion of both these schemes; the Gloucester canal has been brought no farther than Ledbury. The canal projected from Stourport to Kington has never reached either terminus, but a portion of the intermediate space from Leominster through Tenhury to the neighbourhood of the Abberley Hills has been completed. In both these canals the supply of water is deficient.

Roads.—The principal turnpike roads are, from Hereford to Ross, 14 miles; Hereford to Ledbury, 15; Hereford to Hay, 20; Hereford to Kington, 19; Hereford to Abergavenny, 24; Hereford to Monmouth, 20; Hereford to Leominster, 13; Hereford to Ludlow, 24; Hereford to Bromyard, 14.

Not many years ago the roads in this county were proverbially had; now their surfaco is generally good, and on the chief lines the ascents have heen rendered easier, either hy diversions or cutting. The Cheltenham and Aberystwith mail traverses the county from Ledbury through Hereford to Kington; the Gloucester and Caermarthen mail passes through Ross; and the Worcester mail to Kington travels hy way of Bromyard and Leominster. A mail which lately ran from Bristol to Liverpool through Monmouth, Hereford, Leominster, and Ludlow, has lately been discontinued between Liverpool and Hereford, passengers and letters from Bristol heing more expeditiously carried hy way of Birmingham and the Grand Junction Railway. The parish roads are often inexcusahly neglected. No railway has yet heon constructed in this county on which steam-power is applied. The present amount of traffic and travelling renders such speculations unsafe. Tram-roads for the conveyance of corn, coal, &c. have been constructed from Abergavenny to Hereford, and from Brecknock through Hay and Eardisley to Kington and the neighbouring lime-rocks and stone-quarries on the borders of Radnorshire. The henefits derived from hoth these roads have been very great; the supply of coal in Hereford has been rendered certain and its prico lowered from ahout 30 to 18 shillings a ton; an easy transport is also afforded for corn to the Monmouthshire iron-works, whence iron is received in return. The Brecknock railroad has also lowered the price of coal in the district through which it passes, and tended greatly to the improvement of the turnpike roads hy conveying to a tract deficient in roadstono an excellent material from Stanner Rock, a trap formation, at the foot of which the railroad has heen carried.

Climate.—The climate of Herefordshire varies greatly, according to the elevation and exposure. The neighbourhood of Ross and Ledhury, as well as the central portion of the county, enjoys a far superior climate to such portions of the north and west as are in the vicinity of Wales. The air is healthy, and the population long-lived. It is said that Serjeant Hoskins entertained James the First in his progress here with a morrice-dance hy ten old men and women, whose united ages exceeded 1000 years. (Gough's Camden.)

Geology.—To the casual observer the whole of Horefordshire appears to consist geologically of old red sandstone, a formation of great thickness, which has heen suhdivided in the following manner:—1, red conglomerate and sandstone without organic remains; 2, cornstone and argillaceous marls, containing crustacea of undescribed genera, as in the northern and central parts of the county; 3, flaggy highly micaceous tilestone, containing a small number of fossils, as seen in the neighbourhood of Downton Castle.

This trough of sandstone is neither frequently broken through by igneous rocks, nor materially lifted or curved hy their action. On the eastern side, the mean direction of the strata, as determined hy the outline of the trap and sienitic ridges of Abherley and Malvern, is from north to south. But there are many aherrations from that direction, and innumerahle local disturhances, curvatures, and faults. In the neighhourhood of Eastnor Park, three of the grauwacke formations have the north-easterly and south-westerly strike so persistent in Salop and Wales, but this is merely local, heing only maintained in a length of 2½ miles, for the Ledhury ridge, which terminates this group, is seen to strike due south at its apex near Clencher's Mill. The discrepancy is still greater hetween the strike of the major axis of the Woolhope Valley, extending to Flaxley in Gloucestershire (a distance of ahout 18 miles), and that of Shucknell Hill, which, although only two miles distant from the northern end of the Woolhope Valley, and composed of the same rocks, has a direction from south-west to north-east, and at right angles to the former, which runs from north-west to the south-east. The strike of the strata of Shucknell Hill is parallel to the line of bearing of the adjoining trap rocks of Bartestree. On the western houndary the prevailing strike of the deposits is from north-east to south-west; hut there are minor axes of elevation, subordinate to the great line of elevatory movement, which are for the most part marked hy eruptive ridges of trap rock, which tilt the strata upon their flanks hoth to the north-west and to the south-east. Limestone has been raised to the surface in many places; for instance, the valley of elevation at Aymestry, where pentamerus limestone is seen, and at Ledhury and the foot of the Malvern range, where transition limestone appears.

The valley of elevation at Woolhope is supposed to be the most symmetrical in Great Britain; the two superior formations of the grauwacke series are incurvated round a central dome-shaped mass, composed of the shelly sandstones of the third formation, from which the strata dip away on all sides at angles varying from 15° to 70°. The harder strata of each formation having resisted destruction, whilst the shales have been worn away, the former constitute the highor encircling ridges, the latter deep trenches of intervallation. The outer zone contains all the fossils characteristic of the Ludlow rocks, and passes beneath the old red sandstone; the inner zono, those of tho coralline formations of Wenlock and Dudley, and both these are wrapped round a nucleus of the third formation. The outer zone is unhroken hy any transverse gorge throughout two-thirds of its circumference, hut at Mordiford it is violently dislocated, and the result has been a chasm, hy which and by two minor fissures the valley is entirely drained. The whole of the valley is stated to be one of clean denudation, being entirely free from any fragments even of the old red sandstone, though the inferior and denuded strata must have been raised up through that formation. (*Geol. Trans.*, vol. ii., p. 15.) Mr. Murchison, from whose paper, as reported in the 'Proceedings of the Geological Society,' these observations have been extracted, has in the press a detailed account of the geology of this and the neighbouring counties.

Soil and Agriculture.—The soil of this county consists principally of a deep heavy red loam, which varies in its degree of tenacity: in some districts there is a suhstratum of clay; in others gravel approaches nearer to the surface. The wholo is extremoly favourahlo to the growth of trees, especially the apple and the oak. In the neighhourhood of the towns the land here, as in most other counties, is cultivated chiefly either as meadow or pasture; in the rural parishes the quantity of land in tillage is greater, hut scarcely equal to that of grass land, and the management of the land depends upon the olimate and nature of the soil. The high lands, for the most part, are occupied hy oak coppices, which are numerous and extensive; these are felled at periods of from sixteen to twenty years, and fetch a price of from 18*l.* to 26*l.* an acre, the bark included. In the valleys and less exposed elevations, crops are raised in the following succession:—wheat, turnips, harley, clover, wheat, and peas or vetches. It is to the wheat crop that the farmer pays his chief attention: the two last weeks in Octoher or tho first in Novemher are reckoned to he the best sowing time; in few counties is the seed more skilfully or neatly put into the ground. The cultivation of turnips is neither so carefully practised nor so well understood; indeed the greater part of the soil is not well suited to this crop; nevertheless it would less frequently fail if the management was more attentive and skilful; the seed is in general sown too late.

Hop-yards are common in the middle and eastern portions of the county, the hundreds of Broxash, Radlow, and Grimsworth. The hines here are planted in rows and the land ploughed, a method different from that which is practised in Kent, where they are planted on mounds and the soil cultivated with the spade.

Orchards are numerous, and not confined to any particular distriot. The lahour of picking a quantity of apples and converting them into 110 gallons of cider may be estimated at from four to seven shillings; these form a *hogshead* of cider, which is sold at from 3*d.* to 2*s.* a gallon, according to the quality and ahundance of the crop; in ordinary years, the price varies from 4*d.* to 1*s.* 2*d.* a gallon. An orchard of full-grown trees in good condition will sometimes produce as many as 12 hogsheads an acre. Under the article Cider an account of its manufacture and treatmont may he found.

The highest wages paid to agricultural labourers are nine shillings a week; in the northern and western parts of the county eight and seven, and in winter as little as six shillings a week are given; the addition of cider is allowed by all farmers in the summer, and by a large portion during the winter; the labourer prefers receiving a portion of his earnings in 'drink' to being paid wholly in money. The wives and families suffer from the practice, but are not generally averse to it: they think the cider a luxury due to the man for his exertion, and are ignorant of the injury they sustain. From two to four quarts of cider is the usual daily allowance; in harvest time the quantity is unlimited, and food added to it, but the money wages are not raised; some labourers at this season will drink ten or even twelve quarts of cider in a day.

The prevalent breed of cattle is that for which this county is justly celebrated; their colour is red with white or mottled faces, and frequently white along the back and about the legs. Good milkers are occasionally found among the cows, and it is possible that a race might be reared from this stock that would be useful for the pail, but dairy farming is never practised here, and the milk of the cows, which are kept only for the purpose of breeding, is given to the calves. It was formerly the custom to work the oxen at three and four years old, and to feed and send them to market at five, but their inefficiency as beasts of draught, the quantity of fodder consumed by the older oxen, and the slow return of capital, have caused a complete change of system: the oxen are no longer worked, but are commonly fed when they are two years old, and sent to market before they are three: their early maturity and the readiness with which they fatten make them suited for this system of farming. Graziers from the south and the middle of England drive a large number of this popular stock from the Hereford Candlemas and October fairs. The Hereford ox feeds more readily than the Devon (see 'Cattle,' 'Library of Useful Knowledge,' p. 32): and in proportion to the quantity of food consumed lays on a greater weight of flesh than a Durham ox: the result of a trial upon this latter point may be seen in 'Cattle,' p. 34. That the flesh of the Herefords is of a finer quality than the Durhams, is proved by the superior price per stone which it obtains in Smithfield market.

The usual breed of sheep is a cross between the Leicester and the Ryeland, which is found to succeed better than the pure Leicester or Southdown; the pure Ryeland are extinct. Welsh mutton may be procured in most of the country towns. Agricultural horses of average quality are bred in considerable number. The northern part of the county bordering upon Radnorshire and Shropshire produces many useful riding and coach horses, which have lately (1838) been much sought after by London and other dealers: they are highly bred, compact and active; an inferior race, fine in the bone, long in the joints, and generally with bad action, is found throughout the rest of the district. Pigs are chiefly procured from Wales, from whence a large supply of eggs and excellent poultry is sent to the market in Kington, and sold to dealers who forward them to Cheltenham, Gloucester, and other large towns.

Political Divisions.—Herefordshire is divided into the eleven following hundreds:—Broxash, Grimsworth, Greytree, Ewyas Lacy, Huntington, Radlow, Stretford, Webtree, Wormilow, Wigmore, and Wolphy. These contain 221 parishes, and seven market-towns. 1. The town of Bromyard, situated in the north-east of the county, is in the hundred of Broxash, the market-day is Monday, the distance from Worcester 14 miles, from London 126; 2. Hereford has been previously described; 3. Ross stands beautifully on the banks of the Wye, 14 miles below Hereford, in the hundred of Greytree, the distance from Gloucester is 17 miles, from London 120; the market-day is Thursday; 4. Ledbury is in the hundred of Radlow, 15 miles from Hereford, 15 from Gloucester, and 16 from Worcester; the town has lately been improved by the removal of some houses which impeded the thoroughfare of the principal street; the market-day is Tuesday; 5. Leominster, upon the river Lug, is situated in Wolphy hundred, 13 miles from Hereford, 26 from Worcester, and 128 from London. It is a borough and corporate town, returning two members to parliament. The church is handsome and the market-place old, but in an inconvenient situation; the market-day is Friday. Several considerable cattle-fairs are held, and an agricultural society has lately been established here. The following statement respecting this borough is extracted from the population returns.—

Leominster.

	Stat. Acres.	Inhab. Houses.	Males.	Females.	Gross Population.
Borough and Parish	1150	886	1996	2304	4390
Broadwood } Townships	8140	64	175	172	347
and Ivington } Townships		117	306	296	802

6. Kington stands upon the Arrow in the hundred of Huntington, 19 miles north-west of Heroford, 40 miles from Worcester, and 152 from London. The market, which is largely supplied with poultry and eggs, supplied from South Wales, is held on Wednesday; 7. Weobly, in Stretford hundred, is situated 13 miles from Hereford. The town has declined, and no weekly market is held. Many of the houses are extremely picturesque, and the church has considerable beauty. It was formerly a borough in the power of the marquis of Bath, and returned two members to parliament; no charter of incorporation is known, neither does the borough appear to have been governed by any municipal officer.

The principal villages are Eardisland, Eardisloy, Pembridge, Shobdon, Wigmore, Leintwardine, Orleton, Brimfield, Cradley, Mordiford, Abbey Dore, Madley, Letton, and Lynhales. The principal benefices are—

	Patron.	Net annual value without deducting for Curate.
Bromyard, 1st portion	Bishop of Hereford,	£535
Cradley	do.	937
Kington (with chapels)	do.	666
Ross	do.	1284
Whitbourne	do.	533
Lugwardine	Dean and Chapter	929
Woolhope	do.	644
Upton Bishop	do.	708
Shobdon	Lord Bateman	764
Kingsland	Wm. Evans	800

The churches of Kilpeck and Moccas are accounted the oldest in the county; the most distinguished for architectural beauty are at Ledbury, Leominster, Weobley, Dilwyn, Pembridge, Madley, Burghill, Abbey-Dore, and Kilpeck. The principal gentlemen's residences are, Eastnor Castle, a modern building of great size, and of considerable beauty, situated near Ledbury; Hom Lacy, which belonged to the late duke of Norfolk, now the property of Sir Edwin Stanhope; Hampton-Court, which was sold by the present earl of Essex to Mr. Arkwright, who is making extensive alterations under the direction of Mr. Hanbury Tracy; Stoke Edith, Berrington, Shobdon, Croft Castle, Moccas, Garnons, Foxley, Garnstone, Downton Castle, Kentchurch, Goodrich Court, Harewood, and Whitfield. Kinnersley Castle, situated in the parish of the same name, is one of the oldest inhabited houses that we are acquainted with; it is asserted that it was built before the Conquest. Alterynis near Rowlston, on the borders of Monmouthshire, was formerly the residence of the family of Cecils, from which Lord Burghley descended. There is at Brinsop a curious fortified house, now occupied as a farm-house.

In Herefordshire industry is occupied, with little exception, in agriculture and retail trade. The manufacture of gloves employs a considerable number of women in the central and western parts of the county; some coarse hats are also made. No coal or productive ore has been discovered here, and not a single steam-engine is at work. Limestone is burnt at Woolhope, Ledbury, Aymestry, &c.

Ecclesiastical and Legal Divisions.—With the exception of the parishes of Ewyas Harold, Walterston, Dewlas, Michaelchurch Escle, St. Margaret's, Rowlston, Llansillo, and Clodock, which are in the diocese of St. David's, the whole county is comprised in the diocese of Hereford. The diocese is in the ecclesiastical province of Canterbury. Herefordshire is included in the Oxford circuit; the assizes and quarter-sessions are held at Hereford. Three members are returned to parliament for the county, two for the city, and two for the borough of Leominster. Ledbury, Ross, and Bromyard antiently sent members to parliament, but were excused at the request of the burgesses themselves on account of the expense then attached to those who exercised the privilege of electors. The polling-places for the county are Hereford, Ross, Ledbury, Bromyard, Kington, Leominster, and Peterchurch.

Poor Law Unions have been formed, and workhouses been altered or newly erected at Hereford, Bromyard, Abbey Dore, Ross, Ledbury, Leominster, Kington, and Weobly; parishes belonging to this county have been included in the following unions, of which the centres are in other counties:—Abergavenny, Hay, Knighton, Ludlow, Monmouth, Newent, Presteign, and Tenhury.

History and Antiquities.—The greater part, if not the whole, of Herefordshire, was comprised in the territory of the Silures, and was conquered by the Roman general Julius Frontinus, about A.D. 73. A line of Roman and British entrenchments may be traced from the Malvern Hills to Whitbourn, Thornhury, Croft, Brandon (near Leintwardine), and Coxwall Knoll (near Brampton Brian). There are also traces of a camp on the east of Leintwardine, near Downton. Difference of opinion exists as to the exact localities of Magna and Ariconium, two Roman towns, which were probably comprehended within the present limits of this county; one of them douhtless was at Kenchester. The Roman road called Watling Street entered the county near Brandon, passed through Wigmore to Kenchester, and thence by way of Kingston and Dore to Abergavenny in Monmoutbshire. A second Roman road traversed a small portion of the south of this county near Ross; a third entered it from Worcester, and passing Frome-hill, Stretton Grandison, Luggbridge, Holmer, and Stretton Sugwas, reached Kenchester. Entrenchments exist, or are recorded to have existed, near the courses of each of these three roads. During the Heptarchy, Herefordshire belonged to Mercia, and in 680 a synod was held at Hereford. This city was the principal town of Mercia in the time of Offa, whose palace was situated at Sutton, about three miles north-east of the city. The murder of Ethelbert, king of the East Angles, whilst at the court of Offa, as a suitor to his daughter, enriched the town and increased its importance by the attraction of a number of pilgrims to his shrine, where miraculous appearances were supposed to occur. During the pilgrimage of Offa to Rome, whither he went to expiate his crime, he consented to subject his kingdom to the payment of Peter's pence.

The Danes, who bad previously ohtained a temporary possession of the kingdom of Mercia, regained it about A.D. 819, and appointed Cenolph king. Cenolph was defeated by Alured, king of the West Saxons, whose successor Egbert united the seven principalities into one monarchy. In 912 the Danes made an irruption upon the hanks of the Wye, which they had navigated from the Severn, and seized the bishop of St. David's, then resident in Archenfield. King Edward paid 40*l.* for the ransom of the bishop. The position of Herefordshire relative to Wales subjected it to continual inroads from the Welsh. A considerable part of the county was included in the 'Marches,' a term used to express no definite portion of country, hut the frontier in dispute between the Welsh and the English, varying from time to time according to their respective successes. In the time of Edward the Confessor such an invasion is recorded; Gruffyth, a Welsh prince, aided hy Algar, a banished earl of Chester, defeated Ranulph, earl of Hereford, witbin two miles of this city. Seven of the canons were killed in the engagement; the town and cathedral were fired, the walls were levelled, and the marauders retired to Wales loaded with the spoils of their richer neighbours (1055). Edward sent Harold to subdue the Welsh, and Hereford was invested and fortified; in the end a treaty was concluded. The violation of this treaty hy the Welsh induced Harold, after he became king, to march a second time upon their territory; after reducing them to great extremities he made an ordinance that if any Briton was found on the English side of Offa's dyke (an artificial boundary which in part of its great length has been traced through the county of Hereford), his right hand should be cut off hy the king's officers. In spite of these and other severe exactions, attacks continued to be made upon the persons and property of the Marchers. Edric, son of the earl of Mercia, made an assault upon Hereford, but the garrison repulsed bim, and in revenge laid waste his lands. In a second expedition Edric was more successful; with two Welsh princes for allies he ravaged the county as far as the bridge of the city, and returned with 'a marvellous great spoil.'

The survey contained in Domesday book was commenced thirteen years after this period, and completed in six years. Mr. Duncomb's 'History of Herefordshire' (vol. i., 60-65), contains a list of the hundreds and other divisions into which this county was at that time divided, together with the modern names of such districts, as far as they can be ascertained. The antient proprietors are also enumerated. Two of these proprietors, the earl of Hereford and Lord Mortimer, in the first year of William Rufus, joined Odo, bishop of Baieux, in an insurrection, and laid waste parts of the counties of Gloucester and Worcester. The oppressions of the Normans and the loss of liberties and privileges gave the English subjects just cause of complaint. The king raised an army and besieged the insurgents, who had retired to Pevensey. The result was that Odo consented to leave the county, and the king promised to redress the grievances which were complained of. The king granted many lands in Wales to knights and others of the English and Norman nobility, and to the Mortimers and Lacys amongst thom, on the tenure of knight's service. In consequence of the grants, and for their security, many castles were soon afterwards erected. Upon the borders hostilities commenced between the new possessors and the Welsh. With a similar intention of repressing the incursions of the Welsh, a colony of Flemings, driven from their own country by an irruption of the sea, were established in Pembrokeshire by Henry I. Notwithstanding these precautions hostile inroads upon the Marches still occasionally took place, but no event occurred which immediately affected this county, until the crown of England was in dispute between Stephen and Maud, the daughter of Henry I. Geoffrey de Talebot and Robert earl of Gloucester then declared in favour of the empress. Talebot retired to Hereford, hut soon quitted it, and the castle of Weobly, which had heen garrisoned against Stephen, was totally demolished. Stephen afterwards invested the city of Hereford, but the result of the siege is not known.

The demolition of castles enforced by Henry II., in order to limit the power of his barons, had no very beneficial effect on the security of Herefordshire: in some instances a temporary resistance was made to the king's command. These garrisons being destroyed, the Welsh, who had for a long time lived in comparative tranquillity, recommenced their depredations, which were not quelled until an English army had been marched against them. In the reign of Henry III., the whole of England was disturbed through the insubordination of the harons, but the insecurity of the Marches was increased by the neighbourhood of the troops of the Welsh Prince Llewelyn, who had been reinforced by several powerful allies; the lands of the Mortimers were ravaged and many other outrages committed. During the trouhled times of Edward II., Herefordshire was the scene of many executions. The king, who had been captured in Caermarthenshire, was carried to Ledbury on his way to Berkeley Castle; his adherents Hugh de Spenser, Baldoe, and Reding, were executed at Hereford. In the following reign Lord Mortimer with many other of the principal barons and knights of this county accompanied the king in his invasion of France, and John Chaundos Humphrey, earl of Hereford, Sir Richard Pembruge, and Sir Guy de Bryan, received as a reward for their military services the newly instituted order of the Garter.

No particular event occurred by which this county was locally affected, until the rebellion of Owen Glendwr threw the Marches into confusion, and renewed the feeling of insecurity and alarm which the Welsh had so frequently excited. [GLENDWR.]

During the wars of York and Lancaster this county did not escape the general commotion; a battle was fought at Mortimer's Cross in the parish of Kingsland, between the earl of March and the army under the carls of Pembroke and Ormond (1461); the latter, though defeated, effected their escape, but Owen Tudor, husband of Catherine of France, was taken prisoner and afterwards beheaded at Hereford. At the termination of these civil wars, there was again a period of tranquillity. In the 27th year of Henry VIII., 1535, by the act for the incorporation of England and Wales, Herefordshire acquired, or rather recovered, a considerable extent of territory; Wigmore, Stapleton, and Lohameis on the north side of the county, were appointed to constitute the hundred of Wigmore. On the west Ewyas Lacy was formed into the hundred of that name. Huntington, Clifford, Winforton, Eardisley, and Whitney, composed the hundred of Huntington, and Ewyas Harold was united with that of Webtree. Mr. Duncomb mentions that at this timo there wero twenty-one monastic institutions in this county, which were situated at Aconhury, Barton, Clifford, Craswell, Dewlas, Dore, Ewyas, Flanesford, Hereford (4), Kilpeck, Ledbury, Leominster, Lymehrook, Monkland, Shobdon, Titley, Wigmore, and Wormesley. The statement of Tanner is sligbtly at variance with that of Mr. Duncomh: in his 'Notitia Monastica,' an account of these religious houses may be referred to. After the death of Henry VIII., no event of immediate local importance occurred in the district that we are treating of until the period of the civil wars; at this time, notwithstanding the great complaints that the tax of ship-money had raised in this inland county, the greater number of the principal families engaged on the part of the king; on the side of the parliament wero those of Harley, Birch, Hereford, Westfaling, Hardwicke, &c. The city of Hereford was garrisoned for the king, but was surrendered without resistance to the parliamentary army under Sir William Waller. It was soon evacuated and again garrisoned in the royal cause under the command of Lord Scudamore, by whom it was resolutely defended. After the battle of Naseby the king marched to the relief of Hereford, and the Scotch army raised the siege. In the course of the year 1646, tho city was taken by surprise, and the whole county was reduced by detachments in the interest of the parliament, under the command of Sir William Waller and Colonel Birch. Colonel Birch was appointed governor, and his regiment increased to 1200 men. During the period of his concealment, Charles II. more than once passed through different portions of this county. The castle, which was greatly out of repair, was soon afterwards sold by order of the parliament. The keep has since been levelled, and no part of the walls remains: the site of those which cnclosed the larger court is now converted into a public walk.

The following is an alphabetical list of the castles which have existed in this county; in some instances the ruins are still visible, in others the demolition has been complete:—Brampton Bryan, Bredwardine, Clifford, Dorstone, Eardisley, Ewias Harold, Goodrich, Hereford, Huntington, Kilpeck, Longtown, Lynhales, Pembridge, Penyard, Snowdell, Stapleton, Tretire, Urish Hay, Welsh Newton, Weobley, Wigmore, Wilton.

The only druidical remains is a pile of stones called Arthur's Stone, situated in the parish of Dorstone. About a mile north of Hereford, on the Hay road, a monument commemorates tbe removal of the markets to this spot during the prevalence of an infectious disorder which raged in the city. Dr. Charlton, bishop of Hereford, is said to have erected the White Cross in 1347.

There existed in the antient territory of Archenfield, which was probably co-extensive with the present rural deanery of the same name, many privileges, usages, and customs, which would form interesting subjects for antiquarian research. The custom of Gavelkind long continued in force there.

Many persons of celebrity were born in this county: we may enumerate, among them, Roger Mortimer, earl of March; Robert Devereux, earl of Essex; Hakluyt; Garrick; and John Kyrle, the Man of Ross.

Statistics.

Population.—Herefordshire may be considered as entirely an agricultural county. In 1811 it ranked tbe second on the list of agricultural counties, in 1821 the third, and in 1831 the fourth. No manufacture worth notice exists in the county. Of 29,342 males twenty years of age and upwards living in the county in 1831 only 63 were employed in manufactures, about 40 of whom were engaged in making hats and gloves in Leominster; and 16,397 were occupied in agricultural pursuits.

The population of Herefordshire at each of the four enumerations made in the present century was—

	Males.	Females.	Total.	Increase per cent.
1801	43,955	45,236	89,191	..
1811	46,404	47,669	94,073	5·47
1821	51,552	51,691	103,243	9·74
1831	55,838	55,373	111,211	7·49

showing an increase between the first and last periods of 22,020, or not quite 25 per cent., which is 32 per cent. below the whole rate of increase throughout England.

The following table contains a summary of the population, &c., of every hundred, as taken in 1831:—

Summary of the County of Hereford.

Hundreds, Cities, or Boroughs.	Houses.				Occupations.			Persons.			
	Inhabited.	Families.	Building.	Uninhabited.	Families chiefly employed in Agriculture.	Families chiefly employed in trade, manufactures, and handicraft.	All other Families not comprised in the two preceding classes.	Males.	Females.	Total of Persons.	Males, twenty years of age.
Broxash, Hundred	2,315	2,522	10	88	1,702	467	353	6,066	5,715	11,781	3,173
Ewyas-Lacy	672	711	3	61	523	114	74	1,762	1,673	3,435	856
Greytree	2,374	2,508	13	97	1,302	700	506	5,833	5,853	11,686	3,093
Grimsworth	1,430	1,532	5	47	982	331	219	3,526	3,434	6,960	1,938

Wolphy	2,644	2,867	24	99	1,499	811	557	6,585	6,664	13,249	3,532
Wormelow	2,107	2,243	22	76	1,339	431	473	5,583	5,310	10,893	2,819
Hereford, City	2,069	2,278	19	98	70	1,207	1,001	4,709	5,573	10,282	2,602
Militia under Training								525		525	
Totals	21,907	23,565	159	869	12,888	6,105	4,572	55,838	55,373	111,211	29,342

County Expenses, Crime, &c.—The sums expended for the relief of the poor at the four dates of—

		£.		s.	d.	
1801	were	46,471,	being	10	5	for each inhabitant.
1811	„	82,981	„	17	7	„
1821	„	62,728	„	12	1	„
1831	„	62,622	„	11	3	„

The sum expended for tho same purpose for the year ending March, 1837, was 39,218*l.*; and assuming that the population had increased at the same rate of progression as in the ten preceding years, the above sum gives an average of 6*s.* 8*d.* for each inhabitant. These averages are above those for the whole of England and Wales.

The sum raised in Herefordshire for poor-rate, county-rate, and other local purposes, in the year ending the 25th of March, 1833, was 70,287*l.* 16*s.*, and was levied upon the various descriptions of property as follows:—

On land	£62,572	6
Dwelling-houses	7,068	11
Mill, factories, &c.	434	9
Manorial profits, navigation, &c.	212	10

The amount expended was—

For the relief of the poor	£ 60,233	6
In suits of law, removal of paupers, &c.	1,776	5
For other purposes	9,061	6
	71,070	17

In the returns made up for subsequent years, the descriptions of property assessed are not specified. In the years 1834, 1835, 1836, and 1837, there were raised 67,266*l.*

17s., 59,596*l.* 6*s.*, 52,121*l.* 16*s.*, and 48,650*l.* respectively; and the expenditure for each year was as follows:—

	1834. £.	s.	1835. £.	s.	1836. £.	s.	1837. £.
For the relief of the poor .	56,683	0	48,033	0	42,195	7	39,218
In suits of law, removals, &c.	2,244	16	1,224	8	1,701	11	1,073
Payment towards the county-rate . . .	9,354	16	5,436	10	3,539	8	4,248
For all other purposes			5,490	10	5,358	4	3,148
Total money expended	£68,282	12	60,174	8	52,794	10	47,687

The saving effected on the whole sum expended in 1837, as compared with the expenditure of 1834, was therefore 30 per cent.; and the saving effected on the sum expended for the relief of the poor was in 1837 nearly 31 per cent., as compared with that expended in 1834.

The number of turnpike trusts in Herefordshire, as ascertained in 1835, is 14; the number of miles of road under their charge is 553; the annual income in 1835, arising from the tolls and parish composition, was 30,663*l.* 1*s.* 7*d.*; and the annual expenditure, 25,305*l.* 14*s.* 8*d.*

The county expenditure in 1834, exclusive of that for the relief of the poor, was 5,365*l.* 12*s.*, disbursed as follows:—

	£.	s.	d.
Bridges, building, and repairs, &c.	473	9	5
Gaols, houses of correction, &c., and maintaining prisoners, &c. .	1,858	14	6
Shire-halls and courts of justice, building, repairing, &c. . .	172	15	6
Prosecutions . .	1,363	9	5
Clerk of the peace . .	202	19	7
Conveyance of prisoners before trial	180	19	4
„ transports .	169	17	7
Constables, high and special .	62	18	0
Coroner . .	143	8	3
Miscellaneous . .	737	0	5

The number of persons charged with criminal offences in the three septennial periods ending with 1820, 1827, and 1834, were respectively 750, 735, and 1078; making an average of 107 annually in the first period, of 105 in the second period, and of 154 in the third period. The number of persons tried at quarter-sessions, in each of the years 1831, 1832, and 1833, in respect to which any costs were paid out of the county rates, were 78, 57, and 51 respectively. Among the persons charged with offences, there were committed for—

	1831.	1832.	1833.
Felonies . . .	75	55	46
Misdemeanors . .	3	2	5

The total number of committals in each of the same years was 80, 58, and 55 respectively.

	1831.	1832.	1833.
The number convicted was .	53	40	45
„ acquitted .	18	13	5
Discharged by proclamation .	9	5	5

In 1837, at the assizes and sessions, 186 persons were charged with crime in Herefordshire. Of these, 9 were charged with offences against the person, only 2 of whom for common assaults; 18 with offences against property committed with violence; 145 with offences against property, committed without violence; 4 for uttering counterfeit coin; 3 for poaching; and 7 for riot or breach of the peace. Of the whole number of offenders, 102 were convicted, 48 were acquitted, no bill was found against 34, and 2 were not prosecuted. Of those convicted, only 1 was sentenced to death, which sentence was commuted to transportation for life; 4 others were sentenced to transportation for life; 2 for 14 years, 2 for 10 years, 9 for 7 years, and 2 for other periods; 4 were imprisoned for 2 years, 19 for one year, and 54 for 6 months or under; and 5 were fined and discharged on sureties. Of the whole number of offenders, 155 were males, and 31 were females; 79 could neither read nor write; 81 could read and write imperfectly; 23 could read and write well; 1 had received a superior instruction, and the degree of instruction could not be ascertained of the remaining 2.

The number of persons qualified to vote for the county members of Herefordshire is 7175, being about 1 in 15 of the whole population, and about 1 in 4 of the male population twenty years of age and upwards, as taken in 1831. The expenses of the last election of county members to parliament were to the inhabitants of the county 207*l.* 8*s.* 8*d.*, and were paid out of the general county-rate.

There are 4 savings' banks in this county. The number of depositors and amount of deposits on the 20th of November in each of the following years were—

	1832.	1833.	1834.	1835.	1836.
Number of depositors	3,875	4,087	4,562	4,793	5,197
Amount of deposits	£117,127	£118,484	£129,104	£132,773	£145,242

The various sums placed in the savings' banks in 1835 and 1836 were distributed as under:—

	1835. Depositors.	Deposits.	1836. Depositors.	Deposits.
Not exceeding £20	2,755	£19,975	2,938	£21,527
„ 50	1,262	38,073	1,410	42,462
„ 100	528	36,648	570	40,169
„ 150	143	17,725	172	20,280
„ 200	70	11,308	80	13,630
Above 200	35	9,044	27	7,174
	4793	132,773	5,197	145,242

Education.—The following summary is taken from the Parliamentary Returns on Education, made in the session of 1835:—

	Schools.	Scholars.	Total.
Infant schools	7		
Number of infants at such schools; ages from 2 to 7 years:—			
Males		32	
Females . . .		46	
Sex not specified .		224	
			302
Daily schools	327		
Number of children at such schools; ages from 4 to 14 years:—			
Males . . .		2,848	
Females . . .		2,842	
Sex not specified .		2,823	
			8,513
Schools .	334		
Total of children under daily instruction			8,815
Sunday-schools	144		
Number of children at such schools; ages from 4 to 15 years:—			
Males		2,335	
Females . . .		2,727	
Sex not specified .		2,532	
			7,594

If we assume that the whole population has increased since 1831 in the same ratio as it did the 10 years preceding that date, and also that the population between the ages of 2 and 15 has preserved the same relative proportion to the whole population as it did when ascertained in 1821, then we obtain 37,905 as the approximate number of children between the ages of 2 and 15 in this county in 1834, when the educational inquiry was made. Thirteen Sunday schools are returned from places where no other school exists, and the children (437 in number) who are instructed therein cannot be supposed to attend any other school; at all other places Sunday-school children have opportunity of resorting to other schools also; but in what number or in what proportion duplicate entry of the same children is thus produced must remain uncertain. Thirty-nine schools (containing 1937 children) which are both daily and Sunday schools, are returned from various places, and duplicate entry is therefore known to have been thus far created. Allowing for a number of children having thus been entered twice as under instruction, it may perhaps be fairly estimated that little more than one-third of the children between the ages of 2 and 15 are receiving instruction in this county.

Maintenance of Schools.

Description of Schools.	By endowment. Schls.	Scholars.	By subscription. Schls.	Scholars.	By payments from scholars. Schls.	Scholars.	Subscrip. and payment from scholars. Schls.	Scholars.
Infant Schools	—	—	2	64	3	50	2	188
Daily Schools	72	2586	37	1,832	203	3,740	15	355
Sunday Schools	13	830	124	6,321	..	..	7	443
Total...	85	3416	163	8,217	206	3,790	24	986

The schools established by dissenters, included in the above statement, are—

	Schools.		Scholars.
Infant school . .	—	containing	—
Daily schools . .	5,	,,	218
Sunday-schools .	24,	,,	1,494

The schools established since 1818 are—

	Schools.		Scholars.
Infant and other daily schools	138,	containing	4,026
Sunday-schools	105,	,,	5,073

Twenty-three boarding-schools are included in the number of daily schools given above. No school in this county appears to be confined to the children of parents of the Established church, or of any other religious denomination, such exclusion being disclaimed in almost every instance, especially in schools established by Dissenters, with whom are here included Wesleyan Methodists.

Lending-libraries of books are attached to 14 schools in this county.

HERESY, HERETICS. The word 'heresy' (from *αἵρεσις, choice*) was originally used to express any opinion which a man adopted. Thus it was applied to the philosophic sects of Greece and Rome. (Cicero, *Paradox. Proëm.*) In the New Testament the term often simply denotes a religious party, without implying any censure. (*Acts*, v. 17; xv. 5; xxvi. 5; xxviii. 22.) Josephus calls the three great Jewish sects '*heresies*.' (*Antiq. Jud.*, xiii., c. 5, s. 9.) But it is also used in the New Testament as a term of reproach. Thus it was applied by the Jews to Christianity (*Acts*, xxiv. 5, 14), and by the Apostles to those who resisted their doctrines (1 *Cor.*, xi. 9; *Gal.*, v. 20; 2 *Pet.*, ii. 1; *Tit.*, iii. 10). The fathers applied the words *heresy* and *heretics* respectively to opinions which were different from what they considered the doctrine of the Apostles, and to those who held such opinions, though some of the fathers draw a distinction between *heresy*, as a wilful rejection of the doctrines of Scripture, and errors arising from ignorance or weak judgment. When the creed of the church began to be settled by ecclesiastical councils, all who refused to submit to their decisions were denounced as heretics. They were also called *heterodox*, while those who adhered to the opinions of the church were called *orthodox*, or *catholics*. Heretics were distinguished from unbelievers, inasmuch as they professed Christianity. Heresy must not be confounded with schism: the former relates to doctrine; the latter is any division on points of discipline. The number of heresies mentioned by early ecclesiastical writers is from 80 to 150; but Lardner (*Hist. of Heretics*, i. 5) has shown that many of these ought to be excluded from the list; nor have we any evidence that many of them had numerous followers.

Most of the heresies of the first two centuries related to the creation of the world, the origin of evil, the person of Christ, and the connection between Judaism and Christianity; and nearly all may be included under two great sects:—1. The Ebionites and Nazarenes, who, upon embracing Christianity, adhered to many Jewish opinions and ceremonies. 2. The Gnostics, who engrafted upon the Christian religion certain opinions of the Greek and Oriental philosophy. Some however regard the Ebionites as a sect of Gnostics.

Both these heresies are supposed to have commenced in the Apostolic age, and to be referred to in the writings of St. Paul and St. John. [EBIONITES; GNOSTICS.]

The Gnostics appear to have been very early divided among themselves concerning the respect which ought to be paid to the Mosaic law, and a new sect was formed by a Jewish Gnostic named Cerinthus. [CERINTHUS.] The Nicolaitans mentioned in the 'Apocalypse' (ii. 6, 15) are supposed to have been a sect of Gnostics, and some identify them with the Cerinthians. About A.D. 121, Valentinus, an Egyptian, engrafted some opinions of his own upon Gnosticism, and founded a new sect. His party was strongly opposed by Irenæus and Tertullian. Another sect which took its rise from the opinions of the Gnostics was that of Cerdo and the more celebrated Marcion, who began to propagate their tenets at Rome about A.D. 130. The principal feature of this heresy was the adoption of the Oriental belief in two supreme powers, the one good and the other evil. The principal followers of Marcion were Lucian, or Leucius, and Apelles. About A.D. 172, Bardesanes and Tatian gave rise to a new sect of Gnostics, which was chiefly distinguished by the practice of an austere discipline. These people were called, from their habits of abstinence, Encratites, Hydroparastates, and Apotactites. The Docetæ were a sect of Gnostics who sprung up very early. They held that the body of Christ was immaterial, and therefore did not suffer on the cross, but only appeared to die. Several minor sects of Gnostics are mentioned by antient writers, such as the Adamites, the Cainites, the Sethians, and the Ophians, an account of which is given in Lardner's 'History of Heretics.' He doubts the existence of such sects as the Adamites and Cainites. The sect of Eclectics, or New Platonists, was founded at Alexandria in the second century; but though its tenets were embraced by many Christians, it is rather to be regarded as a philosophical than a Christian sect. [ECLECTICS.]

We now come to the heresies which existed from a very early age respecting the divinity of Christ. This doctrine was denied by some of the Ebionites in the second century. [EBIONITES.] About the end of that century Praxeas founded a new sect. Denying the doctrine of the Trinity, he held that the divine nature was intimately united with the person of Christ, whom he considered to be a mere man, but born of a virgin. His followers were called Monarchists, from their rejecting the doctrine of the Trinity; and Patripassians, because they were supposed to believe that the Father suffered on the cross: this opinion however they seem to have disclaimed. In the opinions of Praxeas ecclesiastical historians trace the germ of the Sabellian heresy. His chief antagonist was Tertullian. His opinions were held, with some slight variations, by his contemporaries Artemon and Theodotus. Among the heresies of this age respecting the creation of the world was that of Hermogenes, who believed in the eternity of matter.

The Montanists, who arose in Phrygia about the year 170 (some say 150), are rather to be looked upon as fanatics than heretics. Their leader Montanus claimed the character of a prophet: he appears to have differed from the orthodox in no leading doctrine, but only in some points of discipline. His opinions owe their celebrity chiefly perhaps to the circumstance that they were embraced by Tertullian. [TERTULLIAN.] We find traces of this heresy down to the time of Augustin and Jerome. Some inconsiderable heresies arose in the second century on points connected with the rites and ceremonies of the church, such as the Artotyrites and others. [COMMUNION.]

In the third century Gnosticism still had adherents, though it was fast falling into disrepute. But a new heresy arose out of the Oriental philosophy, headed by Manes, who attempted to unite the doctrines of the Persian Magi with those of the Apostles. [MANICHÆANS.] The controversy on the Trinity and the person of Christ continued with increasing warmth. About the middle of the century the doctrines of Praxeas were revived, with slight variations, by Noëtus of Smyrna, Sabellius, an African bishop, and Beryllus, an Arabian. The last two were opposed by Dionysius of Alexandria and Origen. [SABELLIANS.] Another heresy relating to the same subject was established by Paul of Samosata, bishop of Antioch. A new sect of Ebionites, or Jewish Christians, appeared about the middle of the third century, but it lasted only for a short time. They were called Elcesaites, from their founder Elxai. The Novatians, followers of Novatian, a presbyter of Rome, are reckoned, perhaps erroneously, among the heretics of this century. They held no doctrine different from those of the Catholic church, but maintained a greater severity of discipline; and hence they were called Puritans (*καθαροί*). By some historians they are regarded as austere and turbulent fanatics, while others rank them as the earliest sect of reformers in church discipline.

In the fourth century the attention of the church was chiefly occupied with the Arian controversy [ARIANS; ARIUS.] Out of these disputes other heresies arose respecting the person of Christ, such as that of Apollinaris [APOLLINARIS], Marcellus, Photinus, and Macedonius. Near the end of this century we find a new sect of Gnostics in Spain, under the name of Priscillianists. The Donatists, who caused great commotions in the church during this century, are rather to be classed with schismatics than with heretics. [DONATISTS.] For an account of certain minor sects in the fourth century, see Epiphanius, *De Hæresiis*.

At the beginning of the fifth century the Pelagian controversy arose. [PELAGIANS.] The disputes concerning the Trinity and the person of Christ continued to give rise to new sects, the chief of which were the Nestorians and their opponents the Eutychians, or Monophysites. [EUTY-

CHIANS.] The controversies of these sects with the orthodox and each other continued nearly 200 years, producing various minor sects, such as the Monothelites [EUTYCHIANS], the Anthropomorphites (who maintained, from *Genesis*, i. 27, that God had a human shape), and others.

The rapid spread of the monastic system in this century was warmly resisted by Vigilantius, who thus incurred the enmity of Jerome, and has been ranked among the heretics.

In the sixth century the Monophysites continued to branch out into new sects, several of which arose on the question whether the body of Christ was corruptible or incorruptible. Other minor sects are mentioned by Mosheim. (*Ecc. Hist.*, vol. ii.) After this time most of the antient sects remained in existence in different parts of the Christian world with greater or less vigour. The only new sect which requires a distinct notice is that of the Paulicians, which was formed in Armenia and Cappadocia in the seventh century. After suffering severe persecutions they were dispersed over Europe, in various parts of which they formed settlements about the eleventh century. The origin of the Albigenses is traced to a body of Paulicians which settled in France. [ALBIGENSES.] The doctrines of the Paulicians have been identified by some with those of the Manichæans, while others regard them as reformers of the corruptions of the church. (Vaughan's *Life of Wycliffe*, Introd., c. ii.) The history of later sects merges in that of the Reformation.

(Epiphanius, *De Hæresiis*; Lardner's *History of Heretics*; Gibbon's *Roman Empire*; Mosheim's *Ecclesiastical History*; Neander's *Kirchengeschichte*.)

HERI'ADES, a genus of Hymenopterous insects of the section Mellifera (Latreille), and family Apidæ. Distinguishing characters:—body elongated, slender, almost cylindrical, that of the males with a small cavity beneath near the apex; mandibles triangular; maxillary palpi two-jointed.

The little bees belonging to this genus, we are informed by Latreille, make their nests in holes in old trees; we presume that, as in the genus Chælostoma, the holes are made by the bees themselves.

Heriades Campanularum, a species very common in various parts of England, is about a quarter of an inch in length, of a black colour, and sparingly covered with grayish hairs. This little bee is by far the smallest British species known of the family to which it belongs; it is common during the summer and autumnal months in the flowers of the various species of Campanulæ, and apparently is never found in the flowers of any other genus of plants. 'The males are often taken asleep in these flowers; their abdomen is then doubled, so that the tubercle with which its base is armed fits into the cavity near the anus.' (See Kirby's *Monographia Apum Angliæ*, vol. ii., p. 256-7. For detailed characters of the genus, see Latreille's *Genera Crustaceorum et Insectorum*, Paris, 1806, 1807.)

HERIOT is a feudal service consisting in a chattel rendered to the lord on the death of a tenant, and in some places upon alienation by a tenant. It is stated to have originated in a voluntary gift made by the dying tenant to his lord and chieftain of his horse and armour. (Glanvile.) This render became first usual, then compulsory; and at an early period we find the antient military gift sinking into the render of the best animal (at the election of the lord) possessed by the tenant, and sometimes a dead chattel, or a commutation in money. (Bracton; *Fleta*; *Coke-Littleton*.)

Heriots are either heriots-custom or heriots-service. Where a heriot is due from the dying tenant by reason of his filling the *character* or *relation of tenant* within a particular seigniory, honour, manor, or other district, in which it has been usual from time immemorial to make such renders upon death or alienation, it is called *heriot-custom*: *heriot-service* is a heriot due in respect of the *estate* of the tenant in the particular land held by him.

For heriot-custom the lord cannot distrain, because the duty arises out of the character or relation of tenant sustained by the party within the seigniory, &c., in which the custom is found to exist, and not, as in the case of heriot-service, in respect of the particular land holden. As the selection of the best animal is however with the lord, he may determine his choice by an actual seizure, upon which the property in the animal will vest in the lord by the mere act of seizing it.

But for heriot-service the lord may either seize or distrain. He may seize, because by this act of selection the property is vested in him; or he may distrain, because, the land being the debtor, the lord may, by the coercion of a distress upon that land, compel the succeeding tenant to deliver or procure the delivery of the heriot.

Where the heriot-service has been created since the time of legal memory, it is called a *heriot by reservation*, and sometimes a *suit-heriot*: if its origin go back beyond the limits of legal memory, it is called a *heriot by tenure*.

Heriot-custom formerly prevailed very extensively in freehold lands, but is now more commonly found in lands of customary tenure, whether copyholds,—the conventionary estates in Cornwall, held under the duke of Cornwall,—the customary estates called *customary freeholds* in the northern border counties,—or lands in antient demesne.

Heriot-service may be reserved in respect of a freehold, a leasehold, or a customary tenure; but as, since the statutes of Quia Emptores and Prerogativâ Regis, it is probable that no new sub-tenures in fee have been created, and as it has not been usual to reserve heriots upon gifts in tail, or upon the creation of freehold leases for lives, heriot-service in modern times is generally found in connection with long leasehold estates, where, in consequence of some restriction imposed upon the exercise of the leasing power, or in token of respect for antient usages, this species of render has been retained.

Heriots, whether heriots-service or heriots-custom, are multiplied whenever the land subject thereto becomes divided amongst different tenants holding distinct parts of such lands in severalty. Where therefore land is held subject to a heriot-service to be rendered at the death of a tenant, if the tenant alien part of the land a distinct heriot will be due upon the death of both the alienor and the alienee· and if such distinct heriots have in fact become due and have been rendered or compounded for during the alienation ,whereby the lord will have obtained actual seisin of the several heriots), the liability to pay such multiplied heriots will continue, even though all the land should afterwards be reunited, and vest again in the same person. Inattention to these rules has lately caused some strange and contradictory decisions in the courts of Westminster. (2 Nevile and Mann, 798.)

A distress for heriot-service must be taken upon the land in respect of the tenure, or upon the demise of which it is reserved; and where double or treble heriot has become payable by reason of alienation, the liability attaches severally upon each of the severed portions of the estate. All goods found upon the land, except such as are privileged from distress [DISTRESS], may be taken as a distress for a heriot-service, whether they belong to the tenant or to a stranger, such goods being held merely as a pledge for the performance of the service. But where a heriot-service is by the terms of the reservation commuted for a money payment (or rather, where the reservation of a contingent money payment is improperly designated a heriot), the reservation will be in substance a rent; and therefore the distress taken for this reservation (so miscalled a heriot), if not redeemed by payment, or replevied within five days after notice, may be sold as a distress for rent under the provisions of 2 William and Mary, c. 5.

Heriots were known in England before the complete development of the feudal system which followed upon the Norman conquest. The Normans introduced reliefs [RELIEF] without abolishing the analogous heriot. The *heregeate* (heriot) is mentioned and fixed by the laws of Canute, 67, &c. The Dano-Saxon 'heregeat' is derived by Spelman, and after him by Wilkins, from *herge* (more properly *here*), army. A more probable derivation would be from the word 'herr,' lord. In Scotland, where the render upon the death of the tenant is a pecuniary payment, it is called 'lord's money,' 'hergeld,' or 'herrezeld.'

HERM, sometimes called *Erm* and *Arm*, one of the smaller Channel Islands, lying three miles east of Guernsey, is held by lease, under the governor of Guernsey for the time being, for sixty-one years, renewable every twenty-one years. In February, 1837, the privy-council decided that for all legal purposes Herm forms part of the Island of Guernsey. For a description of Herm see GUERNSEY.

HERMANN, the Arminius of the Roman historians, the son of Sigimer, chief of the Cherusci, was born about 16 or 17 years B.C. [CHERUSCI.] Being sent in early youth as a hostage to Rome, probably in consequence of the victories of Drusus, which had established the supremacy of Rome over the Catti, Cherusci, and other tribes of North Germany, he obtained the favour of Augustus, and was inscribed among the Roman knights. On his return to his native country, he conceived the project of delivering it from the Romans, whose oppression had become intolerable. Quintilius Varus, a rapacious man, was then the Roman governor in Germany. Hermann pretended to be his friend, while at the same time he kept up a secret understanding with the chiefs of the Catti, Bructeri, and other tribes that lived between the Rhine and the Albis (Elbe), some of which broke out into insurrection. Hermann offered Varus his assistance in reducing them to subjection, and thus enticed him to advance some distance from the Rhine into the interior. Varus began his march with three legions, six cohorts, and a body of cavalry, and Hermann served him as a guide through the forests. The Romans were thus drawn into an ambuscade, and found themselves all at once surrounded by numerous bodies of Germans, who were directed by Hermann himself. The Romans fought desperately; but being unacquainted with the localities, and unable to form their ranks owing to the thickness of the forests and the marshy nature of the ground, they remained exposed for two days to the missiles of the Germans, who destroyed them in detail. At last, Varus, being wounded and seeing no chance of escaping, run himself through with his sword, and the other chief officers followed his example. The legions were entirely destroyed, and the cavalry alone cut their way through the enemy and regained the banks of the Rhine. By this defeat the Romans lost all their conquests beyond that river; and although Germanicus some years after again carried their arms to the Weser, they never established anything like a solid dominion over those regions. The defeat of Varus occurred, according to various chronologists, in tho year 763 of Rome (A.D. 9). The scene of the defeat is conjectured to have been in the country of the Bructeri, near the sources of the Ems and the Lippe. The news of this calamity, the greatest that had befallen the Roman arms since the defeat of Crassus, caused much alarm at Rome.

The fears however which were entertained that the Germans might invade Gaul, were not realized. L. Asprena guarded the banks of the Rhine, and the Germans were too little united among themselves to attack the Empire. Augustus in the following year sent Tiberius to the Rhine with a fresh army, who does not seem to have effected anything of importance. Hermann meantime quarrelled with Segestes, chief of the Catti, whose daughter Tusnelda he had carried off, and married against her father's consent. When Germanicus, after tho death of Augustus, marched into the interior of Germany to avenge the defeat of Varus, he was assisted by Segestes, and also by the Chauci and other tribes. [GERMANICUS.] In the first battle against Hermann his wife Tusnelda was taken prisoner by the Romans, and she afterwards figured in the triumph of Germanicus. Germanicus having reached the scene of Varus's defeat, paid funeral honours to the remains of the legions; but Hermann, who was hovering about his line of march, without coming to a pitched battle, harassed him in his retreat, and occasioned a great loss to Cæcina, the lieutenant of Germanicus. (Tacitus, *Annal.*, 1.) In the following year Germanicus advanced again as far as tho Visurgis, or Weser, where he found Hermann encamped ready for battlo. A desperate fight took place, in which Hermann, after performing prodigies of valour, was defeated, and escaped with difficulty. When Tiberius recalled Germanicus, he observed that the Cherusci, Bructeri, and other unsubdued tribes might be left to their own internal dissentions. He seems to have guessed right, for a war broke out soon after between Hermann on one side and Maroboduus, king of the Suevi, on the other, who was accused of aspiring to absolute dominion. The Semnones and the Langobards joined Hermann, who defeated Maroboduus on the borders of the Hercynian Forest, and obliged him to seek refuge among the Marcomanni, from whence he applied to Rome for assistance. Tiberius then sent his son Drusus into the Illyricum; but the Romans did not advance beyond the Danube, and Hermann remained unmolested in Northern Germany. Shortly after however Hermann was killed by his own relatives, being accused, as it would seem, of aspiring to absolute dominion. He died at the age of thirty-seven, in the twenty-first year of our æra, after being for twelve years the leader and champion of Germany.

HERMANSTADT. [TRANSYLVANIA.]

HERMAPHRODITE. [MONSTER.]

HERMAS, a Christian writer of the first century; who is said by Eusebius (*Hist. Eccl.*, iii. c. 3) and Jerome (*De Illustr. Viris*, c. 10) to have been the same individual whom St. Paul salutes in his epistle to the Romans (xvi. 14). He was the author of a work entitled 'The Shepherd;' which is called by this name because the angel who bears the principal part in it is represented in the form of a shepherd. This work is divided into three books; of which the first contains four visions; the second, twelve commands; and the third, ten similitudes. Du Pin remarks (*Eccles. Hist.*, vol. i., p. 27, Eng. Transl.) that 'these three books comprehend very many moral instructions concerning the practice of Christian virtues; but the great number of visions, allegories, and similitudes make them tedious; and all these moral truths would have been more useful if the author had propounded them simply, as the apostles have done in their epistles.' But Hermas appears to have followed the plan of the Apocalypse; which he has imitated in many parts of his work. Lardner in his 'Credibility of the Gospel History' (*Works*. vol. ii., p. 69—72) has given many instances of such imitations. Mosheim (*Eccles. Hist.*, vol. i., p. 100-1, ed. of 1826) and many other critics have mantained that the 'Shepherd' was written by Hermes, who was a brother of Pius, bishop of Rome, in the year 141.

The 'Shepherd' of Hermas is frequently quoted with the greatest respect by almost all the early Christian writers. We learn from Eusebius (*Hist. Eccl.*, iii., c. 3, 5) and other writers that it was received by many churches as a canonical work. It is quoted by Irenæus and Clement of Alexandria as a part of Scripture, and also by Tertullian, before he became a Montanist (see the passages in Lardner's *Works*, vol. ii., pp. 186, 249, 303, 304). Origen also considered it of divine authority; but informs us that it was rejected by some churches. After the time of Origen its canonical authority appears to have been generally denied. Eusebius, Jerome, Athanasius, Ruffinus, Gelasius, and Prosper expressly declare that it should not be included in the canon.

The 'Shepherd' contains no express citations of any books of the Old or New Testament. This work was originally written in Greek; but there is only an antient Latin version of it extant. There is an English translation by Wake, London, 1693 and 1710.

(Lardner's *Works*, vol. ii., pp. 57—73; Du Pin's *Ecclesiastical History*, vol. i., pp. 26, 27; Wake's *Preliminary Discourse*, c. viii.; Tillemont's *Mém. Eccles.*, vol. ii., part 1.)

HERMES, an antient Greek divinity, known to the Romans as Mercurius, was, according to Hesiod (*Theog.*, 942), the son of Zeus and Maia, the daughter of Atlas. The attributes of this deity are numerous and of opposite kinds; but it appears probable that he was originally considered to preside over flocks and herds. Hesiod says (*Theog.*, 441) that the shepherds address their prayers to him; for which reason the statues of Hermes are frequently represented with a ram by his side or on his shoulders. (Pausan., ii. 3, 4; v. 27, 5; ix. 22, 2. See also *Iliad*, xiv. 490-1.) The phallic form, which distinguished the statues of Hermes at Athens (Herod., ii. 51), also appears to indicate that this god was considered to increase the fruitfulness of the fields and cattle. Herodotus informs us (ii. 51) that the Athenians were taught by the Pelasgians this manner of representing the statues of Hermes; and that the reasons for this custom are explained in the Samothracian mysteries. Hermes was represented in a similar manner at Cyllene in Elis. (Pausan., vi. 26, 3.) This custom is also maintained by Cicero (*De Nat. Deor.*, iii. 22) and Macrobius (*Saturn.*, i. 19). According to some traditions, Hermes is said to have been born in Arcadia (Pausan., viii. 16, 1), and to have been the father of Pan; but according to another tradition, he was born at Tanagra in Bœotia. (Pausan., ix. 20, 3.) He was worshipped by the Thessalians above all other deities. (Herod., v. 7.)

In Homer the name of this deity is usually Hermeias. Ho is represented as the messenger of Zeus and the gods, and he conducts the souls of the departed to Hades. In later times he was regarded as the god of eloquence; the inventor of the lyre and weights and measures; the patron of merchants and of gain, and even of thieving; and the protector of heralds, poets, musicians, and wrestlers. Statues of Hermes, which were originally square blocks with a carved head upon them, were placed in the doorways of most private houses and temples at Athens. (Thucyd., vi. 27.) They were also erected where several roads met, to point out the way, and in the gymnasia, or public places of exercise.

Hermes is usually represented with a chlamys, or cloak; a petasus, or winged cap; talaria, or winged sandals; and a caduceus, or wand, with two serpents twined about it, in his hand.

The Egyptian god Thoth was also called Hermes by the Greeks. His attributes correspond in many respects with those of the Grecian deity. According to Plutarch (*Sympos. Probl.* 3), the Egyptian Hermes is said to have invented letters in Egypt. According to Diodorus Siculus, who appears to have confounded the attributes of the Egyptian and Grecian deity, he was the inventor of almost all the arts and sciences (i., p. 14, 15, 41, *Rhodoman; Egyptian Antiquities*, i. 46, 105; ii. 309, 366).

A great number of philosophical and astrological works, purporting to be written by the Egyptian Hermes, were in circulation in the early ages of the Christian æra; most of them appear to have been written at Alexandria by Gnostic Christians or philosophers of the Aristotelian or of the new Platonic schools. Clement of Alexandria mentions (*Strom.* iv., p. 633) forty-two works which bore the name of Hermes; and the number became much greater afterwards. A few of these works are still extant, and are entitled—1, 'Pœmander, on the power and wisdom of God.' The Greek text of this work was first published by Turnebus, Paris, 1554; a Latin translation had previously been published by Ficinus, 1472, 1483. The Greek text has also been published by Rosellus, Cologne, 1630, the best edition; and by Patricius, in his 'Nova de Universis Philosophia,' Venice, 1593; reprinted at London, 1611. The 'Pœmander' has been translated into Italian by Benci, Florence, 1548; into French by De Foix, Bordeaux, 1579; into English by Everard, London, 1650; into German, Anonymous, Hamburg, 1706; and by Tiedemann, Berlin and Stettin, 1781. Tiedemann thinks that the 'Pœmander' was not written before the fourth century. 2, 'Asclepius' is a dialogue between Hermes and Asclepius, the grandson of the inventor of medicine, on the deity, mankind, and the world. This work was originally written in Greek; but there is only a Latin translation extant, which is attributed by some critics to Apuleius. The 'Asclepius' is printed with most of the editions of the 'Pœmander.' 3, 'Iatromathematica,' in which the origin and termination of disease are taught by astrology. The Greek text of this work was first published by Camerarius, together with other astrological works, 4to., 1532; it was reprinted by Hoeschelius, 8vo., 1597. 4, 'Two Books on Nativities,' supposed to have been written by an Arab, published at Basel, 1559. 5, 'Astrological Aphorisms,' published at Venice, 1493; Basel, 1533 and 1551; Ulm, 1651 and 1674. 6, 'Curanides,' on the medical and medicinal virtues of precious stones, plants, animals, and fishes; published by Rivinus, 8vo., Leip., 1638, and 12mo., Frankfort, 1681. There are also several works, attributed to Hermes, on the virtues of metals and the secrets of the philosopher's stone; of which an account is given by Fabricius, in his 'Bibliotheca Græca,' vol. i., book i., c. 10, p. 75—80, ed. Harles.

HERMEIAS. [ARISTOTLE.]

HERMIT CRAB, the common English name for the well-know crustaceans that occupy the empty turbinated shells of testaceous mollusks. [PAGURIANS.]

HERMO'GENES, surnamed Xyster, one of the first rhetoricians of antiquity, was a native of Tarsus, and lived under Marcus Aurelius. At the age of fifteen, it is said, he was professor of Greek eloquence at Rome, where his lectures were attended by that emperor. At the age of eighteen he wrote his work on the oratorical art, consisting of four sections: 1. De Partitione Statuum et Quæstionum Oratoriarum. 2. De Inventione. 3. De Formis Oratoriis. 4. De Eloquentia Methodus. His illustrations and quotations are chiefly taken from the 'Orations' of Demosthenes. The work of Hermogenes was held in high esteem, and became a standard book in all Greek schools. It has been repeatedly printed in the Greek text, and Gaspard Laurent published it with a Latin translation and commentaries, 8vo., Geneva, 1614. Hermogenes had joined to his work a book of 'Progymnasmata,' or specimens of oratorical exercises, which Priscianus translated into Latin, the Greek text of which has remained inedited till the end of the last century, when it was first published by A. H. L. Heeren, and has since been republished by Veesenmeyer, 8vo., Nürnberg, 1812, and by others. At the age of twenty-five Hermogenes is reported to have entirely lost his memory, and to have lived to an advanced age in a state bordering on idiotcy. (Philostratus, *Lives of the Sophists;* Suidas; Fabricius, *Bibliotheca Græca;* Schoell, *History of Greek Literature.*)

HERMOGENES, or HERMOGENIANUS. [CORPUS JURIS.]

HERMUND, or HELMUND. [AFGHANISTAN.]

HERMUS. [ANATOLIA.]

HERNAN, or FERNANDO DE PULGAR. [PULGAR.]

HERNIA (from ἔρνος, *ernos*, a branch), signifies the protrusion of any organ from its natural position in the body; as hernia cerebri, hernia pulmonis, when the brain or lung protrudes through an aperture in the skull or the chest. But when used alone, this term means what is commonly called a rupture, that is, the protrusion of any portion of the intestinal canal from the cavity of the abdomen.

Herniæ sometimes form without any evident cause, the intestine being gradually protruded; but more frequently they result from some violent bodily exertion, as lifting heavy weights, excessive coughing or straining; or from sudden jarrings or shocks, as in jumping or falling; or from blows on the abdomen.

The general characters distinguishing a hernia are, a tumour, neither red nor hot, and often not painful, situated at some part of the abdomen, most frequently in or near the groin; largest when the patient stands up, and often disappearing entirely when he lies down; distended by coughing or other violent expiration, and liable to variation in size by exercise or rest, by abstinence or taking food; often producing disorders of the digestive canal, as flatulency, colic, &c. In the cases in which the hernia forms suddenly, as in consequence of a great exertion, the patient feels as if something had given way at the groin or other part of the abdomen, and on putting his hand there he feels a tumour which may vary in size from that of a nut to that of his fist, is elastic, hard, and tense, and soon after the accident becomes painful and tender. In the other class of herniæ, which may be called spontaneous, the tumour forms almost imperceptibly to the patient, and grows larger regularly but slowly; is attended with no pain, but merely a sense of weakness about the part; and decreases greatly or entirely disappears in the recumbent posture. If a hernia can be returned into the abdomen at pleasure, it is not by itself a dangerous disease; but if it becomes strangulated, that is, if the intestine is so constricted by the parts through which it has passed that its contents cannot pass through it, and its vessels are so much compressed that active inflammation is excited, it constitutes one of the most serious accidents to which the human body is liable. The symptoms indicating strangulation of the intestine are obstinate constipation of the bowels; pain and tenderness of the tumour, and spreading from it over the whole surface of the abdomen; extreme restlessness and languor; nausea and vomiting; a hard, small, and rapid pulse; thirst and coldness of the limbs. If the hernia be not reduced, these symptoms will regularly increase, till mortification of the intestine ensues, and (except in some most rare cases) death rapidly follows.

The above symptoms and other circumstances are common to all herniæ wherever situated, and are only modified slightly by the part of the abdominal contents protruded, the narrowness of the part through which it is forced, and the constitution of the patient. But there are some local circumstances peculiar to each, according to the part at which the intestine is protruded, which require to be noticed in connexion with the mode of returning each into the abdomen and of retaining it there.

The most frequent kind of rupture is the Inguinal, and it is far more common in males than in females. It forms a tumour, occupying either the groin alone, or extending thence more or less obliquely downwards between the thighs. To reduce it the patient should be laid on his back with his loins lower than either his shoulders or his hips, and the knee of the side on which the hernia has formed should be raised and turned a little inwards. The operator grasping a convenient portion of the tumour with his right hand, should press it in the direction contrary to that in which it has protruded, and there retain it, while with his left finger and thumb placed at the narrowest part of the swelling he moves the intestine from side to side, alternately pressing and relaxing it, so as to empty some of its contents, and force it into the abdomen. If any portion be pressed through, a slight gurgling noise will be heard, and by continued efforts the whole will most probably follow.

An inguinal hernia may attain the size of an adult's head or more; but a Femoral hernia, which is the kind most common in females, is rarely more than two inches in diameter, and generally much less. It is usually of a rounded form, situated just below the groin, about two inches from the middle line of the body, and always feels hard and tense. The principal constriction is deep in the thigh, directly under the tumour, which tends to pass upwards over the groin. In reducing it the position of the patient should be the same as for inguinal hernia: if the tumour be large enough to grasp, it should be pressed directly backwards, as if to force it deeper into the thigh; but if it cannot be grasped, it should be pressed in the same direction, with the balls of the thumbs placed side by side upon it.

In umbilical and ventral herniæ, which come straight out from the front of the abdomen, the globular and pendant tumours which they form, and which often attain a considerable size, should be grasped with one hand, and pressed directly backwards towards the spine, while the opposite hand, as in inguinal herniæ, guides the successive portions through the aperture.

Whatever be the situation or condition of a hernia, it should be at once, if possible, reduced. The patient should go to bed, and, after lying a short time on his back, with his knees raised, the intestine will often of itself recede into the abdomen, especially if it have been frequently protruded; but if it do not, then the manual operation just described should be employed. The force used in it should never be so violent as to give much pain, and in old herniæ little or none should be caused; nor should the manipulation be continued for more than a quarter of an hour at a time, nor so long as to bruise the tumour or make it tender. If it fail, there are several auxiliary means that may be employed, of which a selection must be made according to the circumstances of each individual case. The warm bath should be first tried in all cases; the patient should be placed up to the neck in water at a temperature of from 94° to 100°, and remain there till he becomes quite faint. Any pain or irritation that previous attempts at reduction may have produced will be greatly relieved by these means, and the state brought on by the bath is peculiarly favourable for the return of a hernia, both by relaxing all the tissues surrounding it, and, when faintness occurs, by relieving the intestine from the pressure of the muscles, which often present the chief obstacle to its return, but which in that state become powerless. As soon therefore as the patient complains of faintness, or after he has been in the bath for ten minutes or a quarter of an hour, an attempt should be made to reduce the hernia by manipulating it as already directed under water. In strong and robust men, and especially in cases where the hernia has recently formed, bleeding to faintness, either before or while in the bath, should be employed, and the same opportunity taken to try to replace the intestine. The abstraction of blood will be useful, not only by the faintness which it produces being a favourable state for reducing the hernia, but by its relieving the inflammation which always arises when the intestine is strangulated, and by checking it in its fatal progress. If the warm bath and bleeding fail, the patient should be placed between warm blankets to recover from their depressing effects, and no more manual attempts should be made for some time. The next means employed should be the continued application of cold by ice or a rapidly evaporating lotion laid over the tumour, and kept there, unless it produces much pain, till all the tissues are contracted and hard, for it is by their equable and powerful contraction on the intestine, and by the diminution of its volume, that reduction is sometimes thus effected even without manipulation. Should this fail, and the symptoms of strangulation be increasing, the only means left before resorting to operation is the tobacco enema. Great caution is necessary in employing it; it should never be used except in otherwise healthy and tolerably strong persons, nor till the other means have failed. A dram of tobacco being steeped in a pint of boiling water for ten minutes, half the infusion thus made should be used first; and if it produce no evidently depressing effect, the other half may be injected in half an hour afterwards. The usual consequence is an extreme degree of languor and sinking, a kind of deadly coldness and paleness, and the last stage of depression: in this state a last attempt at reduction should be made; and if still unsuccessful, an operation must be resorted to. The tobacco enema should not be employed unless the symptoms of strangulation be quite evident. If the hernia seem merely irreducible, but is not strangulated, and if cold, and warm bath and bleeding (if deemed advisable), have failed, the patient should be left, and an active dose of aperient medicine given him, for sometimes the bowels will, under the operation of these means, return of themselves into the abdomen.

When a hernia has been completely reduced, its recurrence must be prevented by the wearing of a truss. A truss consists of a circular pad, having one side convex and soft, and the other flattened and made very firm by a plate of steel, by which the pad is riveted into the spring, which is a narrow band of highly tempered and very elastic steel, forming when extended somewhat more than a semicircle. In applying a truss, the soft convex surface of the pad should be placed accurately over the part where the neck of the tumour was situated, that is, over the ring through which the intestine first protruded, and which may be felt by the weakness of the abdominal walls, so that the finger may be easily pushed almost into the abdomen, carrying the skin and subjacent tissues before it. The pad being held there, the spring should be made to pass round the haunch to the back, so as to reach just beyond the spine; its elasticity, tending to bring its two extremities together, will thus act so as to press with a certain force upon the ring or the canal through which the hernia was protruded, and thus supply the defect of weakness at that part of the abdominal walls. At that extremity of the spring which is applied near the spine there is affixed, in what are called common trusses, a leathern band, which is to be passed round the opposite haunch, and buckled or buttoned on the pad, so as to prevent its shifting its position during exercise; and in some cases, where this is apt to occur, another band should pass from behind under and inside the thigh and be fixed to the pad. Another very useful form of truss is that commonly called Salmon and Ody's, or the self-adjusting truss, which has a second pad, to be placed behind on the spine, and which requires no bands to keep it fixed, but, by the steady pressure of its two pads towards each other, maintains a firm pressure on the ring, and permits the spring to move up and down upon the haunch during exertion. In applying this, one pad must be placed on the ring, the spring must pass round the opposite haunch, and the hinder pad must rest on the spine, just below the loins, where it is least moveable. When there is a hernia on each side, a double truss, that is, one with a pad for each side, and one or two springs long enough to reach quite round the body, must be worn: if there be two springs, they should be connected by a cross-band and buckle, so that they may be tightened or loosened behind, and another band should pass from one pad to the other to maintain them in their proper position. To determine the necessary length for the spring of the truss, a measure may be taken by a string fixed at one end over the centre of the ring, at the part where, when the patient coughs, the intestine may be felt endeavouring to protrude, and thence carried round in an oblique direction between the most prominent part of the hip and the top of the haunch-bone to an inch beyond the spine. The pad should be of a size proportioned to that of the ring, and the spring should be strong enough to make firm but not painful pressure.

HERO, HEROIC, HEROISM, are used, in their common English sense, to denote an unusual, and, as it were, superhuman degree of bravery and virtue. This meaning flows directly from the original Greek word, which denoted (at least in the times subsequent to the Homeric poems) a person intermediate between gods and men, and usually of divine descent on at least one side. Such were worshipped with divine honours by those cities and races of men which claimed them as their founders or ancestors. This divine origin however was not essential: thus Philippus of Crotona, who fell in battle against the Phœnicians and Egestæans, was made a hero for his beauty; a heroum, or shrine, was built on the spot where he was buried, and sacrifices were offered to him. (Herod., v. 47.) At a later age Aratus and Brasidas were worshipped as heroes at Sicyon and Amphipolis; and the Athenians slain at Marathon received similar honours. Concerning these last, legends were current which show that a supernatural and mythological character was really ascribed to them, and they probably were the latest of the Greeks to whom such a character was attributed. The Heroic age, properly so called, appears however to have terminated with the immediate descendants of the Greeks who returned from Troy, and to have extended backwards for an uncertain length, estimated by Mr. Thirlwall at six generations, or about 200 years. This is the fourth or Heroic age of Hesiod, in which Zeus 'made the divine brood of heroes, better and braver than the third or brazen race' (*Days and Weeks*, 157), the princes and warriors of mythological history, such as Theseus, Perseus, and those who fought in the sieges of Thebes and of Troy. In Homer the word hero occurs frequently, but in quite a different sense: it is applied collectively to the whole body of fighters, Argeii, Danai and Achæi, without reference to individuals of peculiar merit; and indeed often appears to be used for little more than an expletive, when *he*, or *the man*, or *the soldier*, would have done equally well. Indeed the application of the word is not even limited to warriors; but is applied to heralds, wise counsellors, kings, &c. It has been suggested, with considerable plausibility, that the word originally denoted the members of those roving bands who in the earliest times overran Greece, issuing forth from the south of Thessaly and giving extension to the name, first of Achæans, and afterwards of Hellenes, as we learn from the legends in Pausanias and Thucydides; so that in the same sense the Normans who colonized Italy, or the Saxons who settled in England, might justly be called heroes. The root of the word seems to be *her*, whence the Latin and German forms of herus and herr (master), here, hertha, heracles, vir, virtus, &c. The same root seems to exist in the word Arimann, which denoted a particular order of freemen among the Lombards, existing at the time of the establishment of their empire after the Lombard conquests. There seems little doubt that this class originated in the warrior caste of the Lombard invaders; and the establishment of the name thus furnishes an analogy to the theory suggested above as to the origin of the Homeric use of the word hero. Even the name of German, and the meaning of brother attached to the word in Latin, may originate in the same sense of a member of an armed family or body: the root in all cases appearing to involve the notion of might or mastery. The Sanscrit word *sūra* appears to contain the same element as 'heros.'

The promiscuous (or Homeric) use of the word hero disappeared in the age succeeding the Homeric poems. It seems probable that the Hellenic invasion, commonly called the Return of the Heraclidæ, put an end to it. The new conquerors of Southern Greece do not seem themselves to have borne or used the title; and afterwards, when they, or their descendants, looked back to the warlike legends of the earlier race who had borne the title, the lays, exploits, and persons were called heroic; and from the combined effect of poetical exaggeration, reverence for antiquity, and traditions of national descent, the more modern Greek use of the word arose, carrying with it notions of mythical dignity, and of superiority to the later races of mankind. The custom of showing respect or affection by making precious offerings, and celebrating costly sacrifices at the tombs of the dead; the imaginative temper of the Greeks, which, as it loved to ascribe a divine genealogy to the great, was equally willing to admit them to a share of the divine nature and enjoyments after death; and the love of magnifying past ages, common to all nations, will sufficiently explain the change of earthly leaders into protecting genii or dæmons, who were believed immortal, invisible, though frequenting the earth, powerful to bestow good or evil, and therefore to be appeased or propitiated, like the gods themselves. In the age of Hesiod, as is evident from the passage above referred to, the age of heroes was past, and they were already invested with their mythological character, which appears to furnish one, among other reasons, for believing him to have lived after the Homeric age. (Thirlwall's *History of Greece*, ch. v.; *Philolog. Mus.*, No. 4, 'On the Homeric use of the word Ἥρως;' Wachsmuth's *Hell. Alt.*; Von Savigny's *History of the Roman Law during the Middle Ages*, vol. i., ch. 4.)

HERO, or HERON. There are two of this name, both writers on mechanical subjects. Hero the elder was the pupil of Ctesibius, and lived at Alexandria about B.C. 100. The country of the younger Hero is uncertain; in a work attributed to him (on geodesy) he states that the precession of the equinoxes had produced seven degrees of effect since the time of Ptolemy, so that he must have been about 500 years later than Ptolemy: he is generally placed under the reign of Heraclius, A.D. 610—641.

Hero the elder must have enjoyed great reputation, since he is mentioned, by Gregory Nazianzen, with Euclid and Ptolemy: but he is now principally known by some fragments of his writings on mechanics, which are to be found in the 'Mathematici Veteres,' Paris, 1693. His extant writings are: 1. 'On the machine called the Chirohallistra,' which is in the 'Math. Vet.' already cited. 2. 'Barulcus,' a treatise on the raising of heavy weights, which is mentioned by Pappus, and which was found by Golius in Arabic, but has not yet been printed. 3. 'Belopœica,' a treatise on the manufacture of darts, published by Baldi, with an account of Hero, at Augsburg, in 1616, and also in the 'Math. Vet.' 4. 'Pneumatics,' published by Commandine, Urbino, 1575, and Amsterdam, 1680; and also in the 'Math. Vet.' with the additions of Aleotti, who had previously published an Italian version, Bologna, 1542, and Ferrara, 1589. 5. 'On the Construction of Automata,' which is in the 'Math. Vet.,' and was translated into Italian by Bernardino Baldi, with an account of the rise and progress of mechanics, Venice, 1589, 1601, 1661. 6. 'On Dioptrics,' a work said by Lambecius to exist in manuscript in the Vienna library. Other works of Hero, now lost, are mentioned by Pappus, Eutocius, Heliodorus of Larissa, &c., for which see Heilbronner, who is the authority for the preceding summary (see also J. A. Schmidt, 'Heronis Alexandrini Vita Scripta ot quædam inventa,' Helmstad. 1714, 4to.).

The writings of Hero the younger are: 1. a book 'On Machines of War,' edited in Latin by Barocius, Venice, 1572; together with 2. a book of 'Geodesy,' a term then meaning practical geometry. 3. 'On the Attack and Defence of Towns,' printed in the 'Math. Vet.' 4. A book 'On Military Tactics,' said by Lambecius to exist in manuscript in the library at Vienna. 5. 'On the Terms of Geometry;' printed at Strasburg, 1571; and also edited by C. F. F. Hasenhalg, Stralsund, 1826, 4to. with notes. 6. 'Geometrical Extracts,' printed by the Benedictines in the first volume of the 'Analecta Græca,' Paris, 1688, from a copious MS. in the Royal Library at Paris. 7. A Geometrical Manuscript, stated by Lambecius to be in the library at Vienna.

There was another Heron, the teacher of Proclus.

HEROD (HERO'DES), the name of several Jewish princes.

I. HEROD THE GREAT was the second son of Antipater, by whom he was appointed governor of Galilee at the age of twenty-five. In B.C. 43 he obtained from Sextus Cæsar the government of all Cœle-Syria. From this time he became, with his brother Phasael, the chief supporter of Hyrcanus II. against the attempts of Antigonus, the son of Aristobulus. By large presents he obtained the friendship of Antony, who appointed him and Phasael tetrarchs of Judæa. In B.C. 40 the Parthians invaded Judæa, and set Antigonus on the throne, making Hyrcanus and Phasael prisoners. Herod escaped to Rome, where, by the influence of Antony, he was appointed king of the Jews; but the Roman generals in Syria assisted him so feebly, that it was not till the end of the year 38 B.C. that Jerusalem was taken by Sossius. The commencement of Herod's reign dates from the following year. In the year 38 he had married Mariamne, the grand-daughter of Hyrcanus, hoping to strengthen his power by this match with the Asmonæan family, which was very popular in Judæa. On ascending the throne Herod appointed Ananel of Babylon high-priest, to the exclusion of Aristobulus, the brother of Mariamne. But he soon found himself compelled, by the entreaties of Mariamne and the artifices of her mother Alexandra, to depose Ananel, and appoint Aristobulus in his place. Not long after, Aristobulus was secretly put to death by the command of Herod. Alexandra having informed Cleopatra of the murder, Herod was summoned to answer the accusation before Antony, whom he pacified by liberal bribes. When setting out to meet Antony, he had commanded his brother Joseph to put Mariamne to death in case he should be condemned, that she might not fall into Antony's power. Finding on his return that Joseph had revealed this order to Mariamne, Herod put him to death. In the civil war between Octavianus (afterwards the Emperor Augustus) and Antony, Herod joined the latter, and undertook, at his command, a campaign against the Arabs, whom he defeated. After the battle of Actium he went to meet Octavianus at Rhodes; having first put to death Hyrcanus, who had been released by the Parthians, and had placed himself under Herod's protection some years before. He also imprisoned Mariamne and Alexandra, commanding their keepers to kill them upon receiving intelligence of his death. Octavianus received him kindly, and re-instated him in his kingdom. On his return Mariamne reproached him with his intentions towards her, which she had again discovered. This led to an estrangement between Herod and his wife, which was artfully increased by his sister Salome; till on one occasion, enraged at a new affront he had received from Mariamne, Herod assembled some of his friends and accused her of adultery. She was condemned and executed. After her death Herod suffered the deepest remorse, and shut himself up in Samaria, where he was seized with a sickness which nearly proved fatal. In the year 26 B.C. he put to death the sons of Babas, the last princes of the Asmonæan family. He now openly disregarded the Jewish law, and introduced Roman customs, a conduct which increased the hatred of the people towards him. Ten men conspired against his life, but were detected and executed with the greatest cruelty. To secure himself against rebellion he fortified Samaria, which he named Sebaste, and built Cæsarea, and other cities and fortresses. In the year 17 B.C. he began to rebuild the temple at Jerusalem. The work was completed in eight years, but the decorations were not finished for many years after. (*John*, ii. 20.) Herod's power and territories continued to increase, but the latter part of his reign was disturbed by the most violent dissensions in his family, of which a minute account is given by Josephus. He died in March, B.C. 4, in the thirty-fourth year of his reign and the seventieth of his age. Josephus relates that shortly before his death he shut up many of the principal men of the Jewish nation in the Hippodrome, commanding his sister Salome to put them to death as soon as he expired, that he might not want mourners. They were released however by Salome upon Herod's death.

The birth of Jesus Christ took place in the last year of Herod's reign, four years earlier than the æra from which the common system of chronology dates the years A.D. (Clinton's *Fasti Hellenici.*) [CHRIST.]

II. HEROD ANTIPAS, son of Herod the Great, was appointed by his father's will tetrarch of Galilee and Peræa. [ARCHELAUS.] He built the city of Tiberias. About A.D. 26 he divorced the daughter of Aretas, king of Arabia, and married his sister-in-law Herodias. John the Baptist, having remonstrated against this marriage, was imprisoned in the castle of Machærus, and afterwards put to death. (*Luke*, iii. 19, 20; *Mark*, vi. 17—29.) About the same time Aretas marched against Antipas and defeated him. In A.D. 39 Antipas was accused by Agrippa, king of Judæa, of a secret understanding with the Parthians, and was banished by Caligula to Lyon.

III. HEROD AGRIPPA, son of Aristobulus and grandson of Herod the Great, after experiencing many vicissitudes in early life, was appointed, upon the accession of Caligula, king of the dominions formerly held by Philip, namely, Gaulanitis, Batanea, and Trachonitis, to which Caligula added the tetrarchy of Lysanias; and afterwards, when Antipas was banished, the tetrarchy of Galilee and Peræa. Claudius added Judæa and Samaria to his dominions. His government was popular with the Jews, to please whom he persecuted the Christians. (*Acts*, xii. 1—3.) He died of a loathsome disease at Cæsarea, in the third year of his reign over all Palestine, A.D. 44. (*Acts*, xii. 20—23.)

IV. HEROD AGRIPPA, son of the above, was seventeen years old at the time of his father's death. Upon the death of Herod, king of Chalcis, four years afterwards, Claudius bestowed that kingdom upon Agrippa. He did not leave Rome till A.D. 53, when Claudius gave him the tetrarchies of Gaulanitis, Batanea, and Trachonitis. His dominions were enlarged by Nero. It was in A.D. 60 that the trial of Paul before Agrippa took place. (*Acts*, xxvi.) Agrippa exerted himself to the utmost to keep down the spirit of revolt which was now constantly increasing among the Jews. When war broke out, Agrippa joined the Romans. After the taking of Jerusalem he retired with his sister Berenice to Rome, where he died at the age of about seventy years.

(Josephus, *Antiquities of the Jews*, and *Jewish War*; Jahn's *Hebrew Commonwealth*; Prideaux's *Connection*.)

HERO'DES, TIBE'RIUS CLA'UDIUS ATTICUS, a native of Marathon, in Attica, and of an illustrious family, which numbered among its members several officers and magistrates of the latter period of the Athenian commonwealth, was born under the reign of Trajan. He inherited from his father a very large property, which is said to have been originally acquired under curious circumstances. His grandfather Hipparchus had lost his property by confiscation during the civil wars. His son, called Atticus by the historians, and the father of Herodes, supported himself by means of his wife's property. Atticus discovered one day in his grounds, in or near Athens, a vast treasure, probably hidden there during the preceding wars. He informed the then emperor Nerva of what he had found, and inquired what he was to do with it? The emperor's answer was short: 'Utere invento' ('Make use of what you have found'). Atticus represented that the wealth was much above his wants and his station in life; upon which the good-natured emperor replied again in the same laconic style, 'Etiam abutere' ('Do with it even as you list'). In consequence of this Atticus left his son Herodes possessed of enormous wealth. Herodes was educated by the best teachers of his time; he studied under Favorinus and Polemon, and he became an accomplished scholar, rhetorician, and philosopher. He was made by Antoninus Pius prefect of the Greek towns of Asia. Having removed to Rome, his wealth, his connections, and his extemporary eloquence, which is spoken of as wonderful, gave him a considerable degree of importance, and he was made consul with C. Bellicius Torquatus, A.D 143. He was also one of the preceptors of the younger Verus, the adopted son of Antoninus. Herodes married, at Rome, Annia Regilla, of an illustrious and wealthy family. She bore him four children, and died while pregnant of the fifth. His brother-in-law suspected Herodes, who was of a violent and jealous temper, of foul treatment of his wife, and he brought him to trial on the charge of murder: but Herodes was acquitted. Herodes displayed an excessive, and, as some believed, an assumed grief for the loss of his wife, and he dedicated her estate to Minerva and Nemesis. An inscription, which he wrote, or caused to be written, in Greek hexameters, records the fact. There is another inscription, likewise in Greek verse, in which the poet invites the Roman women to honour the memory of Regilla, descanting upon her beauty, virtue, and high lineage: he speaks of the Emperor Marcus Aurelius, whom he compares to Jupiter, for the consolation which he administered to the widower in his old age, left with two young surviving children, upon one of whom, named Atticus, the emperor bestowed the patrician and senatorial sandals, or shoes spangled with stars and ornamented with a crescent, which custom of the Roman patricians the poet derives from Mercury. He then launches out into mythological allusions, and speaks of his own descent from the Athenian heroes and demigods. The whole composition, as well as the one previously mentioned, is curious as a memorial of the Greco-Roman style of poetry in the age of the Antonines. These two inscriptions, which are on two large slabs of Greek marble, and were discovered in the early part of the seventeenth century, under Pope Paul V. (Borghese), have given much employment to critics and philologists. (Visconti, *Iscrizioni Tropee ora Borghesiane*, 4to., Rome, 1794.) Herodes, after the loss of his wife, returned to Greece, and died at Marathon, in the 76th year of his age, towards the end of the reign of Aurelius, or the beginning of that of Commodus. He erected monuments, temples, baths, and aqueducts, in Italy, Greece, and Asia. Pausanias (vii. 20) mentions an Odeon, or Music Theatre, at Athens, as built by him, called the Theatre of Regilla, after his wife: he also embellished the Stadium near the Ilissus, which was originally constructed by the orator Lycurgus, B.C. 350. [ATHENS, p. 12, &c.] Herodes was evidently a conspicuous personage in the age in which he lived, and is mentioned as such by Aulus Gellius, Philostratus, Capitolinus, Zonaras, Suidas, and a number of others. (Fiorillo, *Herodis Attici quæ supersunt*, 8vo., Leipzig, 1801.) Herodes is said by Philostratus to have written orations, epistles, and ephemerides; but none of these compositions have come down to us, except a fragment of an address to the Thebans, published by Reiske, Leipzig, 1773; but its genuineness is doubted by the critics. In the inscription above mentioned, in honour of his wife, he is styled 'the living language of Athens' and 'the king of oratory.' His son Atticus is said to have been a complete idiot all his life.

HERO'DIANS (Ἡρωδιανοί, *Matt.* xxii. 16; *Mark*, iii. 6;

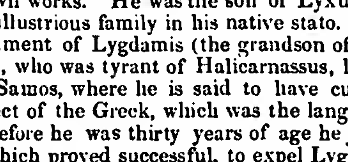
xii. 13; see also *Mark*, viii. 15), were in all probability a political party in Judæa, who were anxious to preserve the government in the hands of Herod's family. Many critics consider the Herodians to have been a religious sect. Tertullian, Jerome, Epiphanius, Chrysostom, and Theophylact maintain, without any sufficient reason, that the name was given to those Jews who owned Herod for the Messiah; and Grotius (*De Veritate Christ. Relig.*, v., s. 14; *Notes upon Matthew*, xvi. 6) and other modern critics hold the same opinion. The Herodians are not mentioned either by Philo, or by Josephus in his enumeration of the Jewish sects. In their religious opinions they probably belonged to the sect of the Sadducees; since that which is called by Mark (viii. 15) 'the leaven of Herod' is styled by Matthew (xvi. 6) 'the leaven of the Sadducees.'

(Prideaux's *Connection of the History of the Old and New Testament*, vol. ii., 478—482; Jennings' *Jewish Antiquities*, i., c. 12; Calmet's *Dissertations*, vol. i., p. 737—743; Lardner's *Credibility*, vol. i., p. 131—133, edition of 1831.)

HERODIA'NUS, a Greek author, who wrote a history, in eight books, of the Roman emperors who reigned successively in his lifetime, beginning with tho death of Marcus Aurelius, A.D. 180, and ending with the accession of the younger Gordianus, A.D. 238. This history comprehends a period of little more than half a century, but it is a most eventful one in the history of the empire, on account of the numerous and violent changes in the persons who held the sovereign power, and also with respect to the domestic and foreign wars, the depravity of manners, and the public calamities which characterized that age. The series of emperors which the history of Herodianus embraces comprises Commodus, Pertinax, Julianus, Niger and Albinus, Severus, Caracalla and Geta, Macrinus, Elagabalus, Alexander Severus, Maximinus, the two Gordiani, and Balbinus. The style of Herodianus is plain and unaffected, and his narrative in general seems written in a spirit of sincerity, but it has no claims to philosophy or critical art. (F. A. Wolf, *Narratio de Herodiano et libro ejus*, prefixed to his edition of Herodianus, Halle, 1792.) Of the private history of Herodianus we know nothing, except that he seems to have lived at Rome, and to have been well acquainted not only with the political events, but also with the court intrigues and scandal of his time. He is the last of the Greek historians of antiquity who lived before the partition of the Roman empire. Among the editions of his history that of Irmisch, in 5 vols. 8vo., Leipzig, 1789—1805, in Greek and Latin, contains numerous notes, chronological and genealogical tables, and several copious indexes. The last edition and the best text is by Bekker, Berlin, 1826, 8vo. There are several German translations of Herodian.

HERO'DII. [HERONS.]

HERO'DOTUS (Ἡρόδοτος), a native of Halicarnassus, a Dorian city in Caria, and once a member of the confederation called the Hexapolis, or Six Cities, was born about B.C. 484. If the passages in his own History (i. 130; iii. 15) were written by himself. he was probably alive in B.C. 408. The facts of his life are few and doubtful, except so far as we can collect them from his own works. He was the son of Lyxus and Dryo, and of an illustrious family in his native stato. Not liking the government of Lygdamis (the grandson of the heroic Artemisia), who was tyrant of Halicarnassus, he retired for a time to Samos, where he is said to have cultivated the Ionic dialect of the Greek, which was the language of that island. Before he was thirty years of age he joined in an attempt, which proved successful, to expel Lygdamis. But the banishment of the tyrant did not give tranquillity to



Coin of Halicarnassus.

British Museum. Actual size. Silver. Weight, 56 grains.

Halicarnassus, and Herodotus, who himself had become an object of dislike, again left his native country, and joined, as it is said, a colony which the Athenians sent to Thurium, in South Italy (B.C. 443). He is said to have died at Thurium, and was buried in the Agora. (Suidas, Ἡρόδοτος, Πανύασις, Θουκυδίδης; Strabo, xiv., p. 656; Photius, *Bibl.* 60.) Herodotus presents himself to our consideration in two points of view; as a traveller and observer, and as an historian. The extent of his travels may be ascertained pretty clearly from his History, but the order in which he visited each place and the time cannot be determined. The story of his reading his work at the Olympic games, which has found its way into most modern narratives, has been well discussed by Dahlmann, and we may perhaps say disproved. (Herodot., *Aus seinem Buche sein Leben*, Altona.) The story is founded on a small piece by Lucian (Ed. Reiz., 4to., p. 831), entitled 'Herodotus or Aetion,' which apparently was not intended by the writer himself as an historical truth; and in addition to this, Herodotus was only about twenty-eight years old (Suidas, Θουκυδίδης) when he is said to have read to the assembled Greeks at Olympia a work which was the result of most extensive travelling and research, and bears in every part of it evident marks of the hand of a man of mature age. The Olympic recitation is not even alluded to by Plutarch in his treatise on the Malignity of Herodotus (iv., p. 431, ed. Wyttenbach). The arguments derivable from this circumstance, as to the truth or falsehood of the story, are considered by Dahlmann (p. 33). Heyse endeavours to maintain the story of the Olympic recitation, and to relieve it from some of its difficulties; but, in our opinion, not successfully. Another recitation at Athens is mentioned by Plutarch and Eusebius.

With a simplicity which characterizes his whole work, Herodotus makes no display of the great extent of his travels. He frequently avoids saying in express terms that he was at a place, but he uses words which are as conclusive as any positive statement. He describes a thing as standing behind the door (ii. 182), or on the right hand, as you enter a temple (i. 51); or he was told something by a person in a particular place (ii. 28); or he uses other words equally significant. In Africa he visited Egypt, from the coast of the Mediterranean to Elephantine, the southern extremity of the country (ii. 29); and he travelled westward as far as Cyrene (ii. 32, 181), and probably farther. In Asia he visited Tyre, Babylon, Ecbatana (i. 98), and probably Susa (v. 52-54; vi. 119). He also visited various parts of Asia Minor, and probably went as far as Colchis (ii. 104). In Europe he visited a large part of the country along the Black Sea, between the mouths of the Danube and the Crimea, and went some distance into the interior. He seems to have examined the line of the march of Xerxes from the Hellespont into Attica, and certainly had seen numerous places on this route. He was well acquainted with Athens (i. 98; v. 77, &c.), Delphi, Dodona, Olympia (ix. 81), Tegea (i. 66), Thasos, Delos, Zacynthus (iv. 195) and numerous other places in Greece. That he had visited some parts of South Italy is clear from his work (iv. 99; v 44, 45). The mention of these places is sufficient to show that he must have seen many more. So wide and varied a field of observation has rarely been presented to a traveller, and still more rarely to any historian, either of antient or modern times; and if we cannot affirm that the author undertook his travels with a view to collect materials for his great work, a supposition which is far from improbable, it is certain that without such advantages he could never have written it, and that his travels must have suggested much inquiry, and supplied many valuable facts which afterwards found a place in his History.

The Nine Books of Herodotus contain a great variety of matter, the unity of which is not perceived till the whole work has been thoroughly examined; and for this reason, on a first perusal the History is seldom well understood. But the subject of his History was conceived by the author both clearly and comprehensively. 'The object of the inquirics (for so we may render the word ἱστορίη) of Herodotus of Halicarnassus is this, that the acts of man may not be forgotten through lapse of time, and that great and wondrous achievements, performed partly by Greeks and partly by Barbarians, may not be without their fame; and also how it came to pass that Greeks and Barbarians waged war together' (i. 1). His object then was to combine a general history of the Greeks and the Barbarians (that is, those not Greeks) with the history of the wars of the Greeks and Persians. Accordingly, in execution of his main subject, he traces the course of events from the time when the Lydian kingdom of Crœsus fell before the arms (B.C. 546) of Cyrus, the founder of tho Persian monarchy, to the capture of Sestos (B.C. 478), an event which crowned tho triumph of the Greeks over the Persians.

The great subject of his work, which is comprised within this space of sixty-eight years, not more than the ordinary term of human life, advances with a regular progress and truly dramatic development, from the first weak and divided efforts of tho Greeks to resist Asiatic numbers, to their union as a nation, and their final triumph in the memorable fights of Thermopylæ, Salamis, and Platæa. But with this subject, which has a complete unity well maintained from its commencement to its close, the author has interwoven, conformably to his general purpose, and by way of occasional digression, sketches of the various people and countries that he had visited in his widely-extended travels. The more we contemplate the difficulty of thus combining a kind of universal history with a substantial and distinct narrative, the more we admire, not tho art of tho historian (for such, in the proper sense of the term, he could not well possess), but that happy power of bringing together and arranging his materials which was the result of the fulness of his information, the distinctness of his knowledge, and the clear conception of his subject. These numerous digressions are among the most valuable parts of his work, and if they had been omitted or lost, barren indeed would have been our investigation into the field of antient history, over which the labour of one man now throws a clear and steady light. It would be difficult to mention any single writer, antient or modern, whose personal knowledge forms so large a part of the materials of his work, and it would not be easy to name one whose accuracy of observation and felicity of description were accompanied with such singleness and rectitude of purpose. Of modern travellers Carsten Niebuhr is the only one whom wo can call to mind as worthy, in this respect, to be placed by the side of the Historian of Halicarnassus. But we know no complete parallel to a writer whose mere digressions elevate him to the rank of an intelligent traveller, and who could combine in harmonious union with a great historical work, designed to perpetuate the glories of his own nation, so endless a variety of matter collected from the general history of mankind. His predecessors in historical composition appear generally to havo chosen subjects of a limited nature, partaking chiefly of the character of local annals. Herodotus chose for his subject a series of events which concerned the universal Greek nation, and not them only, but the whole civilized world; and by the way in which he executed his great undertaking he has earned the honourable and well-merited appellation of the Father of History.

That he was not duly appreciated by all his countrymen, and that in modern times his wonderful stories havo been the subject of merriment to the half-learned, who measure his experience by their own ignorance, we merely notice, without thinking it necessary to say more. The incidental confirmations of his veracity which have been accumulating of late years on all sides, and our more exact knowledge of tho countries which he visited, enable us to approciate him better than many of the Greeks themselves could do; and it cannot now be denied that a sound and comprehensive study of antiquity must be based upon a thorough knowledge of the Father of History.

The style of Herodotus is simple, pleasing, and generally perspicuous; often highly poetical both in expression and in sentiment. But it bears evident marks of belonging to a period when prose composition had not yet become a subject of art. His sentences are often ill-constructed and hang loosely together; but his clear comprehension of his own meaning, and the sterling worth of his matter, have saved him from the reproach of diffuseness and incoherence. His acquirements were apparently the result of his own experience. In physical knowledge he was certainly behind the science of his day. He had no doubt reflected on political questions; but he seems to have formed his opinions mainly from what he had himself observed. To pure philosophical speculation he had no inclination, and there is not a trace of it in his writings. He had a strong religious feeling, bordering on superstition, though even here he could clearly distinguish the gross and absurd from that which was decorous (i. 199). He seems to have viewed the manners and customs of all nations in a more truly philosophical way than many so-called philosophers, considering them as various forms of social existence under which happiness might be found. He treats with decent respect the religious observances of every nation, a decisive proof, if any were wanting, of his good sense.

There is no translation of Herodotus which has yet done justice to the original. and no commentary has yet exhausted one-tenth of the matter which admits and requires illustration.

Tho first edition of Herodotus was the Latin translation of L. Valla, Venice, 1474, fol. The first Greek edition was printed by the elder Aldus, Venice, 1502, fol., reprinted by Hervagius, Basel, 1541, 1557, fol., under the superintendence of Camerarius. The edition of Hervagius is very correct and useful. Tho most complete edition of Herodotus is by J. Schweighäuser, Strasburg, 1816, 6 vols. 8vo. Since that time, Professor Gaisford has again collated the Sancroft manuscript (ono of the best manuscripts of Herodotus) for his edition of Herodotus, Oxford, 1824, but the result of the collation has added nothing of any value to the text of Schweighäuser. The differences between the text of Schweighäuser and Gaisford are shown in the reprint of Schweighäuser, by Taylor and Walton, London, 1830 and 1838. The Lexicon to Herodotus, by Schweighäuser, is a useful aid to students, though it is far from being complete. Rennell's 'Geography of Herodotus' is a valuable work, which will enable a student to appreciate the merits of the old traveller; and Niebuhr's 'Dissertation on the Geography of Herodotus,' of which there is a notice in the 'Westminster Review,' No. 26; Dahlmann's Essay above referred to, and that of Heyse, 'De Vita et Itineribus Herod.,' Berl. 1827, are worth the student's attention. 'The Apology of Herodotus,' by H. Stephens, prefixed to his corrected edition of Valla's translation, Frankfort, 1595, is a clever and amusing vindication of Herodotus against the charge of falsehood, made on the ground that many of his stories were so singular and improbable. L'Archer's French translation, Paris, 9 vols. 8vo., with the Commentary, is a useful book; and Creuzer's 'Commentationes Herodoteæ,' Leip., 1819, may be consulted with profit. The German translation by Lange, Breslau, 1824, 2 vols. 8vo., has the merit of fidelity, and to a considerable degree is a successful attempt to convey a notion of the literary character of the original. There is no English translation that deserves to be recommended. That by Beloe is perhaps in every respect the worst. (*Journal of Education*, vol. i., p. 322.)

A Life of Homer, which bears the name of Herodotus, is subjoined to most editions of the text; but evidently comes from another hand.

HEROIC AGE. [HERO.]

HEROIC VERSE in its antient sense means that which was the vehicle of Greek, and subsequently of Latin epic poetry, of which the actions of the heroes were the appropriate subject. [HEXAMETER.] In English our common ten-syllable couplet passes under this name, chiefly, it should seem, because it is the measure into which the epics of antiquity have been most frequently translated. The Alexandrine of twelve syllables however has been also used by our elder writers for this purpose, as by Chapman in his translation of the 'Iliad.'

HERONS. Under this head it is our purpose to treat of the Cranes (*Gruidæ*) as well as the Herons (*Ardeidæ*), including the Storks, &c.

Willughby thus generally defines his section of *Cloven-footed Piscivorous Water-fowl.* 'These have very long necks; their bills also are long, strong, ending in a sharp point, to strike fish, and fetch them from under stones or brinks: long legs to wade in rivers and pools of water: very long toes, especially the hind toe, to stand more firmly in rivers: large crooked talons, and the middle serrate on the inside, to hold eels and other slippery fishes the faster, or because they sit on trees; lean and carrion bodies, because of their great fear and watchfulness.' He makes the section to consist of the Herons, Bitterns, &c., Storks, 'the Ibis of Bellonius' (*Belon*), and the Spoonbills.

Ray places at the head of the *Aves Aquaticæ*, the '*Fissipedes*' (cloven-footed), 'quæ circa aquas versantur, iis tamen non innatant' ('which haunt the waters, but do not swim in them'). The first section of these, consisting of the 'Maximæ, singulares et sui generis,' contains the Cranes (Grus, including the *Grus Indica* and *Grus Balearica*, the *Jabirus*, the *Cariama*, and the *Anhima*). Then come the *Aves aquaticæ fissipedes piscivoræ, ranivoræ et serpentivoræ*, the Storks and the *Ibis nigra*. Next to these are arranged the *Ardeurum genus* (Herons and Bitterns), and then the *Ardeæ exoticæ*, including the *Soco*, &c., and the Spoonbills.

The Stork, the Heron, the Spoonbill, &c., with a heterogeneous crowd of other birds, are brought under Brisson's 17th order.

The genus *Ardea*, in the 12th edition of the *Systema Naturæ*, embraces the Herons, the Bitterns, and the Cranes (including the Balearic Crane and the Demoiselle, *Anthropoïdes*): the Jabiru, Boatbill, and Spoonbill are generically distinguished under the names of *Mycteria*, *Cancroma*, and *Platalea*. They form part of Linné's fourth order, *Grallæ*.

Dr. Latham's seventh order, *Grallæ*, embraces the *Ardeidæ* and *Gruidæ* among the rest of the wading-birds.

The same families are scattered through M. Lacépède's *Oiseaux de Rivage* (*Grallatores*).

M. Duméril's fifth order of Birds, *Échassiers* (Waders), contains his 16th, 17th, 18th, and 19th families. The Oyster-catcher is included in the 16th (Pressirostres, or Ramphostènes); the open-beak, *Bec-ouvert*, (Anastomus of Illiger), the Heron, the Stork, the Crane, the Jabiru, and Ibis (Tantalus), form the 17th family, the *Cultirostres*, or *Ramphocopes*. The Spoonbill and Boatbill belong to his 18th family, the *Latirostres*, or *Ramphoplates*.

Among the *Grallatores* of Illiger the *Herodii* contain the genera *Grus*, *Ciconia*, *Ardea*, *Eurypyga*, *Scopus*, *Cancroma*, and *Anastomus*. The genera *Tantalus* and *Ibis* form the *Falcati*, and *Platalea* is placed among the *Hygrobatæ*.

Cuvier's *Échassiers* comprehend the *Brevipennes*, the *Pressirostres*, the *Cultirostres*, the *Longirostres*, and the *Macrodactyles*.

The *Cultirostres* consist of the Cranes, the Boatbills, the Herons, the Storks, the Jabirus, the *Ombrettes*, the Open-beaks, the *Tantali*, and the Spoonbills.

M. Vieillot's Echassiers are divided into two tribes: the 1st, the *Di-tridactylous*; the 2nd, the *Tetradactylous*. The 6th family of these waders (*Latirostres*) consists of the Spoonbills and Boatbill; the 7th (Herodions) comprehends the *Ombrette*, the Open-beak, the Herons, the Storks, and the Jabirus, &c.; and the 8th (*Ærophones*), the Cranes (*Grus* and *Anthropoïdes*).

The *Ardeidæ* and *Gruidæ* are placed by M. Temminck under his 2nd family of *Gralles* (waders).

In M. De Blainville's method the *Ardeidæ* and *Gruidæ* are comprehended under the *Ciconiens*, his third family of *Grallatores*, and in the same method as further developed by M. Lherminier, the 23rd family (first subclass or Normal birds), consists of the Cranes (*Grus* of Pallas); and the 24th family (same subclass) of the Herodii of Illiger.

Mr. Vigors considers that the Grallatores are naturally divided into these five families:—*Gruidæ*, *Ardeidæ*, *Scolopacidæ*, *Rallidæ*, *Charadriadæ*; and he places the *Ardeidæ* in the Normal group and the *Gruidæ* in the Aberrant group. He remarks that the species that enter into the family of *Gruidæ*, most of which were comprised originally in the genus *Ardea* of Linnæus, are separated from the remainder of that group by their food, which is chiefly vegetable; by their manners, which approach nearer to those of the land-birds; and by the formation of their bills and feet, the former of which are more obtuse at the end, and the latter shorter than is observable in the true *Ardeæ*. In these characters, Mr. Vigors observes, as well as in their general appearance, more particularly with respect to their plumage, they have a near alliance with the *Struthionidæ*. *Psophia* [AGAMI,* vol. i.] of Linnæus is the first genus of this family to which Mr. Vigors calls our attention. This genus, in the comparative shortness of the bill, is considered by Mr. Vigors to be connected with the *Anthropoïdes* of M. Vieillot, the Numidian Demoiselle; while he regards the Crowned Crane of Africa (the Balearic Crane of authors, *Ardea pavonina* of Linnæus) as uniting this genus to the true *Grus* of the present day. 'If the genus Dicholophus of M. Illiger,' continues Mr. Vigors, 'be found to belong to the wading-birds, of which I have little doubt, its situation will most probably be in the present family, to which it bears a nearer resemblance in plumage and general structure than to any other division of the order. In this case it will form a more immediate link than any group at present known in the family with the *Charadriadæ*, which meet it at the corresponding extreme of the order; its shorter and more elevated hind-toe forming the passage between the fully tetradactyle foot of the *Gruidæ* and the tridactyle foot of the *Charadriadæ*.' We have seen [CARIAMA, vol. vi.] that the habits of *Dicholophus* are not those of the wading-birds, although in the whole of the visceral arrangement a close affinity may be observed to the *Gruidæ*.

Mr. Vigors remarks further that Cuvier has noticed the union that takes place between the last groups alluded to by Mr. Vigors and those of the *Ardeidæ* by means of the genera *Aramus* of Vieillot and *Eurypyga* of Illiger. These, he observes, lead to the extensive assemblage of species contained under *Ardea*, Linn., and *Ciconia*, Briss., both of which groups are connected by their general form and habits, but differ by some minute yet strongly-marked generic distinctions. Intermediate between *Ardea* and *Ciconia* appear those forms which display so remarkable a dilatation of the bill, viz. *Cancroma*, *Phœnicopterus*, and *Platalea* of Linnæus. The two last of these groups, continues Mr. Vigors, are equally distinguished by a greater development of the membrane that connects the toes than is observable in the other waders, which join them on each side; and in one of them, the *Phœnicopterus*, this character, he remarks, is carried so far to the extreme as to have occasioned some systematists to place the birds of that genus among the *Natatores*. [FLAMINGO, vol. x.] 'But,' says Mr. Vigors in conclusion, 'the whole of the family have a membrane more or less extensive at the base of the toes; and if we compare the feet of the common *Ciconia alba*, of the *Platalea*, and the *Phœnicopterus* together, we shall see a gradual increase of this membrane in extent until it reaches the extreme in the latter genus. Among the groups that are allied to *Ciconia* there are many that resemble it in general character, but deviate from it in the form of the bill. Among these we may particularize *Scopus*, Linn.,* distinguished by its more compressed and furrowed mandibles; the *Mycteria*, Linn., where the point of the bill turns upwards; and the *Anastomus*, Ill., where the mandibles, united at the base and at the point, leave an open space in the centre. The genus *Tantalus*, Linn., bears an evident affinity to the same group, and has consequently been united to it in the arrangement of every systematic naturalist. It differs chiefly by the downward curvature of the bill. To this genus may be united the *Ibis* of M. Lacépède, which, in its more slender bill, bears an affinity to *Eurypyga*, from whence we commenced our inquiries into the family.' The same author unites the *Scolopacidæ* with the *Ardeidæ* by means of *Numenius* of Brisson, as approaching *Ibis* most closely in its bill.

The Prince of Musignano (C. L. Bonaparte) makes the *Herodii* the third family of the order *Grallæ*, and includes under it the genera *Grus*, *Ciconia*, *Ardea*, and *Aramus* his fourth family (*Falcati*) consists of the genera *Tantalus* and *Ibis*. (*Specchio Comparativo*.)

Mr. Swainson ('Natural History and Classification of Birds,' vol. ii.) is of opinion that the '*Ardeadæ*,' or Herons, by means of the Cranes, show the strongest affinity to the Ostriches, and thus unite the rasorial with the wading order. 'Nearly all the cranes,' writes Mr. Swainson, 'are large birds, with short and powerless wings, long and frequently naked necks, and more terrestrial in their habits than any of their congeners. The beautiful genus *Phosphia* (Psopbia?), if truly belonging to this family, is more of a gallinaceous than a wading bird.' After referring to the genus *Anthropoides*, Mr. Swainson thus continues:—'The more typical cranes (*Grus*, Pallas) are large birds, few indeed in species, but dispersed over Europe, America, and Asia: they seem to prefer the seclusion and security of marshes, and feed both upon seeds, herbage, worms, and small reptiles. The *Ardeadæ*, or typical herons, differ from the last in being composed of birds decidedly carnivorous: they are known by a larger and more pointed bill, and by the superior length of the legs. The herons, as a whole, are the most beautiful of all the waders, not so much from the colours of their plumage as from the elegant crests and prolonged feathers which ornament nearly all the species. They build in societies, but generally feed and live solitary. Like the Kingfishers and many of the fissirostral birds, the greater part watch for their prey from a fixed station: a sheltered nook by the side of a river, or a projecting rock by the sea-side, over deep water, frequently serves them as a convenient post; here they watch for passing fish, which they dexterously spear or transfix by

* The scientific name of this bird, *Psophia crepitans*, is erroneously printed in the article referred to, where it stands as *Trophia crepitans*.

* The genus Scopus is Brisson's, and there is no such genus in Linné's last edition of the *Systema Naturæ*. Gmelin adopts it in his edition, and places it between *Cancroma* and *Ardea*.

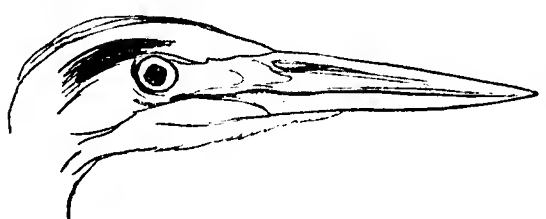
their long and sharp bill. Some of these birds are of a gigantic size; others are very small, but have all a very long neck, covered more or less by strong and loose feathers. The tiger-bitterns (*Tigrisoma*, Sw.) are exclusively found in South America, but the true bitterns seem restricted to no particular climate. The boat-bills (*Cancroma*, L.) differ most essentially from the herons, since they have a short and very broad bill, shaped something like a boat with its keel uppermost.' [BOAT-BILL, vol. v.] * * 'The spoonbills (*Platalea*) show a different but a no less singular form of beak, from which their name has been derived. The storks (*Ciconia*) are among the largest of the heron family; one species (*Ciconia gigantea*) measuring, when standing erect, near five feet and a half: they are social and useful birds, and from destroying vast numbers of reptiles and other vermin, are encouraged in many countries to build on the habitations of man: the chin and eyes are bare of feathers; but in *Mycteria*, which possibly enters into this family, the greatest part of the head and neck is entirely bare: one species inhabits America, one Asia, and one Australia. The tufted umbre forms the African genus *Scopus*, and is the only species known; the plumage is particularly soft, and the back of the head furnished with a lax tuft of feathers: this is obviously allied to the open-bills (*Anastomus*, Ill.), a singular form, remarkable for a thick and very powerful bill gaping in the middle. * * These are the principal genera which appear to enter this family, of which the herons and cranes form the two most typical groups.'

In the Synopsis (same vol.) Mr. Swainson places the '*Ardeadæ*' as the first family of the *Grallatores*, or Waders, with the following definition:—'Size large. Bill long, conic, very hard, straight, and compressed. Hind toe moderate, and placed on the same level as the others.' The family, according to this author, includes the following genera and subgenera:—Ardea = *Ardea*, *Egretta*, *Butor* (Bitterns), *Tigrisoma* (Tiger-Bitterns), *Nyctiardea*, Sw. (Night-Herons); Cancroma; Platalea; Ciconia (including *Mycteria* as a subgenus); Hæmatopus; and Scopus.

Geographical Distribution of the Ardeidæ and Gruidæ. The birds of this group are to be found in all the four quarters of the globe. They seldom occur in the very cold regions.

HERONS.

M. Temminck thus defines the Herons properly so called:—*Bill* much longer than the head, as large as it is high, or larger, at the base; upper mandible nearly straight; a great portion of the tibia naked. Food, fish principally.



Bill of Common Heron.

As our limits will not permit us to give more than a sketch of the leading forms of this group, we proceed to illustrate M. Temminck's first section of the True Herons by the Common Heron, which most authors consider as the type.

The *Common Heron* then is, in the opinion of Belon and some others, the Ἐρωδιός (Erodius) of Aristotle, but we do not consider this as certain: the term Ἐρωδιός is doubtless applied by Aristotle to the form (*Hist. Anim.*, b. viii., c. 3), but what species is meant by him is not so clear; for he says (b. ix, c. 1), *Τῶν δ' ἐρωδιῶν ἐστι τρία γένη· ὅ τε πέλλος, καὶ ὁ λευκὸς, καὶ ὁ ἀστερίας καλούμενος* ('There are three kinds of Erodii, the blackish and the white, and that called Asterias'); the latter being most probably the Bittern. Now the term *πέλλος* is hardly applicable to the plumage of the Common Heron, *Ardea cinerea*. But the bird is, without doubt, the *Ardea* of the antient Italians, and the *Becca-pesce*, *Airone*, *Oca cicogna*, and *Garza*, of the modern Italians; *Garza* of the Spaniards; *Reyger* and *Rheier* of the Germans; *Héron* of the French; *Cryr glâs* of the antient British; and *Common Heron*, or *Heronshaw*, of the modern British.

Description.—Plumage bluish-ash; middle toe, the nail included, much shorter than the tarsus.

Male and Female after the third year.—Long, loose black feathers (plumes effilées) on the back of the head, similar plumes of a lustrous white depend from the lower part of the neck; the equally elongated and subulate scapulars are of a silvery ash. Forehead, neck, middle of the belly, border of the wings and thighs, pure white; occiput, sides of the breast, and flanks, deep black. On the front of the neck are large longitudinal black and ash spots. Back and wings very pure bluish-ash; bill deep yellow; iris yellow; naked skin of the eye bluish-purple; feet brown, but of a lively red towards the feathered part. Length three feet and upwards. In this state M. Temminck, whose description we have given, states the bird to be the *Ardea cinerea* (Mas.) of Latham (Ind.); *Ardea Major* of Gmelin; *Le Héron Huppé* of Buffon; *Héron commun* of Gérard; *Common Heron* (male) of Latham (Syn.), Pennant (*Brit. Zool.*), and Albin; *Ashgrauer Rheier* of Meyer and others; and *Sgarza cenerino* of the *Stor. degl. Ucc.*

Common Heron.

Young up to the age of three years.—No crest, or, at most, the plumes composing it very short; no long loose feathers at the lower part of the neck, nor above the wings; forehead and top of the head ash colour; throat white; neck clear ash, with numerous spots of a deeper colour than the ground; back and wings bluish-ash, mingled with brown and whitish: breast marked with longitudinal spots; upper mandible of the bill blackish-brown, with yellowish spots; lower mandible yellow; iris yellow; skin round the eyes greenish-yellow; feet blackish-ash, but yellowish towards the feathered part. In this state M. Temminck considers the bird to be the *Ardea cinerea* (Femina) of Latham (Ind.); *Ardea Rhenana* of Sander; *Le Héron*, Buff.; *Common Heron* (fem.), Lath. Syn.; *Sgarza marina*, 'Stor. degl. Ucc.;' and *De Blaauwe Reiger* (being the young in the first year) of Sepp.

The edge of the bill is serrated near the point, and the nail of the middle toe pectinated, as in the Herons generally.

Variety.—Nearly perfectly white. A variety of this description is figured by Frisch (t. 204); but it is very rare.

Habits, Food, Reproduction, &c.—The solitary habits of the Common Heron, excepting at the season of reproduction, are well known. At that period they congregate at their breeding stations, or heronries, for which the loftiest trees are generally chosen. Pennant says that at Cressi Hall, near Gosberton, in Lincolnshire, he counted more than eighty nests in one tree. Montagu notices a heronry on a small island in a lake in the north of Scotland, whereon there was only one scrubby oak. This being too small to contain all the nests, the herons, rather than abandon their society and a favourite station, had many of them placed their nests on the ground. In the south and west of England the heronries at Brockley, in Somersetshire, and at Powderham Castle, in Devonshire, are worthy of notice. The nest is built of sticks, and is large and flat. It is lined with wool or other soft materials, and on this lining are deposited four or five bluish-green lustreless eggs. The young are less prepossessing in appearance than nestlings in general, but few of which are pleasant to look upon, and they remain in the nest for five or six weeks, during which time the old birds unceasingly supply them with fish, &c. There are sometimes deadly feuds between the herons and the rooks, originating in a dispute for the possession of the nest-trees. Dr. Heysham's account of one of these battles at Dallam Tower, in Westmoreland, originating in the felling of the fine old oaks occupied by the herons, and their consequent attempt upon the grove in the tenure of the rooks, is well worth perusal. The herons had the best of the fray for two successive seasons, and at length a sort of peace was patched up between the combatants; the rooks and the herons severally setting up their rest on a particular part of the now only remaining grove, and leaving the other moiety to the opposite faction.

Buffon draws largely upon his imagination for a picture of wretchedness, and then makes the heron a personification of it, with as much foundation as characterizes most of his fancies of this description. When on its fishing station, the bird stands immovable as a stump, with the neck bent and between the shoulders, watching for the passing fish, which it unerringly spears with its sharp bill. But besides fish and reptiles, such as frogs, newts, &c., mice, young water-rats, and even young water-fowl, are occasionally devoured by it. Mr. Selby, in his excellent 'Illustrations of British Ornithology,' gives, on the authority of Mr. Neill, of Canonmills, near Edinburgh, two interesting anecdotes in illustration of the habits of this bird in a state of half-domestication. 'The Common Heron (a male),' says Mr. Neill, 'which was winged on Coldingbam Muir in autumn, 1821, when a young bird, and given to me in 1822 by Mr. John Wilson, of the College, has since resided in my garden at Canonmills, and is now so tame that he often follows me, expecting a piece of cheese, which he relishes. Four years ago Mr. Allan, of Lauriston, sent me a young female which had been taken during a severe storm. She soon associated with the older bird. In summer, 1828, she laid three or four eggs (I am not sure which) on the top of a wall next to the mill-pond. She then laid one or two on the flower-border below the wall, and close by the box-edging· here some eggs were broken by the birds suddenly starting off when alarmed by strangers walking in the garden. We supplied their place by some bantam eggs, and only one heron egg at last remained. Alas! the poor hen, having strayed to the margin of the mill-pond, was shot by some thoughtless young man with a fowling-piece. The cock continued to sit for several entire days after the death of the hen, but at last tired. He used to sit when she went off for food. During the whole time of pairing the cock was very bold, raising his feathers and snapping his bill whenever any one approached.'

Mr. Neill further adds a fact, showing that the bird can swim upon occasion. 'A large old willow-tree,' writes Mr. Neill in continuation, 'had fallen down into the pond, and at the extremity, which is partly sunk in the sludge, and continues to vegetate, water-hens breed. The old cock heron swims out to the nest, and takes the young, if he can. He has to swim ten or twelve feet, where the water is between two and three feet deep. His motion through the water is slow, but his carriage stately. I have seen him fell a rat by one blow on the back of the head, when the rat was munching at his dish of fish.'

Geographical Distribution.—Very extensive, and embracing the greater part of the old world. (Selby.) It is permanent in England. Dr. Latham says, 'In England, and the milder climates, this species of heron is stationary, migratory in the colder, according to the season; is rarely seen far north. Inhabits Africa and Asia in general, the Cape of Good Hope, Calcutta, and other parts of India, and is found in America from Carolina to New York.' With regard to the American locality, Dr. Latham appears to have taken the Great Heron, *Ardea Herodias*, Linn., for the *Common Heron*, which last is not mentioned by any of the ornithologists who have made the birds of America their study, as an inhabitant of the New World. Dr. Von Siebold mentions this our European species among the birds which he observed in Japan.

Utility to Man.—In days of old, when the Heron was a principal feature in the noble sport of hawking, and when the destruction of its eggs was visited with a penalty of twenty shillings, it seems to have held as high a place at the tables of the great as it did in the field. Thus, at the 'intronazation' of George Nevell, archbishop of York, in the reign of Edward IV., we find in the bill of fare 400 Heronshawes and 200 Feasauntes (pheasants); and it seems, at one period, to have been valued as a dish at the same price as the latter bird, for from the prices in the household-book of the fifth earl of Northumberland, we find *Hearon-sewys* (Herons) marked at twelve pence, and pheasants at the same rate to a penny. At a marriage-feast in Henry VIII.'s time, we find *Heron-sews* noted at the same price, and at another marriage-feast in the same year two dozen *Heron-sues* marked at twenty-four shillings.* In the first of these records no mention is made of pheasants, but in the second they appear at that earlier time to have been rather more highly valued than Herons, for eighteen pheasants are priced at twenty-four shillings, the amount placed against the two dozen Herons. And in the charges of Sir John Nevile of Chete (the knight in whose family the marriages above alluded to took place), at Lammas assizes, in the twentieth year of the reign of king Henry VIII., the pheasants appear to have cost somewhat more than the *Heronsews*, thirty of which are priced at thirty shillings, while twelve pheasants cost twenty shillings. The heron-plume, made up of the fine large depending feathers, especially those above the wings, was highly valued.

In the present day the bird seems to have sunk into comparative insignificance. Mr. Selby however considers that 'the low estimation in which the flesh of the heron is now held would seem to be in a great degree the effect of prejudice, or the fashion of taste, as under proper treatment and good cookery the Heron, when fat and in fine condition, is but little inferior to some of our most approved wild-fowl.'

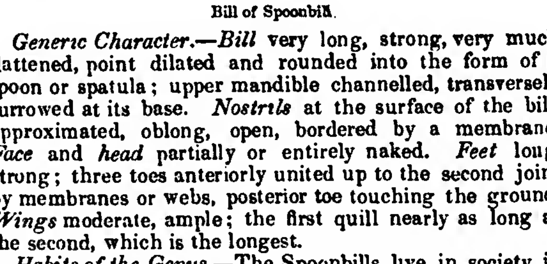
The well-known adage expressive of ignorance, 'He does not know a hawk from a handsaw,' is a corruption of 'He does not know a hawk from a heronshaw.'

Temminck's second section of *Herons* consists of the *Bitterns*, including the Night Herons. As an illustration of this section we must refer to Bittern, vol. iv., and Nycticorax.

Next to the *Bitterns* we may notice the *Boat-bills*. The form of the bill is indeed widely different; but the habits and food of the bird approach very nearly to those of the Herons and Bitterns. [Boat-Bill.]

Spoonbills.

Another extraordinary form of the bill, joined to the general appearance of the Heron tribe, and decided piscivorous habits, is to be found in the Spoonbills, genus *Platalea*, Linn.



Bill of Spoonbill.

Generic Character.—*Bill* very long, strong, very much flattened, point dilated and rounded into the form of a spoon or spatula; upper mandible channelled, transversely furrowed at its base. *Nostrils* at the surface of the bill, approximated, oblong, open, bordered by a membrane. *Face* and *head* partially or entirely naked. *Feet* long, strong; three toes anteriorly united up to the second joint by membranes or webs, posterior toe touching the ground. *Wings* moderate, ample; the first quill nearly as long as the second, which is the longest.

Habits of the Genus.—The Spoonbills live in society in wooded marshes, generally not far from the mouths of rivers, and are rarely seen on the sea-shore. Their food consists of small fishes, spawn, and small fluviatile testaceous mollusks, as well as small reptiles and aquatic insects. According to circumstances they build their nests either in high trees, in bushes, or among rushes. Their moult is

* Marriages in the family of Sir John Nevile, of Chete, Knight.

simple and ordinary, but the young bird does not take the confirmed livery of the adult till the third year; the bill is gradually developed, and appears covered with a membrane. The crest makes its appearance at the second year. The sexes have external distinctions, but the characters are but slightly marked. (Temminck.)

We select as an example the Common White Spoonbill, *Platalea leucorodia*, Linn.

This species is, there can be little doubt, the λευκερωδιος (Leucerodius) of Aristotle (*Hist. Anim.*, book viii., c. 3), of which he says that it haunts περὶ τὰς λίμνας καὶ τοὺς ποταμοὺς ('about the lakes and rivers'); and which he thus describes:—'In size it is less than the other,' the Ἐρωδιός (one of the Herons, perhaps *Ardea cinerea*), 'and has a broad and long bill;' a description which, when coupled with the white colour indicated by the name, can hardly be deemed inapplicable; nor can the term 'broad' be with any propriety referred to the bill of any of the true Herons. It is the *Becquaroueglia* (Belon) and *Cucchiarone* (Bonaparte) of the modern Italians; *Pale, Poche, Cueiller, Truble* (Belon), and *Spatule* of the French; *Weisser Laffler* and *Laffel Gans* of the Germans; *Lepelaar* of the Netherlanders; *Y Llydon big* of the Antient British; and *Spoonbill* and *White Spoonbill* of the Modern British.

Description.—A very full long occipital crest, formed of loose and subulate feathers.

Very old Males.—All the *plumage* pure *white*, with the exception of that of the *breast*, where there is a large patch of *reddish yellow;* the extremities of this patch lessen into bands which unite on the upper part of the back. Naked skin about the eyes and throat pale yellow; but slightly tinged with red on the lower part of the throat. *Bill* black, but bluish in the hollow of the furrows; apex ocreous yellow; *iris* red, *feet* black. Total length 2 feet 6 inches; length of bill 8 inches 6 lines.

Old Females.—Dimensions rather less than those of the male; the crest is less full and shorter, and the sternal patch is only very feebly indicated.

Young of the Year.—White on leaving the nest, with the exception of the external quills, which are black along the shafts and at their ends; all the shafts are also of a deep black. *Head* covered with short rounded feathers; the *bill*, 4 inches and 6 lines long at most, is of a deep ash-colour, soft, very flexible, and covered by a smooth skin; *iris* ash-coloured; naked parts tarnished white. The yellow sternal patch does not begin to appear till the second or third year. (Temminck.)

Mr. Selby observes that in its anatomy it shows an affinity to the Cranes in the form of the windpipe, which, previous to entering the thorax, undergoes a double flexure to the extent of about two inches, and forms a convolution similar to the figure 8. The flexures touch, but do not cross each other, the points of contact being united by fine membranes. This double flexure, according to Willughby and Temminck, was supposed peculiar to the males, but Mr. Selby remarks that Montagu disproves that idea, as the specimen he dissected was a female, and yet possessed the flexure to the extent above described; and this indiscriminate characteristic was corroborated by the dissection of the specimens which Mr. Selby obtained.

Food.—Very small fish, spawn, testaceous mollusks, insects and aquatic worms, small reptiles, and the roots of some weeds and grasses.

Habits, Reproduction, &c.—The Common Spoonbill haunts the mouths of rivers. Its nest is built sometimes on lofty trees, sometimes in rushes and reeds, according to circumstances, and the eggs are from two to four in number, generally three, sometimes entirely white, but most frequently white marked with obscure red spots. They bred annually in the time of Ray in a wood at Sevenhuys, not far from Leyden, but the wood has been long destroyed.

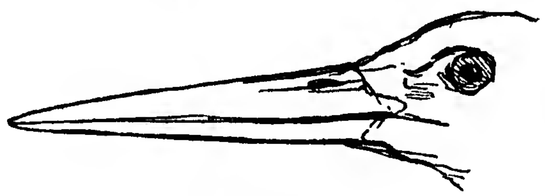
Geographical Distribution.—Europe generally. Holland appears to be a principal place for their summer meetings; and Temminck states that it has two periods of passage along the maritime coasts, and that it journeys with the storks. As winter approaches it migrates to more southern regions till the milder weather recals it. Mr. Bennett states that in winter it takes up its quarters in various parts of Africa, extending southwards even to the Cape of Good Hope. It is, he observes, rarely met with in inland countries except on the banks of the larger rivers; but it is by no means uncommon during the season on the coasts of the great extent of country which it embraces in its visits. In England it only appears occasionally; Pennant mentions a large flight which arrived in the marshes near Yarmouth in April, 1774. Montagu records it as having been sometimes seen during winter on the coast of South Devon, and mentions the receipt of two specimens from that part of the country, one in November, 1804, and a second in 1807. Mr. Yarrell records two specimens which were shot in Lincolnshire in 1826, and Mr. Selby, when in London in 1830, obtained a male and female, in fine adult plumage, from Norfolk. Dr. Latham states an instance of its occurrence on the Kentish coast. The old quatrain in the 'Portraits d'Oyseaux,' speaks of the Spoonbill under the name of *Pale*, as living 'es marches de Bretagne.'

Platalea Leucorodia. Common Spoonbill.

Utility to Man.—The flesh of the Spoonbill, when well fed and fat, is said nearly to resemble that of the goose in flavour.

STORKS. (Ciconia, Brisson.)

Generic Character.—*Bill* long, straight, subcylindrical, in form of an elongated cone, pointed, trenchant, butt (arête) rounded of equal height with the head; lower mandible a little curved upwards. *Nostrils* slit longitudinally in the horny substance of the bill, placed near the base. *Eyes* surrounded with a naked space, which does not communicate with the bill; the *face*, the space *round the eyes*, or a part of the *neck*, often naked. *Feet* long; three *toes* forward, united by a membrane up to the first joint, the posterior toe articulated on the same level with the others; *nails* short, depressed, without dentilations. *Wings* moderate; the first quill shorter than the second, which is rather shorter than the third, fourth, and fifth, which are the longest. (Temminck.)



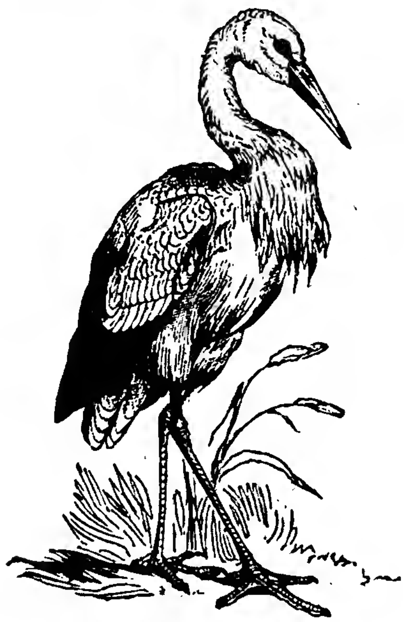
Bill of Stork.

M. Temminck observes that the Storks live in marshes, and feed principally on reptiles, frogs and their spawn, as well as fishes, small mammiferous animals, and young birds. They are, in all the countries of the world where they occur, a privileged race, on account of their utility and of the havoc they make among noxious animals. Their migration takes place in great flocks; they are easily tamed. The moult is autumnal. The sexes do not differ. All the species make a clattering noise with their bills.

The species best known are the White Stork, *Ciconia alba*, and the Black Stork, *Ciconia nigra*. We select the former as an example of that part of the genus which consists of the Storks properly so called.

The White or Common Stork is the Πελαργός of Aristotle and the Greeks; *Ciconia* of the Antient Italians;

Cicogna, Cicogna Bianca and *Zigognia* of the Modern Italians; *Cicogne* and *Cigogne Blanche* of the French; and *Weisser Storch* of the Germans.



Ciconia alba. Common Stork.

Description.—*Bill* straight, smooth naked skin of the cheeks very small, and not communicating with the bill; *plumage white*. *Head, neck*, and all the parts of the body pure white; *scapulars* and *wings* black; *bill* and *feet* red; naked skin around the eyes black; *iris* brown. Length 3 feet 5 or 6 inches.

Young.—The tarnished black of the wings is tinged with brown in the young birds, and the bill of a reddish black.

Habits, Food, Reproduction, &c.—Assured by the kindness with which it is treated in requital for its services in clearing the land of dead as well as living nuisances, the White Stork approaches the dwellings of man without fear. In Holland and Germany especially the bird is treated as a welcome guest, and there, as indeed elsewhere, it annually returns to the nest which has cradled many generations on the steeple, on the turret, on the false chimney that the Hollander has erected for its site, in the box, or on the platform which the German has placed for its use. The stump of a decayed tree is sometimes chosen by the bird, and the nest is made of sticks and twigs, on which are laid from three to five cream-coloured or yellowish-white eggs, about the size of those of a goose. The incubation continues for a month, at the expiration of which period the young are hatched and carefully attended to by the parents until they are fully feathered and able to procure food for themselves. Frogs, lizards, snakes, and other reptiles, mice, moles, worms, insects, eels, the young of ducks and other waterfowl occasionally, and even partridges, according to M. Temminck, are devoured by these birds. In the Continental towns domesticated Storks which have been taken from the nest when young may be often seen parading about the markets, where they are kept as scavengers to clear the place of the entrails of fish and other offal, which they do to the satisfaction of their employers.

Geographical Distribution.—The arrival of the Stork in Europe takes place in the spring. In Seville it is very common; but, according to the Prince of Musignano, it is very rare and only an accidental visiter near Rome. Though so common in Holland, it very rarely arrives in Britain. The general drainage of our marshes may have something to do with this, but is hardly sufficient to account for so striking a difference in the migratory distribution of the bird, more especially as it proceeds to higher latitudes; for it regularly visits Sweden and the north of Russia, and breeds there. The winter is passed by the bird in the more genial climates of Asia, and in the northern part of Africa, Egypt especially. Those who have seen these birds in the act of migration, speak of their numbers as very large: thus Belon remarks, that the Storks are never seen in flocks, except when they are in the air; and he relates how, being at Abydos, in the month of August, a great flight of storks came from the north, and when they reached the commencement of the Mediterranean Sea they there made many circuitous turns, and then dispersed into smaller companies. When Dr. Shaw was journeying over Mount Carmel he saw the annual migration of those which had quitted Egypt; and he states that each of the flocks was half a mile in breadth, and occupied three hours in passing over.

Utility to Man.—The utility of this bird to man in clearing away noxious animals and filth has given it a claim to protection that has rendered it quite at its ease in his presence wherever that protection has been afforded.

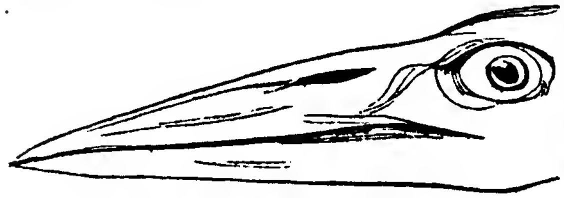
M. Temminck remarks that all those gigantic species of foreign storks arranged by systematists under the name of *Mycteria*, have the same external characters with the European Storks, the same manners and the same habits, and he further refers to the fact that Illiger in his 'Prodromus' has given his opinion that the genera *Mycteria* and *Ciconia* ought to be united.

Mr. Selby, after giving the characters of the genus *Ciconia*, says, 'My readers will observe that these generic characters are not applicable to all the species of the genus *Ciconia* of Bechstein, Cuvier, Temminck, and Wagler, but only to that group of which *Ciconia alba* may be considered the type. The larger species, viz. *Ciconia Marabou, Argala, Mycteria*, &c., seem to me possessed of characters sufficiently distinct to warrant such a separation, a fact indeed admitted by the necessity under which these authors have found themselves of subdividing their genus into sections.'

Of these, the three gigantic species of Stork remarkable for the comparative nakedness of the head and neck, a kind of pouch which hangs externally in front of the neck and a sort of vesicular apparatus or portion of skin at the back of the neck which can be inflated by the bird, and the greater enlargement of the bill, deserve especial notice. These extraordinary and uncouth-looking birds are natives of Africa and the eastern parts of Asia, and have only been known to modern naturalists within the last forty or fifty years.

Ives in his voyage to India (1773) made known a gigantic grallatorial bird from which Dr. Latham described the Adjutant of the British residents at Calcutta (the Argala of the natives), with the name of the Gigantic Crane. At the same time he noticed the observations made by Smeathman the African traveller, on the habits of a bird seen by the latter on the western coast of that quarter of the globe. Gmelin upon this information founded a species, *Ardea dubia*, and Latham, who had figured the bird, and related some additional particulars of its habits in the first supplement to his 'Synopsis' (1787), changed the name in his 'Index Ornithologicus' to Ardea Argala. Mr. Bennett, who adverts to these points, proceeds thus: 'Mr. Marsden, in his "History of Sumatra," makes mention of a bird, called by the natives of that island Boorong-Cambing, or Boorong-Oolar, which was generally believed to be of the same species with the Adjutant of Bengal. Dr. Horsfield however, in a paper published in the thirteenth volume of the "Linnæan Transactions," separates a Javanese bird, which is probably the same with the Sumatran, as a distinct species. Subsequently M. Temminck, in his "Planches Coloriées," has shown that the African species differs in several essential particulars from that of the continent of India, and still more remarkably from that of Java and the neighbouring islands. By his figures of the three species, all taken from living specimens, he has so clearly determined their characters that it is scarcely possible they should ever again be confounded. In one point however he has himself given rise to a different kind of confusion, that of their nomenclature. They all furnish, in more or less perfection, the beautiful plumes, superior in estimation even to those of the ostrich, known by the name of Marabous, from their appellation in Senegal. But those of the Indian species being far superior to the others, M. Temminck has thought fit to transfer to that bird the name of *Ciconia Marabou*, and to rob it of its native appellation *Argala*, which he has bestowed upon the African. The consequence of this perversion of their native names has been such as might have been expected. In the late edition of his "Règne Animal," M. Cuvier quotes the *Ciconia Marabou* of Temminck, with the characters of the Indian bird, as a native of Senegal; while he states the *Ciconia Argala* of the same author, to which he attributes the characters of the African species, to be brought from India. Nothing could more strongly evince the necessity of restoring, as Mr. Vigors had previously done, in the appendix to Major Denham's "Travels in Africa," the name of *Argala* to the Indian, and that of *Marabou* to the African species.'

We shall illustrate this group by *Ciconia Marabou*, Vigors.



Bill of African Gigantic Stork. Ciconia Marabou.

Description of the African Marabou, and differences between that species and the Indian Argala.—M. Temminck has clearly pointed out the differences between these two species. The *African Marabou* is less in size than the *Indian Argala*, the latter sometimes reaching six or even seven feet in height, while the former seldom exceeds five, even when the neck is elongated. The bill of the *Argala* is enlarged in the middle, the culmen of the upper mandible and the edges of the lower form a curved line from the base to the apex; in the *Marabou* the lines are straight and the bill is regularly conical: the nostrils of the Indian bird are ovate; those of the African species are oblong. The iris of the former approaches to pure white; that of the latter is dull-brown. The cervical or sternal pouch often hangs down more than a foot in the *Argala*; in the *Marabou* it is much shorter. The back and wings of the *Argala* are dull-black; in the *Marabou* there is a greenish tinge on the black of the back, with the exception of the larger wing-coverts and secondaries, which are of a more decided black, edged more or less broadly and distinctly, according to the age of the individual, with pure white bands. In the young birds these last distinctions are imperceptible. In both species the bill is inclined to livid yellow in colour, and is more or less spotted with black towards the base, as is the head, which is dusky. When the bird is at rest the pouch as well as the neck are of a pale flesh-colour, but when it is excited they acquire a redder tinge. These parts are sparingly covered with a few scattered brownish hairs, most numerous in the young birds, and resembling down in the early stages of its growth. The tail is black; the under parts pure white, more especially the under tail coverts, which afford the beautiful plumes. These are sometimes of a greyish-slate colour in the Indian species; but the white of the African feathers is not so clear and brilliant as that of the Indian plumes, to which a decided and just preference is given. The natural colour of the legs is dusky-black, but in living birds these limbs are generally whitened by the dust shaken out of the plumage and other excrement.

African Gigantic Stork, or Crane Ciconia Marabou.

Geographical Distribution of the African species, or Marabou.—Nearly the whole of Tropical Africa to the Cape of Good Hope, where it is not common. (Temminck.) Banks of the Nile. (Rüppell.) Neighbourhood of the large towns of the interior. (Denham.) Western coast. (Smeathman.)

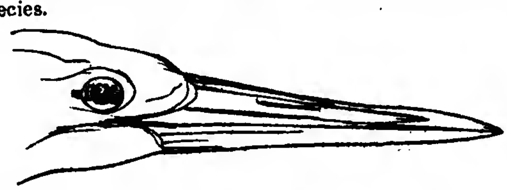
Habits, Food, &c.—Nearly resembling those of the White Stork, like which, it is privileged on account of its utility as a scavenger in freeing the villages and towns of offensive substances, like its Indian congener. Its omnivorous voracity is well described by Denham. Where carrion and filth are scarce, reptiles, small birds, and small quadrupeds fall victims to its appetite. These are usually swallowed entire. Smeathman gave to Dr. Latham an anecdote of a domesticated individual which roosted very high among the silk-cotton trees and would descry the servants bringing the dishes to the dinner-table from a distance of two or three miles from its perch. It stood behind its master's chair waiting to be fed, and occasionally helped itself, notwithstanding the guardianship of the servants who carried switches to prevent its snatching the meat, which it nevertheless sometimes contrived to do: in this way it had been known to swallow a boiled fowl at a single mouthful. Besides the pouch the skin at the back of the neck can be inflated so as to have somewhat the appearance of a counterpoise to the former. When the sun is shining upon the bird, we have observed this latter pouch, if pouch it may be called, very prominent, apparently from the rarefaction of the air. The bird flies high and roosts high, probably for the purpose of taking in a large area of observation to enable it to perceive those objects on which its feeds. May not these pouches assist, balloon-like, in supporting or balancing the great head and bill?

CRANES.

We now come to a subfamily whose food is much more vegetable than that of any of the others which we have noticed; and there is, as might be expected, a conformable change in the structure of the bill and stomach.

Grus (Pallas).

Generic Character.—*Bill* of the length of the head or rather longer, strong, straight, compressed, the point in the form of an elongated cone, obtuse towards the end; lateral base of the mandible deeply channelled; base of the bill elevated. *Nostrils* in the middle of the bill, pierced through and through in the groove, and closed backwards by a membrane. *Region of the eyes* and base of the bill often naked, or covered with warty excrescences (mamelons). *Feet* long and strong, a large naked space above the knee; three anterior *toes*, the middle one united to the external by a rudiment of a membrane, interior toe divided, posterior toe articulated higher on the tarsus. *Wings* moderate; first *quill* shorter than the second, which last is nearly as long as the third, and that is the longest; *secondaries* nearest to the body arched, or very long and subulate in some foreign species.



Bill of Common Crane.

In the greater part of the species the trachea of the male forms circumvolutions upon itself; in the other similar sinuosities occur in both sexes, which do not differ in external appearance. Moult once in the year. (Temminck).

Example, *Grus Cinerea*.

Description.—General *plumage* ashy grey; throat, front of the neck, and occiput very deep blackish grey. *Forehead* and space between the eye and the bill furnished with black hairs; top of the *head* naked and red. Some of the *secondaries* arched, longer, and loose-barbed. *Bill* greenish black, horn-coloured towards the point, and reddish at the base; *iris* red brown. *Feet* black. Length from the bill to the end of the tail, 3 feet 8 or 10 inches.

Old Birds.—These have a large whitish space behind the eyes and along the lateral part of the upper portion of the neck.

Young Birds before their second autumnal moult.—No nakedness on the top of the head, or the space hardly visible. The blackish ash colour of the front of the neck and occiput non-existent or only indicated by longitudinal spots.

This is the Γέρανος (Geranus) of the Greeks; *Grus* of the Antient Italians; *Grue* and *Grua* of the Modern Italians; *Grue* of the French; *Grulla* of the Spanish; *Kranich* and *Aschgrauer Kranich* of the Germans; *Trane* of the Danes; *Goran* of the Antient British; and *Crane* and *Common Crane* of the Moderns.

Habits, Food, Reproduction, &c.—The habits of the Crane are migratory and gregarious. Mr. Selby remarks that in its contour and gait it bears a considerable resemblance to some of the *Struthionidæ*, and that we are reminded of the ostrich by the long flowing plumes that overhang the tail. He is of opinion that through this and other families its affinity to the Rasorial birds is readily traced; and he observes that in its internal conformation it differs very essentially from the more typical families of the *Grallatores*, and that its strong and muscular stomach indicates a different general economy from that of the *Ardeidæ*. This is quite true; but whilst the Crane frequents open and cultivated lands for the sake of the newly sown corn and seeds to be found in such tracts, it is far from averse to small testaceous mollusks, worms, frogs, and other reptiles. Temminck says that the nest is placed among the rushes, &c., and sometimes on the walls of isolated houses. The pale bluish-green eggs, marked with brown, are two in number.

Grus cinerea. Common Crane.

Geographical Distribution.—Temminck states that this crane inhabits the marshy plains of the Oriental countries; that it is common in the north, migrates regularly in spring and autumn, is rare in its passage in Holland, and only in very severe winters. Asia is one of the tracts of country much frequented by it. Dr. Von Siebold notices it in his list of birds killed at Japan. Mr. Selby states that its equatorial migrations extend to India, Egypt, and other warm parts of Asia and Africa, but that it retires in summer to the northern and eastern parts of Europe to breed. The migrations are performed high in the air, and the progress of the flock may be traced by the loud cries of the birds when they are beyond the reach of sight. The night-time is frequently chosen for these changes of locality. The Prince of Musignano notes it as very rare and accidental near Rome; Willughby however saw many of them in the poulterers' shops in winter. But it is in England that the alteration of the country by drainage and enclosure has caused perhaps the most remarkable absence of these fine birds. They were numerous in the time of our ancestors, and highly esteemed by them, both as objects of sport and as furnishing a dish fit for the table of princes. By 25 H. VIII., c. 11, confirmed by 3 & 4 Edw. VI., c. 7, twenty pence was the forfeiture for each egg of the crane taken and destroyed. Willughby says, 'They come often to us in England; and in the fen countries in Lincolnshire and Cambridgeshire there are great flocks of them; but whether or no they breed in England (as Aldrovandus writes he was told by a certain Englishman, who said he had often seen their young ones), I cannot certainly determine, either from my own knowledge or from the relation of any credible person.' In Pennant's time he had come to the conclusion that the Cranes had forsaken our island. 'A single bird,' says he, 'was killed near Cambridge, about three years ago, and is the only instance I ever knew of the Crane being seen in this island in our time.' Dr. Latham mentions only four instances as occurring within his memory of the Crane having been met with in England. (Pennant, *Brit. Zool.*, 1812.) Montagu and Dr. Fleming mention a small flock that visited Zetland in 1807, and Mr. Selby received information of one killed in Oxfordshire, in December, 1830. The Crane can now be only regarded as an accidental and rare visitant to our islands.

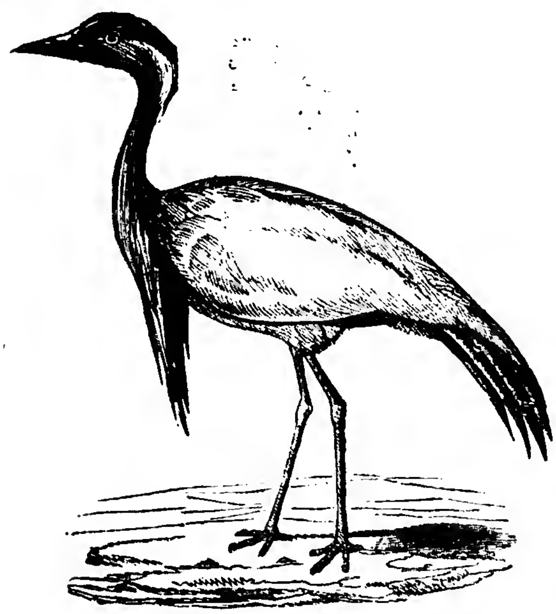
Utility to Man.—'The flesh is very savoury and well tasted, not to say delicate' (Willughby), and indeed it seems to have been highly prized in former days. At the 'intronazation of George Nevell, the archbishop above alluded to, 204 Cranes were served, and in the Northumberland Household-book the price of the Crane (Cranys) is marked sixteen pence. At the marriage-feasts also above mentioned, one of the items in the first is '9 Cranes, every Crane three shillings and four pence;' and in the second we find 'Item for a Standert, Cranes 2 of a dish' for the second course; and in the expenses we find 'Item, in Cranes 9.. £0 30s. 0d.' The long drooping feathers are valuable as plumes.

Anthropoïdes. (Vieillot.)

Mr. Bennett remarks (*Gardens and Menagerie of the Zoological Society*) that the name of *Anthropoïdes*, conferred upon this genus by its founder, M. Vieillot, owes its origin to a mistaken reading of a passage in Athenæus, which the French academicians of the seventeenth century improperly applied to the Demoiselle, or Numidian Crane, regarding the resemblance to man implied by the term *Anthropoïdes* as a convincing proof that the *Otus* of the Greeks was a synonym of the bird, which they were themselves describing under the name of Demoiselle, from its elegant attitudes. 'It is difficult however,' says Mr. Bennett, 'to conceive how these learned men, with Mr. Perrault at their head, could have stumbled on so gross a misapprehension; for the passages cited by them from the Greek and Roman authors prove beyond all question that the *Scops* and *Otus* of the former and the *Asio* of the latter were in truth nothing else than owls, and had consequently no connexion with the Numidian Crane. M. Savigny, on the other hand, refers the latter bird to the *Crex* of Aristotle and other classical authors; but we must confess that we entertain considerable doubt of this opinion also. The scattered notices of the antient *Crex* appear to us by far too scanty and indefinite to admit of their positive appropriation; and they combine moreover several traits which are quite irreconcilable with the identity of the two animals. With the exception of this distinguished naturalist, almost all the modern authors who have spoken of the Demoiselle have merely copied Buffon, who with singular inconsistency, at the same time that he corrects the error of synonymy into which the academicians had fallen, adopts all their quotations founded upon this very mistake. The truth is, that the real history of the bird cannot be traced with certainty beyond the period of M. Perrault's memoirs, in which it was for the first time described under the fanciful denomination which it has since attained.' We have given this passage entire, because the exemplary and industrious zoologist who penned it is, in our opinion, borne out in his observations, and because it conveys a good lesson of the danger of hastily appropriating Greek or Roman names to existing animals. Such an appropriation should never be made without the clearest evidence of the identity of the species. But however right Mr. Bennett may be, the term *Anthropoïdes* is now generally received by ornithologists as the generic appellation for certain species of cranes, and must be retained, the only question being what species should be arranged under it. The Demoiselle and the Balearic Crane were the only two species of *Anthropoïdes* (Vieillot), till a third and most elegant species, *Anthropoïdes*

Stanleyanus (Vigors), *Anthropoïdes Paradisæus* (Bechstein), was added. Mr. Vigors would include the whole of these three species in the genus; but Mr. Bennett remarks, that the discovery of that species, closely allied as it is to the Demoiselle, seems to determine the existence of that form as a distinct type, and to render it more necessary to isolate the Crowned or Balearic Crane, *Balearica pavonina*, *Ardea pavonina*, Linn., under another generic name, *Balearica* (Brisson).

The *Demoiselle* (*Anthropoïdes Virgo*, *Ardea Virgo* of Linnæus) is about 3 feet 6 inches high, measured to the top of the head: from the point of the bill to the tip of the tail it is about 3 feet in length. Upper part of the *head* light grey; sides of the *head*, *neck*, and *depending breast feathers*, blackish; head and neck fully feathered. A tuft of pure white loose-barbed feathers, three or four inches long, directed backwards with a curvature downwards behind each eye. General tint slaty-grey; outer portions of all the quill-feathers dingy-black. Secondaries longer than the primaries, forming when the wings are folded dependent downward-curved plumes. *Bill* yellowish or flesh-coloured; *iris* reddish-brown.



Demoiselle. Anthropoides Virgo.

Habits, Food, &c.—The habits of the Demoiselle are migratory, and its food consists in great measure of grain and seeds, though it occasionally takes small fishes, mollusks, and insects. Gizzard muscular. The Demoiselle produced young in the menagerie at Versailles, and one which was hatched and bred there lived twenty-four years.

Geographical Distribution.—Africa. It has been observed in the north, along the Mediterranean, the west from Egypt to Guinea, in the interior, and in the south near the Cape of Good Hope. It has been killed in Nepaul, according to Mr. Gould; is found on the southern coasts of the Black Sea and Caspian, and has been observed at Lake Baikal. It is occasionally seen in Europe, and appears about Constantinople in October. At the inundation of the Nile great numbers arrive in Egypt.

The Stanley Crane, *Anthropoïdes Stanleyanus* (so named by Mr. Vigors in honour of the earl of Derby, then Lord Stanley, President of the Zoological Society of London), *Anthropoïdes Paradisæus* of Bechstein, is in its general plumage bluish-grey, the top of the tumid head, which is well covered with soft feathers, is whitish, and there is a brownish post-ocular band; the irides are chestnut-black, and the points of the quills, tail, &c., are brownish-black. Length from the tip of the bill to the end of the tail 3 feet 6 inches. Mr. Vigors mentions particularly the greater length and development of the *hallux* in this species, in which character, he observes, the bird seems to be intermediate between *Anthropoïdes Virgo* and the more typical *Gruidæ*. He considers the Balearic Crane as according with this species in this particular, and by the additional character of the naked cheeks and caruncle under the chin, as exhibiting a still nearer approach to the true *Grus Anthropoïdes Virgo*, on the other hand, by the slight development of the *hallux*, appears to him to possess the nearest affinity of all the birds in the group to the *Charadriadæ*.

Stanley Crane. Anthropoides Paradisæus (Bechstein).

Habits, &c.—'In manners and gestures,' says Mr. Vigors, 'the *Anthropoïdes Stanleyanus* appears to conform most intimately with the *Demoiselle*, displaying the same delicacy and elegance of attitude, and the same majesty, together with the same graceful playfulness in all its movements. I once had the good fortune to see it when released from the place of its confinement and set at liberty into an adjoining yard; and it was scarcely possible to witness a scene of more grace and animation. The bird, when after a few movements it felt itself free, bounded into the air, and traversed the yard with singular velocity, and a peculiarity of motion which could neither be termed running nor flying with its wings expanded, and its long quill-feathers streaming just above the ground, it sailed and swept along the open space, without regard to the numerous spectators who watched its movements, luxuriating in all the buoyancy and excursiveness of new-felt liberty. I understand that it is particularly eager in its pursuit after insects, which it takes when they are upon the wing; and that they seem to be its natural and most acceptable food. We may readily conceive what myriads of winged creatures it would encircle within its wings as it swept along its native marshes, in the manner observed above, and which it would thus bring within the compass of its prey.' (*Zool. Journ.*, vol. ii.)

Locality.—East Indies.

The Balearic or Crowned Crane (*Anthropoïdes pavoninus* of Vieillot and others; *Balearica pavonina* of Brisson and others; *Ardea pavonina* of Linnæus) received its English and French common name from its being supposed to be the Balearic Crane of the antients. Its height when full grown is about four feet. We select Mr. Bennett's description: 'Its plumage is of a bluish-slate colour on the neck and on both surfaces of the body; the quill-feathers of the tail and the primaries of the wings are of a beautiful black; the secondaries, which extend beyond the base of the tail, of a bright and glossy brown; and the wing-coverts pure white. The cheeks and temples are entirely naked, and are coloured of a bright rosy red, which sometimes over spreads the whole of the naked surface, and sometimes is confined to a portion of it, the remainder in this latter case becoming perfectly colourless and of a dull white. Beneath the upper part of the throat a similar naked space is gradually developed, which terminates in a dependent fold of the skin, like the wattle of a turkey, but more uniform on its surface, and of a brilliant red. As this prolongation is not always met with, it has been considered by some writers as a mark of sex; but of the two birds examined by the

French academicians, the one possessed it and the other not, and yet both were females: it may therefore with greater probability be considered as the result of age. The fore part of the head is covered by a close tuft of short, smooth, even, velvety feathers of a deep black; and behind these rises a very remarkable crest, consisting of a large number of flat yellowish filaments, each twisted spirally on itself, fringed along its edges with a series of black-pointed hairs, and terminating in a blackish pencil. These filaments are of nearly uniform length, and measure four or five inches from base to tip. They take their origin from a roundish space on the back of tho head, and expand equally at their extremities into a circle of considerably larger diameter than the head itself. The bill, legs, and feet are of a dusky black; and the iris is remarkable for being almost destitute of colour. As in most of the birds of this family, the feathers of the lower part of the neck are long, narrow, and gracefully dependent over the breast.'

This description is so good in the main that we have given it in the author's own words; but his observations with regard to the wattle require observation. Indeed, he himself, as secretary to the Zoological Society, subsequently (1833) brought under tho notice of a meeting of its members specimens, from the Society's museum, of Crowned Cranes from Northern and from Southern Africa, with the view of illustrating the characters which distinguish as species the birds from those several localities. Their specific distinction, he stated, on the authority of Professor Lichtenstein, had been pointed out, nearly thirty years from that timo, by the Professor's father, who gave to the Cape bird the name of *Grus Regulorum.* This distinction had not however, Mr. Bennett remarks, been generally known among ornithologists, although to those connected with the Society it had for some time been familiar, from observation both of numerous skins and of living individuals. In the bird of North Africa, for which the specific name of Pavoninus will be retained, the wattlo is small, and there is much red occupying tho lower two-thirds of the naked checks: in that of South Africa the wattle is large, and the cheeks are white, except in a small space at their upper part; the neck also is of a much paler slate-colour than that of the North African species. Mr. Bennett added that the latter characters had been observed to be permanent in an individual presented to the Society in April, 1829, from the collection of the late Marchioness of Londonderry, then still living at the Gardens. They existed also in both the individuals presented by Sir Lowry Cole.

Mr. Gray at the same time took occasion to remark that the oval form of the nostrils in the *Crowned Cranes,* added to other distinguishing characters which had frequently been pointed out, might be regarded as indicating a generic difference between them and the *Demoiselle* and *Stanley Cranes,* in which the nostrils have the lengthened form usual in the genus *Grus,* a genus from which they scarcely differ, except in the comparative shortness of their bill. For the group including the *Crowned Cranes* the name of *Balearica* might, he thought, be retained, and that of *Anthropoïdes* be appropriated to the one comprehending *Anthropoïdes Virgo,* Vieill., and *Anth. Paradisæus,* Bechst. (*Zool. Proc.,* 1833.)

The species with the small wattle and other differences will, according to this proposition, stand as *Balearica pavonina: Locality,* Northern and Western Africa. The species with the large wattle, &c., will stand as *Balearica Regulorum: Locality,* Southern Africa.

Habits, &c.—Presumed to be migratory; but little is known of them, except in captivity, to which the birds are easily reconciled, living in friendship with the domestic poultry, and other captives, and even, as we have heard, interfering to prevent disputes. In a stato of nature they are said to frequent swampy places, and to subsist partly upon fishes, worms, and insects, and partly on vegetable substances. They run with the wings expanded, and with great rapidity. Their note is loud, trumpet-like, and hoarse. In the catalogue to the African Museum, now (June, 1838) just coming to the hammer, one of the species, there called the *Kaffir Crane,* is said to be held sacred by the Kaffirs bordering upon the Cape colony; and if one should happen to be killed, even by accident, a calf or young cow must be slaughtered as an atonement. Mr. Swainson ('Classification of Birds') notices specimens of *Ardea pavonina,* Linn., as having been brought to him when in Malta, from the little island of Lampidosa, where, he says, they are by no means scarce.

Crowned Crane. Balearica.

Our English readers will find most of the birds above described living in the Gardens of the Zoological Society in the Regent's Park, together with many others of this great family. Among them there is a fine specimen of the gigantic *Indian* or *Sarrus Crane, Grus Antigone* of Linnæus

HERO'PHILUS, a native of Chalcedon, was one of the most celebrated physicians of the Alexandrian school, and lived in the reign of the first Ptolemy of Egypt. Of his works, which appear to have been very voluminous, nothing now remains except the extracts made from them by Galen and Cœlius Aurelianus, in which they are so interwoven with those of his contemporary Erasistratus, that it is impossible to say what portion of the progress which medicine made in their time was owing to the labours of each.

The chief feature which marks the time of Herophilus in the history of medicine is the commencement of the study of anatomy from dissections of tho human body, for which purpose the bodies of all malefactors were appropriated by the government. With such zeal did Herophilus pursue this science, that he is said to have dissected 700 subjects, and it was against him and Erasistratus that the very improbable charge was first made of having frequently opened living criminals that they might discover the secret springs of life. (Celsus, *Præfat.*) From tho peculiar advantages which the school of Alexandria presented by this authorised dissection of the human body, it gained, and for many centuries preserved, the first reputation for medical education, so that Ammianus Marcellinus, who lived about 650 years after its establishment, says that it was sufficient to secure credit to any physician if he could say that he had studied at Alexandria.

By the labours of Herophilus and Erasistratus nearly every part of the anatomy of the human body was rendered clearer, and many most important discoveries were made. They first determined that the nerves are not connected with the membranes which cover the brain, but with the brain itself, though as yet the distinction of tho nerves from the tendons and other white tissues had not been made out. The description which Herophilus gave of the brain itself was far superior to those of previous authors: he discovered the arachnoid membrane, and showed that it lined tho ventricles, which he supposed were the seat of the soul; and the chief meeting of the sinuses into which the veins of the brain pour their blood still bears the name of Torcular Herophili. He noticed the lacteals, though he was not aware of their use; he pointed out that the first division of the intestinal canal is never more than the breadth of twelve fingers in length, and from this fact proposed for it the name (duodenum) by which it is still called.

Herophilus practised surgery as well as medicine, but it is probable that very soon after his time the division of surgery and medicine into distinct professions took place. Of his knowledge of medical practice there is not sufficient evidence in the extracts which Galen makes from his works to enable us to form an accurate idea, and his fame must rest rather on the indirect assistance which he afforded by his anatomical researches, than on any immediate addition to the means of curing disease. He does not appear to have drawn many pathological conclusions from his knowledge of the healthy structure, but his observations on the pulse, of which his master Praxagoras had taught him some of the value as a means of discriminating diseases, were important and interesting; and it was he who first showed that paralysis is the result not of a vitiated state of the humours, as was previously imagined, but of an affection of the nervous system. Herophilus seems to have founded a school which took its name from him. According to Strabo (xii. p. 580) there was a great school (διδασκαλεῖον) of Herophilists in his time established in a temple between Laodiceia and Carura in Phrygia.

HERPES. The word herpes was employed in a very vague sense, and applied to many eruptions of different kinds, until restricted by Willan to a well-defined affection of the skin, characterised by the eruption of clusters of transparent globular vesicles, situated on a red and inflamed base extending some lines beyond them. The vesicles of each cluster commonly vary in size from a millet-seed to a very small pea; the clusters themselves are distinct, being separated by portions of perfectly healthy skin, and they generally rise in quick succession.

The eruption is preceded and accompanied by a degree of constitutional disturbance which generally varies with the extent of the local affection, being often slight and attracting no notice, when this is limited and consists of a few clusters only, but very great and marked by a high degree of fever, when the clusters are numerous and spread over an extensive surface in a young and plethoric subject.

The local affection is announced by a sensation of heat and tingling experienced in the part, and first appears as a small bright red spot, having in its centre a few very minute vesicles. These vesicles, which contain a transparent colourless fluid, rapidly enlarge, and, in the course of some hours, attain the size and present the form and aspect of very small pearls: in the thickest part of the cluster two or three of the vesicles coalesce, forming one of irregular figure and larger size. There is a sensation of pricking and smarting pain experienced in the part. The vesicles gradually become opaque, in the course of a few days shrivel, and are succeeded by brownish scabs: the heat and irritation of the portion of skin on which they are situated subside; and the scabs fall off, leaving a tender and reddened state of the skin, which soon disappears. The duration of the individual clusters, from their first appearance to the falling off of the scabs, varies from one to two weeks. When there is a succession of clusters, they all follow the same march; the febrile state persists as long as fresh vesicles continue to arise, and the affection may be prolonged to three or four weeks. In some cases the fluid is absorbed, the vesicles shrivel, and, at the end of four or five days the affection terminates in desquamation; in others, the fluid in the vesicles becomes purulent, and they are succeeded, especially when seated on the back, by superficial ulcerations, which prolong considerably the duration of the disease.

The clusters of vesicles, though they retain in all cases the same characters, and follow nearly the same march, are sometimes confined to a particular locality, justifying the designation, *H. labialis*, *H. præputialis*, or assume a particular arrangement, giving rise to the varieties, *Herpes zoster*, when they are situated on one half of the body and extend in a line or band; *H. phlyctenodes*, when they are disseminated; and *H. circinnatus*, when they occur in circles or rings

In *H. labialis* the clusters are disposed irregularly about the mouth, generally on the external surface of the lips, in some cases extending to the cheeks and alæ nasi, and in rare instances occurring also in the pharynx. It occasionally comes on after irregularities in diet, or unusual exposure to cold winds, or to the atmosphere, as in travelling; at the termination of the hot stage, in ague; and during the course of catarrhal fevers and pneumonia. It is always a slight affection in itself, requiring no treatment beyond that of the disorder which it accompanies.

Herpes præputialis. In this variety there are one or more small clusters of vesicles, either on the external or internal surface of the prepuce. When situated externally, they follow the ordinary march or terminate in desquamation, and require no treatment, with the exception of the application of lint soaked in the lotion of acetate of lead, for the purpose of alleviating the itching and preventing the rupture of the vesicles and the consequent formation of an ulcer. When they occur on the internal surface of the prepuce, the vesicles are kept continually moist, break at the end of four or five days, and often give rise to an excoriation or superficial ulceration, which by an inattentive observer may be mistaken for a syphilitic sore. It soon heals under the influence of cleanliness, the local application of the lead lotion, and the administration of a few alteratives.

In *Herpes zoster*, familiarly known by the name of shingles, there is a succession of clusters of white silvery vesicles, forming an oblique line or band, limited to one-half of the body, and almost always occurring on the trunk. It is generally ushered in by severe febrile symptoms, and by smarting or deeply-seated pains, which indicate the future course of the eruption. Each cluster follows the march we have described, and the febrile state continues as long as there is a succession of vesicles. It is unattended with danger, excepting in old persons, where the clusters are occasionally followed by gangrenous and sloughy sores. In young and plethoric subjects the treatment should consist of bleeding, saline purgatives, diet, and the application to the part of a sedative lotion. This treatment alleviates the sufferings of the patient, but has very little influence on the march of the vesicles. Mr. Plumbe says, 'If care be taken to puncture each vesicle early, so as to allow the free escape of the fluid, the pain is much diminished, and the irritation sooner subsides.' In old persons, care should be taken that they do not lie on the affected side.

Herpes phlyctenodes differs from the preceding variety in the arrangement of the clusters, which are disseminated, and have no particular seat. When occurring extensively, the vesicles do not attain the size common to more limited forms of the eruption. It is often met with in children during dentition.

In *Herpes circinnatus*, or herpetic ringworm, the eruption is limited in extent, frequently of a circular form, and consists of extremely minute vesicles, which dry up and terminate in exfoliation, leaving a scurfy areola. It occurs frequently on the cheeks in children and in women of delicate complexion, and is often confounded with a disease entirely different in its nature, contagious, and also, in popular language, denominated ringworm. This form of Herpes soon disappears under the influence of the local application of almost any astringent solution.

None of the varieties of Herpes are contagious, and all occur most frequently in the young, during spring and autumn, and in warm climates.

The existence of distinct groups of vesicles on red and inflamed bases is sufficient to distinguish Herpes from every other cutaneous affection.

HERPESTES. [ICHNEUMON.]

HERPETO'LOGY, that branch of science which treats of the organization, natural history, and arrangement of *reptiles*. The term, literally construed, means a discourse upon reptiles, from 'Ερπετόν (Herpeton) a reptile, and Λόγος (Logos) a discourse. [REPTILE.]

HERRE'RA, FRANCISCO DE, surnamed *El Viejo* (the Elder), was born at Seville, 1576. He was one of the most eminent of the Spanish painters of the school of Seville. He excelled both in design and colouring, and though his execution was decided and rapid, his works will bear the test of minute investigation. Among his best works are the Last Judgment in the church of St. Barnard, the Descent from the Cross and the Effusion of the Holy Ghost, in the church of S. Ines, and, in fresco, the cupola of S. Bonaventura; all at Seville. His easel pictures, mostly representing subjects of common life, kitchens, alehouses, inns, &c., are admirable, and fetch high prices. He also worked in bronze, and has left some etchings. In 1647 he completed his works in the episcopal palace at Seville, and went, in 1650, to Madrid, where he died, some say, in the same year; others in 1656.

HERRE'RA, FRANCISCO DE, the Younger (*El*

Mozo), painter and architect, son of the preceding, inherited his father's talents. The father being a man of a tyrannical disposition, his son left him, and went to Rome to pursue his studies. After his father's death he returned to Seville, and painted for the churches. An academy being established in 1660, he was made sub-director; but being too proud to brook the superior authority of Murillo, he went to Madrid, where he rivalled the most eminent artists. He painted both in oil and fresco. His frescoes in the chapel of St. Philip so pleased King Philip IV., that he commissioned him to paint the chapel of the Madonna de Atocha, where he painted the Assumption of the Virgin. This and other works procured him the honour of principal painter to the king, and superintendant of the royal edifices. He died in 1685, aged 63.

HERRE'RA, ANTONIO, Coronista mayor de las Indias y Castilla, born at Cuellar, 1549, died at Madrid on the 19th March, 1625. He is extolled by Robertson (*Hist. of Amer.*, h. v., note 70), and many other distinguished writers. Quintana (*Vida de Pizarro*, appendice vii.) points out some inaccuracies, which however he extenuates as unavoidable in that work, the chief and still the best source of information which Herrera left for subsequent writers on American history from 1492 to 1554. The first and now rare edition of that laborious performance bears the title of 'Historia General de los Hechos de los Castellanos en las Islas y Tierra Firma del Mar Oceano, en 8 décadas,' 4 vols. fol., Madrid, 1601. A second edition, that of Antwerp, 4 vols. fol., 1728, is very incorrect. A highly-improved edition, with corrections and additions, is entitled 'Descripcion de las Indias Occidentales,' 4 vols. fol., Madrid, 1730. Barlæus published this history in his 'Novus Orbis,' 1622; and Nicolas Coste, in his 'Histoire Générale des Voyages des Castillans,' 1659; and Captain Stevens, in his 'History of America,' 1725. The rarest perhaps of several other politico-historical works of Herrera is entitled 'Historia de lo Sucedido en Escocia y Inglaterra en 44 años que vivió Maria Estuarda,' 8vo., Madrid, 1589, and 8vo., Lisbon, 1590. (Nicolaus Antonius, *Biblioth. Hispa. Nova; Allgemeine Encyclopädie*, von Hassel und Hoffman; and Brunet, *Manuel du Libraire.*)

HERRERA, FERNANDO, a native of Seville, lived in the sixteenth century, the golden age of Spanish poetry, among the reformers of which he was prominent. He won the admiration of his contemporaries, who prefixed to his name the epithet of Divine. Inspired by Pindar, he became the first classical ode writer in modern Europe; and however severely he may be judged by Bouterwek, the Allgemeine Encyclopädie, in Lardner's Cyclopædia, or by any other critics, his odes on the battle of Lepanto are worthy of his Greek model, and equal to those of Horace. Indeed Bouterwek himself acknowledges this, and moreover bestows just and high commendation on his 'Ode to Sleep.' An attempt so congenial to Herrera's aspirations, and to those of his age—that of elevating his native poetry to the level of the Greek and Roman—led Herrera to overstrain the powers of his own language by the adoption of antique modes of expression, which the learned of that age endeavoured to establish as the sole expressions of the beautiful and the sublime.

It was chiefly to inculcate these principles, or to foster a corresponding taste, that Herrera commented on Garcilaso, a practical way of developing a theory, which has been followed by a host of commentators.

An edition, now rare, of his poetical works appeared after his death under the title 'Obras en Verso de Hernando de Herrera,' Sevilla, 1582, 4to. Another equally raro is, 'Versos de Hernando de Herrera, emendados y divididos por él en 3 libros,' Sevilla, 1619, 4to.

Of his prose writings those remaining are, 'Relacion de la Guerra de Chipre, y Suceso de la Batalla de Lepanto,' Sevilla, 1572, 8vo.; and 'Vida y Muerte de Thomas Moro,' (translated from the Latin of Stapleton), Sevilla, 1592, 8vo., and Madrid, 1625, 8vo.

HERRERA, GABRIEL ALONSO, a native of Talavera, called the New Columella, lived in the second half of the fifteenth and the beginning of the next century. He was a professor at the university of Salamanca, and had from an early age a predilection for rural economy. Accordingly he collected the best information that he could derive from the antients, as well as from his travels at home and abroad, in a treatise which he published under the patronage of Cardinal Cisneros, with the title of 'Obra de Agricultura copilada de Diversos Autores,' Alcala, 1513, fol. (black letter) None of its 28 subsequent editions presented, according to Juan Iriarte, the original text; but this was restored at last by the Sociedad Económica Matritense, in their 'Agricultura General, corregida y adicionada,' Madr., 1818, 4 vols. 4to.

HERRICK, ROBERT, was born in the year 1591. Of his life few or no particulars are known, except that he was vicar of a parish called Dean Prior in Devonshire for the space of twenty years, was ejected by Cromwell and restored by Charles II., and long held in remembrance by his parishioners as a poet. His poems are of two very different kinds, sacred and love pieces; the latter often disgraced by indecency, but both exhibiting a richness of fancy mingled with the quaintness of the age in which he lived, such as to render him worthy of one of the highest places in the scale of British lyrical poets. His poems were published in 1647-8 under the title of 'Hesperides, or the Works, both Human and Divine, of Robert Herrick, Esq.' The 'Hesperides' have been reprinted in 2 vols. 4to. and 2 vols. sm. 8vo.; 'Select Poems,' 1 vol. sm. 8vo.; 'Poetical Works,' 2 vols. sm. 8vo.

(*Retrospective Review*, vol. v.; *Quarterly Review*, vol. iv)

HERRING. [CLUPEIDÆ.]

HERRING FISHERY. [FISHERIES.]

HERRNHUT, or HERRNHUTH, a small town in the Saxon province of Upper Lusatia, the original and principal seat of the Moravian brethren. It lies between Zittau and Lobau, on the southern declivity of the Hutberg, from which it has its name. It was founded in 1722 by Count Zinzendorf. The situation is pleasant, and the buildings, especially the house of the Brothers, and that of the Sisters, very neat. The inhabitants, about 1500 in number, are very simple and pious, and order and cleanliness prevail even among the poorest. [MORAVIANS.]

HERSCHEL, WILLIAM, frequently, but erroneously, written Herschell. The materials for the life of this singularly gifted man are but few, and those few not well authenticated. There is no need to say to what quarter the public should look for such an account of his life and labours as shall be worthy of the sagacious activity of the first, and the enormous extent and value of the second.

William Herschel was the second son of a musician at Hanover, and was born November 15, 1738. His father brought him up to his own profession, with four other of his sons, giving them at the same time a good education in other respects. At the age of fourteen, he was placed, it is said, in the band of the Hanoverian regiment of guards, which regiment he accompanied to England at a period which is variously stated from 1757 to 1759. Another account states that he came to England alone. After his arrival, he was for some time at Durham, where he is said to have superintended the formation of a band for the militia, and afterwards was for several years organist at Halifax, where he employed himself in teaching music and studying languages. There is a mass of stories relating to his musical occupations, none of which have any certain foundation, as—that he played in the Pump-room band at Bath—that upon the occasion of being a candidate for the situation of organist, he helped his performance by little bits of lead placed upon holding notes, which he dexterously removed in time—that in Italy, to procure money to pay his passage home, he gave a concert, at which he played at once upon a harp and two horns, one fastened to each shoulder—&c. The last story must be incorrect, as he never was in Italy; and, though much given to music, he never (latterly at least) played the French horn, or any other military instrument, but only the violin and organ; from which, as well as the vagueness of the accounts, it may be doubted whether his professional talents were ever employed in a band.

About 1766 he was organist of the Octagon chapel at Bath; in which place he began to turn his attention to astronomy. How well his talents suited that pursuit was afterwards seen, and his preliminary studies had been amply sufficient for the purpose. Though not a mathematician of the first order, his attainments in that science were more than respectable, and his power of applying his knowledge was, like that of Young, so great as to make it a source of regret that he did not pay special attention to the exact sciences. The earliest writing of Herschel which has come to our knowledge is the answer to the prize question in the 'Ladies' Diary' for 1779, proposed by Peter Puzzlem (a name which the celebrated Landen always adopted in his contributions to that work), namely 'The length, tension, and weight of a musical string being given, it is required to find how many vibrations it will make in a given time, when a small given weight is fastened to its middle and vibrates with it.'

His astronomical pursuits led him to desire a telescope, and as the purchase of a good reflector was 'fortunately' above his means, he resolved to make one for himself. After many trials he succeeded in making a Newtonian telescope of five feet focal length, and we find him before long not only in possession of adequate means, the work of his own hands, but employing those means with a true perception of the field in which his services were wanted, and a persevering determination to throw light upon our knowledge of the organization of the universe.

There are two great branches of astronomy; the first consisting of those investigations, theoretical and practical, by which the mighty clockwork of the heavens is made our measure of time, and our means of settling the relative positions of places on the earth, and of guiding a vessel from one port to another; the second consisting of inquiries, theoretical and practical, into those phenomena which guide us to such knowledge as we can obtain of the constitution of the heavenly bodies. The study of the science of optics, the improvement of telescopes, the application of sound reasoning to the collective phenomena pointed out by such instruments, and, subordinate to the last, a knowledge of the past history of observation, are the keys to the advance of this part of the science. Herschel devoted himself sedulously to every part of this task, and the consequence was success such as the world had never seen before, and a reputation of twofold splendour, appreciable in its different parts by men of the lowest as well as of the highest order of cultivation.

Herschel began to contribute to the Philosophical Transactions in 1780, and in 1781 announced to the world his discovery of a supposed comet, which soon turned out to be a new planet. [URANUS.] We have not here to describe the details of this discovery, the merit of which in itself is small. It is the method which gave rise to it on which this part of Herschel's fame must rest. Perceiving how much depended upon an exact knowledge of telescopic phenomena, and a perfect acquaintance with the effect produced by differences of instrumental construction, he commenced a regular examination of the heavens, taking the stars systematically in series, and using one telescope throughout. If an indifferent person were by accident to pick up a manuscript out of a large number lying in a library, and were to find it on examination to be a lost classic author, he would be entitled to praise, since it is not every one who would know what he had got hold of, even when the writing was in his hands; but if the same person were to make the same discovery while voluntarily engaged in the formation and classification of an immense catalogue requiring knowledge of antient and modern languages and literature, the credit due to the discovery would be very much increased. This case is analogous with that of Herschel, who was not a mere dilettante star-gazer, but a volunteer carrying on with no great pecuniary means a laborious and useful train of investigation.

The announcement of this comet or (as it turned out) planet drew Herschel immediately into the full blaze of fame; and George III. honoured his reign by immediately attaching the new astronomer to his court under the title of private astronomer to the king, and with a salary of 400*l.* a year. Herschel fixed his residence first at Datchet, and afterwards at Slough, near Windsor, and his abode became, as Fourier remarks, one of the remarkable spots of the civilized world. His family consisted at first of one of his brothers, and his sister, Miss Caroline Herschel, who was his coadjutor and assistant in his computations and reductions, and also actively employed in observation, having been, among other things, the discoverer of more than one comet. This lady retired to Hanover at the death of her brother, and is still alive, though much past eighty years of age.

Herschel married a widow lady, Mrs. Mary Pitt, and left one son, whose name has long been known to the public as one of the most active and successful adherents of science that our day has produced. We write this on the eve of the public dinner given to Sir John Herschel on his return from the Cape of Good Hope, where he has been for the last four years engaged in making a survey of the southern hemisphere similar to those which his father made of the northern. Amidst the gratification with which all who are interested in the progress of astronomy will regard this truly remarkable fête, it may suggest itself to some that the clear and powerful results of William Herschel's mind lie buried in the Philosophical Transactions, inaccessible to the larger portion of those who might learn from them to form a true taste in speculative astronomy and a true notion of the state of our knowledge of the fabric of the universe. A public subscription to defray the expense of reprinting all those writings would be a compliment worthy of the fame of both father and son, and of the sentiments with which the whole community regards the recent expedition of the one in continuation of the labours of the other.

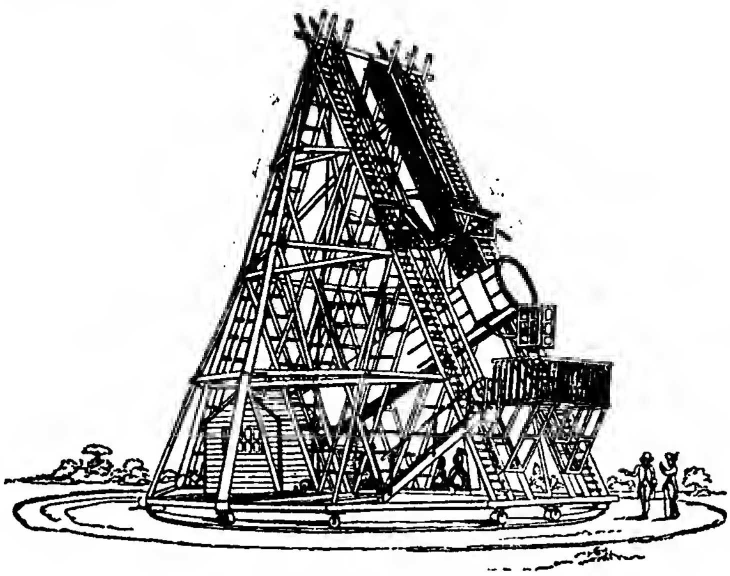
The deficiency of authentic information leaves us little more to say on the private life of Herschel. He was knighted, and received the degree of doctor of laws from the university of Oxford, but we cannot find the dates of either. He was soon in affluent circumstances, partly by the profits arising from the sale of his mirrors for reflecting telescopes, and partly by the jointure of his wife, which was considerable, and he died wealthy. His death took place on the 23rd of August, 1822.

Instead of giving any detailed account of Herschel's labours, we have preferred to extract the titles of his papers in the Philosophical Transactions, both because no words could give so good an idea of the unwearied activity of their author, and because many of the subjects are such as are well described by titles. It may also be useful to the astronomical reader to know in what volume and in what year the several communications were made. A few words therefore preceding this list will be all which its length will allow us to give.

Herschel must be remembered by the number of bodies which he added to the Solar system, making that number half as large again as he found it. Including Halley's comet, and the four satellites of Jupiter and five of Saturn, the number previously known was eighteen; to which he added nine, namely, Uranus and six satellites, and two satellites to Saturn. His discovery of the rotation of Saturn's ring, his measurements of the rotation of Saturn and Venus, his observations of the belts of the former, and his conjectural theory, derived from observation, of the rotation of Jupiter's satellites, with a large number of minor observations, prove that no one individual ever added so much to the facts on which our knowledge of the solar system is grounded. To this we must add, that his announcement (in 1803) of the motions of binary stars round each other was accompanied by the first proof that there exist in the universe organized systems besides our own; while his magnificent speculations on the Milky Way, the constitution of nebulæ, &c. &c., first opened the road to the conception that what was called the universe might be, and in all probability is, but a detached and minute portion of that interminable series of similar formations which ought to bear the name. [MILKY WAY; NEBULÆ; STARS, DOUBLE, &c.] Imagination roves with ease upon such subjects; but even that daring faculty would have rejected the ideas which, after Herschel's observations, became sober philosophy. On matters of detail the views of Herschel are beyond enumeration in an article like the present; the list given below will furnish some notion of them.

The instrument by which this great work was achieved was the reflecting telescope, the second reflecting surface which is found in the constructions of Newton, Gregory, and Cassegrain having been rejected, and the eye-piece applied directly to the image produced from the large mirror, which is the distinguishing feature of the Herschelian telescope. Herschel had constructed more than one such instrument of 20 feet focal length before he attempted the enormous one of 40 feet, the apparatus for supporting and directing which strikes the eye of the traveller in passing through Slough. This instrument was begun in 1785, and Herschel dates the completion from August 28, 1789, on which day he discovered with it the sixth satellite of Saturn.

The catalogues of double stars, nebulæ, &c., and of the comparative brightness of stars, would alone constitute a title to the name of a distinguished astronomer; and the optical researches, with those on the refrangibility of heat, are highly valuable; while the papers on the power of telescopes should be read by all who wish to understand those instruments. But we have no further room for specification, and shall therefore proceed at once to the list of Herschel's labours, observing that though no well authenticated account of his private character has appeared, the testimony of many now living has been given to the rectitude of his conduct and the goodness of his heart.



Herschel's great telescope at Slough.

List of Sir William Herschel's Papers in the Philosophical Transactions, specifying the year and volume in which each appeared.

1780, vol. 70. Astronomical observations on the Periodical Star in Collo Ceti. In his abridgment of the Phil. Trans., Dr. Hutton adds the following note to this title of Herschel's first memoir: 'See some authentic memoirs of this extraordinary character in the European Magazine for January, 1785.'

1780, vol. 70. Astronomical observations relating to the Mountains of the Moon.

1781, vol. 71. Astronomical observations on the rotations of the planets round their axes, made with a view to determine whether the earth's rotation is perfectly equable.

1781, vol. 71. Account of a Comet. This supposed comet was afterwards found to be the planet now called Uranus [URANUS], discovered on Tuesday the 13th of March, between 10 and 11 in the evening.

1781, vol. 71. Description of a Micrometer for taking the angle of position.

1782, vol. 72. On the Parallax of the fixed Stars.

1782, vol. 72. Catalogue of double Stars (containing 269 stars).

1782, vol. 72. Description of a Lamp Micrometer and the method of using it.

1782, vol. 72. A paper to obviate some doubts concerning the great magnifying powers used.

1783, vol. 73. On the name of the new Planet. Herschel called it Georgium Sidus, 'as an appellation which will conveniently convey the time and country where and when it was brought to view.'

1783, vol. 73. On the diameter and magnitude of the Georgium Sidus, with a description of the dark and lucid disc and periphery micrometers.

1783, vol. 73. On the proper motion of the Sun and Solar system, with an account of several changes that have happened among the fixed stars since the time of Mr. Flamsteed.

1784, vol. 74. On the remarkable appearances at the polar regions of the planet Mars, the inclination of its axis, the position of its poles, and its spheroidical figure; with a few hints relating to its real diameter and atmosphere.

1784, vol. 74. Of some observations tending to investigate the construction of the heavens.

1785, vol. 75. Catalogue of double Stars (second catalogue, containing 434 new ones).

1785, vol. 75. On the construction of the heavens.

1786, vol. 76. Catalogue of 1000 new nebulæ and clusters of stars.

1786, vol. 76. Investigation of the cause of that indistinctness of vision which has been ascribed to the smallness of the optic pencil

1787, vol. 77 An account of a new comet, by Miss Caroline Herschel, with remarks by Sir William Herschel.

1787, vol. 77. Discovery of two satellites revolving round the Georgian planet.

1787, vol. 77. Of three Volcanos in the Moon.

1788, vol. 78. Of the Georgian planet and its satellites

1789, vol. 79. Observations of a Comet.

1789, vol. 79. Catalogue of a second thoussnd of new nebulæ and clusters of stars, with a few introductory remarks on the construction of the heavens.

1790, vol. 80. Discovery of a sixth and seventh satellite of the planet Saturn; with remarks on the construction of its ring, its atmosphere, its rotation on an axis, and its spheroidical figure.

1790, vol. 80. On the satellites of the planet Saturn, and the rotation of its ring on an axis.

1791, vol. 81. On nebulous Stars, properly so called.

1791, vol. 81. On the ring of Saturn and the rotation of the fifth satellite on its axis

1792, vol. 82. Miscellaneous Observations—account of a Comet—periodical appearance of o Ceti—disappearance of 55 Herculis—remarkable phenomena in an eclipse of the Moon.

1793, vol. 83. Observations on the planet Venus.

1794, vol. 84. Discovery of a Comet, by Miss Caroline Herschel.

1794, vol. 84. Observations of a quintuple belt on the planet Saturn.

1794, vol. 84. On some particulars observed during the late eclipse of the Sun.

1794, vol. 84. On the rotation of the planet Saturn on its axis.

1795, vol. 85. On the nature and construction of the Sun and fixed Stars.

1795, vol. 85. Description of a 40-feet reflecting telescope

1796, vol. 86. Discovery of a new Comet, by Miss Caroline Herschel, with remarks by Sir W. Herschel.

1796, vol. 86. On the method of observing the changes that happen to the fixed Stars; with some remarks on the stability of the light of our Sun: to which is added a catalogue of the comparative brightness, for ascertaining the permanency of the lustre of Stars.

1796, vol. 86. On the periodical star α Herculis, with remarks tending to establish the Rotatory Motion of the Stars on their axes. To which is added a second catalogue of the comparative brightness of the Stars.

1797, vol. 87. A third catalogue of the comparative brightness of the Stars; with an introductory account of an index to Mr. Flamsteed's observations of the fixed stars contained in the second volume of Historia Cœlestis; to which are added several useful results derived from that Index.

1797, vol. 87. Observations of the changeable brightness of the Satellites of Jupiter, and of the variation in their apparent magnitudes; with a determination of the time of their rotatory motion on their axes; to which is added, a measure of the diameter of the second satellite, and an estimate of the comparative size of all the four.

1798, vol. 88. On the discovery of four additional Satellites of the Georgium Sidus: the retrograde motion of its old Satellites announced; and the cause of their disappearance at certain distances from the planet explained.

1799, vol. 89. A fourth catalogue of the comparative brightness of the Stars.

1800, vol. 90. On the power of penetrating into space by telescopes; with a comparative determination of the extent of that power in natural vision, and in telescopes of various sizes and constructions; illustrated by select observations.

1800, vol. 90. Investigation of the powers of the prismatic colours to heat and illuminate objects; with remarks that prove the different refrangibility of radiant heat. To which is added, an inquiry into the method of viewing the Sun advantageously with telescopes of large apertures and high magnifying powers.

1800, vol. 90. Experiments on the refrangibility of the invisible rays of the Sun.

1800, vol. 90. Experiments on the solar and on the terrestrial rays that occasion heat, with a comparative view of the laws to which light and heat, or rather the rays which occasion them, are subject, in order to determine whether they are the same or different. Two papers in the same volume.

1801, vol. 91. Observations leading to investigate the nature of tho Sun, in order to find the causes or symptoms of its variable emission of heat and light; with remarks on the use that may possibly be drawn from solar observations.

1801, vol. 91. Additional observations on the same, with trials to set aside darkening glasses, by transmitting the solar rays through liquids; and a few remarks to remove objections against the former paper.

1802, vol. 92. Observations on the two lately discovered celestial bodies (Ceres and Pallas).

1802, vol. 92. Catalogue of 500 new nebulæ, nebulous Stars, planetary nebulæ and clusters of Stars; with remarks on the construction of the heavens.

1803, vol. 93. Observations of the transit of Mercury over the disc of the Sun, to which is added an investigation of the causes which often prevent the proper action of mirrors.

1803, vol. 93. Account of the changes that have happened during the last twenty-five years, in the relative situation of Double Stars; with an investigation of the cause to which they are owing.

1804, vol. 94. Continuation of the last paper.

1805, vol. 95. Experiments for ascertaining how far Telescopes will enable us to measure very small angles, and to distinguish the real from the spurious diameters of Celestial and Terrestrial objects; with an application to Mr. Harding's lately discovered star (Juno).

1805, vol. 95. On the direction and velocity of the motion of the Sun and Solar System.

1805, vol. 95. Observations on the singular figure of the planet Saturn.

1806, vol. 96. On the quantity and velocity of the Solar Motion.

1806, vol. 96. Observations and remarks on the figure, the climate, and the atmosphere of Saturn and its ring.

1807, vol. 97. Experiments for investigating the cause of the Coloured Concentric Rings, discovered by Sir Isaac Newton, between two object-glasses laid on one another.

1807, vol. 97. Observations on the nature of the new Celestial Body (Vesta) discovered by Dr. Olbers; and of the Comet which was expected to appear last January in its return from the sun.

1808, vol. 98. Observations of a Comet, made with a view to investigate its magnitude and the nature of its illumination. To which is added, an account of a new Irregularity lately perceived in the apparent figure of the planet Saturn.

1809, vol. 99. Continuation of the last paper but two (Newton's rings).

1810, vol. 100. Supplement to the last.

1811, vol. 101. Astronomical observations relating to the Construction of the Heavens, arranged for the purpose of a critical examination, the result of which appears to throw some new light upon the organization of the celestial bodies.

1812, vol. 102. Observations of a Comet, with remarks on the construction of its different parts.

1812, vol. 102. Do. of a second Comet, with do. do.

1814, vol. 104. Astronomical observations relating to the Sidereal part of tho Heavens, and its connexion with the Nebulous part, arranged for the purpose of a critical examination.

1815, vol. 105. A series of observations of the satellites of the Georgian planet, including a passage through the node of their orbits; with an introductory account of the Telescopic Apparatus that has been used on this occasion; and a final exposition of some calculated particulars deduced from the observations.

In the first volume of the Memoirs of the Astronomical Society (1822) is to bo found (with the date 1821) a paper entitled 'On the places of 145 new Double Stars.'

HERSCHELLITE, a mineral which occurs in attached hexagonal crystals, associated with Phillipsite, in the cavities of trap, and also in granular olivine. Primary form a rhomboid; cleavage not ascertained; fracture conchoidal; hardness 4 to 4·5; specific gravity 2·11; translucent or opaque; colour white. Found at Aci Reale in Sicily.

HERSFELD. [FULDA.]

HERTFORD. [HERTFORDSHIRE.]

HERTFORD COLLEGE, one of the colleges of Oxford. As a college this foundation was comparatively recent, but as a hall it had been of much greater antiquity. Hertford Hall, or, as it was corruptly designated, Hert or Hart Hall, appears to have obtained its name from Elias de Hertford, who, in the reign of Edward I., let it out to clerks. Chalmers, in his 'History of the University of Oxford,' traces the conveyance of the building through several hands previous to its becoming the property of De Hertford.* Its situation was then nearly on the site of the hall of the college, in New College Lane. In A.D. 1312 it was conveyed to Walter Stapledon, bishop of Exeter, and founder of Exeter College, who procured a licence from the king to grant this and another messuage, called 'Arthur Hall,' to twelve scholars studying in Oxford. The scholars of these halls, which appear to have been incorporated together, under the title of Hertford or Hart Hall, were, with their rector, removed to Exeter College, of which the hall became a dependency. The principals were appointed by the authorities of Exeter College, except during a short period, when the scholars of New College, which was then building, were admitted, and the society was governed by tho wardens of that college.

In 1710 Dr. Richard Newton was inducted as principal. This gentleman, having conceived the project of raising Hart Hall to the rank of a college, settled a yearly annuity as an endowment for four senior Fellows, at the rate of 13*l.* 6*s.* 8*d.* each per annum. He also expended about 1500*l.* in building a new chapel and in adding to the previously existing buildings of the foundation. In the year 1739 he completed the body of statutes which he had drawn up for his intended foundation; and on August 27, 1740, obtained a royal charter for raising Hart Hall into a perpetual college for the usual studies. The society was to consist of a principal; four senior fellows or tutors, whose allowance has been mentioned above; eight junior fellows or assistants, who were to have 26*l.* 13*s.* 4*d.* yearly; eight probationary students, with an allowance of 6*l.* 13*s.* 4*d.* each; twenty-four actnal students, with an allowance of 13*l.* 6*s.* 8*d.* each, which might be augmented by an allowance of sixpence per diem for commons; and four scholars.

The statutes of Dr. Newton appear to have been injudiciously framed. The regard to rigid economy which led him to fix the maximum of remuneration was inconsistent with a consideration of the rise of markets; and the benefactions which were added subsequent to the foundation of the college were insufficient for its maintenance.

The society subsisted for some years on its scanty funds; but upon the death of the principal, Dr. Bernard Hodgson, A.D. 1775, the office was not filled up. The foundation was dissolved in the year 1818. A certain portion of the college funds, reserved for the use of the then only surviving Fellow, was, on his death, appropriated to the establishment of a university scholarship for the encouragement of Latin literatnre. The election is yearly. The greatest proficient in

* 'Before the foundation of colleges all education in the university was carried on in certain houses, or sets of buildings, called halls, inns, or hostels, which were the property of citizens of Oxford, who let them partially to individuals, or generally to societies connected under one roof, in which case they were denominated 'halls.' When they thus became halls, though the proprietors still continued to receive rent, and to be in other respects the landlords yet they could not divert them from the purposes of education; nor does it appear they could raise the rents at pleasure.' (Chalmers.)

the Latin language among the candidates is elected, and no scholar is admissible for re-election.

Among the eminent men who were scholars of Hart Hall may be enumerated Lord Buckhurst, Selden, Dr. Donne (afterwards of Cambridge), Sir William Waller, Sir Richard Baker, author of the well-known 'Chronicle.' Among those who were scholars of Hertford College are Edward Lye, the Saxon lexicographer; Thomas Hutchinson, the editor of Xenophon; Dr. Thomas Hunt, professor of Arabic; Dr. Benjamin Blayney, the translator of Jeremiah; and Charles James Fox. Dr. Newcome, archbishop of Armagh, translator of Ezekiel, the Minor Prophets, and the New Testament, is also claimed by this college.

HERTFORDSHIRE, an inland county of England, situated between 51° 36′ and 52° 5′ N. lat., and 0° 13′ E. and 0° 45′ W. long. It is bounded on the north by Cambridgeshire, on the east by Essex, on the south by Middlesex, on the west by Buckinghamshire, and on the north-west by Bedfordshire. Its greatest length is from north-east, near Royston, to south-west, not far from Rickmansworth, 39 miles; its greatest breadth is, from the neighbourhood of Hitchin to Waltham Cross, 25 or 26 miles. Its area is estimated at 630 square miles. The population, in 1831, was 143,341, being about 228 to a square mile. It is in point of size the thirty-fifth of the English counties, in number of inhabitants the thirty-fourth, and in density of population the sixteenth. Hertford, the county-town, is 20 miles due north of St. Paul's, London, in a straight line, or 21 miles from Shoreditch Church, London, by the road through Cheshunt, Hoddesdon, and Ware.

Surface, Hydrography, Communications.—Hertfordshire has no lofty hills. The highest elevations are the Chalk Downs, which form the continuation of the Chiltern Hills north-eastward into Essex and Cambridgeshire. Kensworth Hill, just within the border of the county, near Dunstable (in Bedfordshire), is 908 feet high. The surface of the county is generally undulating, and from the abundance of woods presents a variety of pleasing scenery.

The rivers for the most part belong to the basin of the Thames. The principal are the Colne and the Lea: the Hiz and some other streams in the northern part of the county belong to the system of the Ouse. The Lea rises in Luigrave or Leagrave Marsh, near Luton, in Bedfordshire; and flowing first east and then south-east for ten miles, enters Hertfordshire on the north-west side of the county, and flows 9 miles south-east to the neighbourhood of Hatfield: from thence it flows east-north-east 9 miles by Hertford to Ware. At Hertford it receives the Maran or Mimram and the Beane, and between Hertford and Ware the Rib; all on the left bank. From Ware, just below which it receives the Ash on the left bank, it flows 4 miles to the border of Hertfordshire and Essex, where it receives the Stort, also on the left bank. From the junction of the Stort the Lea flows south 6 miles to Waltham Cross, where it quits Hertfordshire altogether. Its whole length, from the source to its junction with the Thames at Bromley, near London, is above 50 miles. The navigation commences at Hertford.

Of the feeders of the Lea mentioned above, the Stort, which rises in Essex and flows on or near the border of Essex and Herts, is 21 miles long, and is navigable for about half its length, namely, to Bishop Stortford.

The Colne, a feeder of the Thames, rises between Idlestree, or Elstree, and Barnet, and flows through a projecting part of the county of Middlesex into Hertfordshire again. It has a very circuitous course of 13 miles to the junction of the Verlam, or Muse, on its right bank, near St. Alban's: from this point it flows 13 miles south-west by Watford and Rickmansworth, partly through and partly on the border of the county, till it quits it to form the boundary of Buckinghamshire and Middlesex. Its whole length is about 40 miles. It receives, between the junction of the Verlam and Rickmansworth, the Gade and the Chess, both on the right bank.

Some of the feeders of the Thame, another affluent of the Thames, have their source in the north-western part of the county, near Tring.

The streams which belong to the system of the Ouse have but a small part of their course in this county. They rise on the northern slope of the Chalk Downs. They are the Oughton, the Hiz Proper, and the Pirral, which are commonly considered as the sources of the Ivel [BEDFORDSHIRE], but are rather the sources of the Hiz, a feeder of that stream. The Rhee, which rises at Ashwell, a few miles from Baldock, is a feeder of the Cam.

The New River, which is brought to London from springs in the neighbourhood of Ware, has a feeder from the Lea near that town. A part of its course is in Hertfordshire: it is carried along the valley of the Lea, and nearly parallel to the course of that stream. The New River was begun A.D. 1608.

The only navigable canal in Hertfordshire is the Grand Junction, which enters the county near Tring, and runs first south-east along the valley of the Quin, then south along that of the Gade, and finally south-west along the valley of the Colne, till it enters Middlesex. It passes by or near the towns of Tring, Berkhamsted, Hemel Hempstead, Watford, and Rickmansworth. Near Rickmansworth it passes through a small tunnel. There are cuts from the main line of this canal in the neighbourhood of Tring, one to Aylesbury, and another to Wendover; and one in the neigbourhood of Watford to the town of Watford. The Wendover Cut is a feeder rendered navigable.

The high North road runs through this county, through Chipping Barnet, Hatfield, Welwyn, Stevenage, and Baldock: the Liverpool road branches off from the North road, and runs through St. Alban's to Dunstable: the Cambridge road runs by Waltham Cross, Hoddesdon, Ware, and Puckeridge, where it divides into two branches, one of which passes through Buntingford and Royston.

The London and Birmingham railroad runs through this county, nearly in the line of the Grand Junction Canal.

Geological Character.—This county is comprehended in the chalk basin of London. The south-eastern corner at Cheshunt, and the south-western part, comprehended within a line drawn from North Mimms by Ridgehall, Aldenham, and Bushey, to Harefield, in Middlesex, are occupied by the London clay. From under this the plastic clay crops out, and extends to a line drawn from the Stort, between Sawbridgeworth and Bishop Stortford, to the north of Ware, Hertford, and Hatfield, to St. Alban's, and from thence along the valley of the Colne. To the north-west of this line all the county is occupied by the chalk, excepting a few spots along the border of Bedfordshire, where the subjacent strata crop out.

This county has no minerals of any value: there are a few medicinal springs, chiefly chalybeate; the principal are on Barnet Common, Northaw Common, and at Cuffley, in Northaw parish, all near the Middlesex border.

Agriculture.—The climate of Hertfordshire is as mild and genial as that of most of the inland counties. The harvest is early where the soil is light and rich, as is the case in some of the valleys. On the cold wet clays, which are found in some parts of the county, and the most exposed tops of the chalky hills, the crops are later. The soil may be divided into chalk, clay, and gravel, according as each ingredient prevails; and the mixture of them forms loams of various qualities. The whole of the county is upon chalk at a greater or less depth below the soil; and in the north-western part, towards Bedfordshire, the chalk rises to the surface in considerable hills. Where the chalk lies deeper, the soil on the hills is mostly a heavy clay; and the valleys between them have variations of gravel and loam much intermixed.

The proportions of these soils are stated by Arthur Young as follows, in his view of the agriculture of Hertfordshire:—

Chalk	46,720 acres.
Clay.	90,240
Loam	142,720
Rich loam	5,120
Poor gravel. . . .	17,280
Total . .	302,080

The rich loam occurs on the borders of Essex along the road from London to Bedford, and has given a greater reputation to Hertfordshire for general fertility than the average quality of the soils in the county will warrant.

The loams are generally well cultivated, but the heavy clays are capable of much improvement. Wherever the turnip husbandry prevails, the superiority of the crops is striking. The supply of manure from London gives also an advantage to the southern part of the county, where the soil is inferior and will only produce good crops by abundant manuring. Wherever the soil is not adapted to the growth of turnips, few improvements are visible. Wheat, beans, oats, and fallows, are the only varieties. Clover is much less in quantity than might be desired, and by no means so clean as it ought to be. Draining has been resorted to by some spirited proprietors and lessees; but where farms are let at rack-rent, and from year to year, as is often the case, no permanent improvement can be expected. Even if the landlord is liberal, and offers to furnish draining tiles, the tenant has not a sufficient interest to avail himself of the offer, or to put them down in the most efficacious manner.

The number of resident gentry in Hertfordshire tends to introduce a high state of cultivation around their immediate residences; but, as the mansions are generally erected in the driest and best situations, the cold wet clays are neglected; the roads also on the clay soils are not so good; the fences are not so well kept; and a more slovenly husbandry is observed. The old heavy plough with four horses in a line may still be seen; and in some places the heavy loam mixed with flints and stones can scarcely be moved with less power: but a great improvement might be made in the construction of the plough; and effectual draining, with the use of the subsoil plough, would greatly lighten the texture, and enable lighter ploughs and fewer horses to stir them sufficiently.

Hertfordshire has been remarkable for its high banks and hedges. In many of the lanes, where two carriages could scarcely pass one another, it is difficult for a man standing on a waggon to see over the hedge. This makes the surface of the country look rich when seen from the hills, especially when there are woods and coppices interspersed amongst the fields, and many trees in the hedgerows; but these hedges are a great impediment to the proper cultivation of the soil. They are left to grow till the wood in them is valuable for fuel, and they are cut down more for the sake of the faggots than to keep up the fence. Hence there are many large gaps, which are stopped up by cutting half through some of the stems in the hedge, and laying them down, which is called *plashing*. [HEDGE.] Wherever the old high banks have been levelled, and neat quick hedges have been planted in their stead, and kept cut and trimmed, the ground which has been gained, together with the earth of the old banks, to mix up with lime and vegetable matters in a compost, have soon repaid the expense. The injury done by a hedge in a growth of ten or twelve years is poorly repaid by a few faggots sold to the bakers or brick-burners.

It cannot be said that there is any peculiar system of cultivation in Hertfordshire. Every system may be occasionally met with. The resident proprietors, many of whom hold considerable farms in their own hands, employ bailiffs, who come from various parts of the country, and introduce the systems which they are accustomed to: some are from Norfolk, others from Northumberland or Scotland. Before the common fields were enclosed, as they are now almost universally, a fixed rotation was unavoidable, as there were rights of pasture over certain portions of the field in what was called the fallow year; but as soon as the fields were freed from this impediment to good cultivation, each proprietor introduced his own method, whether good or bad. The consequence has been a very great difference in the crops of adjoining farms, according as they have fallen into the hands of industrious men with science and capital, or remained with those who follow the example of their forefathers. The crops are reaped as close to the ground as possible, in order that the straw may be sold in London and manure brought back in return. The corn is threshed chiefly by hand, the straw thus produced being of greater value for horse litter. Fewer cattle are fed in winter than in more distant counties, as manure can be obtained without them.

A species of rough garden husbandry has been introduced on the best soils nearest to London for the growth of early potatoes, cabbages, peas, and other culinary vegetables, which are succeeded in the same year by other crops, the whole being forced by an abundance of manure. The plough is used, but a great portion of the labour is done by the spade and the hoe.

There are many orchards in Hertfordshire, chiefly for apples and cherries, which are sold in London. No cider is made. A good cherry-tree full-grown will give in a good year fifty dozen pounds of cherries, and occupies nine square perches of land. The grass under the trees is generally fed off. Many old orchards have ceased to be productive, although young trees have been planted where the old were past bearing. This is caused by the deterioration of the soil. But good orchards might be made by planting a succession of young trees in fresh soil, and converting old orchards into arable land. The old orchards will be admirably calculated to produce lucerne or any other valuable crop.

There are many woods and coppices in the poorer soils, but they are fast diminishing in number, and the land is gradually brought into cultivation as arable or pasture. They are usually cut every ninth year. Where they contain Spanish chestnut, which is valuable for hurdles and rough fences, the produce is considerable, while the timber-trees are improving in value every year; but unless they are well managed, woods do not pay a rent proportionate to the value of the land, if it were in cultivation.

There are no breeds of cattle peculiar to Hertfordshire. The Suffolk cart-horses are esteemed for farm-work, being active and tractable. Some farmers buy young horses of the black Northampton or Lincolnshire breed, which they sell again with a good profit for dray-horses in London when they are six years old. Few horses are bred in the county. The grass-lands are reserved for hay, and there are few rough pastures. A few pigs are bred, as they are on most well managed farms; the breeds are the Essex or Berkshire, and crosses of these with the Chinese and Neapolitan, than which there are none more profitable. By judicious crossing the principal qualities of the hog may be kept up to a high degree, uniting prolific breeding with early fattening.

The principal fairs in Hertfordshire are the following.—St. Alban's, March 25, October 1; Baldock, March 7, last Thursday in May, August 5, October 2, December 11; Barnet, April 8, 9, and 10, September 4, 5, and 6 (both these are great cattle fairs); Berkhamsted, August 5, September 29, October 11; Buntingford, June 29, November 30; Hempstead, Thursday after Whit-Wednesday; Hertford, May 12, July 5, November 8; Hitchin, Easter Tuesday, Whit-Tuesday; Redburn, first Wednesday after January 1, Easter-Wednesday, Whit-Wednesday; Rickmansworth, July 20, November 24; Royston, Ash-Wednesday, Easter-Wednesday, Whit-Wednesday, Wednesday after October 11; Sawbridgenorth, April 23, October 20; Stevenage, day after Holy Thursday; Ware, last Tuesday in April, Tuesday before September 21; Watford, March 28, August 31, September 9.

Divisions, Towns, &c.—The county is divided into eight hundreds, namely:—

Name.	Situation.	Pop. in 1831.
Braughing	E.	17,827
Broadwater	Central	17,043
Cashio	Central and S.W.	33,291
Dacorum	W.	28,872
Edwinstree	N.E.	9,237
Hertford	S.E.	19,217
Hitchin & Pirton	N.W.	10,711
Odsey	N.	7,143
		143,341

In the foregoing table we have given the general situation of each hundred; but it is to be observed that several of the hundreds of this county are most irregularly formed. Cashio hundred, in particular, has detached or outlying portions in various parts of the county, as the parishes of Norton and Newnham near Baldock, Hexton near Hitchin, and others. Dacorum and Broadwater hundreds have also outlying portions.

Hertfordshire has no city: it contains two boroughs and market-towns, namely, Hertford and St. Alban's; and twelve other market-towns, namely, Baldock, Barnet, Berkhamsted, Bishop Stortford, Hatfield, Hemel Hempstead, Hitchin, Hoddesdon, Royston, Tring, Ware, and Watford. The markets of Buntingford and Rickmansworth have fallen into disuse; but these places are still frequently enumerated as market-towns. Of some of these an account is given elsewhere. [ALBAN'S, ST.; BARNET; BERKHAMSTED; BISHOP STORTFORD.]

Hertford, the county-town, is in a low valley below the junction of the Maran or Mimram, and just above that of the Beane with the Lea, which last-mentioned river runs through the town. It is in the hundred of Hertford. The limits of the borough jurisdiction, as determined by the Boundary Act and the Municipal Reform Act, include parts of the parishes of St. Andrew, St. John, and Bengeo, the parish of All Saints, and parts of the liberties of Brickendon and Little Amwell, which, together with the parish of St. John, are attached for ecclesiastical purposes to the parish of All Saints.

The parliamentary borough was, before the Reform Act, much smaller than the municipal borough, which was divided into two parts, distinguished as the in-borough (parliamentary), and the out-borough. By the Boundary Act the parliamentary borough comprehends the whole of the out-borough, with the addition of a small space beyond the then municipal boundaries, and the Municipal Reform Act extended the municipal boundary, and made it co-extensive with the parliamentary. The population of the in-borough, by the census of 1831, was 4028: with that of the out-borough (partly determined by conjecture), it amounted to 5631. The part added by the Boundary Act contained probably about 200 persons. The town is irregularly laid out, but the streets are well paved and lighted with gas, and the general appearance of the place indicates prosperity and improvement. It has two parish churches: All Saints, a large cross church, with a square tower and spire at its western end, and St. Andrew's. There aro some remains of an antient castle, consisting of little except a lino of embattled wall and a mound. A handsome brick edifice was built on tho site of tho castle probably in the time of James I. or Charles I.; but some parts of it are perhaps of older date. This building was occupied for a time by the East India College. It is now occupied by the East India Company as a preparatory school to the college now at Hailcybury. The shire-hall is over the corn and general market. The county gaol and house of correction is out of the town, on the east side: one ward of it is appropriated as the borough prison. There is a town-hall. Near the east end of tho town is a large building belonging to the governors of Christ's Hospital, in London, at which a number of the girls and of the younger boys of that charity receive their education. The buildings will contain 500 children, with their needful attendants.

No manufacture is carried on at Hertford, but a good deal of business is done in malting, and thero are many corn-mills on the Lea or the Mimram. The market, which is on Saturday, is one of the largest corn-markets in the kingdom. There aro four yearly fairs, chiefly for cattle. The borough council consists of four aldermen and twelve councillors; the borough has a commission of the peace. There are quarter-sessions held for the borough, and the assizes and sessions for the county are also held here. Hertford returns two members to parliament.

Hertford is a place of considerable antiquity. Sir Henry Chauncy would have fixed here the Durocobrivæ of Antoninus, which is now more commonly fixed at Maiden Bower near Dunstable. In A.D. 673 a national ecclesiastical council was held at Hertford; and about A.D. 905 Edward the Elder built the castle, and rebuilt the town, which had probably been ruined by the Danes. In the civil war of the reign of John this castlo was taken, after a brave defence, by the Dauphin Louis and the revolted barons: it subsequently came to the crown, and was granted in succession to John of Gaunt, and to the queens of Henry IV., V., and VI. Jean II., king of France, and David, king of Scotland, spent part of their captivity here during the reign of Edward III. Queen Elizabeth occasionally resided and held her court in this castle.

The living of All Saints is a vicarage united with that of St. John, of the yearly value of 290*l.* with a glebe-house; that of St. Andrew (with which are incorporated St. Mary and St. Nicholas) is a rectory of the clear yearly value of 271*l.* with a glebe-house. Both livings are in the deanery of Hertford, the archdeaconry of Huntingdon, and the diocese of Lincoln. There are several dissenting places of worship.

In 1833 there were in Hertford the following schools: the branch school of Christ's Hospital; a free grammar-school with 33 day-scholars on the foundation and 24 boarders; the green charity-school, with 45 boys; two national schools, with 161 boys and 45 girls; another charity-school with 45 girls; an infant school with about 20 children, and eleven other day or boarding and day-schools, with 329 children; one evening-school with 40 girls; and three Sunday-schools with 196 children.

Haileybury College, two or three miles from Hertford, has residences for the principal and for several professors, and accommodation for 100 students, who are trained for the civil service of the East India Company; about 30 are sent out to India every year.

Baldock is in the hundred of Broadwater, [illegible] miles from London, on the great North-road. The parish contains only 200 acres; the town occupies a low situation, surrounded on all sides by an open chalky country. It is said to have been built by the Knights Templars before the time of Henry III. The church is a large and handsome Gothic edifice, with a square embattled tower at its west end. There is a range of six almshouses in the High-street. The population of Baldock in 1831 was 1704, about one-fifth agricultural. A considerable trade is carried on in malt, the barley of the surrounding district being of excellent quality. The market is on Thursday: there are five fairs in the year. The living is a rectory of the yearly value of 126*l.*, in the deanery of Baldock, the archdeaconry of Huntingdon, and diocese of Lincoln. There are places of worship for Methodists and Independents.

There were in 1833 nine day or boarding and day schools, with 277 children; and three Sunday-schools, with 361 children; a school-room was then building for a national school, to contain 200 children.

Hatfield, distinguished as Bishop's Hatfield, is in Broadwater hundred, on the high North road, 19½ miles from London. The parish comprehends 12,700 acres, or, according to others, 12,312 acres, 2 roods, 27 poles; it is subdivided into five hamlets, of which the 'town quarter' is one. The manor of Hetfelle (as it is called in Domesday) was granted by King Edgar to the abbey or monastery of St. Ethelred at Ely, and upon the erection of that abbey into a bishopric, A.D. 1108, is supposed to have acquired the designation of Bishop's Hatfield. The town lies on the slope of a hill, and consists of a principal street intersected by a smaller one. The bishops of Ely had a palace at Hatfield, which, with the manor, was made over to the crown in the time of Henry VIII.: the palace was tho residence of Prince Edward, afterwards Edward VI., immediately before his accession. The princess (afterwards queen) Elizabeth was here in the care or custody of Sir Thomas Pope, during the latter part of the reign of her sister Mary: upon tho intelligence of whose death she held her first privy-council here. The palace and manor were, soon after the accession of James I., made over in exchange for Theobalds, in the parish of Cheshunt, to Sir Robert Cecil, afterwards earl of Salisbury, in whose family they have ever since continued. The gateway and west end of the palace are still standing. Hatfield-house, tho residence of the earls (and now of the marquis) of Salisbury, was built by Sir Robert Cecil, and is a fine specimen of the architecture of the Elizabethan period. It was almost destroyed by fire in the month of November, 1835. The grounds are beautifully laid out. The church is at the upper end of the town: there is an Independent chapel. The population of the parish was, in 1831, 3593, three-fifths agricultural. There is a weekly market on Thursday for corn and provisions, and two yearly fairs. The living is a rectory united with the chapelry of Totteridge in the deanery of Hertford, the archdeaconry of Huntingdon, and the diocese of Lincoln, of the yearly value of 2097*l.* There were, in 1833, thirteen day-schools (one with 18 children, endowed,—one with 158 children, a national school), containing altogethor 485 children; and three Sunday-schools with 83 children.

Hemel Hempstead is in Dacorum hundred, 23½ miles from London, through Watford. The parish comprehends 7310 acres, with a population in 1831 of 4759: including the dependent chapelries of Bovingdon and Flaunden, it comprehends 12,440 acres, with a population of 6037. The town, which is on the side of a hill sloping down to the rich valley of the Gade, consists chiefly of one long street. The females of the town are much engaged in making the straw-plat, and there are corn and paper mills in the neighbourhood. The London and Birmingham railroad and the Grand Junction Canal pass near the town. The town-hall is a long narrow building with an open space under for the market, which is held on Thursday, and is one of the largest in the county for corn. The church, a large building, is partly of Norman architecture, of which the west door is one of the richest specimens in the county. The living is a vicarage with the dependent chapelries mentioned above, in the deanery of Berkhamsted, the archdeaconry of Huntingdon, and diocese of Lincoln, of the yearly value of 709*l.* There were in 1833, in the parish and two chapelries, two infant-schools with 56 children, two national schools with 98 children, two schools of industry with 67 girls; ten other day-schools and four boarding-schools with 374 children, and five Sunday-schools with 280 children; there were also twenty-four schools in which about 247 children were taught to plat straw and read. The town of Hemel Hempstead was incorporated under Henry VIII.; but the corporation is not noticed either in the Commissioners' Reports or in the Municipal Corporation Reform Act.

In the year 1837 several curious Roman relics were discovered by the Rev. J. F. Girton in the burial-ground of Box Lane Chapel near Hemel Hempstead. They consist of two glass vases (one globular and thin, the other square and of thick glass with a handle), an earthern pitcher and some nails. The square vase, which is entire except a slight chip off the handle, is three times as thick as the globular vase, and is a good specimen of glass. This square vase was filled with human bones; the globular one was only partially filled. For these facts and a drawing of the different objects we are indebted to a communication from the Rev. J. F. Girton.

Hitchin is in Hitchin and Pirton hundred, 34 miles from London, on the little river Hiz. The parish comprehends 6150 acres, and had in 1831 a population of 5211, about one-third agricultural. The town, which consists of several streets, is irregularly laid out. It was formerly the seat of a woollen manufacture: the principal trade is now in corn and malt, of which latter a considerable quantity is made. Much straw-plat is made; there are some breweries, and also a silk-mill. The church is a handsome edifice near the centre of the town, built upon the foundations of a more antient structure. The south porch is a remarkably fine specimen of Gothic architecture in the perpendicular style, and there is a font of the same character; also numerous sepulchral monuments and brasses. There are meeting-houses for Independents, Baptists, and Quakers; and several sets of almshouses. The town is divided into three wards, for each of which constables and other officers are elected at a court-leet. There was formerly a small priory for Carmelite monks, and one for Gilbertine nuns. The market is on Tuesday, and there are three yearly fairs. The living is a vicarage in the deanery of Hitchin, the archdeaconry of Huntingdon, and the diocese of Lincoln, of the yearly value of 650*l.* with a glebe-house. There are the ruins of a chapel at Langley, in the parish of Hitchin, three miles from the town. There were in 1833 one infant school with 50 children, two endowed day-schools with 36 boys and as many girls, two Lancasterian schools with 171 boys and 100 girls, a school partly supported by subscription with 25 children, and five day or boarding and day-schools with 127 children, and four Sunday-schools with 581 children.

Hoddesdon is a hamlet chiefly in the parish of Broxbourn, in the hundred of Hertford, 17 miles from London, on the North road, through Ware and Royston. The population in 1831 was 1990; the area is 2650 acres. The town consists chiefly of two long streets. The antient market-house, a wooden edifice supported on arches and pillars curiously carved, is in the middle of the town, and near it is a conduit by which the town's people are supplied with water. There is a chapel, a square brick building. The site of a more antient chapel is marked by a building called the clock-house. There are two Dissenting meeting-houses. The market, which is on Thursday, has much declined; there is one yearly fair.

The chief business of the town is malting: there is a cotton-mill in the neighbourhood. There are some almshouses. The living of Broxbourn, of which the chapelry is a dependency, is in the deanery of Braughing, the archdeaconry of Middlesex, and the diocese of London, of the yearly value of 361*l.*, with a glebe-house: the yearly value of the chapelry of Hoddesdon is 54*l.* The church is a large church of perpendicular character, with some elegant chapels, and antient monuments and font. There were in that part of Hoddesdon hamlet which is in Broxbourn parish, in 1833, seven day-schools with 117 children, two national schools with 142 children, and one Sunday-school with 90 children.

Royston is in the hundred of Odsey, on the North road through Huntingdon, 37½ miles from London. The parish extends into Armingford hundred, Cambridgeshire, and the town extends beyond the parish boundaries. The area of the parish is 320 acres: the population in 1831 was 1757, about one-tenth agricultural. The town is situated in a bottom surrounded by chalk downs, and consists of four principal streets. The principal business is malting; a large corn trade is also carried on. The market is on Wednesday; the market-house is quite a modern building. The church was formerly the conventual church of a priory of the regular canons of St. Augustine; the yearly revenues of this priory at the dissolution were 106*l.* 3*s.* 1*d.* gross, or 89*l.* 16*s.* clear. The living is a vicarage in the deanery of Braughing, archdeaconry of Middlesex, and diocese of London, of the yearly value of 107*l.* There are three or four meeting-houses for different classes of dissenters. A brick building in the northern part of the town was once the occasional residence of James I., who came here to hunt and shoot dotterels, which then abounded on the neighbouring downs. In the town there was discovered, in A.D. 1742, a curious bell-shaped subterraneous cavern, 30 feet high, and nearly 20 feet in diameter, cut out in the solid chalk, and ornamented with rude carvings of sacred subjects, supposed to have been a hermitage. The downs round the town are frequented by 'the hooded-crow,' a species not found in other parts of England, and popularly called the Royston crow: it is a migratory bird, and passes the winter here. There were in Royston parish, in 1833, one infant school with 53 children, a Lancasterian school with 53 girls, eleven day or boarding and day-schools with 194 children, and three Sunday-schools with 259 children.

Tring is in Dacorum hundred, 33 miles from London on the road to Aylesbury. The parish comprehends 7390 acres, and had in 1831 a population of 3488, nearly one-third agricultural. The town is neat, and contains several good houses. The church is an antient building, with a massive tower, and contains some antient monuments. There is a weekly market on Friday, and two yearly fairs. There are several dissenting meeting-houses. The living is a perpetual curacy united with the chapelry of Long Marston; the joint annual value is 157*l.*, with a glebe-house, in the deanery of Berkhamsted, the archdeaconry of Huntingdon, and the diocese of Lincoln. There were in the parish, in 1833, six day-schools with 240 children, and five Sunday-schools with 659 children.

Ware is in Braughing hundred, on the east bank of the Lea, 20 miles from London on the road to Cambridge. The parish comprehends 4430 acres, and had in 1831 a population of 4214, including the population of Amwell End; of the population, about one-eighth or one-tenth is agricultural. Up to this place the Danes, in the reign of Alfred, brought their vessels, and protected them by a dam or wear across the river, from which wear the town is said to have obtained its name; but this is disputed. Ware consists of one long street and several smaller ones. The church consists of a chancel, with a chapel on each side; a nave with two side aisles, and two projections resembling transepts; with a square embattled tower: the font is of perpendicular architecture, with considerable enrichments. There is considerable trade at Ware; the market, which is on Tuesday, is one of the greatest in the county for corn, and there are two yearly fairs. At one of the inns in this town (the Saracen's Head) is a large bedstead, twelve feet square, elaborately carved in oak, and probably of the age of Queen Elizabeth. It is alluded to by Shakspeare (*Twelfth Night*, act iii., scene ii.), and is popularly known as the Bed of Ware. The living of Ware is a vicarage united with that of Thundridge, of the yearly value of 333*l.*, in the deanery of Braughing, the archdeaconry of Middlesex, and the diocese of London. There were in the parish, in 1833, two infant or dame schools with 26 children, an endowed grammar school with 28 boys, a Lancasterian school with 120 boys, a national school with 75 boys, two charity schools with 94 girls, ten day or boarding and day-schools with 190 children, and a Sunday-school with 38 girls.

Watford is in Cashio hundred, 15 miles from London, on the road to Aylesbury, near the Coln. The parish comprehends 10,980 acres, and is divided into four hamlets: the population in 1831 was 5293, more than one-third agricultural. The town, which is neat, consists principally of one main street, about a mile in length, near the centre of which stands the church. There are considerable silk-mills, and also a paper-mill. The market is on Tuesday. The living is a vicarage in the archdeaconry of St. Alban's and diocese of London, of the clear yearly value of 730*l.*, with a glebe-house. There were in the parish, in 1833, an endowed school with 60 children, another endowed school with 11 boys, two schools with 70 boys and as many girls, supported by the earl of Essex, thirteen other day-schools with 279 children, and five Sunday-schools with 419 children.

Buntingford and Rickmansworth are still frequently spoken of as market-towns.

Buntingford is in Edwinstree hundred, in the parish of Layston, on the road to Cambridge, 31 miles from London. It has a brick chapel built above two hundred years ago. There are also some almshouses, forming three sides of a quadrangle. The population of the parish in 1831 was 1093, two-fifths agricultural. The market was on Monday, but has been discontinued. The living of Layston is a vicarage in the deanery of Braughing, the archdeaconry of Middlesex, and the diocese of London, of the yearly value 149*l.* There is an Independent congregation. There were in Layston parish in 1833, one grammar-school with 3 boys, one charity-school with 36 girls, and one Sunday-school of 70 children.

Rickmansworth, or Rickmersworth, is 18 miles from London, in Cashio hundred, in a low and flat situation near the confluence of the Coln, the Chesham or Chess, and the Gade. The parish comprehends 9740 acres, and had in 1831 a population of 4574, more than one-third agricultural. The town is irregularly laid out. The church has been lately rebuilt: the former church was a large antient building; the tower, which is in the perpendicular style, is yet standing. There are several paper and flour mills near the town; and some straw-platting and horse-hair weaving is carried on. The Grand Junction Canal passes through the town. The living is a vicarage in the archdeaconry of St. Alban's and diocese of London, of the yearly value of 510*l.*, with a glebe-house. There are two dissenting places of worship. There were in 1833 three infant or dame schools with 20 children, an endowed national school with 86 children, a Lancasterian school with about 80 boys (since, we believe, discontinued), eighteen day or boarding and day-schools with 312 children, one day and Sunday Lancasterian school with 40 to 60 children, and two Sunday-schools with 81 children. Near Rickmansworth is Moor Park, which was the residence of Cardinal Wolsey, of the unfortunate James, duke of Monmouth, and of Lord Anson.

Cheshunt, though only a village, has some claims to notice. The parish comprehends an area of 8430 acres, and had in 1831 a population of 5021, from one-fourth to one-third agricultural. It is divided into three wards, Cheshunt Street, Waltham Cross, and Woodside. The name is written in Domesday 'Cestrehunt,' from which it has been conjectured that it was a Roman station. Waltham Cross takes its name from one of the crosses erected by Edward I., to mark the resting-places of the corpse of his wife Eleanor, when conveyed to Westminster for interment. This beautiful cross, which had become much mutilated, has been lately restored by Mr. W. B. Clarke. In Cheshunt parish was Theobalds Park, a favourite residence of James I. Richard Cromwell retired to this village upon his abdication.

Divisions for Ecclesiastical and Legal Purposes.—Hertfordshire is comprehended in the dioceses of London and Lincoln, which are here conterminous. That part which is in the diocese of London constitutes the deanery of Braughing, in the archdeaconry of Middlesex, containing 37 benefices; and the deanery and archdeaconry of St. Alban's, containing 22 benefices. That part which is in the diocese of Lincoln constitutes the deaneries of Baldock, containing 24 benefices; Berkhamsted, 21 benefices; Hertford, 18 benefices; and Hitchin, 15 benefices: all in the archdeaconry of Huntingdon. Of the whole 137 benefices, 65 are rectories, 52 vicarages, 4 donatives, 14 chapelries, and 2 curacies. The number of parishes is only 130; some of the benefices not being distinct parishes.

Hertfordshire is included in the Home circuit. The assizes and quarter-sessions are held at Hertford, except for the hundred of Cashio, the quarter-sessions for which are held at St. Alban's. The county returns three members to parliament. The place of election is Hertford: the polling-stations are Hertford, Stevenage, Buntingford, Bishop's Stortford, Hoddesdon, Hatfield, and Hemel Hempstead. Two members each are returned for the boroughs of Hertford and St. Alban's.

History and Antiquities.—At the time of Cæsar's invasion, Hertfordshire seems to have belonged to the Catyeuchlani (Καττευχλανοι, Ptol.) or Catuellani (Κατουελλανοι, Dion), of whom we have elsewhere supposed Cassivellaunus, the antagonist of Cæsar (B.C. 54), to have been the chief. [BRITANNIA.] Whether the Trinobantes, who occupied Essex and perhaps Middlesex, possessed any portion of Hertfordshire is not clear. Camden would place the Cassii, a tribe which submitted to Cæsar before the final defeat of Cassivellaunus, in the hundred of Cashio: but as the narrative of Cæsar would rather lead to the conclusion that the stronghold of Cassivellaunus, which he stormed, and which is commonly supposed to have been on the site of the Roman Verolamium, was not in the country of the Cassii, though it is in Cashio hundred, the conjecture is hardly probable. Hertfordshire was probably the scene of contest in the struggle of the Britons under Togodumnus and Cataratacus or Caractacus (A.D. 43—51), but we cannot identify any locality in it with the events of that struggle. In the revolt under Boadicea (A.D. 61), Verolamium was taken and the inhabitants massacred. The martyrdom of Alban occurred during the persecution in the reign of Diocletian. [ALBAN'S, ST.]

Several of the antient British roads or trackways crossed this county: Watling Street crossed it in a north-west direction not varying much from that of the present road from London by Edgware and St. Alban's to Dunstable; Ermin Street nearly coincided with the present road from London by Enfield, Hoddesdon, Ware, and Buntingford, to Royston (it was divided near Ware into two branches which reunited near Buntingford); Icknield Street ran along the downs from Dunstable toward Royston. The traces of the British Watling Street are obliterated by the Roman road afterwards carried along the same line. Traces of Ermin Street and still more of Icknield Street may yet be recognised. There were probably some smaller British roads branching from these. The Verolamium of the Romans has been mentioned as having been probably a British town: it has been conjectured that there were British towns or posts at Royston, at Braughing a few miles beyond Ware on the Ermin Street, in the neighbourhood of Berkhamsted at Ravensburg, on the border of the county, near the Icknield Street, and perhaps at other places. The Romans included Hertfordshire in the province of Flavia Cæsariensis. They fortified the town Verolamium, near St. Alban's [ALBAN'S, ST.], on which they conferred the rank of a municipium; and made military roads along Watling and Ermin Streets, and in other directions. A Roman post or town, Ad Fines, on the Ermin Street between Londinium (London) and Durolipons (Godmanchester), was most likely at Braughing, where are the remains of a vallum of a regular shape, and where a tesselated pavement, many silver coins, and other Roman antiquities have been found. It has been supposed that there were posts at or near Bishop's Stortford, at Royston (where some have proposed to fix the station Ad Fines), and at Cheshunt, but the evidence on which the supposition rests is not decisive.

At Wilbury Hill, three miles west of Baldock, is an antient camp on the Icknield Way, enclosing about seven acres; the rampart (four or five feet high) and ditch remain on the west side. Between Caldecot and Hinxworth, four or five miles north of Baldock, various Roman funeral and other antiquities have been dug up, including large urns full of burnt bones and ashes, pateræ of fine red earth with names impressed on the bottoms, glass lacrymatories, rings, beads, and fibulæ. Roman coins have been found at Ashwell in the same part of the county. A brass figure of Mars, and some thin plates with figures and inscriptions engraven upon them, were dug up in Rockley Wood, near Barley, not far from Royston; two Roman vessels of pale earth at Westmill, not far from Braughing, and coins at Bishop's Stortford and Cheshunt. Salmon proposed to fix the Roman station Durolitum at this last place. The Roman antiquities dug up near Hemel Hemstead have been noticed before.

When the Saxons subjugated Britain, Hertfordshire appears to have been included in the two kingdoms of Essex and Mercia: possibly the boundary of the dioceses of London and Lincoln may be nearly coincident with the boundary of the kingdoms. St. Alban's abbey, which was founded by Offa, king of Mercia, is indeed in the diocese of London; but Offa appears to have held the kingdom of Essex at this time in subjection, and therefore would not hesitate to found a religious house in it. Offley, not far from Hitchin, where Offa had a palace, and Bennington and Berkhamsted, also residences of the kings of Mercia, are in the diocese of Lincoln.

In the invasions of the Northmen which troubled the close of the reign of Alfred (A.D. 896), they brought their vessels up the Lea to the neighbourhood probably of Hertford or Ware. But Alfred, who pursued them, diverted the waters of the Lea into another channel, and obliged the Northmen to abandon their vessels and march across the island to the

Severn. Edward the Elder, son of Alfred, built Hertford Castle, probably with the view of checking the incursions of the Northmen who had been allowed to settle in East Anglia. An antient castle at Bishop's Stortford was probably built with the same design.

When William the Conqueror, after the battle of Hastings (A.D. 1066), advanced into the interior of the kingdom, his march was impeded near Berkhamsted by the bold conduct of Fretheric, abbot of St. Alban's, who caused the trees that grew by the road-side to be cut down. The same spirited ecclesiastic placed himself at the head of a confederacy, with which the Conqueror found it necessary to come to terms, by swearing, in a grand assembly of the clergy and nobles at Berkhamsted, to govern according to the antient laws of the realm, and especially those of St. Edward the Confessor: but when he thought himself strong enough, he scrupled not to break his oath.

In the civil broils of the reign of John, Hertford castle was defended for the king by Walter de Godarvil, a retainer of Fulk de Brent, against the revolted barons and the dauphin Louis of France; and in the troubles in the reign of Edward II. the barons confederated against Gaveston, the king's favourite, assembled their troops at Whethamsted, a few miles from St. Alban's, A.D. 1312. After the general rising of the peasantry under Wat Tyler and Jack Straw, many of the ringleaders were tried and executed at St. Alban's, the king being there at the time with a guard of 1000 men.

In the war of the Roses this county was repeatedly the scene of contest. In tho year 1455 three thousand men from the north, under Richard duke of York and the earls of Salisbury and Warwick, advanced towards London in order to seize and bring to trial the duke of Somerset, who had been impeached of treason by the House of Commons, but released by the influence of the queen, Margaret of Anjou. The insurgent nobles reached the neighbourhood of St. Alban's, which was occupied by the king, who had advanced from London with a body of two thousand men to impede their progress. After a vain attempt at negotiation the town was stormed by the Yorkists; the duke of Somerset and several other nobles and gentlemen of the royalist side fell in the battle, and the king himself was wounded and taken prisoner. In the year 1461 a second battle was fought at St. Alban's. The queen, who had just vanquished and slain the duke of York at Wakefield in Yorkshire, was advancing to London when she was met near St. Alban's by the Yorkists under the earl of Warwick, having the king with them. The battle was bloody, but the Lancastrians prevailed, and the king was restored to the keeping and use of his own faction. The battle of Barnet, A.D. 1468, in which Warwick fell in battle against Edward IV., whom he had been mainly instrumental in seating on the throne, was fought in Middlesex just beyond the boundary of Hertfordshire.

Of the monastic or castellated buildings of the middle ages Hertfordshire possesses but few remains. St. Alban's Abbey [ALBAN'S, ST.] is the chief; to which may be added Royston church, formerly conventual, and some remains of the priories at Hitchin and Ware. There are castles at Hertford and Berkhamsted [BERKHAMSTED]; some slight remains of a castle at Bishop's Stortford, and the earthworks of Austey or Anstic Castle, between Royston and Bishop's Stortford. Waltham Cross and Hatfield Palace have been noticed; there are some remains of a palace built by king Henry III. at King's Langley, between Watford and Berkhamsted.

In the breaking out of the war between Charles I. and the Parliament, this county was the scene of one of Cromwell's earliest exploits. While yet a captain of a troop of horse which he had raised, he arrested the high-sheriff of Hertfordshire as he was proceeding to St. Alban's to publish the king's proclamation declaring all the parliamentary commanders traitors. There has been no public event since of any moment connected with the county; but a circumstance which occurred in April of the year 1751 deserves notice as marking the extent of popular ignorance and barbarity at that period. A publican near Tring being troubled with fits, conceived that he was bewitched by an old woman named Osborne. Notice was given by the crier that two witches were to be tried by ducking; and in consequence a vast mob assembled at the time appointed. The old woman and her husband, who had been in Tring workhouse, were removed into the church for safety; but the mob obtained possession of the old man and old woman, whom they then dragged two miles to a muddy stream, ducked them, and otherwise so maltreated them that the woman died on the spot, and the man with difficulty recovered. Thomas Colley, one of the perpetrators, was executed on the spot; but so strong was the infatuation of the populace that it was thought necessary to have a guard of more than 100 troopers to escort the cavalcade to the place of execution.

STATISTICS.

Population.—Hertfordshire is principally an agricultural county; of 34,910 males twenty years of age and upwards, only 290 are employed in manufactures or in making manufacturing machinery, while 16,617 are occupied in agricultural pursuits; of those engaged in manufactures, 180 are employed at Tring, Watford, St. Alban's, and Tittenhanger (collectively) in spinning and winding silk and cotton, and in making ribbons; there are 49 machine-makers at Hemel Hempstead, and a few are employed at Royston in making wire-floors for malting. This county ranks the 13th in the list of agricultural counties.

The population of Hertfordshire at each of the four following periods was—

	Males.	Females.	Total.	Increase per cent.
1801	48,063	49,514	97,577	..
1811	55,023	56,631	111,654	14·42
1821	64,121	65,593	129,714	16·17
1831	71,395	71,946	143,341	10·50

showing an increase between the first and last periods of 45,764, or not quite 48 per cent., on the whole population; being 9 per cent. below the whole rate of increase throughout England.

The following table contains a summary of the population, &c., of every hundred, as taken in 1831:—

Summary of the County of Hertford.

HUNDREDS, CITIES, OR BOROUGHS.	HOUSES.				OCCUPATIONS.			PERSONS.			
	Inhabited.	Families.	Building.	Uninhabited.	Families chiefly employed in Agriculture.	Families chiefly employed in trade, manufactures and handicraft.	All other Families not comprised in the two preceding classes.	Males.	Females.	Total of Persons.	Males, twenty years of age.
Braughing, Hundred	3,307	3,641	15	136	1,272	1,120	1,249	8,971	8,856	17,827	4,436
Broadwater	3,103	3,303	8	51	1,931	782	590	8,607	8,436	17,043	4,138
Cashio	5,225	5,820	22	132	2,667	1,786	1,367	14,164	14,355	28,519	7,123

Edwinstree	1,782	1,991	2	49	1,164	396	431	4,707	4,530	9,237	2,262
Hertford	2,650	2,826	23	94	1,064	798	964	6,842	7,128	13,970	3,483
Hitchin and Pirton	1,991	2,179	6	41	1,189	643	347	5,244	5,467	10,711	2,518
Odsey	1,308	1,522	13	14	990	316	216	3,675	3,468	7,143	1,756
Hertford, Borough	841	913	2	9	36	390	487	2,757	2,490	5,247	1,266
Alban's, St.	800	1,105	3	33	92	560	453	2,245	2,527	4,772	1,095
Totals	26,549	29,250	119	699	13,268	8,552	7,430	71,395	71,946	143,341	34,910

County Expenses, Crime, &c.—The sums expended for the relief of the poor at the four dates of—

		£.		s.	d.	
1801	were	56,380,	being	11	6	for each inhabitant.
1811	„	76,701	„	13	8	„
1821	„	89,129	„	13	9	„
1831	„	94,336	„	13	1	„

The sum expended for the same purpose for the year ending March, 1837, was 49,670*l.*; and assuming that the population had increased at the same rate of progression as in the ten preceding years, the above sum gives an average of 6*s.* 6*d.* for each inhabitant. These averages are above those for the whole of England and Wales.

The sum raised in Hertfordshire for poor-rate, county-rate, and other local purposes, in the year ending the 25th of March, 1833, was 111,934*l.* 19*s.* and was levied upon the various descriptions of property as follows —

On land	£79,473	19
Dwelling-houses	26,124	12
Mills, factories, &c.	5,215	5
Manorial profits, navigation, &c.	1,121	3

The amount expended was—

For the relief of the poor	£91,323	17
In suits of law, removal of paupers, &c.	2,952	14
For other purposes	19,963	13
	£114,240	4

In the returns made up for subsequent years, the descriptions of property assessed are not specified. In the years 1834, 1835, 1836, and 1837, there were raised 108,189*l.* 16*s.*, 95,190*l.* 12*s.*, 77,749*l.* 12*s.*, and 59,369*l.* respectively; and the expenditure of each year was as follows:—

	1834. £.	s.	1835. £.	s.	1836. £.	s.	1837. £.
For the relief of the poor	85,799	13	70,997	17	59,368	17	49,670
In suits of law, removals, &c.	2,056	19	1,949	3	1,402	8	756
Payment towards the county-rate	19,720	12	9.465	13	8,053	19	5,230
For all other purposes			12,187	2	7,558	18	3,628
Total money expended	£107,577	4	94,599	15	76,384	2	59,284

The saving effected on the whole sum expended in 1837, as compared with that expended in 1834, was therefore about 45 per cent.; and the saving effected on the sum expended for the relief of the poor was rather more than 44 per cent. in 1837, as compared with the expenditure in 1834

The number of turnpike trusts in Hertfordshire, as ascertained in 1835, is 11; the number of miles of road under their charge is 170; the annual income in 1835, arising from the tolls and parish composition, was 28,336*l.* 6*s.* 10*d.*, and the annual expenditure 26,753*l.* 19*s.* 9*d.*

The county expenditure in 1834, exclusive of that for the relief of the poor, was 5500*l.* 11*s.* 6*d.*, disbursed as follows:—

	£.	s.	d.
Bridges, building, and repairs, &c	68	3	6
Gaols, houses of correction, &c., and maintaining prisoners, &c.	2832	9	6
Shire halls and courts of justice, building, repairing, &c.	72	13	0
Prosecutions	768	17	8
Clerk of the peace	385	5	6
Conveyance of prisoners before trial	536	1	11
Conveyance of transports	70	1	6
Vagrants, apprehending and conveying	73	19	8
Constables, high and special	198	7	0
Coroner	131	19	6
Debt, payment of, principal and interest	106	13	4
Miscellaneous	255	19	0

The number of persons charged with criminal offences in the three septennial periods ending with 1820, 1827, and 1834, were 747, 1047, and 1730, respectively; making an average of 107 annually in the first period, of 149 in the second period, and of 247 in the third period.

The number of persons tried at quarter-sessions in each of the years 1831, 1832, and 1333, in respect to which any costs were paid out of the county-rates, were 64, 76, and 106 respectively. Among the persons charged with offences, there were committed for—

	1831.	1832.	1833.
Felonies	49	49	88
Misdemeanors	15	21	18

The total number of committals in each of the same years was 95, 101, and 167 respectively.

	1831.	1832.	1833.
The number convicted was	59	71	109
„ acquitted	12	15	29
Discharged by proclamation	24	15	29

In 1837 there were 335 persons charged with crimes at the assizes and sessions in Hertfordshire. Of these, 9 were charged with offences against the person, 6 of which were for common assaults; 21 for offences against property committed with violence; 283 for offences against property, committed without violence; 1 for killing and maiming cattle; 8 for uttering counterfeit coin; 10 for poaching; and 2 for other misdemeanors. Of the whole number committed, 243 were convicted, 68 were acquitted, 6 were not prosecuted, and no bill was found against 18. Of those convicted, 4 were sentenced to death, the sentence of 3 of whom was commuted to transportation for life, and of 1 for 7 years; 17 others were transported for life, 1 for 15 years, 4 for 14, 11 for 10, 29 for 7 years, and 1 for some other period; 2 were imprisoned for three years or above 2 years, 7 for two years or above 1 year, 8 for 1 year or above 6 months, and 154 for 6 months or under; and 5 were fined. Of the whole number of offenders, 306 were males, and 29 females; 194 could neither read nor write, 91 could read and write imperfectly, 45 could read and write well, and the degree of the remaining 5 could not be ascertained.

The number of persons qualified to vote for the county members of Hertfordshire is 5098, being about 1 in 28 of the whole population, and about 1 in 7 of the male population twenty years of age and upwards, as taken in 1831. The expenses of the last election of county members to parliament were to the inhabitants of the county 496*l.* 14*s.* 10*d.*, and were paid out of the general county-rate.

There are 5 savings' banks in this county. The number of depositors and amount of deposits on the 20th November in each of the following years were—

	1832.	1833.	1834.	1835.	1836.
Number of depositors	3,055	3,209	3,320	2,485	2,073
Amount of deposits	£130,449	£134,415	£137,120	£92,395	£72,044

The various sums placed in the savings' banks in 1835 and 1836 were distributed as under:—

		1835. Depositors	1835. Deposits.	1836. Depositors.	1836. Deposits.
Not exceeding	£20	1,224	£9,166	1,009	£7,984
„	50	699	21,541	621	19,128
„	100	320	22,125	267	18,290
„	150	120	14,290	92	10.886
„	200	82	14,127	70	11,861
Above	200	40	11,.46	14	3,895
		2,485	92,395	2,073	72,044

Education.—The following summary is taken from the Parliamentary Returns on Education made in the session of 1835:—

	Schools.	Scholars.	Total.
Infant schools	55		
Number of infants at such schools; ages from 2 to 7 years:—			
Males		310	
Females		378	
Sex not specified		269	
			957
Daily schools	451		
Number of children at such schools; ages from 4 to 14 years:—			
Males		6,110	
Females		5,555	
Sex not specified		2,130	
			13,795
Total number of schools	506		
Total of children under daily instruction			14,752
Sunday schools	191		
Number of children at such schools; ages from 4 to 15 years:—			
Males		5,067	
Females		5,879	
Sex not specified		2,173	
			13,119

Assuming that the population between the ages of 2 and 15 is in the same proportion to the whole population as it was in 1821, and that it has increased in the same ratio since 1831 as the whole population did in the ten years preceding that date, we find by approximation that there were 49,214 children between the ages of 2 and 15 in the county of Hertfordshire, in 1834, the time the Educational Inquiry was made. Sixteen Sunday-schools are returned from places where no other school exists, and the children, 924 in number, who are instructed therein, cannot be supposed to attend any other school: at all other places Sunday-school children have opportunity of resorting to other schools also; but in what number, or in what proportion, duplicate entry of the same children is thus produced, must remain uncertain. Forty schools (containing 2291 chidren), which are both daily and Sunday schools, are returned from various places, and duplicate entry is therefore known to be thus far created. Making allowance from this cause for a number of children having been entered twice as under instruction, we may perhaps fairly conclude that about half of the children between the ages of 2 and 15 are receiving instruction in this county.

Maintenance of Schools.

Description of Schools.	By endowment.		By subscription.		By payments from scholars.		Subscrip. and payment from scholars.	
	Schls.	Scholars.	Schls.	Scholars.	Schls.	Scholars.	Schls.	Scholars.
Infant Schools	..	..	9	262	39	448	7	247
Daily Schools	46	1,691	65	2,977	302	6,899	38	2,228
Sunday Schools	11	660	162	11,219	1	56	17	1,184
Total....	57	2,351	236	14,458	342	7,403	62	3,659

The schools established by Dissenters, included in the above statement, are—

	Schools.		Scholars.
Infant schools . .	—		—
Daily schools . .	12,	containing	433
Sunday schools . .	51	„	4,824

The schools established since 1818 are—

			Scholars.
Infant and other daily schools	240,	containing	7,574
Sunday schools . .	110	„	8,587

Forty-six boarding-schools are included in the number of daily-schools given above. No school in this county appears to be confined to the children of parents of the Established Church, or of any other religious denomination, such exclusion being disclaimed in almost every instance, especially in schools established by Dissenters, with whom are here included Wesleyan Methodists, together with schools for children of Roman Catholic parents.

Lending libraries of books are attached to 32 schools in Hertfordshire.

HERTHA, or HERTHUS, the Goddess of Earth among the antient Germans. Tacitus (*Mor. German.*, c. 40) says that she was worshipped by the Suevi, and that her sanctuary was in a grove in an island of the ocean, and was served by a single priest. A cart, covered by a cloth to conceal the goddess, was taken out of the sanctuary on certain occasions, and was drawn by cows about the country with great solemnity. This was a time of general rejoicing, especially for those places which were honoured by the visit of the goddess. During that time a cessation of war took place, arms were laid aside, and peace reigned over the land, until the priest thought proper to restore the goddess to her sanctuary, where the cart and the clothing, and the goddess herself, or her image, it was said, were washed in a secret pond, and the attendants who assisted at these ablutions were immediately after swallowed up by the flood. The report of these mysterious circumstances served to inspire the ignorant people with a dread of the power of the goddess, whom no mortal could behold with impunity.

HERVEY, JAMES, born in 1714, was educated at Lincoln College, Oxford, where he became acquainted with the first Methodists, whose views and society, though he did not enter into their connexion, influenced his course through life. He took orders in the Established church, devoted his whole life to acts of piety and beneficence, and the sedulous discharge of his clerical duties, and died early, of a decline brought on by labouring beyond his strength, in 1758. For some years preceding he had been rector of Weston-Favell in Northamptonshire. His works are numerous, and all religious: his style is metaphorical, flowery, diffuse, abounding in turgid declamation and strained fancies. Faulty as it is, it enjoyed its season of extensive popularity; and probably has won the notice of many who would have been less attracted by a purer writer. In doctrine he leaned towards the Calvinistic school. The most popular of his works were, 'Meditations among the Tombs,' 'Contemplations in a Flower-Garden, 'On the Night,' &c., 1746-7; and 'Theron and Aspasia; or, a series of Dialogues and Letters on the most important Subjects,' 1753. (Watt, *Bibl. Britann.*)

HESIOD (in Greek, Hésiodos) was a native of Ascra, a village at the foot of Helicon, whither his father had migrated from Cuma in Æolis. From thence he went to Orchomenos, according to his editor Goettling, who thinks that by the line 'Ascra, foul in the cold, oppressive in heat, bad at all times,' he expresses resentment at the iniquitous conduct of the Ascræan judges with respect to the division of his patrimony. Thirlwall doubts the truth of the interpretation, although Goettling quotes a passage of Paterculus (i. 7), which might by possibility refer to it. These facts are collected from the 'Works and Days,' a poem which there is no reason not to ascribe partially, although only partially, to Hesiod. Plutarch tells us that he met his death in consequence of the suspicions of some young men regarding their sister's honour, and we learn from Pausanias that he was revered in later times as a hero.

The only works that remain under the name of Hesiod are, 'The Theogony,' 'The Shield of Hercules,' and the 'Works and Days.'

The Bœotians themselves are said to have considered the last as Hesiod's, although they doubted the authenticity of the other works ascribed to him; but the ingenuity of modern times professes to discover interpolations even in this poem, which consists of advice given by Hesiod to his brother Perses, on subjects relating for the most part to agriculture and the general conduct of life. Whatever may be the decision which is arrived at regarding the authorship, we think one thing must be very evident to all who read the poem, that in its present state it shows want of purpose and of unity, too great to be accounted for otherwise than on the supposition of its fragmentary nature. Ulrici considers the moral and the agricultural instruction as genuine, the story of Prometheus and that of the Five Ages as much altered from their original Hesiodic form, and the description of Winter as latest of all.

The 'Theogony' is perhaps the work which, whether genuine or not, most emphatically expresses the feeling which is supposed to have given rise to the Hieratic school.* It consists, as its name expresses, of an account of the origin of the world, including the birth of the gods, and making use of numerous personifications. This has given rise to a theory that the old histories of creation, from which Hesiod drew without understanding them, were in fact philosophical and not mythological speculations; so that the names which in after-times were applied to persons, had originally belonged only to qualities, attributes, &c.; and that their inventor had carefully excluded all personal agency from his system. Thus much we may safely assert respecting the 'Theogony,' that it points out one important feature in the Greek character, and one which, when that character arrived at maturity, produced results of which the 'Theogony' is at best but a feeble promise; we mean that speculative tendency which lies at the root of Greek philosophy.

The 'Shield of Hercules' is a fragment, or rather a cluster of fragments; some of them by very late Rhapsodists who copied, according to Aristophanes the grammarian, from Homer's description of the shield of Achilles.

Those who are desirous to pursue the subject of the 'Theogony,' will do well to consult Ulrici, *Geschichte der Hellen. Dichtkunst*, 1, 360, 199; Hermann and Creuzer's *Briefe über Homer und Hesiod;* Creuzer's *Symbolik;* and especially Mr. Thirlwall's *History of Greece*, and Müller's *Prolegomena.*

The best modern editions of Hesiod are Goettling's (in 1 vol. 8vo., published in the *Bibliotheca Græca*), and Dindorf's, Leipzig, 1825, 8vo.

HE'SIONE (Zoology), the name of a genus of *Dorsibranchiate Annelids* [DORSIBRANCHIATA, vol. ix.], with a short but rather stout body, composed of a few ill-defined rings. A very long cirrhus, which probably executes the

* We use the word Hieratic with reluctance, but we are not aware what other single word would express what we mean, namely, that school of epic poetry which is connected with the religious life of the Greeks in the same way as Homer and the heroic poets were with the political.

function of branchiæ, occupies the upper part of each foot, which has also another lower one and a packet of fine bristles. The proboscis of *Hesione* is large, and without either jaws or tentacles. The reader will find, in the great work on Egypt, figures and descriptions of *Hesione splendida*, Sav., and *H. festiva*, Sav.

HESPE'RIDES, in Greek mythology, a family of Nymphs, of the same parentage, and apparently the same with the Atlantides, though there are differences between them, especially in number (the Atlantides being usually reckoned seven, and the Hesperides three in number), which we must leave to be accounted for by the general uncertainty of mythological story. They are named Ægle, Arethusa, and Hesperethusa, and were the daughters of Atlas, by Hesperis, the daughter of Hesperus. They dwelt in a beautiful garden in the western parts of the earth, in which grew the celebrated tree which bore golden apples. These apples were guarded by a fierce dragon named Ladon, which never slept. Hercules killed the dragon and carried off the precious fruit. Some authors make the treasure to consist of sheep instead of apples, both being called by the same Greek word, *mela*. Some think them citrons or oranges. The Gardens of the Hesperides are variously placed, in an oasis of the African desert, in Cyrenaica, at the foot of Mount Atlas, and in the Happy Islands of the Atlantic.

HESPERI'IDÆ (Stephens), a family of Lepidopterous insects of the section *Lepidoptera Diurna* of Latreille. Distinguishing characters:—Antennæ terminated by a distinct club, generally with a minute hook at its extremity; tibiæ with two pairs of spurs, one at the apex, and the other near the middle; claws very small, bifid, body thick, wings small, the posterior pair with a groove to receive the abdomen. The larvæ are pubescent, or naked, and have a large head; pupa smooth, enclosed in a web.

These little butterflies have a large head, and a thicker body and smaller wings than the more typical species; they are moreover at once distinguished from them by their possessing two pairs of spurs, or spines, to the legs; their flight is short and in frequent jerks, hence they have received the name of *skippers*.

Hesperia Sylvanus is about one inch and a quarter in width; the wings are of a rich brownish yellow above, with the outer margins deep brown; the anterior wings are spotted towards the apex with yellow, and have an oblong black dash near the base; the posterior wings have some indistinct spots.

This butterfly, which is very common in various parts of England, and is chiefly found on the borders of woods, will afford an example of the tribe of which we are treating.

There are several other species of the family Hesperiidæ found in this country, of which the *Thymele alveolus* may be noticed. This is a little black butterfly with numerous silver-like spots, and is known by the English entomologists by the name of the *Grizzled Skipper*.

HESPERIDIUM, one of those fruits which, in common botanical language, is confounded with the word Bacca [BACCA], but which indicates a different structure. It has a tough separable rind, the seeds hardly lose their attachment when ripe, and the cells readily separate through the dissepiments. Of this nature is the fruit of the orange, which is the type of the Hesperidium.

HESSE, an extensive country of Germany, which, in antient times, was inhabited by the Catti, part of whom however emigrated before the Christian æra to the Low Countries, where they were called Batavi. The Catti are mentioned under the emperors Augustus and Tiberius. Germanicus burnt their chief seat, Mattium (probably Marburg), A.D. 15. [CATTI.] In the sequel they belonged to the great empire of the Franks, losing their name in the third or fourth century. The Christian religion was introduced even before Charlemagne's reign by Boniface, the apostle of the Germans, archbishop of Mainz (Mayence), who preached here; and Christian churches and convents flourished in the seventh century at Hersfeld, Fulda, Frizlar, Amöneberg, &c. Till about the middle of the thirteenth century the history of Hesse was blended with that of Thüringen; but Henry Raspe, landgrave of Thüringen, dying without children, in 1247, a war for the succession took place, which was terminated in 1263 by a compact, by which Hesse was separated from Thüringen, and assigned to Henry, son of Sophia, duchess of Brabant, daughter of the late landgrave's brother, who was the common ancestor of all the succeeding landgraves of Hesse. It is beside our purpose to detail the various changes that occurred in consequence of the alternate partitions of the territory among the sons of the sovereigns, and the re-unions on the extinction of collateral lines. Philip I., surnamed the Generous, who succeeded his father William II. in the sovereignty of the whole country in 1509 (the other line becoming extinct in the person of William III.), and who introduced the Reformation, divided his dominions among his four sons: William IV., the eldest, obtained one-half, with Cassel, the capital; Louis IV. a fourth part, with Marburg; Philip II. an eighth, with Rheinfels; and George I. an eighth, with Darmstadt. But Philip II. dying in 1583, and Louis IV. in 1604, without issue, there remained only the two still flourishing main branches of Hesse-Cassel and Hesse-Darmstadt.

HESSE-CASSEL, from the time of William IV., 1592, suffered, in the successive wars which desolated Germany, but did not sustain any loss of territory; on the contrary, it made several acquisitions. After the Thirty Years' War Hessian mercenaries in the service of other Continental powers were employed in almost all the European and Turkish wars; a system which indeed enriched the princes of Hesse, but did not tend to promote the prosperity of the country. Frederick II., who succeeded to the government in 1760, though he embraced the Roman Catholic religion, signed an engagement to his family and the Estates, under the guarantee of England, Denmark, Sweden, Prussia, and Holland, not to change the constitution in church and state, and he also had his children educated in the Protestant religion. He kept a splendid court, beautified his capital, Cassel, and liberally promoted the arts and sciences. All this he was enabled to do by increasing his military force, of which he let out several thousand men to England in the American war, and received for them, from 1776 to 1784, above three millions sterling. He died in 1785, and was succeeded by the landgrave William IX., who in the war of the French revolution not only furnished his contingent as a prince of the empire, but had also a body of troops in the pay of England. In 1796 he joined in the treaty of Basel, and allied himself with Prussia. For the loss of his territories beyond the Rhine he received ample indemnities, and on the 25th February, 1803, obtained the dignity of elector, on which he took the title of William I. When war broke out between Prussia and France in 1806, both parties recognised the neutrality of Hesse; but within less than a month afterwards Napoleon, pretending that the elector was partial to the Prussians, seized on Cassel; and by the peace of Tilsit the greater part of the electorate was incorporated with the new kingdom of Westphalia. A secret article reserved to the elector, as an indemnity for the loss of his dominions, an annuity to be paid by Westphalia, which he refused to accept, and retired first to Holstein, and then to Prague, where he lived as a private individual. After the battle of Leipzig, 1813, he returned to his capital, where he was enthusiastically received by his subjects. He concluded a treaty with the allied powers, and subsequently became a member of the German Confederation. Unfortunately he did not live on good terms with his subjects, to whom he thought of giving a new constitution, but could not agree about it with the antient Estates. He alienated the affections of the people by reviving old monopolies, by refusing to recognise the validity of any act of the late government, and by harassing those who had served under it. He died in 1821. His son and successor, William II., has embroiled himself still more seriously with his subjects; in the first instance, by the scandal of his connexion with the countess of Reichenbach, who took the title of countess of Lessonitz from an estate purchased for her in Moravia. A pseudonymous letter, threatening both with death, unless a constitution were given to the country and the influence of the countess in the government put an end to, gave occasion to arbitrary inquisitorial proceedings, which incensed the people, and caused dissension in the elector's own family. The fermentation increased, serious riots took place in 1830, the countess left Cassel, the elector consented to assemble the Estates, and the constitution being presented to them by the elector on the 9th January, 1831, general joy prevailed, which was interrupted by the return of the countess on the 11th. Fresh disturbances arose, and the countess left Cassel; but the elector was so angry that he also left Cassel, and could not be induced to return. He appointed his son, the electoral prince, regent, who entered on his functions October 1, 1831 Fresh discontents arose, and new troubles were caused by the accession of the electorate to the Prussian commercial league.

Situation; Extent; Boundaries.—The electorate of Hesse is situated between 50° 6′ and 52° 25′ N. lat. and 8° 25′ and 10° 45′ E. long. It consists of three distinct portions, of which the largest, extending only to 50° 40′ lat. and 10° 15′ long., is bounded on the north-east by Hanover and the Prussian province of Saxony, on the east by Weimar and Bavaria, on the south by Bavaria, on the west by Nassau and Hesse Darmstadt. The detached portions are the county of Schaumburg to the north, surrounded by Hanover and Lippe, and the lordship of Schmalkalden to the east, surrounded by the Saxon principalities and the Prussian circle of Schleusingen. The area of the whole is 4350 square miles.

Divisions.—The electorate is divided into four provinces, with a total population, at the end of 1835, of 700,583 inhabitants.

I. Lower Hesse (337,400 inhabitants), divided into ten circles, with 34 towns, 8 market-boroughs, and 519 villages. Chief towns, Cassel, the capital of the electorate [Cassel], with 29,931 inhabitants (garrison included); Eschwege, 5086 inhabitants. There is no other town with 5000 inhabitants. Among the principal are, Frizlar (2882 inh.), Hofgeismar (3195 inh.), Melsungen (3341 inh.), Rothenburg on the Fulda, with a palace, late the residence of the landgrave, and 4 churches (3461 inh.), Rinteln (3297 inh.), Witzenhausen (2490 inh.), Allendorf (2853 inh.), Wolfshagen (2761 inh.), Volkmarsen (2796 inh.), Homberg-on-the-Efze (3007 inh.).

II. Upper Hesse (114,769 inh.), divided into 4 circles, with 16 towns, 4 market-boroughs, and 206 villages; chief towns, Marburg, the capital (7640 inh.), and seat of the university; Frankenburg (2868 inh.)

III. Fulda (133,577 inh.), 5 towns, 7 market-boroughs, and 198 villages. It consists of, 1, the grand-duchy of Fulda (48,314 inh.), chief town Fulda (9571 inh.); 2, the circle of Hersfeld (31,414 inh.), chief town Hersfeld (6307 inh.); 3, the circle of Hünfeld (2896 inh.), chief town Hünfeld (2000 inh.); 4, the lordship of Schmalkalden (25,749 inh.), chief town Schmalkalden (4832 inh.).

IV. Hanau (114,797 inh.), 7 towns, 14 market-boroughs, 189 villages, divided into 4 circles; chief towns, Hanau, capital of the principality (Hanau, according to the most recent account, 14,834 inh.) [Hanau], Gelnhausen (2137 inh.), Steinau (2317 inh.).

Hesse-Cassel, as a member of the German Confederation, is the eighth in rank, has in the full council 3 votes, one in the minor council, furnishes a contingent of 5679 men, which forms part of the second division of the eighth corps of the army of the Confederation, and contributes 1500 florins annually to the treasury of the Confederation.

Face of the Country, Soil, Climate.—The country is in general hilly; but it contains numerous valleys, which in some places expand into more extensive plains. On the south-east and south the Thüringerwald, the Rhön, and the Spessart, extend their branches into the country from the Saxon duchies and Bavaria, and cover the province of Hanau, and the whole tract between the Werra and the Fulda. Schmalkalden is situated on the mountain called the Thüringerwald, on the northern frontier of which is the Inselberg (2932 feet high). The mountain is thickly-wooded, chiefly with red pine and fir. The other principal chains are the Hundsrück, the Wesergebirge, and the Vogelsgebirge. The soil of Hesse is not indeed distinguished in general by great fertility, but it can by no means be called sterile. The finest parts are the beautiful valleys of the Fulda, the Schwalm, the Edder, and the Werra. The climate is on the whole temperate, and everywhere healthy; mildest on the banks of the Main, and most severe in Fulda, on the summits of the Rhön. The principal rivers are the Maine, the Weser, the Werra, the Lahn, and the Fulda. The last, though not the largest, is the most important river of Hesse; rising in Bavaria, it traverses the circles of Fulda, Hersfeld, Rothenburg, Melsungen, and Cassel, becomes navigable at Fulda, and joins the Werra at Münden, in the kingdom of Hanover, both together forming the Weser. The Maine only just touches the south-west corner of the country, and being joined by the Kinzig near Hanau, flows into the Rhine. The Lahn, traversing the circle of Marburg, joins the Rhine below Coblenz. There are no lakes, but numerous large ponds, of which there are forty of various sizes in the district of Diemel alone.

Natural Productions.—Corn, maize, pulse, and potatoes in great abundance, especially in the mountainous parts, are cultivated. Flax and timber are staple articles: tobacco, hemp, madder, a few hops, and rapeseed, are also among the products. The vine is cultivated only in some parts of Hanau. The pasturage is in general good. Garden produce of excellent quality is raised about Cassel and Hanau; fruits are cultivated chiefly in Upper Hesse, Hanau, and Hersfeld, whence large quantities of dried fruits are exported. The breeding of cattle is pretty general, but much neglected in some parts; there are horses enough for the purposes of agriculture; and sheep chiefly in Lower Hesse, Hanau, and Fulda. Domestic poultry and game are very abundant. Hesse abounds in mineral wealth, producing silver, copper, lead, iron, quicksilver, cobalt, salt (from saline springs in great quantities), saltpetre, vitriol, and alum. There are also coals, marble, very fine white alabaster, porcelain, potter's, and pipe clay, &c.

Manufactures and Trade.—The manufactures, which are chiefly in Cassel, Hanau, and Fulda, are insufficient for home consumption. The principal are linen, mostly coarse, which is exported to the value of 300,000*l.* sterling annually fine linen is made in Cassel and Herzberg. Cotton spinning has been introduced of late years, and is become pretty general. Schmalkalden manufactures almost all the steel and iron of the country; Grossalmerode is celebrated for its crucibles, which are exported to all parts of the world. With respect to trade, there is properly no commercial town, and the two fairs at Cassel are of little importance. The exports are corn, dried fruits, timber, leaf tobacco, wrought iron, linen, earthenware, crucibles, salt, &c. The imports are colonial produce, wines, silk, cotton, and manufactured articles of all kinds, but not to a large amount, the inhabitants being very simple in their habits and mode of living. The proximity of Frankfort favours a profitable transit trade with the North of Germany, and the treaties lately concluded between Holland and the States on the Rhine will doubtless tend to promote the foreign commerce of Hesse.

The Revenue.—By the triennial budget for 1837—1839, the expenditure is estimated at 3,330,070 dollars, and the receipts at 3,314,810 dollars; leaving a deficiency of 15,260 dollars; but there is reason to expect that there will be a surplus. On the 1st of January, 1837, the public debt was 1,540,850 dollars, at 4 per cent. interest, of which however 900,000 dollars are in the hands of the government. The interest of the debt has been reduced to 3½ per cent.

The *army* consists of six regiments of infantry of the line, two battalions of foot guards, two battalions of light infantry, and two regiments of cavalry.

The *Constitution* of January, 1831, is one of the most liberal in Germany. The estates form only one chamber; the electoral dignity is hereditary, to the exclusion of females. Though there is no longer an emperor of Germany, and consequently no elector, the sovereign of Hesse-Cassel has thought fit to retain the title of elector. Since the introduction of the constitution, many good laws have been passed, and many material improvements introduced; but unhappily, there have been serious differences between the government and the states, some of which have been compromised, but one of much importance remains undecided. It arose on the extinction of the collateral branch of Hesse-Rotbenburg by the death of the landgrave Victor Amadeus, in Nov. 1834; the revenue of his domains (250,000 dollars) is claimed by the Estates as public property, whereas the elector affirms it to belong to the private property of his family.

Religious Education.—The great majority of the inhabitants are Protestants (for the most part, with the court, Calvinists), the Roman Catholics 102,000, the Jews about 9000. A law for the emancipation of the Jews was passed in 1833. The Protestant Church is under superintendants; and the Roman Catholic under the bishop of Fulda, which was erected into a see in 1822. Hesse has a university at Marburg; 1 lyceum, 6 gymnasia, 1 episcopal seminary, 3 seminaries for schoolmasters, 2 academies of drawing and painting, and 63 town schools, and elementary schools in all the villages.

HESSE-DARMSTADT, the grand-duchy of which is governed by the second main branch of the house of Hesse, was founded in 1567, as stated under Hesse-Cassel, by George I., youngest son of Philip the Generous, of whose dominion he obtained one-eighth with Darmstadt, and a small addition on the death of his brother Philip without issue. On the death of George his dominions were divided among his three sons. Louis V. succeeded him in the principal line; Philip obtained Butzbach, which reverted on his death to the main line; and Frederick, the youngest, was the founder of the junior line of Hesse-Darmstadt, namely, that of Hesse-Homburg. Excepting the ruinous effects of the Thirty Years' War, the reigns of the succeeding princes were on the whole prosperous, and various acquisitions of territory were made. Louis IX., who reigned from 1768 to 1790, was a friend of peace and a patron of the arts and sciences. He found the country burdened with a large debt, which he paid off, and left to his son, Louis X., an improved territory with 300,000 inhabitants. This prince, during his long reign of forty years, was a greater gainer than almost any other German sovereign by the consequences of the French revolution; that is to say, he acquired very large additions to the extent of his dominions and the number of his subjects. By the treaty of Luneville, 1801, and by the settlement of the affairs of the empire, in 1803, he lost territories containing above 100,000 inhabitants, and obtained instead, provinces more than double the extent, with 218,000 inhabitants. In 1806 he joined the Confederation of the Rhine, and obtained from Napoleon still further accessions of territory, with 112,000 inhabitants, and the dignity of grand-duke, on which he took the title of Louis I. In 1809 his troops acted against Austria, and the peace brought him new accessions of territory. In 1813 he was at first obliged to let his troops serve with the French; but after the battle of Leipzig he joined the allies, on their engaging to let him retain his newly-acquired provinces. In 1815 the grand-duke joined the German Confederation. By the decision of the congress at Vienna he indeed made large cessions on the right bank of the Rhine, with 185,000 inhabitants, to suit the convenience of Prussia and other states, but obtained on the left bank a part of the then late French department of Mont Tonnère, with Bingen, Mainz, and other towns, containing 203,854 inhabitants; so that he gained an addition of above 18,000 subjects. It is to be hoped that these continual changes, these transfers of entire provinces backwards and forwards, like so many bales of merchandise, are now at an end. They are but ill-calculated to ensure that affection of the people to their princes which is the firmest support of hereditary sovereignty; though they may perhaps have the effect of rendering the princes more solicitous to acquire, by good government, the affection of their new subjects. His son and successor Louis II. has been engaged in continual disputes with the Estates; and disturbances, in some instances attended with bloodshed, have broken out on different occasions. The Polish revolution caused a very great excitement in Hesse-Darmstadt; the deepest sympathy was felt for the Polish fugitives; associations of ladies were formed for their relief; addresses from Mainz and Darmstadt in their favour were presented to the German diet, but it did not accept them; the influence of the French propagandas was felt; and severe ordinances were issued by the government against popular festivals and meetings, distinctive badges, political associations, &c. Many changes made by the grand-duke in the internal administration were disapproved by the Estates; and though they acknowledged, in 1832, that there was on the whole a progressive improvement, a strong opposition was formed in the second chamber. Prosecutions for political offences were instituted; yet, in spite of many attempts to inflame the people's minds, the grand-duke's family received on several occasions, for instance on the marriage of the hereditary grand-duke in 1833, unequivocal marks of loyalty and attachment. Yet emigration to America has rather increased than diminished, and even families in good circumstances leave their native land to seek another home beyond the Atlantic.

The grand-duchy of Hesse-Darmstadt consists of two large portions, which are separated from each other by a long strip of land, extending from east to west, belonging to Hesse-Cassel and the city of Frankfort. Taking the town of Bingen for the most westerly and Schlitz for the most easterly point, Wimpfen (in a small detached portion in Würtemberg) as the most southerly, and the village of Eimelrod (in the lordship of Itter) as the most northerly point, the grand-duchy is situated between 7° 50′ and 9° 40′ E. long. of Greenwich, and between 49° 12′ and 51° 20′ N. lat. The northern portion is bounded on the west by Prussia and Nassau; and on the north, east, and south, by Hesse-Cassel. The southern portion is bounded on the north by Nassau, Frankfort, and Hesse-Cassel; and on the other sides, by Bavaria and Baden.

The area of the whole is about 5000 square miles.

Divisions.—The grand-duchy is divided into 3 provinces.

I. STARKENBURG (256,745 inhab.) contains 22 towns, 24 market-villages, and 382 other villages; chief towns, Darmstadt (24,500 inh.), the capital of the grand-duchy [DARMSTADT]; Pfungstadt (2800 inh.), Griesheim (2400 inh.), Bensheim (4000 inh.), Heppenheim (3600 inh.), Gernsheim (2900 inh.), Lorsch (2749 inh.), Lampertheim (2900 inh.), Dieburg (3000 inh.), Offenbach on the Main (8000 inh.), and Offenbach.

II. RHEINHESSEN, that is, RHENISH HESSE (190,000 inh.), contains 10 towns and 180 villages: Oppenheim (2200 inh.), Mainz (31,000 inh.), the greatest fortress of the German confederation [MAINZ]; Worms (8000 inh.) [WORMS], and Alzei (4200 inh.).

III. OBERHESSEN, or UPPER HESSE (271,642 inh.), with 34 towns, 10 market-villages, and 510 other villages; chief towns, Giessen, the provincial capital (8000 inh.) [GIESSEN], Friedberg (3200 inh.), Bübingen (2700 inh.), Alsfeld (3700 inh.), Lauterbach (3400 inh.), Schlitz (3200 inh.), Biedenkopf, on the Lahn (3200 inh.).

To the province of Upper Hesse belongs the entirely detached district of Wöhl, or Itter, the most northern part of the grand-duchy, a wild sterile country, surrounded by the territory of Waldeck.

The grand-duchy of Hesse, as a member of the German Confederation, is the ninth in rank, has three votes in the full council and one in the minor council, furnishes a contingent of 6195 men to the 2nd division of the 8th corps, and contributes 1500 florins annually to the treasury of the Confederation.

Face of the Country, Soil, Climate.—A large part of the surface of the country is mountainous. The banks of the Rhine, and the Wetterau, which contain about 400 square miles, are pretty level and very fertile: the remainder of the country is traversed by branches of the Vogelsgebirge, the Odenwald, Taunus, and the Westerwald; but of the two latter only small portions extend into the grand-duchy. The Vogelsgebirge, in Upper Hesse, is a volcanic mass, which with its branches occupies 400 square miles: it consists chiefly of basalt, and of various compact and porous lavas. The Odenwald, in Starkenburg, presents a pleasing and picturesque rather than a wild mountain character. Most of its summits are clothed with forests of oak, beech, and fir, while the broad well-watered valleys and middle declivities are covered with numerous habitations and carefully cultivated. Hesse-Darmstadt is on the whole an agricultural country. The chief productions are corn of all kinds, likewise maize and spelt; wheat and rye chiefly in Rhenish Hesse and the Wetterau; flax, hemp, hops, tobacco, pulse, potatoes, wines, both white and red, garden vegetables and fruit, and timber. Rhenish Hesse is nearly destitute of timber. The valleys of the Odenwald and Vogelsgebirge are well adapted to the breeding of cattle, of which there are about 250,000 horned cattle, and 200,000 sheep. Swine are kept chiefly in Upper Hesse and Starkenburg. The breeding of horses is much neglected. Domestic poultry is abundant; game is not scarce, but it is not plentiful. Mining is not carried on so extensively as might be expected: it is confined to copper, iron, coals, salt, and brown coal. Cobalt, basalt, lime, sandstone, marble, and slate, are found in different parts of the grand-duchy. The chief rivers are the Rhine (2500 feet broad at Mainz), and the Main, and next to these the Lahn, the Schwalm, the Nidder, the Ohm, and the Itter.

Manufactures and Trade.—Though the manufactures have greatly improved of late years, yet much still remains to be done. The chief manufactures are of woollens, cottons, and linen (of which latter 600,000 ells are annually made in Schlitz), leather, and hardware. Wine is produced chiefly in Rhenish Hesse. The most considerable manufacturing and trading town is Offenbach, which has two annual fairs. Mainz is the principal place for the transit-trade. The exports consist of the natural productions of the country and of some manufactures. Hesse-Darmstadt joined the Prussian commercial league in 1828.

The Revenue is estimated at 6,576,105 florins, and the expenditure at an equal sum, including the interest of the debt, which is above ten millions of florins. Provision is made for the gradual extinction of this debt.

The military establishment in time of peace is fixed at

6288 men, namely, 908 cavalry, artillery 308, infantry 4965, a company of sappers and miners 61, general staff 6. The war establishment is 9469 men.

Religion, Education.—Of the 718,000 inhabitants, 516,000 are Protestants (in 1822 the Lutherans and Calvinists in Rhenish Hesse united in one Evangelical church), 177,888 Roman Catholics, about 1300 Mennonites, and 22,174 Jews. In education Hesse is not so forward as some other German states; but considerable improvements have lately been made. There is one university (Giessen), a philological seminary, an episcopal seminary, 2 seminaries for schoolmasters, eight gymnasia, 4 schools of arts and sciences, one military school, one midwifery school, 16 schools of industry, and at least one elementary school in every commune.

HESSE-HOMBURG was formerly a part of the landgraviate of Hesse-Darmstadt, till it came, in 1596, into the possession of Frederick I., youngest son of George I., who was the founder of the still flourishing line of Hesse-Homburg. Frederick Charles Louis, who succeeded to the government in 1751, experienced various vicissitudes in his long reign. In 1806, on the foundation of the Rhenish Confederation, he was obliged to give up the sovereignty to Hesse-Darmstadt, on which he became dependent. The Congress of Vienna however, in 1815, not only restored to him the sovereignty of his antient principality of Hesse-Homburg, but added to it the lordship of Meisenheim, on the other side of the Rhine. The landgrave therefore is now a sovereign prince, and was unanimously received in 1817 as a member of the German Confederation, and as such has one vote in the full council, making the whole number 70. Frederick Joseph, his successor, was married in 1818 to the Princess Elizabeth of England, and dying without issue in 1829, was succeeded by the reigning landgrave, Louis William Frederick.

Divisions.—I. The lordship of Homburg, which contains about 58 square miles and 8800 inhabitants. The chief town, Homburg vor der Höhe, with 3600 inhabitants, is situated under an eminence, on which the palace of the landgrave is built, commanding an extensive prospect of extraordinary beauty. Homburg is divided into the old and the new towns, the latter of which is open, and regularly built.

II. The lordship of Meisenheim, which contains 126 square miles and 15,200 inhabitants. It lies between the Prussian province of the Lower Rhine, the Bavarian circle of the Rhine, and the principalities of Lichtenberg and Birkenfeld. The chief town is Meisenheim, with 1750 inhabitants. The territory of Hesse-Homburg contains a considerable proportion of arable land. Meisenheim, which is occupied by the offsets of the Hundsrück, has mines of coal, iron, stone-quarries, and considerable forests. The landgrave possesses also the bailiwicks of Winningen, Hötensleben, and Oebesfelde, in the Prussian province of Saxony, and some other private estates. The revenue, including 34,000 florins from the Prussian bailiwicks, and an appanage paid by Hesse-Darmstadt, is 180,000 florins (18,000*l.*). The public debt is 450,000 florins, for the gradual extinction of which provision is made. The military consists of a contingent of 200 men, furnished by Hesse-Darmstadt to the reserve of the army of the Confederation.

Religion.—14,000 Calvinists, 6000 Lutherans, 3000 Roman Catholics, 150 Jews. The supreme power is vested in an hereditary landgrave, and descends only in the male line. There is no assembly of estates.

HESSE-PHILIPPSTHAL, the younger collateral line of the house of Hesse-Cassel, was founded in 1685 by Philip, the sixth son of Landgrave William VI., and was divided by his sons into the two still flourishing branches of Hesse-Philippsthal and Hesse-Philippsthal Barchfeld: the residence of the former prince is at Kreuzberg or Philippsthal, that of the second at Barchfeld, both on the Werra. They are both of the Calvinist religion, and are neither of them sovereign princes.

HESSE-ROTHENBURG. This line was founded by Ernest, the youngest son of the Landgrave Ernest, born 1623, died 1693, who embraced the Roman Catholic religion. The line, as stated under HESSE-CASSEL, became extinct by the death of Landgrave Victor Amadeus without issue on the 12th November, 1834, when the revenue, about 250,000 dollars per annum, came to Hesse-Cassel.

(J. D. A. Höck, *Statistik und Topographie des Kurf. Hessen;* E. Wiegand, *Erdbeschr. des Kurf. Hessen;* A. F. W. Crome, *Statistik des Grossherzogthums Hessen;* P. A. Pauli, *Statist.-topogr. Beschreibung des Grossherz. Hessen;* G. W. J. Wagner, *Statist.-topogr.-histor. Beschreibung des Grossherz. Hessen*, 4 vols., 1829-31.)

HESSE, WILLIAM, LANDGRAVE OF, was born at Cassel about the middle of the sixteenth century, and died in the year 1597. He immortalized his name by the encouragement which he gave to all kinds of philosophical research, and more particularly by the zeal with which he endeavoured to advance the science of astronomy. With the assistance of Christopher Rothmann and Juste Byrge, he erected an observatory, and furnished it with the best instruments that were then obtainable. His observations, which are said to have been of a very curious nature (Hutton's *Dictionary*), were published at Leyden twenty-one years after his death, by Willebrord Snell, and are spoken of by Tycho Brahé, both in his Epistles, and in the second volume of 'Progymnasmata.' (Martin's *Biographia Philosophica*, Lond., 1764, p. 248.)

HESSE'NES, commonly called **ESSENES**, one of the three great sects into which the Jews were divided in the time of Christ. They are not mentioned in the New Testament; but it has been conjectured that they are alluded to in *Matt.* xix. 12, *Col.* ii. 18, 23. Many particulars concerning the customs and religious opinions of this sect are given by Josephus and Philo. Their statements differ in several points; but those of Josephus appear worthy of more credit, since he had in his youth passed some time among the Essenes. (*Life of Josephus*, c. 2.)

The Essenes generally lived at a distance from large towns, in communities which bore a great resemblance to the monkish societies of later times. They employed themselves in agriculture, and had no slaves. They had all things in common, ate at a common table, and were exceedingly abstemious, never partaking of food before sunset. They were clothed in white garments, abstained from wine, and generally led a life of celibacy. They sent gifts to the Temple, but never offered any sacrifices there. They were divided into four classes, according to the time of their initiation. They admitted no one to their society till after a probation of three years: those who were admitted had to take solemn oaths that they would worship and serve God, and be just towards their fellow-creatures; that they would love and speak the truth, and that they would never disclose the mysteries of the sect. The Essenes were exemplary in their religious duties, and were particularly distinguished by their rigid observance of the Sabbath-day. They believed in the immortality of the soul, but not in the resurrection of the body, and maintained the absolute predestination of all events: they held the Scriptures in the greatest reverence, but considered them as mystic writings, and explained them allegorically. They also appear to have possessed sacred books, which explained the peculiar doctrines and practices of their sect. (Philo, *De Vita Contempl.*, vol. ii., p. 475.)

The origin of this sect is uncertain. Some writers consider them the same as the Assidians, or Chasidim, who are mentioned in 1 *Macc.*, ii. 42; vii. 13. It would appear from the account of Pliny (*Nat. Hist.*, v. 17) that their principal society was on the western side of the Dead Sea; and that from this society other smaller ones afterwards proceeded, and spread themselves over Palestine, Syria, and Egypt. Their numbers were never considerable; according to Philo and Josephus, there were only 4000 in Palestine.

The Essenes of Egypt were divided into two sects: the practical Essenes, whose manner of life was the same as the Essenes of Palestine; and the contemplative Essenes, who were also called Therapeutæ. Both sects maintained the same doctrines, but the latter were distinguished by a more rigid mode of life.

From a passage in Eusebius (*Hist. Eccles.*, ii. 17), it has been argued by Bellarmine, Baronius, and other Roman Catholic writers, that the Therapeutæ were Christian monks formed into a society by St. Mark, who was the founder of the Christian church at Alexandria. But it is evident from the account of Philo, that the Therapeutæ were not Christians, but Jews.

It has been supposed, with considerable probability, that the early Christians derived many of their customs and opinions from the Essenes. Mr. Taylor, the editor of Calmet's 'Dictionary to the Bible,' gives many reasons for believing that John the Baptist belonged to this sect.

(Josephus, *Antiquities of the Jews*, xiii., c. 5; xv., c. 10

xviii., c. 1; *Jewish War*, ii., c. 8; Philo; Pliny, *Nat. Hist.*, v., c. 17; Prideaux's *Connection of the History of the Old and New Testament*, vol. ii., pp. 450-470; Jennings' *Jewish Antiquities*, i., c. 13.)

HESY'CHIUS. There is a valuable Greek Lexicon extant, bearing the name of this author, of whom however nothing except the name is certainly known; he is supposed to have lived in the fifth or sixth century after the Christian æra. That which has come down to us is said to be only an epitome of the original, but of this assertion no proof can be made. It has the appearance of rough notes put down in the course of reading, rather than of a finished work; and consists chiefly of short explanations of unusual Greek words, or forms of words, and technical terms. It was not known until the 16th century. But one MS., in the library of St. Mark at Venice, is said to be preserved, and that is full of abbreviations, and has many erasures; which accounts for the great corruption of the text, in spite of the labours of many able editors. The first edition was that of Aldus, 1513, fol.; the most complete, that of Alberti, 1746, 2 vols. fol., of which the second volume was published by Ruhnken in 1766. This edition has a copious body of Prolegomena, containing all that can be said concerning this author.

HESYCHIUS, named the Illustrious, of Miletus, lived in the sixth century, and wrote a universal history in six parts, from Belus down to his own age. Some extracts of it have been preserved; which, with an abridgment of the 'Lives of the Philosophers,' chiefly from Diogenes Laertius, are edited in one volume by Meursius, 1613; he also wrote the reign of Justinus. (Photius, *Bibl.*, 69.)

HESYCHIUS was a common name under the Greek empire: we find many ecclesiastics and martyrs so called. For a list of those concerning whom something is known, see Fabricius, *Bibl. Gr.*, lib. 5, c. 5, and the Prolegomena to Alberti's edition of the Lexicon.

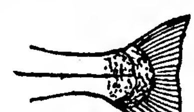
HETEROBRANCHIA'TA, M. De Blainville's name for the fourth order of his *Acephalophora*.

The 1st Family (*Ascidians*) is divided into two tribes: 1. *Simple Ascidians*, of which examples have been given under the heads of *Bipapillaria*, vol. iv.; and *Fodia*, vol. x.; 2. *Aggregated Ascidians*, an example of which has been given under the title of *Botryllus*, vol. v. [ASCIDIA, vol. ii.]

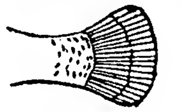
The 2nd Family consists of the *Salpaceans*, and is also divided into two tribes: 1. the *Simple*, (*Biphora*, *&c.*); 2. the Aggregate (*Pyrosoma*). [SALPA.]

HETERO'CERCAL, the term chosen by M. Agassiz to express a peculiar form of the tails of fishes, which affords a very obvious, and, as far as yet appears, a very correct indication of the geological age of formations. Among existing fishes the tail is either simple, as in the eel, bifurcate, as in the salmon, expanded to a round figure, as in the wrasse, or unequally bilobate, as in the shark. It is to this latter irregular form of tail that the term Heterocercal is applied: the others, by way of distinction, are called Homocercal.

Eel.



Salmon.



Wrasse.

Shark.

The peculiarity of the Heterocercal fishes is that the vertebral column runs along the upper caudal lobe: in the other forms of tail it is symmetrically placed with respect to the posterior finny expansion. M. Agassiz has found this peculiarity of the tail, which is least common among living fishes, and confined to particular groups, to belong to every species of fishes, of whatever group, and however differing in other respects, which occur in strata older than the oolitic system, while in and above that system Homocercal forms appear. It is therefore a characteristic of geological time; and among the conjectures as to the relations of this form to physical conditions of the surface, or laws of the animal economy, we prefer the opinion that it is one among several marks of the sauroid character of the fishes which lived in early geological periods. Some of the fishes of the oolitic rocks exhibit a slight inequality of the lobes of the tail, and some difference in the arrangement of the scales thereon, but without (we believe) the characteristic continuation of the vertebral column into the upper lobe. These may be thought to mark the gradual transition from the Heterocercal to the ordinary types of structure. Lepidosteus, with sharks, and other cartilaginous fishes of the existing creation, which were ranked by Linnæus as 'Amphibia Nantes,' thus appear the few surviving representatives of organic forms which, in earlier periods of the history of the globe, were exclusively predominant. (Agassiz, *Recherches sur les Poissons Fossiles*.)

HE'TERODON, M. De Blainville's name for a genus of Dolphins. [WHALES.] The term *Heterodon* had been applied by M De Beauvois to a genus of serpents placed by Cuvier under his great genus *Coluber*.

HETEROGANGLIA'TA. The *Heterogangliata* of Professor Owen comprise all the *Mollusca* of Cuvier, with the exception of the *Cirripeda*.

HETEROGENEOUS. [HOMOGENEOUS.]

HE'TEROMYS, a genus of Rodents, which, in M. Lesson's opinion, may be advantageously used, though M. Desmarest proposed it without adopting it. The genus is described as having the cheek-pouches of the Hamsters, the general form of the body and tail of the rats properly so called, and the dorsal flattened spines of *Echimys*, Geoff. (*Loncheres*, Illiger). Dental system unknown; feet with six callosities below, and five toes, the internal toe very small. (Lesson.) Example, *Heteromys Thompsonii*, Lesson (*Cricetus anomalus*, Desm.; *Mus anomalus*, Thompson) Habits and size of a rat. Locality, the Carib Island of Trinidad. (See 'Linn. Trans.,' vol. xi., p. 161, t. 10.)

HETERO'PODA. [GASTEROPODA, vol. xi., p. 92.]

HETERO'PORA, a genus of Polyparia, proposed by De Blainville to include species of the genus Ceriopora of Goldfuss, which have unequal cellules. From the chalk of Maestricht. (*Manuel d'Actinologie.*)

HETEROSCII (other-shadowed), an old astronomical term for persons living in such parts of the earth that their shadows at noon are always turned contrary ways. Thus the only heteroscii are those who are situated without the tropics, and in different hemispheres; since in the northern hemisphere those who are situated north of their tropic have the shadow at noon always turned northward, and those south of the southern tropic, southward.

HETEROSTEGI'NA. [FORAMINIFERA, vol. x., p. 348.]

HEVE'LIUS, JOANNES, or more properly JOANNES HEVEL, a Polish astronomer of great eminence, was born at Danzig, of a noble family, January 28, 1611. After visiting the principal countries of Europe (1630—1634), he returned to his native city, and was occupied in business or public affairs till 1639, when, by the advice of Cruger, whose pupil he had been, he applied himself almost exclusively to the study of astronomy. In 1641 he built an observatory in his own house, and furnished it with a quadrant and sextant of three and four feet diameter, together with large telescopes constructed by himself. His scientific pursuits did not however preclude his being elected consul in 1651, to which distinction his rank in society and philosophic character entitled him, and of which he continued to discharge the duties to the time of his death. In 1647 he published a description of the moon, under the name of 'Selenographia' (Gedani, fol.), to which was added a representation of the other planets as seen by the telescope. In 1654 appeared his treatise 'De motu Lunæ Libratorio' (Gedani, fol.), in the form of a letter to Riccioli, wherein he gave an explanation of the libration of the moon. (Montucla, *Hist. des Mathém.*, tome ii., p. 638.) To these succeeded an account of the eclipses of 1654; a treatise, 'De Natura Saturni Faciei ejusque Phasibus' (1656); 'Observations on the Transit of Mercury' in 1661, to which he added an account of the transit of Venus in 1639, as observed by Horrox (Gedani, 1661); 'Observations of the Comets of 1664 and 1665, published in 1665 and 1666; and in 1668 appeared his 'Cometographia.' In 1672 appeared an epistle to Oldenburg on the comet of that year, and in 1673 the first part of the 'Machina Cœlestis' was published. It was this last work which gave rise to public controversy between Hevelius and Dr. Hooke, who published *Animad. in Mach. Celest. Hevelii*, Lond. 1674, in 4to. Hevelius always imagined that better observations could be made with plain sights than with telescopes. Hooke recommended the use of the latter to Hevelius on the receipt of a copy of his 'Cometographia,' and some correspondence took place, which was increased into a quarrel by the dictatorial manner of Hooke in the work just cited. Halley was requested by the Royal Society of London to visit Hevelius at Danzig, and judge of the goodness of his observations. This voyage, which was made in 1679, produced a report from Halley highly favourable to Hevelius. In 1664 Hevelius was elected a member of the Royal Society of London. In 1679 he sustained considerable loss by the destruction of his house and observatory by fire. The whole of his instruments and library were destroyed, including most of the copies of the second part of his 'Machina Cœlestis,' which had only been published that year. This second part is now extremely rare. This accident appears only to have had the effect of increasing his ardour in the pursuit of astronomy, for he shortly after erected a new observatory, though on a less magnificent scale, and by 1685 he had another volume of observations ready for publication. He had now been occupied forty-nine years as an observer, and had attained sixty-three years, the climacteric, as it used to be called, of life, for which reason this volume (the last published during his lifetime) is entitled 'Annus Climactericus.' His posthumous works are 'Firmamentum Sobieskianum' (1690) and 'Prodromus Astronomiæ' (1691). He died at Danzig, universally respected, in 1687-8, and in his 76th year. During his lifetime he carried on an active correspondence with most of the learned men of Europe. The letters of his correspondents, and numerous observations, in seventeen folio volumes, were purchased of his family by M. Delille in 1725, and some of these were published by J. P. Kohlius in the supplement to the ninth volume of the 'Acta Eruditorum,' sect. viii., p. 359: the rest are at the Royal Observatory at Paris. His relation, J. E. Olhoff, published a considerable number of letters written to him in 1683.

Hevelius comes next to Flamsteed among the men of his day, as a diligent and accurate observer of the heavens. His 'Firmamentum Sobieskianum' is a standard catalogue of stars, containing the places of 950 stars known to the antients, 603 observed by himself, and 373 southern stars by Halley. For a full account of all his labours, see Delambre, *Hist. Astron. Mod.*, vol. ii., pp. 434-484; see also Weidler, *Hist. Astron.*, p. 485.

HEXACHORD (ἕξ, *six*, and χορδή, a *gut*, a *string*), a name given by the antient Greeks to a lyre of six strings; also to a scale of six sounds. In what is denominated the System of Guido, musical sounds are divided into three scales, named *Hexachords*. The first, from C to A, is called the *Natural* hexachord; the second, from G to E, the *Durum*; and the third, from F to D (the B flattened), the *Molle*. To the notes of each scale are assigned, as names, the syllables *ut, re, mi, fa, sol, la*. This most perplexing and irrational system, which has been well designated *Crux tenellorum ingeniorum*, is now utterly discarded.

HEXAGON, a figure of six sides. [REGULAR FIGURES.]

HEXAHEDRON, a solid of six faces. [CUBE; REGULAR SOLIDS.]

HEXA'METER (ἕξ, six, μέτρον, measure) is the most important form of dactylic verse. [DACTYLICS.] It consists of six feet, either dactyls or spondees, with no limit in their arrangements, except that the fifth is usually a dactyl, and the sixth invariably a spondee. Great part of the beauty of a long poem written in this measure depends on the varied cadences, which may be produced by varying the cæsura. [CÆSURA.] The most usual places are the middle of the third and the middle of the fourth foot: of these, the former is called by prosodians the *penthemimeral*; the latter, the *hephthemimeral cæsura*; as for example —

Vix e conspectu | Siculæ telluris in altum.
Non aliter quem qui adverso | vix flumine lembum.

That which is called the *bucolic* cæsura, at the end of the fourth foot, hardly seems to deserve special mention, being in no respect essential to the harmony of the verse, and invariably accompanied by one of the two before mentioned. These are essential; and one or other of them is always observed in well-constructed verse, except in rare cases where the omission is intentional, with a view to some special effect. For the niceties of the measure, see the treatise of Hermann, *De Metris*, lib. ii., 32.

HEXHAM. [NORTHUMBERLAND.]

HEYDEN, JOHN VAN DER, a very eminent Dutch painter, born at Gorcum in 1637 (some say 1640). He is one of the most admirable painters of external architecture of the Dutch, or indeed of any other school. His views of temples, palaces, churches, cities, and country-houses, are not only painted with incomparable precision and minuteness of detail, but this miniature-like finishing is combined with the most admirable keeping of the masses, the most striking effects of light and shade, and a clear and powerful tone. The value of his early works is enhanced by their being adorned with figures by A. Van der Velde, after whose death in 1672 Van der Heyden very successfully imitated his manner. His drawings, both in Indian ink and red chalk, are highly valued, as well as his admirable etchings. He died in 1712 at Amsterdam.

HEYLIN, PETER, born in 1600, at Burford, in Oxfordshire, studied at Oxford, where he took his degree of D.D. He gave lectures on history and cosmography in that university; and afterwards, in 1625, he published his 'Microcosmos,' or description of the globe, which met with great success, and was reprinted several times with alterations and additions. Heylin was appointed chaplain in ordinary to King Charles I., who presented him to several livings, of which he was afterwards deprived in the Rebellion, when his own property also was confiscated. On the restoration of Charles II. he was made sub-dean of Westminster, and he died in 1662. He wrote a number of works on the religious and political controversies of the times; among others a 'Defence of the Church of England;' a 'Life of Bishop Laud;' a 'History of the Tithes,' and a 'History of the Sabbath.'

HEYNE, CHR. GOTTLOB born at Chemnitz, in Saxony, in 1729, studied at Leipzig, and distinguished himself early as a classical scholar. The chair of eloquence and poetry in the university of Göttingen having become vacant by the death of J. M. Gesner, Heyne was appointed to it in 1763. From that time till his death Heyne was one of the most distinguished members of that learned institution, whose reputation he greatly contributed to uphold both by his lectures and by his publications. The department to which Heyne particularly applied himself was that of classical criticism and the illustration of the writings of the antients, by showing how they ought to be studied with reference to the manners and character of their respective ages. He published his ideas on these subjects in his notes to the 'Bibliotheca' of Apollodorus, and afterwards in numerous dissertations inserted in the Transactions of the University of Göttingen. His disciples M. Hermann, Voss, Manso, and others, have followed in the same path. Heyne's 'Opuscula Academica,' 6 vols. 8vo., Göttingen, 1785-1815, contain many learned and valuable disquisitions on antient history. Heyne published editions of Homer, Pindar, Diodorus Siculus, Epictetus, Virgil, Tibullus, &c., all enriched with ample commentaries. His 'Antiquärische Aufsätze,' in 2 vols., are essays on the history of antient art. As librarian to the university of Göttingen he introduced an excellent method of cataloguing the books of that extensive collection, which under his superintendence increased prodigiously both in number of works and value. (*Journal of Education*, vol ii.) Heyne died at Göttingen at a very advanced age, in July, 1814. His life, which has been written at some length by his son-in-law Heeren (Göttingen, 1813, 8vo.), contains an interesting account of the difficulties that this scholar had to encounter in early life.

HEYWOOD, THOMAS, was a well known dramatist who lived in the reigns of Elizabeth, James I., and Charles I., though, like many of his contemporaries, the dates of his birth and death are unknown. He has been compared to the Spaniard Lope de Vega for fertility, and in his preface to the 'English Travellers' has himself acknowledged that there are two hundred and twenty plays in which he had 'either an entire hand, or at least a main finger.' The practice of two or more authors uniting to form one play was very common among our old dramatists. Of all these pieces about twenty-four are left, of which 'A Woman killed with Kindness,' published in Dodsley's Collection, is much admired.

HIANS, Lacépède's name for the Grallatorial bird called the *open-beak* or *open-bill*, *Anastomus* of Illiger. [HERONS.]

HIATELLA. [PYLORIDEA.]

HIBERNIA. [IRELAND.]

HIBISCUS, a genus of plants of the natural family of Malvaceæ, so named from one of the Greek names (ἰβίσκος) of the Mallow. The species, upwards of 100 in number, of this genus, are chiefly herbaceous, though of a large size, but a few are perennial and arboreous. They abound in the hot parts of Asia and America, and also in Africa and the tropical islands; a few extend into Europe, North America, and to the Cape of Good Hope. *H. Trionum*, which occurs in Europe, is also found in Cashmere. The genus is characterized by having an exterior many-leaved calyx; carpels united into a five-celled capsule; valves with the partitions in their middle; cells many-seeded, or very rarely containing only a single seed. The species are remarkable, like the family to which they belong, for abounding in mucilage, and for the tenacity of the fibre of their bark, whence several are employed for many economical purposes in the different countries where they are indigenous.

The abundance of mucilage in some of the species renders them useful as articles of diet, as the unripe fruit of *H. esculentus*, the *okro* or *gombo* of the West Indies, which is employed both for thickening soup and as a vegetable; so in India *H. longifolius*, there called *ram turai*, is similarly employed, and much approved of by many Europeans, but objected to by others on account of its clamminess. The calyxes of *H. Sabdariffa* as they ripen become of a red colour and are pleasantly acid, whence in the West Indies the plant is called *red sorrel*. The calyxes are employed there, as well as in India, for making tarts; and a decoction of them, sweetened and fermented, is described in Browne's 'Jamaica' as a cool and refreshing drink, much used in many of the sugar islands. *H. syriacus* and *H. Rosa sinensis* are known as ornamental plants; the flowers of the latter are employed for blackening the eyebrows, as well as leather, both in India and China.

The species of Hibiscus are chiefly useful for the tenacity of their fibre, and hence several are employed in rope-making. Thus *H. cannabinus* is cultivated everywhere in India in the rainy season for this purpose; and its fibre is often imported into Europe as a substitute for hemp. It is known by the name *sun* in Northern India, *ambaree* in Western India, and *mesta pat* in Bengal. In the island of Otaheite rope and string are manufactured from the bark of *H. tiliaceus*, which is also made into matting of a white colour, and of different degrees of fineness. Forster states that the bark is also sucked as an article of diet, when the bread-fruit fails there: it is also so employed in New Caledonia. Indeed the mucilage which all these plants contain will no doubt afford some nourishment. In the West Indies, the whips with which the slaves are lashed are made from the fibres of *H. arboreus* (*mohoe* or *mohaul*). The bark of so many species of this genus being used for its tenacity, it is impossible to enumerate all. Dr. Roxburgh particularly recommends the cultivation in India of *H. strictus*, in consequence of its long, fine, and strong fibres, of a beautiful glossy white appearance, and as likely to be an advantageous substitute for such as are already cultivated for this purpose.

Hibiscus abelmoschus, so called from *hab-al-mooshk*, the Arabic name of its musk-scented seeds, is now often named *Abelmoschus moschatus*, and formed into a new genus. Its seeds are said to be added to coffee in Arabia, and are in India employed as a cordial medicine. The plant abounds in mucilage, and is employed in the process of clarifying.

HIBO'LITHUS, one of De Montfort's subdivisions of Belemnites.

HICKES, GEORGE, an eminent English divine and philologist, was born June 20th, 1642, at Newsham, in Yorkshire, where his parents were settled in a large farm. He was first sent to the grammar-school of North Allerton, and in 1659 to St. John's College, Oxford, whence he removed first to Magdalen College, afterwards to Magdalen Hall, and in 1664 was chosen Fellow of Lincoln College. In 1665 he became M.A., and was admitted into orders in 1666. In 1673 he travelled with Sir George Wheler in France. In 1676 he was made chaplain to the duke of Lauderdale, whom he accompanied in the following year to Edinburgh, when his grace was appointed high commissioner to the church of Scotland. In 1679 he was created D.D. at Oxford, having received the same degree the year previous from the University of Glasgow.

Between 1679 and 1683 he had several preferments, and in August of the latter year was made dean of Worcester. In 1688 he refused to take the oaths of allegiance, fell under suspension in 1689, and in the month of February following was deprived. He was subsequently consecrated suffragan bishop of Thetford by archbishop Sancroft. He died of the stone, Dec. 15, 1715.

Dr. Hickes was a man of general learning, deeply read in the fathers, and particularly skilful in the northern languages. His controversial pieces on politics and religion, especially those against popery, are very numerous, but for the most part forgotten. The work which goes by the name of his 'Thesaurus, or Treasure of the Northern Tongues,' in three volumes, folio, Oxford, 1705, is that which is most likely to sustain his literary reputation.

HI'ERAX. [FALCONIDÆ, vol. x., p. 180.]

HIE'RES. [HYERES.]

HIERO-FALCO, Cuvier's generic name for the Gyrfalcons.

HIE'ROCLES, the name of several Greeks:—

1. Hierocles, a rhetorician of Alabanda, in Caria, lived in the beginning of the first century before the Christian æra. He excelled in what Cicero termed the Asiatic stylo of eloquence. (*De Orat.*, ii. 23; *Brutus*, c. 95.)

2. Hierocles, a stoic philosopher, lived in the time of Hadrian, or perhaps later. (*Gell.*, ix. 5.)

3. Hierocles, a lawyer, wrote a work on veterinary medicine, addressed to Cassianus Bassus, of which three chapters are preserved in the 16th book of the 'Geoponica,' published by Needham, Camb., 1704, p. 424, 425.

4. Hierocles, who probably lived in the sixth century, was the author of a work entitled 'Synecdêmos' (συνέκδημος), that is, 'a travelling companion,' which gives an account of the provinces and towns of the Eastern empire. The 'Synecdêmos' is printed by Wesseling in his 'Vetera Romanorum Itinera,' Amst., 1735.

5. Hierocles, præfect of Bithynia, and afterwards of Alexandria, is said by Lactantius (*Inst. Divin.*, v. 2; *De Morte Persec*, c. 17), to have been the principal adviser of the persecution of the Christians in the reign of the emperor Diocletian. He also wrote two books against Christianity, entitled Λόγοι φιλαλήθεις πρὸς τοὺς χριστιανούς, 'truth-loving words to the Christians,' in which, according to Lactantius, 'he endeavoured to show that the sacred Scriptures overthrow themselves by the contradictions with which they abound; he particularly insisted upon several texts as inconsistent with each other; and indeed on so many, and so distinctly, that one might suspect he had sometime professed the religion which he now attempted to expose. He chiefly reviled Paul and Peter and the other disciples as propagators of falsehood. He said that Christ was banished by the Jews, and after that got together 900 men, and committed robbery. He endeavoured to overthrow Christ's miracles, though he did not deny the truth of them; and aimed to show that like things, or even greater, had been done by Apollonius.' (*Inst. Divin.*, v. 2, 3.)

6. Hierocles, a celebrated Alexandrine philosopher of the fifth century, wrote a Commentary upon the Golden Verses of Pythagoras, which is still extant; and also a Discourse on Foreknowledge and Fate, of which Photius has preserved large extracts. Stobæus has also preserved the fragments of several other works, which are ascribed to Hierocles. The Greek text of the Commentary on the Golden Verses of Pythagoras was first published by Curterius, Paris, 1583; reprinted at London, 1654; and has also been published at London, 1742, and Padua, 1744. The fragments of the Discourse on Foreknowledge and Fate, in which Hierocles attempts to reconcile the free-will of man with the foreknowledge of God, have been edited by Morell, Paris, 1593, 1597; and by Pearson, London, 1655, 1673; the latter edition contains the fragments of the other works of Hierocles. A complete edition of his works was published by Needham, Cambridge, 1709. The Discourse on Foreknowledge and Fate was translated into French by Regnaud (Lyon, 1560). Grotius translated part of this work into Latin in his 'Sententiæ Philosophorum de Fato,' Paris, 1624; Amst., 1648; reprinted in the 3rd vol. of his theological works, 1679. The Commentary on the Golden Verses has been translated into English by Hall, London, 1657; Norris, London, 1682; Rayner, Norw., 1797; and into French, by Dacier, Paris, 1706.

There is also another work, entitled Asteia (ἀστεῖα), which contains an account of the ridiculous actions and sayings of pedants, frequently printed with the editions of Hierocles; but it was probably written by another individual of the same name. This work is translated into English in the 'Gentleman's Magazine' for September, 1741.

HIEROGLYPHICS, a compound Greek word which means 'sacred engravings,' is the name given to the well-known figures of animals, plants, and other material objects sculptured on the Egyptian obelisks, temples, and other monuments, and which were used as a sort of ideographic writing among that people. The name 'hieroglyphics' has been also applied to other figures of a similar kind, used likewise for historical records on the monuments of the Mexicans and other nations. [AZTECS.] The earliest and simplest mode of recording events seems to have been that of picture-writing, that is to say, by a rude delineation of objects, such as that by which the Mexican scouts informed their master Montezuma of the arrival of Cortez and his band of followers, by sketching as faithfully as they could the appearance of the Spaniards, their ships, horses, and fire-arms. This however was only resorted to by the Mexicans on extraordinary occasions, in order to depict new objects. For ordinary purposes they had symbolical or conventional hieroglyphics to express historical events and other occurrences. As time passes on and events recur, and the relations of society increase, picture-writing becomes too cumbersome and inadequate a process for recording facts, and some method must be contrived for shortening and facilitating the task. This is effected at first perhaps by sketching only a part for the whole, such as a scaling-ladder for a siege, some flying arrows to indicate a battle, &c. The path of figurative imagery being once entered into, leads to symbols or tropical signs, in which one thing is put for another on account of some real or supposed resemblance between them: thus an eye with a sceptre underneath denotes the king or kingly power; a hawk's head surmounted by a disc represents the sun, &c. By a combination of such symbols an event may be recorded, and will present itself at once to the mind of the beholder who has the key of the system, without the assistance of words. In fact even to many of us Europeans who are in the constant habit of reading, the written or printed words often act upon our minds as hieroglyphics; the sight of a group of certain characters to which we have been long accustomed immediately conveys to our minds the idea expressed, without any reference to sound or alphabetical spelling. Herodotus and Diodorus say that the Egyptians had two kinds of written characters, Demotic and Sacred. The Rosetta inscription calls the common or vulgar character Enchorial. Clement of Alexandria, in a celebrated passage (*Stromata* v.) says that 'Those who are instructed among the Egyptians first of all learn that kind of Egyptian writing which is called epistolographic; next the hieratic, which the sacred registrars use, and last of all the hieroglyphic. Of the hieroglyphic there are two kinds, one of which expresses its meaning by the first elements, and the other is symbolic. Of the symbolic, one part expresses its meaning by imitation, a second part as it were tropically, and the third is purely allegorical, expressed by a kind of enigmas. Accordingly when they wish to represent the sun they make a circle; for the moon they make a crescent, the form of the object indicating the meaning. In the tropical mode of representation, following a certain analogy in the transfer and the change, they use the symbols, modifying some and in many ways altering others; consequently when they record the praises of their kings in sacred mythi, they express them in anaglyphs. Of the third or enigmatical mode of representation the following may serve as examples: they indicate the rest of the stars (planets), on account of the obliquity of their course, by serpents; but the sun is indicated by a beetle.' Clement gives no specimen of the first-mentioned sort of hieroglyphics, 'which expresses its meaning by the first element,' a phrase sufficiently obscure, but which is now generally supposed to refer to the phonetic use of the hieroglyphics. This phonetic system is a discovery of recent times. Zoega first suspected that some hieroglyphics might be expressive of sounds, and Dr. Young, having observed that certain groups of characters which were repeated in the enchorial text of the Rosetta inscription corresponded to the name of Ptolemaios in the Greek text, soon discovered corresponding groups of signs in the hieroglyphical text of the same inscription, enclosed in a kind of ring or cartouche. Dr. Young then endeavoured to fix the alphabetical or syllabic value of each sign, so as to produce the name of Ptolemaios. This was the beginning of the discovery of the phonetic use of hieroglyphics by the Egyptians, who, it was afterwards ascertained, wrote in this manner the names of foreign sovereigns, Persian, Greek, and Roman, who ruled over them in succession. It appears that they employed each hieroglyphic to express the initial letter of the spoken name by which the material object represented was known, and that by a series of such signs so employed they wrote the proper name which they wished to denote. The Chinese, whose characters are also ideographic, expressing objects and ideas, not sounds, use a somewhat similar contrivance when they wish to write a European proper name, but with them each character represents the entire syllable or sound which it expresses in ordinary use. Thus to write Maria or Maliya, as they pronounce it, the Chinese use three characters, the first of which means in their language 'jasper' and stands for *ma*, the second is the character which expresses profit, and it stands for *li*, and the third, which means 'second in rank,' stands for *ya*. For a further account of the phonetic hieroglyphics, and the respective merits of Dr. Young and Champollion in discovering them, and the extent and value of the actual discovery, see CHAMPOLLION and the authorities quoted there. Various hieroglyphics appear to have been used in different instances to express the same letter, a circumstance which increases the difficulty of deciphering the names written phonetically. There are, according to Champollion, 864 distinct hieroglyphical signs; Zoega reckons 958: of these the phonetic value of 134 only has been fixed, and one half of the 134 have only a conjectural value which has not been tried by a sufficient test. Besides this, the arrangement of the signs themselves is very capricious; sometimes they are ranged from right to left, sometimes up and down, at other-times they seem to be thrown pell-mell together. And then it must be remembered that in many instances we do not know the antient Egyptian name of the object which the hieroglyphic represents, and we cannot trust much to the word in the modern Coptic, which is a corrupt dialect mixed up with many foreign words. Still something has been done, and proper names of Persian, Ethiopian, Greek, and Roman rulers, besides those of native kings, have been traced on the monuments of Egypt by means of the phonetic interpretation. Whether the discovery will extend much further is a matter of doubt. We do not know (at least, we do not consider it proved) whether the Egyptians wrote other words phonetically besides proper names, and their language being in great measure lost, it is not very likely that we shall be able to solve the question.

The hieratic or sacerdotal character appears to have been a tachygraphy, or abridged form of the hieroglyphic signs, adopted for the sake of convenience and expedition, and used by the priests in their records.

The enchorial, or demotic, or epistolographic, appears to be a further abridgment of the hieratic. The signs, having lost nearly all trace of their original hieroglyphical form, have the appearance of a running alphabetical writing, and are written from right to left. The distinct characters of the enchorial writing appear hardly to exceed forty. Akerblad and Dr. Young have composed alphabets of them ('Rudiments of an Egyptian Dictionary, in the antient Enchorial character,' London, 1831, and article 'Hieroglyphics' in the last edition of the 'Encyclopædia Britannica.') Whether the enchorial was used entirely alphabetically is perhaps a question. We are told however by Plato, that Thoth, an Egyptian, invented the alphabet, and this may refer either to the phonetic use of the hieroglyphics, or to the enchorial characters which may have been derived from the hieroglyphics themselves. The writer of an article on the enchorial language of Egypt, in No. 3 of the 'Dublin University Review,' contends that the enchorial was a distinct language from that expressed by the hieroglyphics, and that both are different from the Coptic. (See varieties of hieratic and enchorial characters in *Hieroglyphics, collected by the Egyptian Society and arranged by Dr. Young*, fol., London, 1823, where, by comparing the enchorial writing found on fragments of earthenware at Elephantine, plates 53, 54, and 55, with the enchorial inscriptions from Sakkara, plates 74, 75, and 76, we perceive the gradations through which the enchorial character dwindled into a running and almost indistinct hand. See Robiano, *Etudes sur l'Ecriture, les Hiéroglyphes, et la Langue de l'Egypte*, Paris, 1834; and Young, *Account of some recent Discoveries in Hieroglyphical Literature and Egyptian Antiquities*, London, 1823, containing translations of corresponding Greek and Enchorial MSS. on papyrus.)

HI'ERON I., succeeded his brother Gelon, as tyrant or ruler of Syracuse, 478 B.C. He committed many acts of violence, encouraged spies, and kept a mercenary guard about his person. He was ambitious of extending his dominion, and his attempts proved successful. After the death of Theron, prince of Agrigentum, Hieron defeated his son Thrasydæus, who was soon after expelled by his countrymen. Hieron took Naxus and Catana, and having driven away the inhabitants from both towns, he replaced them by Syracusan and Peloponnesian colonists. He changed the name of Catana into that of Ætna, and he himself assumed the name of Ætnæus. Having joined his fleet to that of the people of Cumæ, he succeeded in clearing the Tyrrhenian sea of the Etruscan and other pirates which infested it. His chariots repeatedly won the prize at the Olympic games, and his success on those occasions formed the theme of some of the odes of Pindar, who was his guest and friend. Æschylus, Simonides, Bacchylides, and Epicharmus, were also well received at the court of Hieron, who was fond of the society of learned men. Hieron died at Catana, 467 B.C., and was succeeded by his brother Thrasybulus, who had all his faults, without any of his good qualities, and was at last driven away by the Syracusans, who restored the government of the Commonwealth. (Diodorus, xi. 48-66.) Ælianus (ix. 1) gives Hieron credit for a much better character than Diodorus; probably the latter part of his reign, after he had firmly established his authority, was better than the beginning.

Coin of Hieron I.

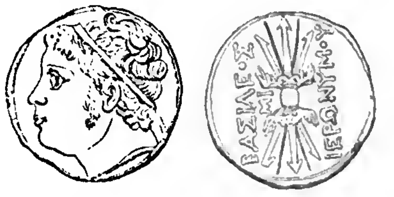
British Museum. Actual Size. Silver. Weight, 428¼ grains.

HIERON II., son of Hierocles, a wealthy citizen of Syracuse, and a descendant of Gelon, distinguished himself in early youth by his brilliant qualities; and he served with distinction under Pyrrhus in his Sicilian campaigns. After Pyrrhus had suddenly abandoned Sicily, the Syracusans found themselves threatened on one side by the Carthaginians, and on the other by the Mamertines, a band of Campanian mercenaries, who had treacherously taken possession of Messana. The Syracusan troops, being in want of a trusty leader, chose Hieron by acclamation, and the senate and citizens, after some demur, ratified the choice, 275 B.C. By marrying the daughter of Leptines, a man of influence among the aristocratic party, he secured their support. Having led the army against the Mamertines, he divided it into two bodies, in the foremost of which he placed the mercenaries in the pay of Syracuse, who had of late shown a mutinous disposition, and ordered them to begin the attack. They did so, but were overpowered by superior numbers; and Hieron, instead of supporting them with his Syracusan soldiers, withdrew, and left them to be slaughtered by the Mamertines. He then recruited his army among his own countrymen, and having deceived the Mamertines, who were waiting for him at the pass of Tauromenium, he marched round the western base of Ætna, attacked and took Tyndaris, Abacænum, Mylæ, and other towns, before the main body of the enemy could come to their relief, and lastly defeated the main body itself in a pitched battle on the banks of the river Longanus. He was on the point of attacking Messana, when the Carthaginian commander in Sicily, who was then in the island of Lipara, came to offer his mediation, but in fact for the purpose of introducing a Carthaginian garrison into Messana. In this object he succeeded, having deceived both parties; and Hieron, unwilling to bring on himself the whole might of Carthage, returned to Syracuse, where, through the influence of Leptines, he was proclaimed king, B.C. 270. Shortly after, the Mamertines at Messana quarrelled with the Carthaginians and drove them out of the citadel, upon which the Carthaginians invited Hieron to join his forces to theirs, in order to drive the Mamertines out of Sicily. Hieron having assented, encamped himself under the walls of Messana on one side, and the Carthaginians fixed their camp on the other, whilst their squadron guarded the strait. The Mamertines meantime had applied to the Romans for assistance, claiming a common origin with them as being descended from Mars, called Mamertus in the Oscan language; and Rome eagerly seized this opportunity of obtaining a footing in Sicily. The consul Appius Claudius marched to Rhegium, and having contrived to pass the strait in the night, unobserved by the Carthaginian cruisers, he surprised Hieron's camp, routed the soldiers, and obliged Hieron to seek for safety in flight. The consul next attacked the Carthaginian camp with the same success, and this was the beginning of the first Punic war, 264 or 265 B.C. In the following year the Romans took Tauromenium and Catana, and advanced to the walls of Syracuse, when Hieron sued for peace, which he obtained on condition of paying 100 talents of silver and supplying the Roman army with provisions. He punctually fulfilled his engagement, remaining faithful to Rome during the whole of the war, and by his supplies was of great service to the Roman armies, especially during the long sieges of Agrigentum and Lilybœum. Hiero was included in the peace between Rome and Carthage, by which his territories were secured to him, and he remained in friendship with both states. He even assisted Carthage at a very critical moment by sending her supplies of provisions during the war which she had to sustain against the disbanded mercenaries. The period of peace which elapsed between the end of the first and the beginning of the second Punic wars, from 241 to 218 B.C., was most glorious for Hieron and most prosperous for Syracuse. Commerce and agriculture flourished, and wealth and population increased to an extraordinary degree. Hieron paid particular attention to the administration of the finances, and issued wise regulations for the collection of the tithe or tax upon land, which remained in force throughout Sicily long after this time, and are mentioned with praise as the Lex Hieronica by Cicero (ii. and iii. *in Verrem*). Hieron introduced the custom of letting the tax to farm every year by auction. He embellished and strengthened Syracuse, and built large ships, one of which, if we are to trust the account given of it by Athenæus, (v. 40,) was of most extraordinary dimensions and magnificence. This ship he sent as a present to Ptolemæus Philadelphus. Archimedes lived under Hieron's reign. When the second Punic war broke out, Hieron continued true to his Roman alliance, and after the Trasymenian defeat he sent a fleet to Ostia with provisions and other gifts, and a body of light troops to the assistance of Rome. He lived to see the battle of Cannæ, after which his own son Gelon embraced the part of the Carthaginians. Gelon however died, not without suspicion of violence, and Hieron himself, being past 90 years of age, died shortly after, 216 B.C., leaving the crown to his grandson Hieronymus. With Hieron the prosperity and independence of Syracuse may be said to have expired. (Livy, xxii. and xxiii.; Polybius, vii.)

Coin of Hieron II.

British Museum. Actual Size. Copper. Weight, 282¼ grains.

HIERO'NYMUS, grandson of Hieron II., king of Syracuse, succeeded him on the throne at the age of fifteen (B.C. 216), and under the guardianship of several tutors, among whom was Andronorus, his aunt's husband, who, seconded by other courtiers, and in order to monopolize the confidence of the young king, indulged him in all his caprices and follies. The court of Syracuse, which under Hieron was orderly and respectable, soon became as profligate as it had been under the younger Dionysius. Andronorus persuaded Hieronymus, against the dying injunctions of his grandfather, to forsake tho Roman alliance for that of Carthage, and messengers for that purpose were sent to Hannibal in Italy, and also to the senate of Carthage, which gladly agreed to an alliance with Syracuse, in order to effect a diversion against the Romans. The Prætor Appius Claudius, who governed that part of Sicily which the Romans had taken from the Carthaginians, sent messengers to Hieronymus to exhort him not to forget the old friendship existing between Rome and Syracuse. The messengers were received contemptuously, and the young king sneeringly asked them for some details concerning the battle of Cannæ, which had occurred not long before. War being at last declared by Rome, Hieronymus took the field with 15,000 men: but a conspiracy broke out among his soldiers, and he was murdered, after a reign of only thirteen months. On this news a popular insurrection took place at Syracuse, the daughters and grand-daughters of Hieron were murdered, and royalty was abolished. But the people were distracted by factions and by the mercenaries in their pay, and revolution succeeded revolution until two adventurers of Syracusan extraction, but natives of Carthage, who had been sent by Hannibal to keep in countenance the Carthaginian party in Syracuse, became possessed of the chiof power, and so provoked tho Roman Consul Marcellus, that ho laid siege to Syracuse.



Coin of Hieronymus.
British Museum. Actual Size. Silver. Weight, 125½ grains.

HIERO'NYMUS, a native of Cardia, or Cardiapolis, a town in the Chersonese of Thrace, lived in the times of the immediate successors of Alexander. He wrote a work entitled 'Historical Memoirs' concerning the successors of Alexander the Great and the wars which followed the death of that conqueror, which is mentioned by Suidas, and also by Dionysius of Halicarnassus in the preface to his history. The work of Hieronymus is unfortunately lost. Diodorus appears to have made use of it in several parts of his work. Gerrard Vossius (*De Historicis Græcis*, b. 1, ch. xi.) distinguishes Hieronymus of Cardia both from Hieronymus of Rhodes, a disciple of Aristotle, and from Hieronymus the Egyptian, who was governor of Syria under Antiochus Soter, and who wrote a history of Phœnicia, quoted by Josephus, *Antiqu. Jud.*, b. 1. (See also *Recherches sur la Vie et les Ouvrages de Jerôme de Cardie*, par l'Abbé Sevin, in the *Mémoires de l'Académie des Inscriptions et Belles-Lettres*, vol. xiii.)

HIGDEN, RANULPH, or RALPH, author of the Polychronicon,' was a Benedictine monk of St. Werburgh's monastery in Chester, where he died at a great age, after having lived in the convent sixty-four years; according to Bale, in 1367; according to Pits, in 1373. Dibdin, in his edition of Herbert's 'Ames,' and Chalmers, in his Biographical Dictionary,' say Higden died about 1360. Gale published a portion of Higden's original work in the 'Scriptores,' xv., fol., Oxford, 1691. John de Trevisa's translation of the 'Polychronicon' was printed by Caxton in folio, in 1482, in seven books, to which Caxton added an eighth. The Chester Mysteries, exhibited in that city in 1328, at the expense of the several trading corporations, have been ascribed to Higden. That a monk of the name of Randle, or Ranulph, contemporary with Higden, had some concern in them, there seems no doubt. It is not quite so clear that Higden was himself the person. (See Tanner, *Bibl. Brit. Hib.*, p. 403; *Pref.* to Markland's *Chester Mysteries.*)

HIGGINS, or HIGINS, JOHN, was born about 1544, according to the author of a note in a late edition of 'The Mirror for Magistrates.' He was educated at Oxford, but whether he took a degree is uncertain. He was one of the contributors to the book above mentioned, to which he supplied forty legends, relating mostly to the mythical history of England. In one of the 'envoys' he tell us that he did not 'take the pain to learn tho tongues and write' until he was twenty; that French and Latin were his chief studies, and that he published his part of the 'Mirror for Magistrates' when thirty. One stanza from the introduction will give a fair specimen of his manner, and at the same time supply information on the nature of the poem. He tells us that he bought the hook to which he was then employed in making additions, and goes on to enumerate those who were celebrated therein:

> ——Some perdy were kings of high estate,
> And some were dukes and came of regal race;
> Some princes, lords, and judges great, that sate
> In council still, decreeing every case.
> Some other, knights, that vices did embrace;
> Some gentlemen; some poor exalted high;
> Yet every one had played his tragedy.'

The 'Mirror for Magistrates' went through many editions from its first appearance as Lidgate's 'Fall of Princes' to its latest shape in the impression of 1610. Its importance has, we think, been little seen; but the very evident application of many of the stories (such, for instance, as that of James I. of Scotland) must have had its effect in the sixteenth and seventeenth centuries. (Wood's *Ath. Oxon.*; *Mirror for Magistrates*, edition of 1815.)

HIGHGATE. [MIDDLESEX.]

HIGHWAY. [WAY.]

HILA'RION, SAINT, the founder of monastic institutions in Palestine, was born at Tabatha, near Gaza, about A.D. 291. His parents, who were heathens, sent him at an early age to Alexandria to pursue his studies, where he made great progress in philosophy and literature. Having been converted to the Christian religion, he resolved, in imitation of Antonius, with whom he had spent two months in the deserts of Egypt, to retire from the world. Accordingly, on his return to Palestine, he divided among his relatives the property which his parents had left him, and retreated at the age of fifteen to the desert country south of Gaza. After remaining in this place for twenty-two years, during which time he practised the greatest austerities, his reputation for sanctity became so great, that numbers of people resorted to him in order to be cured of their diseases. According to Jeromo, Hilarion performed the greatest miracles, and 'was so full of the power of the Holy Ghost as to be able to discover from the smell of the bodies and the clothes of men, or of anything else they had but touched, to what particular dæmon or to what vice they were severally subject.' Hilarion afterwards went to Egypt, and successively visited Sicily, Dalmatia, and Cyprus, where he died about the year 371. We are informed by Jerome, that 'by the influence of Hilarion's example innumerable monasteries began to be founded through all Palestine.'

The life of Hilarion has been written by Jerome, and is printed in vol. iv., part ii., pp. 74-90, of the Benedictine edition of his works.

HILA'RIUS, a native of Sardinia, was made deacon of Romo about A.D. 354. He is frequently mentioned by Jerome (*Adv. Lucif.*) as a rigid Luciferian, a sect which derived its namo from Lucifer, bishop of Cagliari, in Sardinia, who separated from the church on account of the absolution that had been granted to those Catholics who had become Arians during the reign of Constantius. Hilarius wrote several works in favour of the opinions of Lucifer; in which he maintained, among other things, that Arians and all other heretics ought to be baptized again when they were converted to the orthodox faith.

Hilarius is generally supposed to have been the author of a Commentary on thirteen of St. Paul's Epistles, which is usually printed with the works of St. Ambrose; and also, though this is more doubtful, of 'Quæstiones in Vetus et Novum Testamentum,' usually joined with St. Augustine's works. The Benedictine editors of St. Ambrose inform us that the MSS. of the Commentary on St. Paul's Epistles differ considerably, and that in some parts there appear to be interpolations of long passages. This commentary is said by Du Pin to be 'clear, plain, and literal, and to give the meaning of the text of St. Paul well enough; but it gives very different explanations from St. Augustine in those places which concern predestination, provocation, grace, and free-will.'

(Lardner's *Credibility, Works*, vol. iv., p. 381-385; Du Pin's *Ecclesiastical History*, vol. ii., p. 189-190, Engl. Trans.)

HILA'RIUS, SAINT, was born at Poitiers, of which place he was afterwards made bishop about A.D. 354. He is distinguished in ecclesiastical history by the active part which he took against the Arians during the reign of Constantius. He was banished by this emperor to Phrygia, shortly after he had been elected bishop of Poitiers, on account of his defence of Athanasius, in the council of Béziers, against Saturninus, bishop of Arles. In the East he continued his exertions in favour of the Catholic faith. In 359 he attended the council of Seleucia in Isauria, which had been summoned by order of Constantius, and boldly defended the doctrine of the Trinity against the Arian bishops, who formed the majority of the council. He afterwards followed the deputies of the council to the emperor's court, and presented a petition to Constantius, in which he desired permission to dispute publicly with the Arians in the emperor's presence. In order to get rid of so formidable an opponent, the Arians, it is said, induced the emperor to send him away from the court. But previous to his departure, Hilarius wrote an invective against Constantius, in which he denounced him as Anti-Christ, and described him as a person who had only professed Christianity in order that he might deny Christ. After the Catholic bishops had recovered their liberty under Julian, Hilarius assembled several councils in Gaul for the re-establishment of the Catholic faith and the condemnation of Arian bishops. He also travelled into Italy for the same purpose, and used every exertion to purify the churches of that country from all Arian heresies. When Auxentius was appointed bishop of Milan by the Emperor Valentinian, in 364, Hilarius presented a petition to the emperor, in which he denounced Auxentius as a heretic. Though this charge was denied by Auxentius, Hilarius still continued his attacks upon his orthodoxy, and created so much confusion in the city that he was at length ordered to retire to his own diocese, where he died shortly afterwards, in the year 367.

The most important of Hilarius's works are:—1, 'Twelve Books concerning the Trinity;' 2, 'A Treatise on Synods,' addressed to the bishops of France and Britain, in which he gives an account of the creeds which had been adopted by the Eastern churches since the council of Nice; 3, 'Three Discourses addressed to Constantins,' on the Arian Controversy; 4, 'A Commentary on St. Matthew;' 5, 'A Commentary on the Psalms.' These commentaries are entirely taken from the commentaries of St. Augustin. 6, 'A Book of Fragments,' which contains extracts from several of the last works of Hilarius.

The writings of Hilarius are very obscure, and often unintelligible, which is principally owing to his fondness for antithesis and metaphorical expressions, and to the length and intricacy of his periods. Though he was very severe in condemning the erroneous opinions of others, he differed in many particulars from the doctrines of the Catholic church. He maintained, among other things, that Christ experienced no pain at his crucifixion, and that the souls of men are material.

The works of Hilarius have been published by Miræus, Paris, 1544; Erasmus, Bas., 1523, reprinted 1526, 1535, 1550, 1570; Gillot, Paris, 1572; reprinted with several improvements, 1605, 1631, 1652; by the Benedictines, Paris, 1693; the Marquis de Maffei, Verona, 1730; and Oberthür, 4 vols. 8vo., 1781-88.

(Du Pin's *Ecclesiastical History*, vol. ii., p. 64-79, Eng. Transl.; Lardner's *Credibility, Works*, vol. iv., p. 178, 179.)

HILA'RIUS, SAINT, was born A.D. 401, and became bishop of Arelate (Arles) in 429, on the death of Honoratus, who had been the means of converting him to Christianity. Hilarius was distinguished by the holiness of his life and his zeal for monastic institutions; but he is more known in ecclesiastical history on account of his controversy with Leo, bishop of Rome. Celidonius, bishop of Vesontio (Besançon), who had been deposed from his office by a council, at which Hilarius had presided, appealed to Leo against this decision. Leo gladly availed himself of this opportunity of extending the power of the Roman see, and accordingly reinstated Celidonius in his bishopric. Hilarius strongly opposed the decision of Leo; but his opposition only drew upon him the enmity of the Roman bishop, who soon found an opportunity of depriving Hilarius of the bishopric of Arelate. Several of the Gallic bishops, whom he had offended by the severity with which he had enforced the discipline of the church, accused him of various ecclesiastical offences; and Leo accordingly, supported by a rescript of the Emperor Valentinian III., deposed Hilarius from the exercise of his episcopal duties. Hilarius however still continued to possess great influence in his diocese, in which he died in 449.

Hilarius was highly esteemed by all his contemporaries; even Leo, after his death, declared that he was an upright and pious man. (*Epistles of Leo*, 106.) The writings of Hilarius are lost, with the exception of a life of Honoratus, a letter to Eucherius, and a poem upon the beginning of Genesis; which are published by Quesnel at the end of Leo's works, Paris, 1675. His life of Honoratus has also been published by Genebrard, Paris, 1578.

HILARIUS, a native of Sardinia, succeeded Leo I., or the Great, as bishop of Rome in the year 462. He had been employed by Leo in important affairs; among others he was sent as legate to the council of Ephesus, A.D. 449, against the Eutychians, and was well versed in matters concerning the discipline of the church, which he displayed great zeal in enforcing. He interfered in the election and consecration of bishops by their metropolitans in France and Spain, and he justified his interference by alleging the preeminence of the see of Rome over all the sees of the West, a preeminence which he however acknowledged, in one of his letters, to be derived from the Emperor's favour. He also forbade bishops nominating their successors, a practice which was then frequent. He however did not declare elections or nominations to be illegal merely from his own authority, but assembled a council to decide on those questions. Hilarius died at Rome, A.D. 467, and was succeeded by Simplicius.

HILDBURGHAUSEN. [SAXE MEININGEN.]

HILDESHEIM, a principality in the kingdom of Hanover, forming part of the province of the same name. It lies between 51° 44′ and 52° 25′ N. lat., and is bounded on the north by Calenberg and Lüneburg, on the east by Brunswick, on the south by Göttingen and Brunswick, and on the west by Calenberg. Its area is about 680 square miles, and its population, which in 1812 was 128,938, is now 155,014, of whom 30,000 are Roman Catholics, 167 Calvinists, and 1000 Jews: the remainder are Lutherans. In the south the surface is traversed by branches of the Harz. The soil is stony and not generally fertile. In the centre and north the surface is undulating, and the soil rich and fertile. The principal rivers are the Innerste, Leine, Ocker, Ecker, and Fuse. The climate is healthy. The agricultural products are corn, garden vegetables, fruit, flax, hops, and timber: the mineral products are iron, coal, and salt. The trade is very considerable. The exports consist of the natural productions, and of some manufactures, chiefly linen, which is the principal manufacture of the principality. The exports amount to about four millions of dollars annually; the imports to three millions.

Hildesheim was formerly a bishopric, founded in 822 by Louis the Pious. The diocese was enlarged by several successive bishops; but in 1519 the bishop engaging in an unsuccessful contest with the duke of Brunswick was placed under the ban of the empire, and stripped of a great part of his territories; and it was not till 1643 that a considerable portion of them was restored. As all the towns and most of the nobles had embraced the Protestant religion, and the bishopric remained Roman Catholic, the religious liberty of the subjects was guaranteed by several compacts. After the treaty of Luneville, the king of Prussia took possession of Hildesheim and Goslar in 1802, giving a pension to the bishop. In 1807 the principality was incorporated with the kingdom of Westphalia, and in 1813, by a convention with Prussia, was annexed to Hanover, to which it was confirmed by the congress of Vienna, 1815. The principality has 660 schools, in which 46,211 children are educated.

HILDESHEIM, the capital of the principality, situated in 52° 9′ 31″ N. lat. and 9° 55′ 38″ E. long., is a place of considerable extent, and, like most of the antient German cities, very irregularly built. It is divided into the old and the new towns. There are seven gates; but the antient ramparts have been levelled and converted into public walks. The city is situated at the foot of the Gallaberg, near the Innerste, in which river there is a beautiful island converted into gardens. The inhabitants, 13,100 in number, are mostly Lutherans; but many, with the bishop, are Roman Catholics. The principal public buildings and institutions are, a palace, 4 Roman Catholic and 8 Lutheran churches, 12 Roman Catholic and 8 Protestant hospitals, 3 orphan houses, a convent (7 others have been secularized), a synagogue, a

Roman Catholic and a Protestant consistory, a Lutheran gymnasium, with a good library, schools of industry, and an admirably-regulated poorhouse, where nearly 600 children receive gratuitous education, beggars are employed, the sick nursed, &c. The cathedral, founded in 818 by Louis tho Pious, has 10 altars, very fine paintings on glass, magnificent iron doors covered with bas-reliefs, and numerous antiquities, among which is the celebrated pillar, erroneously called the Irmensäule, a hollow cylindrical pillar of greenish marble sixteen feet high, which now bears an image of the Virgin Mary.

HILL, AARON, was born at Beaufort Buildings, in the Strand, 1684-5, and having been deprived of an extensive family estate by his father's imprudence, was left dependent on his mother and grandmother. He was educated at Westminster school, and in his sixteenth year went to Constantinople with the design of visiting the English ambassador, Lord Paget, who was a relation of his mother's. The nobleman received him kindly, and provided him with a tutor, with whom he travelled through a great part of the East. Having subsequently lost his kinsman's favour, he was engaged by Sir William Wentworth, of Yorkshire, as his travelling companion through Europe. On his return he wrote in 1709 a History of the Ottoman Empire, compiled from materials collected at the Turkish court, and about the same time was made 'master' of Drury Lane Theatre. At this time he wrote his first tragedy of 'Elfrida.' He started several commercial projects with indifferent success, and in 1738 withdrew to Plaistow, in Essex, where he devoted himself to study. Here he translated Voltaire's tragedy of 'Merope,' and lived just long enough to see it produced. He died in 1749-50.

Aaron Hill wrote about fifteen pieces, of which only two are now remembered, 'Alzira,' and 'Zara,' both of which are adaptations from Voltaire. The English national feeling is so entirely averse to tragedies on the French model, that although such attempts may obtain a transient reputation from adventitious circumstances, there is little chance, when they are once forgotten, of their ever being recalled from oblivion.

HILL, SIR JOHN, was born about 1716, and began life as apprentice to an apothecary in London, in which capacity he gained that knowledge of botany which is his only claim to honourable notice: though being possessed of lively parts, industry, and impudence, he managed to obtain in his lifetime no little notoriety. He pushed his way into fashionable life; published a fashionable and scandalous newspaper called the 'Inspector;' made, puffed, and sold quack medicines; and yet found time to compose a great number of works, many very voluminous, principally on botanical subjects. He was very desirous to obtain admission into the Royal Society; but being rejected, on account of his equivocal character, he published in revenge a 'Review of the Works of the Royal Society,' 4to. 1751, in ridicule of that body, which sealed his exclusion from it for ever. No doubt subjects enough for satire might be found in their voluminous Transactions; but the Review is said to have shown as much unfairness as ingenuity, and no little of both. Hill obtained a Scotch diploma of medicine, and assumed the titlo of Sir John in virtue of a Swedish order of knighthood presented to him by the king of Sweden in exchange for a present of his botanical publications. He died in 1775. The following are some of his most considerable works:—'History of the Materia Medica,' 4to., 1751; 'General Natural History,' 1748-52, 3 vols. fol.; 'British Herbal,' 1756, fol.; 'Vegetable System,' 1759-75, 26 vols. fol., a magnificent book, containing 1600 plates, published at 38 guineas plain, and 160 coloured; 'Constitution of Timber from its Early Growth,' fol., 1770, a work highly praised by Haller. (Watt, *Bibl. Britann.*; and a *Short Account of the Life, &c., of Sir J. Hill*, Edinb., 1779.)

HILLAH. [BABYLON.]

HILLEL, one of the most celebrated of the Jewish Rabbis, was descended on his mother's side from king David; but his father belonged to tho tribe of Benjamin. His birth is placed by Bartolocci (*Biblioth. Rabinic.*, vol. ii., p. 784) in A.M. 3648 (B.C. 112), which agrees with tho account of Jerome, who says that he lived shortly before the birth of Christ. According to Jewish tradition he was born in Babylon. At the age of forty he came to Jerusalem, where he applied himself to the study of the law, and became so eminent for his sanctity and knowledge that he was appointed president of the Sanhedrim at the age of eighty. He continued to discharge his duties as president for forty years; and died at the advanced age of 120.

Hillel is not mentioned by Josephus; but it has been supposed that he must have been the same as Pollio, or the high-priest Hananeel.

The disciples of Hillel were very numerous, amounting, according to tradition, to a thousand, of whom one of the most eminent was Jonathan Ben Uzziel, the author of the Chaldee paraphrase upon the prophets. The decisions of Hillel on several points in the Jewish law differed from those of Shammai, vice-president of the Sanhedrim; and the disciples of each frequently disturbed the peace of Jerusalem by their divisions and quarrels. Hillel's party at length prevailed, in consequence it is said of a *bath kol*, that is, a voice pretended to come from heaven. The decisions of Hillel are supposed to have been the ground-work of the Mishna.

Another rabbi of the name of Hillel, the son of Rabbi Juda Nasi, and a descendant of Hillel, of whom we have spoken above, who lived in the fourth century of the Christian æra, is said to have established the present calendar of tho Jewish year.

HIMA'LAYA, or HIMMA'LEH MOUNTAINS, extend along the north-eastern boundary of Hindustan and constitute likewise the northern boundary of the valley of Asam. They are situated between 27° and 35° N. lat. and 73° and 98° E. long. The most western portion (between 73° and 88° E. long.) lies in a general direction from north-west to south-east, forming a slightly curved line, so that the north-western extremity runs north-north-west and the south-eastern nearly due east. The eastern portion (between 88° and 98° E. long.) runs west and east. In the first direction the range extends more than 900 miles, and in the last about 600; its whole length is 1500 miles. Its breadth, as far as it is known, varies between 80 and 120 miles. The whole range may therefore occupy a surface of 150,000 square miles and upwards.

This extensive mountain-range lies between two plains, a low and level one, which is drained by the Ganges and the Brahmapootra, and extends along its south-western and southern declivity, and the elevated and partly hilly table-land of Tibet, which lies to the north-east and north of the range. The plain of the Ganges and Brahmapootra, at its southern extremity, is little elevated above the sea, and where it is farthest from the shore its elevation does not much exceed 1000 feet. The table-land of Tibet, as far as it is known, rises to the elevation of 10,000 feet and more. The Himalaya Mountains may therefore be considered as an extensive slope, by which the elevated table-land of Tibet descends to the low plain of the Ganges. But as in most cases where two plains of different elevations lie near one another, the descent by which the higher sinks down to the level of the lower is partly occupied by a mountain-range running along the border of the more elevated plain, so the Himalaya Mountains rise far above the level of the table-land of Tibet, and where they are contiguous to it they constitute an uninterrupted range, covered with snow in its whole extent, with the exception of a few mountain-passes, which are partly free from snow during the hottest months. They terminate on the plain of the Ganges, in a wall-like range from 4000 to 5000 feet high, which however is frequently broken by gaps through which the rivers escape that carry off the water collected in the interior of the mountain-region. This interior tract between the two border-ranges varies considerably in the form of its surface in different parts.

The most north-western extremity of the Himalaya is separated from the extensive mountain-region of Eastern Persia, which from its highest mountain-range has obtained the name of Hindu Coosh, by the narrow valley of the Indus. This valley has not been visited by Europeans, and nothing is known of the course of the Indus through it, except that it is probably more than 60 miles in length. We know however that a high snow-topped rango protrudes into the most northern bend of the river, and skirts its banks as far south as the neighbourhood of Attock. This range, called the Gosseie Mountains, constitutes therefore the most north-western extremity of the Himalaya.

The river Sutlej, an affluent of the Indus, originates on the table-land of Tibet, and traverses the Himalaya between 31° and 32° N. lat. in its winding course from east to west. That portion of the mountains which lies between the val leys of the Indus and Sutlej forms towards the table-land of Tibet, so far as is known, one uninterrupted range; its northern portion, which encloses the valley of Cashmire on the north-east, is called by the natives of that country Tibet Panjahl; the southern, between the upper course of the Chinab and the Sechoo, bears the name of the Paralasa Mountains. At the point of junction of these two ranges (between 33° 30′ and 33° 40′ N. lat.) are its highest summits, the Mer and Ser, which rise considerably above the snow-covered range, but their elevation has not been determined. From this elevated range, the mountain-region spreads south-west about 80 miles, and is formed of several ranges parallel to the principal range, but at unequal distances from one another, so that the valleys which are enclosed by them are of different widths. Though the ranges themselves are not covered with snow in all their extent, they contain several summits which rise far above the snow-line. These ranges are not continuous, but several breaks of considerable extent occur between them. The valleys which lie between the ranges are probably between 5000 and 7000 feet above the sea. The best known is the valley of Cashmire, which is nearly enclosed by snow-covered mountains, on the north-east by the Tibet Panjahl range, and on the south-west by the Peer Panjahl Mountains.

Twelve mountain-passes connect the valley of Cashmire with the adjacent countries, among which the four following are the most frequented:—1, the Kandrihall Pass over the Tibet Panjahl range (near 34° 20′ N. lat.) to Leh, or Ladak, on the table-land of Tibet; 2, the Sagam Pass, from Islamabad in Cashmire to Kishtewar and Jummû on the Chinab; 3, the Barramulla Pass, traversing the Peer Panjahl range by Canhorn to Prunch; and 4, the Barramulla Pass, running along the course of the river Jhilum to Mozufferabad and Attock. The passes which traverse the Paralasa Mountains are little known, except the Para Laha Pass, which traverses the mountains between 32° and 33° N. lat., and leads from the valley of the Upper Chinab to Leh.

We know very little of the mineral wealth of this range, except that at its western extremity, where the offsets of the Gosseie Mountains approach the Indus south of Attock, extensive layers of rock-salt occur, which are worked to a great extent. As to the other natural riches of this portion of the Himalaya, Cashmire may perhaps be considered as offering the most favourable specimen. [Cashmire.] The whole of this part of the range is now subject to Maharaja Runjit Sing, the raja of Lahore.

We pass to the central part of the Himalaya, or that which extends between the valley of the Sutlej and Bootan (from 77° to 88° E. long.). Here the mountain region is about 100 miles across, and is not composed of parallel ranges, but enormous mountain-masses protrude from the principal range nearly to the middle of the mountain-region. These masses, which are of great extent and elevation, contain between them only a few transverse narrow valleys, which, when compared with the height and extent of the surrounding mountains, may appropriately be called ravines. Such protruding masses are the Moral-ka-kanda Mountains between the valley of the Sutlej and the upper branches of the Jumna, which exhibit numerous peaks rising to between 18,000 and 20,000 feet above the sea; the Mandjri Mountains, with their extensive snow-field, between the Supin, a tributary of the Jumna, and the last mentioned river; the Uncha-ka-Dunda Mountains between the Jumna and the Bhaghiratee, the principal branch of the Ganges. Farther east lie the mountain-masses of Jaunli and of the Panch-Kedar, which with their extensive snow-fields and numerous peaks, several of which rise to more than 20,000 feet, fill up the country between the two principal branches of the Ganges, the Bhaghirateo and the Alakananda. Between the last mentioned river and the upper branches of the Kali and Gogra, the most southern elevated mass is called the Tri Sula Mountains. It is overtopped by several peaks rising to more than 20,000 and 21,000 feet, and contiguous to it on the north is the great mass of the Jawahir, which in its most elevated summit rises to 24,238 feet, and is surrounded by other peaks not much inferior in elevation. To the east of the upper branches of the Gogra River lies an extensive mountain-region, called Mallebum, of which we hardly know anything else than that it is covered with very high mountains and partly with snow. It extends to the Dhawalaghiri range, the highest mountain-mass in the whole region, which occupies the space between 28° 30′ and 29° N. lat., and 83° and 84° E. long., and is traversed by the Gandaki Ganga or Gun duck. Its highest summit, called Ghosa Cotee, attains an elevation of 28,000 feet above the sea, and is the highest known land on the surface of the globe. Contiguous to the Dhawhalaghiri Mountains on the east is the great mass of the Dhayabung Mountains, whose highest pinnacle rises to 24,560 feet. These extensive masses fill up the space between the Gandaki Ganga and the Bori Gadaki, and terminate north-west of Khatmandu on the banks of that river. The space between the Bori Gandaki and the Arun, an affluent of the Coosy, is mainly occupied by the Salpoo range, which contains two summits exceeding 24,000 feet in height, and many others nearly as high. The elevation and extent of the mountains between the Arun river and the boundary of Bootan are imperfectly known.

The enormous mountain-masses are separated from one another by long but very narrow valleys, which descend towards the south and south-west with rather steep slopes, especially in their higher parts. During the summer these upper valleys are covered with a vigorous vegetation, and are used by the inhabitants of the lower valleys as pasture-ground; but during the greater part of the year they are buried in snow, and uninhabited. Through these valleys lie the few roads by which the plain of the Ganges communicates with the countries on the table-land of Tibet. The most northern of these roads follows the valley of the Sutlej. At Puari, where the great mountain-masses of the Moral-ka-kanda Mountains begin, the road is 6160 feet above the sea-level; and at Shipkee, where it issues on the table-land, 10,484 feet. North of the Moral-ka-kanda Mountains the principal range of the Himalaya bears the name of the Kailas range, and the Charung Ghaut leads over it from the valley of the Buspa to that of the Todang Ghad; this pass attains the height of 17,400 feet above the sea. Out of the valley of the Bhaghiratee, or rather from that of its upper branches, the Jahneree river, the Gangtang Ghaut leads from Nilung to Chaprung, which is built on the banks of the upper Sutlej. It attains only the height of 10,150 feet, and is practicable for horses. The Manah Ghaut leads from the Vishnu Ganga, one of the upper branches of the Alakananda, to Chaprung, and rises to 18,080 feet. The road from the valley of the Douli, an affluent of the Alakananda, leads to Dumpo, on the banks of the upper Sutlej over the Necætee Ghaut, which rises to 16,620 feet. The Oola Dhoora Ghaut (30° 35′ N. lat.) rises to 17,790 feet, and contains the road which connects the valley of the Gori, an affluent of the Kali, with Dumpo. This seems to be the most frequented of all the roads traversing the Himalaya Mountains, as far as they are within the British dominions. The Neo Dhoora Ghaut, whose elevation has not been determined, is traversed by the road which leads from the valley of the Douli, an affluent of the Gogra, to the sacred lakes of Rhawan Hrad and Manas Sarowar: it is only frequented by Hindu pilgrims. The Taklakot Ghaut, which attains an elevation of 17,600 feet, is traversed by the road which connects the upper valley of the Kali, an affluent of the Gogra, with Taklakot, a place built 16,700 feet above the sea, near the sources of the Gogra, and on the table-land of Tibet. From Taklahot the road runs through another mountain-pass to the sacred lakes. We have only a very imperfect knowledge of the passes by which a communication is maintained between Nepaul and Tibet. From the Alpine province of Mallebum a long pass leads along the Gandaki Ganga over Mastang, where it attains its summit-level, to the plains extending along the river Sanpoo. The road by which the Chinese army in 1792 invaded Nepaul, begins on the side of Tibet at Kheru, attains its highest level at Siapi, and thence descends to Dhayabung, Noyakote, and Khatmandu. It seems to offer greater advantages than the other roads. Another road leads from Khatmandu along the Bhootya Coosy to Cuti, and thence over the Langur Pass to Tingri, on the table-land. Farther east a road leads to Tibet along the river Coosy and its affluent the Arun, beginning at Vijayapoor and passing through Seksura and Manigumbah to the table-land. The most eastern of these passes is the Phakali Ghaut, which leads from Sikim north-east to Tangchim, and thence over the mountains to Tibet; a part of this road runs through the territories of the raja of Bootan. Nearly all these passes are too steep and high for any beasts of burden, except sheep, which in the Himalaya mountains are used for the transport of merchandise.

The high mountain-masses advance so far from the principal range into the interior of the mountain-region, as to occupy more than one-third of it, when they descend with a rapid declivity. The other two-thirds of it are of a very different character. The general elevation of this lower portion may be between 4000 and 5000 feet above the sea. Almorah, the capital of Kumaon, on the river Kosila, and only 15 miles in a straight line from the lower edge of the mountain-region, is 5485 feet above the sea-level. Only the valleys, which are drained by the Bhaghiratee and Alakananda, the two principal branches of the Ganges, sink considerably below this level; Tiri, on the Bhaghiratee, being 2272 feet, and Sireenuggur, on the Alakananda, 1800 feet above the sea. Though the surface of this portion of the mountain-region is extremely uneven, and consists of continual elevations and slopes, with narrow spots of level ground between them, the summits which rise above it are not numerous; they are also considerably below the snow-line, as they generally do not rise above 8000 or 9000 feet. They are either isolated, or united by lower ridges, above which they rise 1000 feet and more. But these ridges do not run parallel to the mountain-region, except towards its lower border. This description however does not apply to the tract between the upper branches of the Jumna and the Sutlej river, which is much more mountainous. Here the mountain-ranges are higher, more continuous, and occupy a greater space, and several of the summits attain the snow-line. The Chur-Peak (30° 50′ N. lat., and 77° 30′ E. long.), which is hardly 20 miles from the lower edge of the mountain-region, is 12,160 feet above the sea. The difficulty which the great unevenness of this tract presents to an easy communication between the inhabited places, explains the circumstance of there being in it a great number of sovereigns whose dominion frequently extends only over a few villages. The remainder of this lower portion of the Himalaya range contains more cultivable land than is generally found in mountain-regions, and is also pretty well inhabited, though the villages are mostly very small.

The mineral wealth of that portion which belongs to the British, or is under their protection, is unknown; but Nepaul contains, according to Sir Francis Hamilton, rich mines of copper, iron, lead, and sulphur. Corundum is very common. In such a mountainous country the climate must of course vary extremely. We shall confine ourselves on this point to observing that the snow-line rises much higher on the north-eastern than on the south-western declivity: on the former it occurs at about 16,600 feet, and on the latter at 12,500 feet above the sea-level. It follows that the vegetation also must be different at the same elevation on the two sides. [ASIA, vol. ii., p. 467.]

The portion of the Himalaya between the Sutlej and Bootan is partly immediately subject to the British, or under their protection, and partly subject to the independent raja of Nepaul. The British dominions comprehend the countries between the Sutlej and the Kali Gogra. About one half of the country between the Sutlej and Kali Gogra is governed by rajas under British protection, and the other half constitutes the British province of Kumaon. The mountainous country along the banks of the Sutlej river is occupied by thirty-two petty rajas, among whom the raja of Indur, who resides at Ramgur, and the raja of Kuhlur, who resides at Bulaspur, on the Sutlej, are the most powerful. But the territories of these rajas do not extend to the table-land of Tibet. The higher mountain-region is possessed by the raja of Bissahir, whose territories extend along both sides of the Sutlej river and beyond the Kailas Mountains, over a mountainous tract which ought to be considered as a part of the table-land of Tibet, and approach the town of Shipkee on the Sutlej. He resides in Rampur on the Sutlej. The raja of Sirmur governs the countries situated in the middle of the lower region west of the Jumna river. His residence is at Nahun, a town built not far from the edge of the mountains towards the plain extending between the Ganges and Indus. The territories of these princes occupy about half of the countries which are under British protection; the other half belongs to the raja of Gurwal, whose territories stretch over the whole breadth of the Himalaya range, comprehending all the countries drained by the Bhaghirattee, and by the upper course of the Jumna and Supin. He resides in the town of Tiri, on the banks of the Bhaghirattee; but the most important place is Dhera, a large town not far from the lower edge of the mountain-region, in a low and warm valley. North of this place, on the mountains of Massura-ke-kanta, an establishment has been made for Europeans who have lost their health in the sultry climate of the plains on the Ganges, at Lundur, 7000 feet above the sea-level (30° 26′ 30″ N. lat., and 78° 4′ E. long.). The British province of Kumaon is annexed to the presidency of Allahabad; its capital is Almorah. [ALMORAH.] The countries within the Himalaya range, extending from the eastern banks of the Kali Gogra to the boundary of Bootan, are subject to the independent raja of Nepaul, with the exception of a very small portion contiguous to Bootan, which is possessed by the raja of Sikim, an ally of the British, who resides in the town of Sikim. Within his territory also a sanatory is established for the presidency of Calcutta, at Dargiling, near the Teesta river, an affluent of the Ganges. Its mean temperature is about 36° lower than that of Calcutta.

The eastern portion of the Himalaya range, extending from the western boundary of Bootan to the very sources of the Brahmapootra river, is almost entirely unknown. We are only acquainted with it as far as it is contiguous to the road which leads from the plain of the Ganges through Tassisudon, the capital of Bootan, to the table-land of Tibet. [BOOTAN.] Farther east the range has never been visited by Europeans. When seen from the valley of Asam it does not appear to rise to the snow-line west of 92° E. long.; but probably the lower ranges which are visible cover much higher mountains which lie north of them. Between 92° and 98° E. long. however, extensive ranges are visible, which rise above the snow-line, and they appear to attain a very great elevation near the sources of the Brahmapootra. [ASAM.]

The word Himâlaya is a Sanscrit word, compounded of *hima*, 'cold, or frost, or snow,' and *alaya*, 'abode.' (Wilson's *Sanscrit Dict.*) The resemblance of the first part of the compound to the name of the Hæmus (Balkan), to the Greek *cheima* (χεῖμα), and the Latin *hiems*, is obvious. The Greek and Roman geographers were acquainted with this enormous mountain-range under the general name of Imaus or Emodus, though their limited geographical knowledge does not allow us to assume that their term Imaus comprehended so much as the word Himalaya. It was known to Pliny that the word 'Imaus' signified, 'in the language of the natives, snowy' (vi., c. 17).

Journal*; Fraser's *Journal of a Tour through Part of the Snowy Range of the Himala Mountains*; Gerard's *Journal of Part of a Journey in the Himalaya Mountains*; Mundy's *Journal of a Tour in India*; Skinner's *Excursions in India*; Johnson's *Journal through the Himaleh Mountains*; Archer's *Tour in Upper India*, Ritter's *Erdkunde II. and III.*; Berghaus, *Karte von Assam und Spezialkarte vom Himalaya in Kumaon, Gurhwal, Sirmur, &c.*)

Botany.—The vegetation of the Himalaya Mountains is particularly interesting, whether we consider it in a special or in a general point of view.

These mountains have their south-west or Indian base clothed with a dense and almost impenetrable jungle, which separates them from the plains of India. This belt diminishes in breadth as we proceed northwards, until it altogether disappears to the north of the Jumna, where, in the country of the Sikhs, cultivation is carried on close to the foot of the mountains. From the proximity of water to the surface of the soil, this tract of country is usually called the Tarai, or Wet-land; but between the Ganges and Jumna rivers, Khadir-lands. The moisture is maintained by the want of free evaporation from the surface of the soil, and is increased by the great quantities of watery fluid transpired by the multitudinous leaves of this dense forest; its dispersion being prevented by the want of free ventilation. With this uniformity of moisture we have also greater equability of temperature than in the open plains; for as less solar heat is absorbed during the day, so is radiation less free during the night under this umbrageous covering, as is the case in the open plains in cloudy weather. Accordingly we have the characteristics of tropical climate, and with it tropical or Indian vegetation, which therefore extends much farther north along this tropic-girt base, emphatically called by Bishop Heber the belt of death, than in the open plains, where great heats alternate with great cold. In the south-east parts, as in Silhet, Chittagong, and Lower Asam, the forests are composed of gigantic trees, with extensive climbers reaching to their tops, epiphytes covering their branches, and tall grass concealing their trunks, as well as the elephants, which are found there of the finest description. The trees are composed of Artocarpeæ, Terebinthaceæ, Euphorbiaceæ, arboreous Leguminosæ and Malvaceæ, Combretaceæ, Ebenaceæ, Aurantiaceæ, Cinchonaceæ, Guttiferæ, &c. Ficus elastica, the Caoutchouc-tree of Silhet, occurs in great abundance and of gigantic size, as well as the Theetsee, or Varnish-tree, of the Burmese (Melanorrhœa usitata of Dr. Wallich). Hiptage madablota, Bauhinia corymbosa, and Robinia macrophylla, form the climbers, with species of Cathartocarpus, Erythvina, Butea, Bombax, Hibiscus, and Cochlospermum Gossypium, with large and showy flowers. Here splendid tree-ferns are found, and numerous scitamineous plants, with the plantain and peppers. Great uniformity extends along the whole of this tract, as many of the species of southern parts are found in the northern as far as 30°, as the Dipterocarpeæ, Shorea robusta, Ebenaceæ, Diospyros glutinifera, Lauraceæ, Cinnamomum albiflorum, Piperaceæ, Piper longum; a dwarfish Phœnix, P. humilis, and a trailing Calamus, represent the Palms.

In the tract of forest between the Ganges and Jumna are found many species which occur also beyond the limits of India, as Cassia elata, at the mouth of the Irrawady, in the Birman empire, Marlea begonifolia in Java, and Deeringia celosioides in New Holland. In the most northern parts Nerium odorum, or Oleander, is found along the banks of rivulets, as it is on those of watercourses in the north of Africa.

In this tropic-like forest the elephant reaches his most northern distribution on the banks of the Jumna, where a Paradoxurus is common: the rhinoceros does not extend beyond the eastern bank of the Ganges. Many tropical birds travel even farther north in the rainy season. A huge Python is found in the lower hills, as well as a Monitor of large size. Most of the insects also are those of hot and moist climates: Papilio Parakekte, found by Dr. Horsfield in Java, is also common at the foot of the hills in 30° N. lat.

The decrease of temperature being gradual as we ascend mountains, so is the disappearance of tropical forms in the Himalayas; and we continue for some time to meet with plants like Nyctanthes arbor tristis, which are common in the plains of India. But Indian trees and shrubs soon disappear. On reaching the region of Rhododendron arboreum and Quercus lanata, at about 5000 feet, scarcely any but European forms are visible. But as a few species of tropical genera travel into northern latitudes, so we find some such among the European-like vegetation met with at 6000 and 7000 feet of elevation, in 30° N. lat., as a few laurels and some Acanthaceæ, with species of Loranthus, even on an oak. But annuals which require only a few months to grow and ripen their seed indicate the temperature of the season, and not that of the year. Thus many tropical plants may be cultivated in the summer of European countries, and European plants and cultivation may be seen in the plains of India from November to March, or in what is the winter, as of more northern latitudes. In the same way we may see annuals characteristic of Indian or tropical vegetation at a much higher elevation in the Himalayas in the summer months than appears compatible with the prevalence of snow and great cold in winter. This anomaly presents itself at much greater elevations than would be expected, or indeed possible, were it not that the whole of the southern face of the Himalayas is under the influence of the tropical rains, during which they are inundated like the plains, and at the same time enveloped in clouds. The air, as it rises from the heated plains loaded with moisture, deposits it on reaching the point of saturation in these mountains. Hence continual moisture is preserved, and also equable temperature; for the cloudy covering prevents much absorption of heat during day, as it does radiation during night. The cooling besides of a ridge or a peak has but small influence on the mass of the atmosphere by which it is surrounded. Hence we observe but little change in the thermometer from night to morning, or from day to day, or week to week, and the temperature does not vary 10° of Fahr. for three months, or from the middle of June to the end of September. During this season therefore we see many plants in luxuriant growth which could not exist here for even a single day if either the moisture was less or the cold greater, as balsams, Begonias, some Melastomaceæ, numerous Cyrtandraceæ, tropical Orchideæ and Scitamineæ. The branches of the trees become covered with mosses and ferns, as well as epiphytes, such as Dendrobium alpestre and Cœlogyne precox: even Thalictrum radiatum and Arum viviparum are found on trees at this season of the year. A small bamboo even may be seen at 9000 and 10,000 feet, as well as Roscoea alpina at the former height, both having their roots protected by the earth and the covering of snow during winter.

It is in those months that rice is cultivated in these mountains, as well as other tropical grains, together with a species of arum, which is one of the principal articles of the chiefly vegetable diet of the hill-people.

The climate however of these mountains at about 7000 and 8000 feet of elevation being temperate, with greater uniformity however, and a less range of the thermometer, or from about 25° to 80°, supports a European-like vegetation, as has already been mentioned in Asia, *Botany of Himalayan region*, to which the reader is referred. Instead however of all the species being Indian, but of European form, as there stated, many species are identical with those found in the plains of European countries. Of such there are several instances in the families of Cruciferous and Labiate plants, also among the Compositæ and Leguminosæ. We may mention as instances, Ranunculus arvensis, common thyme, marjoram, and some of the mints; shepherd's purse, Prunella vulgaris, and the widely diffused Samolus valerandi, though nowhere met with in the plains of India. This identity of species is not confined to herbaceous plants, as we have the yew and the walnut, with the ivy and Rubus fruticosus. The apricot and pomegranate may be supposed to have been introduced, but the latter is undoubtedly wild. Pyrus baccata is a small Siberian tree found also in these mountains. Several of the Caucasian genera are also met with; and there is great similarity between the vegetation of the Hindu Coosh and that of the Himalayas in genera, and probably also in species.

It is curious to find among the above many which have hitherto been thought the peculiar genera of China and Japan, as Stauntonia, Abelia, Deutzia, Eurya, and Camellia. Thea itself has now been found in Upper Asam, but probably escaped from cultivated places; even some of the same species occur in the Himalayas and these countries; as Cleyera ochnacea, Hovenia dulcis, Kadsura and Lonicera Japonica, Houttuynia cordata, Ophiopogon spicatus, Pardanthus chinensis, and many others. Hence inferences were drawn that many parts of these mountains were fitted for the cultivation of the tea, long before it was known that it already was so in Asam. It is still more interesting to find here some North American genera and species; as Triosteum, Osmorrhiza, and Phryma; and even identical species, as O. brevistylis and P. leptostachya, with Desmodium nudiflorum, and a species of Panax closely allied to the Chinese P. Ginseng and American P. quinquefolium, which Dr. Wallich has named P. pseudo-Ginseng.

The vegetation of the upper belt has also been noticed vol. ii., p. 479), as well within as beyond the limit of forest. Here the climate bears some resemblance to that of polar regions in the same season, as the peaks are covered with snow for nine months in the year, which only melts when the sun has great power and the light is bright in the rarified atmosphere of these elevated regions. Junipers, dwarf-willows, and Rhododendrons, with Andromeda fastigiata, closely allied to the Siberian A. tetragona, reach the highest limits. Along with showy Primulas may be seen plants which are very similar to those of Arctic regions, as Ranunculus polypetalus to the Siberian R. glacialis of Fischer; a species of saxifrage, S. stenophylla, hardly to be distinguished from S. stolinifera, brought from Melville Island. This similarity in form to the plants of very distant regions is not however confined to genera containing numerous species, but is observable in others where two or three only constitute the genus, and of which one is found in these mountains; as of Sieversia which occurs also in Melville Island and Kamtchatka, and Dalibarda in North America and the Straits of Magalhaens, where many of the same genera are found as on these lofty peaks. The genera Oxyria, Gymnandra, Wulfenia, Dictamnus, Coriaria, and Staphylea, afford other instances, though some are found at a lower elevation. Ourisia is found in these mountains as well as in Van Diemen's Land and the Straits of Magalhaens.

The snowy passes exhibit many of the phenomena characterising these lofty peaks. The resemblance in form however is not confined to the vegetable kingdom. The Himalayan fox can scarcely be distinguished from the European species. Many birds are identical in species with those found in Europe: the woodcock may be adduced as an instance. Many insects also do not differ from those found in Europe. At still greater elevations the Alpine hare, or Lagomys, is found, which hardly differs from the Siberian Pika. A jay (Garrula bispecularis) is of an American form, as is the genus Paussus among insects, which, until brought from the Himalayas by Mr. Downes, was thought to be confined entirely to North America.

In crossing the snowy mountains by the passes, which are flanked by snowy peaks usually 3000 or 4000 feet more elevated, and which prevent the passage across of the air loaded with moisture, we have a very different set of phenomena presented. The district of Kunawur may be considered a portion of Tartary, or Tibet, instead of India, though some Indian forms still show themselves in the bed of the Sutlej, in Lower Kunawur. The climate is extremely dry, and evaporation very rapid. Very little rain falls at any time. The country is covered with snow from the end of October until April, but the layer is never very thick, from the great dryness of the climate. The cold is intense during winter, but the thermometer in July and August ranges from 55° to 58° in the morning, and rises even as high as 80° or even 85° during the day, in villages elevated 10,000 feet. 'When the snow is melted, these elevated tracts, surrounded and confined by towering mountains, absorb heat as readily during the presence of the sun, as they radiate it freely during his absence; and becoming, like the surface of the earth at ordinary levels, the source whence the heat received from the sun is diffused to surrounding objects, they cause the line of perpetual congelation (and consequently of vegetation) to rise higher and higher in proportion to their own elevation. Peaks and pinnacles, on the contrary, projected into the air like promontories into the ocean, partake rather of the equability of the media into which they intrude, than impress on them, like plains and table-lands, their own extremes of heat and cold.' (Royle, *Illust.*, p. 39.)

Kunawur is everywhere intersected by elevated ridges which are crossed by passes varying in elevation from 12,000 to 18,000 feet: on some of those to the eastward, even at the latter height, little snow is seen in summer, and that only in streaks. Vegetation extends to 16,600 or even 17,000 feet. Junipers are found at 14,500 feet, Rhododendron lepidotum below them, but above the birch, which is found at 14,000 feet. Pines do not extend beyond 12,300 feet. The highest cultivation was seen by Dr. Gerard near Dabliug, at 13,600 feet, consisting of barley, buckwheat, and turnips.

The Tartar province of Hungarung lies north of Kunawur, but separated by a lofty range which is crossed by a pass at an elevation of 14,800 feet, coinciding here with the limit of snow. The mountains have rounded outlines with gentle declivities. The country is destitute of trees, and presents everywhere a picture of arid barrenness. The villages are at elevations of 10,000 to 12,000 feet. Nako is at the latter height, on the western face of lofty mountains, yet there are produced luxuriant crops of wheat, barley, buckwheat, and turnips 700 feet higher, rising by steps or terraces, enclosed by hedges of gooseberry, barbary, and juniper. Caragana Gerardiana and versicolo extend to 13,000 feet, and are the plants called Tartarian Furze by travellers. Dr. Gerard also found this at a village at a height of 14,700 feet, where the barometer gave 14,900 feet as the elevation of the highest field of cultivation.

The vegetation of the northern face of the Himalaya has been noticed (vol. ii., p. 478), under the head of *Tartaric region*. The cultivation has been indicated above; the fruit trees consist of species of Pyrus and Persica, with the apricot, of which the fruit is dried, and the grape-vine, from which wine is manufactured. The families and genera of plants which prevail here are strikingly similar to those occurring in the Altai Mountains, as described by Ledebour in his 'Flora Altaica,' also in the south of Siberia and on the Caucasus, as among them we not only find such genera as are common to these countries and other parts of the world, but several which are remarkable and peculiar, as well genera as species. Among the latter we find Lithospermum amplexicaule, Cuminum Cyminum, and Hyoscyamus niger (the last found both in Caucasus and in Europe); Biebersteinia odora, in Persia and on the Altai range; Crambe cordifolia and Tauscheria desertorum of the Caucasian Flora, the latter also found on the deserts of the Kirghis and the banks of the Irtisch. Many others might be enumerated, but the above are sufficient as examples, and it is impossible within our limits to attempt a complete view of so extensive a subject. Notwithstanding the apparent barrenness of much of the country on the northern face of the Himalaya, nowhere are the flocks of cattle more conspicuous for number and variety. The cold and dry atmosphere is particularly favourable to the shawl-goat. The sheep and goat are both used as beasts of burden, and the dog is of large size, and, like the others, furnished with fine wool under the upper shaggy hair. The Bhural (Asiatic Argali), the Yak (Bos grunniens), the wild horse, the Yuckur, or wild ass, and the Dziggtai, or Equus Hemionus of Pallas, are all found here, and obtain nourishing food from the grasses of European genera, and the Leguminous Astragali and Caraganas. Among birds, Gypaëtus barbatus and the chough, or red-legged crow, are common, with three species of pheasants, and the Chukor, which is most frequently seen on the most barren hills. (Dr. Royle's *Illustrations of the Botany and other branches of the Natural History of the Himalayan Mountains.*)

HIMA'NTOPUS, the generic name for the *Long-legged Plover*, *Longshanks* or *Stilt*. [PLOVERS.] The term is also applied by Müller to a genus of *Microzoaria*.

HI'MERA, a city in the interior of Sicily, which took its name from the river Himeras, was founded by the Zanclæans of Mylæ in Sicily (Strab., vi. 272), and after existing as a flourishing town for 240 years, was destroyed by the Carthaginians, and its ornaments carried off. The inhabitants who survived this calamity established themselves at Thermæ, near the site of the antient town (Cic., *In Verr.*, ii. 35), and enriched their new abode with such works of art as they had saved from the wreck. Upon the capture of Carthage, Scipio restored to the people of Thermæ, of Gela, and other Sicilian towns, those monuments of art of which they had respectively been plundered in their wars with Carthage. (*In Verr.*, iv. 33.)

Coin of Himera.

British Museum. Actual Size. Silver. Weight, 265¼ grains.

HIMMEL, FRIEDRICH-HEINRICH, a German composer of celebrity, the reputed son of Frederic William II., of Prussia, was born in the duchy of Brandenburg in 1765. He was intended for the church, and studied theology in the university of Halle, but devoted all his spare time to music, in which he became so skilful that the king, his supposed father, encouraged him to pursue the art as a profession, and settled on him a pension to enable him to study it under proper instruction. He chose Naumann as his guide, with whom he made such progress that in two years he produced the oratorio of *Isacco*. He then travelled into Italy, and at Venice brought out a pastoral opera, *Il Primo Navigatore*. In 1794 he succeeded Reichardt as kapellmeister at Berlin, and in the following year produced his *Semiramide*. The operas on which his fame chiefly rests, are *Fanchon das Leiermädchen* (*Fanchon, the Lyre-maiden*), and *Die Sylphen* (*the Sylphs*). His best compositions are a *Funeral Cantata* on the death of Frederic William in 1799, and a *Te Deum* for the coronation of his successor.

Himmel wrote many good sonatas for the piano-forte, and his romances, songs, &c., which are very numerous, abound in sweet and original melody. He visited London in 1801, but made only a short stay. His death took place at Berlin in 1804.

HIMILCON, the name of several Carthaginians.

1. Himilcon, who is said by Pliny (*N. H.*, ii. 67) to have been contemporary with Hanno, was sent by the Carthaginian government to explore the north-western coast of Europe. A few fragments of this voyage are preserved by

Festus Avienus (*Ora Maritima*, l. 90), in which the Hiberni and Albioni are mentioned, and a promontory, Œstrymnis, and islands, Œstrymnides, which are usually considered to be Cornwall and the Scilly Islands. (Gosselin's *Recherches sur la Géographie des Anciens*, vol. iv., pp. 162, 163.)

2. Himilcon, who commanded the Carthaginians in their wars with Dionysius I., tyrant of Syracuse, B.C. 405-368. Himilcon was an able and successful general. He took Gela, Messana, and many other cities in Sicily, and at length besieged Syracuse by sea and land; but he was defeated by Dionysius, who burnt most of the Carthaginian ships. (*Diodor. Sic.*, b. xiii. xiv.)

3. Himilcon, a supporter of the Barcine party at Carthage (*Liv.*, xiii. 12), was sent by the Carthaginian government to oppose Marcellus in Sicily. (*Livy*, xxiv. 35-39; xxv. 23-36.)

HINDUSTAN, that is, the country of the Hindus, in the Persian language: this term has been adopted by geographers to designate that part of India, or the East Indies, which was formerly called the Peninsula within the Ganges, and which extends from Cape Comorin, its most southern extremity, to the foot of the Himalaya range and the mountain-chains which separate the high table-land of Iran (Persia) from the low plain traversed by the Indus, or Sinde, after this river has issued from the Himalaya mountains. As the long declivity of the last-mentioned extensive mountain-chain slopes towards the plains of Hindustan, which extend along its base, and as the rivers originating within this range descend towards these plains, the Himalaya mountains are commonly and properly included in Hindustan. The seas which surround Hindustan on the south-east, south, and west, and the mountains which enclose it on the north-west and north-east, mark distinctly its boundary on these sides. On the east, where the valleys traversed by the Brahmapootra and the Soormah open into the plains of Bengal, the boundary-line is uncertain; but we may fix it at 92° 30′ E. long., to which meridian the possessions of the East India Company now extend, if the coast of Aracan, which properly does not belong to Hindustan, is excluded. Within these boundaries Hindustan extends from Cape Comorin, 8° 4′ N. lat., to Attock on the Indus, 34° N. lat., and from Cape Monze, west of the delta of the Indus, 67° 30′, E. long. to the meridian of 92° 30′. Its length, in round numbers, is about 1800 miles, and its greatest breadth between Cape Monze and Silhet, on the Soormah river, along the parallel of 25° N. lat., about 1500 miles. Its surface is stated to be 1,200,000 square miles, or three times the extent of France and Austria taken together; but this statement is exaggerated; and it probably does not exceed 1,000,000 square miles.

The coast-line of Hindustan amounts, according to a rough calculation, to about 3280 miles, of which 1830 miles are washed by the Indian Ocean, and 1290 by the Bay of Bengal; about 160 miles, or somewhat more, extend along the Gulf of Manaar and the Palk Strait. Beginning with the innermost corner of the Bay of Bengal, at Chittagong, or Islamabad, the coast for about 320 miles is traversed by the numerous mouths of the Ganges, all of which admit small vessels; the Hoogly branch admits vessels of good size, and the Horigottah branch vessels of any size. Contiguous to the Hoogly is the open Bay of Balasore, with a coast of 120 miles, terminating at Cape Palmyras. From this point the coast stretches in a south-west direction to the mouth of the Kistna for about 420 miles, and is without harbours, except that of Coringa, near the mouth of the Godavery. From the mouth of the Kistna to Cape Calymere, an extent of about 430 miles, no harbour occurs, even for vessels of moderate size. Between Cape Calymere and Cape Comorin, about 160 miles, there is only the small and shallow harbour of Tuticorin. The coast, which stretches north-north-west, and afterwards nearly north, between Cape Comorin and the innermost corner of the Gulf of Cambay, a distance of about 1150 miles, contains a great number of small and several very good and safe harbours. The coast-line of the peninsula of Gujerat, which, exclusive of the Lesser Runn, is about 380 miles in extent, has several harbours for vessels of moderate size. The coast-line of the island of Cutch, exclusive of the Runn, but inclusive of the Koree, or eastern mouth of the Indus, extends about 150 miles. The coast intersected by the several mouths of the Indus extends as far as Cape Monze, about 150 miles, but it cannot be approached by vessels of more than 50 tons burden, except at the harbour of Currachee, which admits vessels of moderate size.

The surface of Hindustan is characterized by very marked features on a large scale. From the mouths of its two great rivers, the Ganges and the Indus, two low and level plains extend in a converging direction along both sides of these rivers till they meet between 28° and 31° N. lat., and 76° and 77° E. long. Near 28° N. lat. the country begins to rise rather abruptly, constituting between the two plains, and afterwards between the two seas (the Indian Ocean and the Bay of Bengal), a series of table-lands in the form of terraces, which rise higher and higher as they advance southward, until they attain their greatest elevation in the table-land of Mysore, at the foot of the Nilgherry mountains (between 11° and 12° N. lat.). South of this range a low plain, in some parts less than 20 miles in width, extends across the peninsula. This narrow portion of the plain is called the Gap of Coimbatore; and south of it is a mountain region which occupies about half the breadth of the peninsula in this part, but as it advances southwards grows narrower till it terminates at Cape Comorin in a narrow ridge. The table-lands do not extend to the shores of the sea, but are divided from it by flat tracts varying in breadth. The table-lands themselves are divided into two unequal portions by two deep valleys which traverse them obliquely, beginning on the west near 22° and terminating on the east near 25° N. lat. In these valleys run the rivers Nerbudda and Sone, the former of which falls into the Gulf of Cambay, and the latter joins the Ganges north of 25° N. lat.

Following this natural division we shall give a general description of the surface, soil, rivers, climate, and principal products of Hindustan under five heads:—1, Southern Region, comprehending the southern extremity as far north as the Gap of Coimbatore; 2, Deccan, which extends to the river Nerbudda, and includes the maritime countries of Malabar, Canara, and Concan, on the Indian Ocean, and the Carnatic and the Circars on the Gulf of Bengal; 3, Mountain-region of North Hindustan, comprehending the terraces north of the Nerbudda, together with the peninsulas of Gujerat and Cutch; 4, the Plain of the Ganges; and, 5, the Plain of the Indus. To these may be added, as a sixth natural division, the Himalaya Mountains. [HIMALAYA MOUNTAINS.]

I. *The Southern Region.*—The narrow sea which separates Hindustan from the island of Ceylon is traversed by a chain of islands and sand-banks called Adam's Bridge. [ADAM'S BRIDGE.] The island of Rameserum is low, sandy, and not cultivated, but celebrated for its great pagoda, the extent and splendour of which have called forth the admiration of many travellers; it is still visited by pilgrims from all parts of Hindustan. At the western extremity of the island is a small place called Paumben, where travellers cross the Paumben Passage to the continent. It is about a mile wide, and has six feet of water at high tide. The adjacent coast is low and sandy, but at a short distance from the sea some sand-hills occur, between and behind which are numerous salt swamps and lagoons, whose exhalations render these tracts unhealthy. These swamps often extend several miles inland. Behind them the country rises but very slowly to the foot of the mountains on the west, a distance of from 40 to 60 miles. This tract is very well supplied with water, numerous small rivers descending from the mountains, and supplying plentiful means of irrigation. It is accordingly well cultivated and presents a succession of rice-fields and palm-groves. Among its rivers is the Vaygaroo, which passes near the town of Madura, which formerly contained a population of 40,000 inhabitants, but now has hardly half that number. Farther south is the town of Tinnevelly, in a very well cultivated country not far from the mountains. The harbours are shallow, with the exception of that of Tuticorin, which however is small; in its neighbourhood pearls are fished.

At the foot of the mountains the plain may be about 300 feet or less above the sea. The mountain-regions which border on it on the west are very little known, except that between 9° 10′ and 10° 20′ N. lat. they occupy a considerable surface. Their elevation seems to be considerable. Mount Permaul, north-west of Dindigul, which appears to be the most north-eastern offset of the range, was found by Colonel Lambton to be 7364 feet high, and it is conjectured that much higher summits may occur farther west. According to a native account they even attain the snow-line. This isolated mountain-region therefore may be considered as the highest land in Hindustan south of the Himalaya range. The Aligherry Mountains, south-west of Madura, another offset of the same stock, rise to 4219 feet. South of 9° 10′ the mountain-mass runs out southwards in one single range, which is lower, but continues at a considerable elevation to a distance of about 20 miles from Cape Comorin, where it suddenly lowers about 2000 feet. The remainder is a low ridge of granite overgrown with thick forests of a vigorous vegetation, in which are numerous large boulders of granite. As these mountains are exposed to the immediate effects of both monsoons, they are everywhere covered with trees, among which the teak is abundant, and forms one of the chief sources of wealth to the country. In these forests pepper-vines and cardamom-plants frequently occur, but most of their vegetable productions are yet undescribed. Two passes are at present known to exist across these mountains. The northern, called the Ariangawal Ghaut occurs near 9° N. lat., and leads from Tinnevelly on the east to Quilon on the west, through Cotallum. The southern, the Amboli Ghaut, lies about 20 miles from Cape Comorin, near the place where the mountain-range suddenly lowers.

The country which lies to the west of the mountains exhibits a much more diversified surface than that to the east of them. Numerous offsets consisting only of low hills advance towards the coast and leave a level tract along the sea some miles broad. Between Quilon and Anjengo the hills reach even to the shores, which are sandy and mostly covered with cocoa-palms. At a short distance from the coast are lakes, among which that is particularly remarkable which extends with its branches from Cochin on the north, to Quilon on the south, and offers very advantageous means for the transport of goods. The low country, which extends east of the lakes some miles inland, is in many places swampy, and used as pasture-ground in the dry season, or covered with jungle and forest trees; but the higher tracts produce rice and other grain in abundance. These tracts are mostly uninhabited. The villages are built farther inland on the low ranges of the hills, where they are surrounded by extensive plantations of palms, jack, plantains, and mangos. Still farther inland the mountains rise with a steep ascent, and are covered with forests, especially of teak. The navigation along this coast is safe and very pleasant from November to March, but during the south-west monsoon no vessel ventures to approach it. A very heavy surf always runs along this coast, and renders landing difficult.

This tract is subject to two native princes, allies of the English. The king of Travancore possesses the southern portion, which is about seven-eighths of the whole; and the raja of Cochin is in possession of the most northern districts. The English and Dutch have some settlements. Tivandrum, the capital of Travancore, a few miles distant from the sea, is a large and well-peopled place with a castle. Anjengo is a small harbour, where the English had a factory up to 1813, when it was abandoned. Between it and Quilon is the Dutch factory of Eddava. Quilon was formerly in possession of the Portuguese, and afterwards of the Dutch, but it has been abandoned. It has a small harbour, but a considerable population. Cochin, which was first possessed by the Portuguese, and afterwards by the Dutch, is now in possession of the English; it has a good harbour, and a considerable commerce with Bombay, Surat, Arabia, the Sunda Islands, and China. It exports pepper, cardamoms, teak, and sandal-wood, cocoa-nuts, coir, cassia, and the produce of its fisheries, a branch of industry much attended to along this coast. No place is better adapted for the exportation of teak than Cochin, as the timber is floated down the various small rivers which fall into the lake, and then easily conveyed to Cochin. Cochin has 30,000 inhabitants. North of it is Cranganore, where a Catholic bishop resides.

The Gap of Ponany or Coimbatore, which extends between 10° 40′ and 11° N. lat., is a long valley which unites the wide plains of the lower Cavery with the level coast of Malabar. It takes its name from the town of Coimbatore, which lies near its eastern extremity, but without it, or from the river Ponany, which drains it in all its length. The most elevated part near the sources of the river is only about 400 feet above the sea, and not sufficiently high to hinder the north-east monsoon from penetrating through the Gap. Rennell observed that vessels sailing in the fine season along the coast of Malabar always experience a stronger eastern wind when they approach the mouth of the river Ponany. It is also stated that Coimbatore participates in both monsoons. Between the last-mentioned town and the fortress of Palighat is the narrowest part of the valley, which is only from 12 to 15 miles across. Its surface is encumbered with a great number of boulders of granite, but is everywhere overgrown with high forests, and during the south-west monsoon the greater part of it is converted into a swamp. It is not cultivated, and almost exclusively frequented by immense herds of wild elephants and other beasts. Cultivation begins at the strong fortress of Palighat, where the Ponany river becomes navigable for canoes, and the culture of rice and other productions increases on the banks of the river as it advances towards its mouth, where the town of Ponany is built, which has a good harbour and a population of about 10,000 souls. It carries on a considerable commerce with the towns along the Malabar coast, Arabia, and Bengal. Its rich merchants are mostly Mohammedans.

II. *Deccan.*—This term, which is derived from the Sanscrit Dakshina (the south), was originally applied to the whole peninsula south of the river Nerbudda, including also the country south of the Gap of Coimbatore. It was afterwards used to indicate that portion of the peninsula which had become subject to the Mongol emperors. We have however applied it, in a geographical view, to the peninsula north of the Gap of Coimbatore, and we fix its northern boundary at the valley of the Nerbudda, the elevated table-land of Omercuntuc, and the range of mountains which, branching off from the table-land to the east, terminates in the Nelligreen mountains, in the neighbourhood of Balasore, on the Gulf of Bengal. This boundary-line runs across the whole peninsula between 21° and 23° N. lat.

The interior and by far the greater part of this extensive region is an elevated table-land, which is enclosed on all sides by low plains extending to the sea-shore. The edges of the table-land are here, as in every other part of the world, raised above the surface of the table-land itself, and appear in the form of mountains or high hills, and the descent from them to the low plains on the sea-shore is steep, and full of impediments to easy communication.

The *Table-land* extends from south of 12° to 21° N. lat. Between 12° and 16° its average breadth probably does not exceed 150 miles, but north of 16° it widens gradually to 400 miles. Its boundary will be determined by a survey of the ranges which surround it. By the natives it is called Bala-Ghaut, or the country above the Ghauts; and the low plains of the coast are named Payan-Ghaut, or the country below the Ghauts. The name Ghaut signifies the narrow passes by which the mountains which divide the Payan-Ghaut from the Bala-Ghaut are traversed. The resemblance of the word in form and meaning to our word *gate* is obvious, and it appears to be a form of the Sanscrit 'gati,' a way or path.

The elevation of this table-land varies to a certain extent. The country south of 15° N. lat., which is called the table-land of Mysore, is the highest part, and it is higher towards the east than towards the west. Bangalore is 3026 feet, and Colar 2900 feet above the sea; but Seringapatam is only 2412 feet, being built in a deep depression on the river Cavery. North of 15° N. lat. the table-land grows lower, and the greatest depression seems to occur between 15° and 17° in the region drained by the Kistna and its tributaries. In this part the country slopes slowly from west to east. Dharwar, near the western edge, is 2352 feet above the sea; Bellary, nearly 77° E. lat., 1488 feet; and Gooty, between the rivers Penn-air and Kistna, 1182 feet. Farther north it again rises higher, and the western and higher districts, as far east as 77°, may vary between 2000 and 2500 feet. But east of 77° its slope, which is mostly directed to the south-east or south, is more rapid. Hydrabad is 1696 feet, and Nagpoor only 900 feet above the sea.

The surface of this table-land is a level plain, on which hills rise here and there in a conical form, and in a few places ridges of sandstone appear, but these ridges are not continuous; they are frequently interrupted by depressions, which sink to the level of the plain. These eminences rise from 300 to 900 feet above their base. Towards the mountains which constitute the western edge of the table-land the surface is much more uneven; numerous short spurs branching off from the mountains and advancing about 30 or 35 miles into the plain. The isolated hills, as well as these spurs, are of very steep ascent, and on them are built the numerous strong fortresses called droogs or durgas,* which served for a long time as places of retreat to those who laid waste the table-land with their hostile incursions. They are now mostly in the hands of the English, and are going rapidly to decay.

Here, as in other countries between the tropics, the year is divided into two parts, a rainy and a dry season. The rainy season does not occur, as on the eastern coast, during the north-east monsoon, but during the south-west monsoon, as on the western coast. It begins however not immediately with the change of the monsoons, but in May, in which month only small showers fall. In June or July they become more regular and continuous, and they last till October. But the quantity of rain is not great, being estimated to amount only to 20 or 26 inches annually, whilst on the western coast it is 116 inches, and on the eastern 45 inches. It is further observed that more rain falls in the districts which skirt the Western Ghauts than farther east; and likewise that the quantity of rain also decreases towards the north. The last circumstance is ascribed to the direction of the Western Ghauts, which do not run exactly south and north, but decline some points to the north-west. In the districts which skirt this mountain-range a cool westerly wind blows during the night, even in the season of the north-east monsoon. The mean annual temperature of the higher districts of the table-land seems to be nearly 10° less than at Madras; it is stated to be at Darwar 75°, and at Madras 84° of Fahrenheit.

The table-land here also, as in other parts of the world, is destitute of trees so far as the plain extends. On the low spurs of the Western Ghauts and in the valleys between them the country is wooded, and this is also the case with the most southern corner along the river Cavery. All the remainder contains only a comparatively small number of bushes, but is generally covered with grass. It is however rather fertile. On the whole surface of the table-land a black soil prevails, which, from being favourable to the growth of cotton, has been called the black cotton ground, or *regur;* this soil is never manured nor does it ever lie fallow, and yet it produces rich crops every year when skilfully managed. The hills which rise on the table-land are bare and sterile, like most of the small valleys between them, some of which however exhibit a great deal of fertility. The northern districts of the table-land are less fertile, probably on account of the deficient quantity of moisture. Vast tracts without cultivation frequently occur here. During the rainy season and the cool months which immediately follow, this country, especially in the southern districts, presents a pleasant view, being covered with a fine sward of grass, and mostly cultivated or planted. But towards the spring the plains lose their verdure, and their surface becomes a brown level, intersected by numerous deep rents. Clouds of dust are raised by the dry hot winds, and when a calm suddenly occurs they remain for some time stationary in the air. The excessive heat produced by the vertical rays of the sun extinguishes every trace of life; even the smallest insects disappear. The rivers flow slowly in their deep beds, and their bare black banks descend abruptly 20 or 30 feet to their channels, and thus have the appearance rather of artificial cuts than of rivers. All the smaller streams dry up, and the larger, which during the rainy season rise from 20 to 30 feet, and even inundate a few tracts along their course, are during the dry season so deep below the surface of the adjacent fields that the water cannot be used for irrigation, as in the plains of the Ganges, and in some of the tracts along the Bay of Bengal.

The cultivation of rice is only carried on where there are artificial means of irrigation; tanks for this purpose are numerous in some places. But the number of other grains, plants, and fruits is very great.

By far the greatest portion of this table-land is still under the sway either of Hindu or of Mohammedan princes. The districts immediately subject to the British government comprehend only about 40,000 square miles, whilst the territories belonging to the princes under the protection of the British extend over an area exceeding 200,000 square miles.

1. The most southern part is the kingdom of Mysore, governed by a Hindu prince, now Maharaja Krishna Adiaver. It comprehends more than 30,000 square miles, or an area 4000 square miles larger than Scotland. Its capital is Seringapatam. The ancient capital, Mysore, south of Seringapatam, is said still to contain 10,000 inhabitants. Besides, there are two large towns, which carry on a considerable commerce, Bangalore and Bednore. [BANGALORE; BEDNORE.]

2. The territories of the Nizam, or raja of Hydrabad, a Mohammedan prince, occupy the centre of the northern portion of the table-land, and comprehend an area of about 110,000 square miles, or little less than the British islands, and are inhabited by more than ten millions of souls. The capital, Hydrabad, is a large town, whose population by some is stated to amount to 120,000 souls, by others even to 200,000; it is noted for its extensive traffic in diamonds. In its neighbourhood is Golconda, a fortress on a high hill, from which the whole country once received the name of the kingdom of Golconda. Other remarkable places are Beder, a commercial town, situated on one of the great thoroughfares of the table-land, Aurungabad [AURUNGABAD], Dowletabad [DOWLETABAD], and Elora with its famous ruins [ELORA].

3. The possessions of the raja of Berar, called Boonslah, extend to the east of Golconda over a surface of about 65,000 square miles, or an extent of country greater than England and Wales together. The population is estimated at about three millions. The capital, Nagpoor, situated towards the northern boundary of the table-land, is a large town, with a population of 100,000 and a circuit of seven miles. The prince is a Hindu of a Mahratta family.

4. The raja of Satara governs a country containing about 9000 square miles, or nearly the extent of the island of Sicily, and inhabited by more than half a million of souls. It extends along the Western Ghauts, but reaches far into the table-land. The prince is a Hindu, and resides in the town and fortress of Satara, which is situated in a very fertile and well cultivated country. In his territories are the ancient town of Bejapore [BEJAPORE], and Punderpore on the Beema river, a commercial town and noted place of pilgrimage.

5. The raja of Colapore possesses a territory of about 3000 square miles, nearly equal to the county of Devonshire. It extends likewise along the Western Ghauts, south of the territories of the raja of Satara. The prince is a Hindu, and his capital is Colapore.

6. The English possessions are partly annexed to the government of Madras and partly to that of Bombay. Only the ceded districts, or Balaghauts, belong to Madras. [BALAGHAUTS.] They contain the fortresses of Gootydroog and Bellary. Two districts are annexed to the presidency of Bombay; Darwar, or the South Mahratta country [DARWAR], and Deccan [DECCAN], the first lying south of the territories of the rajas of Colapore and Satara, and the second lying north of it. In Darwar is the town of Darwar [DARWAR] or Dharwar, and in Deccan are the towns of Poonah, Ahmednuggur, a considerable and thriving commercial town, situated on one of the great thoroughfares of the table-land, with more than 20,000 inhabitants, and Nassuck, with 27,000 inhabitants. Near Nassuck are the excavated temples of Pandu Lena; and not far from Poonah those of Carli.

In surveying the higher lands, which encircle the table-land, we begin with the most northern portion, the elevated table-land of Omercuntuc, which lies between 22° and 23° N. lat. and 80° 30′ and 82° 30′ E. long. It rises considerably above the surrounding tracts; but as it has not been visited by Europeans, its elevation is not known. On its eastern declivity rises the Sone river, and the Nerbudda traverses it in its length from east to west, until it leaves it near Mundlah. Near the source of the Nerbudda is a Hindu temple, which is a place of pilgrimage. The table-land of Omercuntuc is the central link by which the higher lands of the Deccan are united to those which extend to the north of the Nerbudda. Below Mundlah the high lands contiguous to the table-land extend westward on both sides of the narrow valley of the Nerbudda in extensive masses, which, near 79° E. long., take the form of three distinct ranges. The ridges diverge between 78° and 79° E. long., but farther west they run nearly parallel. The most northern range is the Vindhya Mountains, the middle range is called the Sautpoora Mountains, and the southern, which is less distinct in its features, being only the northern declivity of the table-land of the Deccan, has no general name, but may perhaps with propriety be called the Northern Ghauts. Between these three ranges lie the two parallel valleys of the Nerbudda and Tapty

* 'Difficult of access or approach,' &c.; 'a fort, a stronghold, a *Droog*, or hill-fort.' Wilson's 'Sanscrit Dict.'

The Northern Ghauts may be said to begin in 22° N. lat., between 78° and 79° E. long., with the high lands, on whose eastern declivity the upper branches of the Whurdah, an affluent of the Godavery, and on whose western declivity those of the Tapty rise. These mountain-masses, which extend from north to south, have probably an elevation of 4000 feet above the sea, and send off a very distinct and elevated range westward between the two upper branches of the Tapty. This last-mentioned range, called Mahadeo Phar (the mountain of the great god), rises to the height of 4000 feet near the fortress of Gawulgur. The remainder of the Northern Ghauts, from the neighbourhood of Oomrawutty (20° 55′ N. lat. and 77° 45′ E. long), lies in a general westerly direction along the southern side of the valley of the Tapty, and joins the Western Ghauts between Chandore and Soolgana, west of 74° E. long. It rises with a very steep ascent from the valley of the Tapty, where it presents the appearance of a mountain-range, between 2000 and 3000 feet high, but its descent on the south is short and easy, the table-land of the Deccan being on an average perhaps only 500 feet lower than the range. The mountain-passes are very difficult, especially those leading from the valley of the Tapty to the table-land. The most frequented is the mountain-pass of Ajunteh, through which the road runs which leads from Boorhampoor on the Tapty to Dowletabad and Aurungabad. Near the mountain-pass are some temples excavated in the rock.

The Western Ghauts, which constitute the boundary of the table-land of the Deccan towards the Indian Ocean, begin about 10 miles from the southern bank of the Tapty and about 60 miles from the sea-shore. Between 21° and 19° N. lat. the highest portion of the range preserves the same distance from the sea, but somewhat north of the parallel of Bombay it approaches within about 30 miles. At about this distance it runs parallel to the shore to 15° N. lat., where it gradually approaches nearer, until the mountains come close up to the coast, at the mouth of the river Gangawally (14° 30′ N. lat.). They continue to constitute a high coast along the sea as far south as the town of Barcelore, or Barcoor (13° 30′). South of this place these mountains again recede farther inland, so that opposite Mangalore they are more than 30 miles from the sea. Farther south the distance is less, and between Chandergherry (12° 30′) and Mount Delli several elevated offsets come up to the sea. The Western Ghauts terminate a little south of the parallel of Calicut, about 11° N. lat., where they constitute the northern border of the Gap of Ponany.

This range varies considerably in elevation and width. North of Bombay it is stated not to exceed 3000 feet in height, and to be only about 1000 feet above the table-land on the east. But south of Bombay it rises higher, and the Mahabalipoora Mountains, nearly opposite Fort Victoria, about 18° N. lat., rise to the elevation of 5036 feet. A sanatory has been established on them for Bombay. It is not known how far south this elevation is continued, but opposite Goa (15° 30′) the mountains are traversed by a pass which is only 2477 feet high, and hardly more elevated than the contiguous plains of Darwar. The pass, which leads from Sadashevagur to Yellapoor and Soonda, seems to be still lower. The small difference observed in the temperature between the coast and the summit of the pass induced Dr. Fr. Buchanan to think that the difference of the elevation could not exceed 1000 feet, but probably it is much more. Opposite Bednore (south of 14° N. lat.) the mountains rise to 4000 feet, and they seem to continue with this elevation to the Hosso Angady Ghaut (13° 42′) south of which they rise to between 5000 and 6000 feet in the Alpine region of Coorg, and at their termination they probably are not much lower. The width of the Western Ghauts is inconsiderable, and perhaps nowhere except towards its southern extremity exceeds 12 miles, if the low spurs, which advance from them eastward into the plain to the distance of 30 miles and more, are not taken into account. South of the Hosso Angady the mountains extend near 40 miles east and west, and fill up the country between the upper branches of the Cavery river.

The rapidity with which the Western Ghauts descend to the sea renders it very difficult to ascend the table-land of the Deccan on this side. The mountain-passes or ghauts are not numerous, and most of them are not passable for beasts of burden. These most used are, from north to south, the following:—1. The Bor Ghaut, which begins at Panwelly, opposite Bombay, and leads between steep rocks over Khandoola to the excavated temples of Carli, which are on the table-land; 2. The Colpar Ghaut, which leads from Fort Victoria (17° 56′ N. lat.) along the river Bancut to the town of Mharr, and hence through the pass northward to Poonah and southward to Satarah; 3. The Ghaut of Balgaum, which leads from Goa to Darwar, and rises to 2477 feet; 4. The Kutaki Ghaut, which begins on the coast at Sadashevagur (south of 15° N. lat.), and leads through the mountains to Yellapoor on the table-land; 5. The Hosso Angady Ghaut (13° 42′ N. lat.), one of the most frequented passes of the Ghauts, keeps up the commercial communication between Bednore and Mangalore; but we have no particular account of it; 6. The Kordadibol Ghaut (13° 8′) leads from Mangalore and Jamallabad, near the high mountain of Balaroyn Droog (5000 feet above the sea), to Wustara; 7. The Bessely Ghaut (12° 40′) connects Mangalore with Uscottah on the table-land, traversing Bessely, situate at the foot of the northern declivity of Mount Subramani (5611 feet above the sea); 8. The Yallanir Ghaut runs along the southern declivity of Mount Subramani, between Mariara, the capital of the raja of Coorg, and Mangalore; 9. The Manantoddy Ghaut (11° 45′), through which the road passes, which leads from Tellicherry on the coast to the table-land on the banks of the river Cubany, and hence to Seringapatam. The highest point on this road rises to 3000 feet, and seems to be hardly more than 100 feet higher than the table-land to which it leads.

These mountains, which are merely the broken and abrupt declivity by which the table-land of the Deccan descends towards the Indian Ocean, are entirely covered with thick forests of tall trees, except in a few places where the rocky masses are too steep to permit any accumulation of earth. In all other parts the mountains are covered with a thick layer of earth, capable of maintaining a vigorous vegetation. Many of the trees are very valuable. On the upper parts are forests of bamboo, which grow to the height of trees. Lower down the sandal-wood tree is abundant, and supplies an important article of exportation to China, Japan, &c. The middle of the range is occupied by forests of teak. During the rainy season, when the numerous torrents descending from the mountains acquire a great volume of water, the teak timber is floated down to the several harbours on the coast, especially to Mangalore, and thence to the other ports of Hindustan. On these mountains alone in Hindustan sandal-wood grows (Buchanan), and it occurs only between 12° and 14° N. lat. Cassia and cardamoms are also collected in these forests, but the latter not north of Goa.

The whole of the narrow coast which intervenes between the Western Ghauts and the Indian Sea is sometimes comprehended under the name of Malabar. But properly the northern part of it, as far south as 15° N. lat., is called the Concan; the middle part, between 15. N. lat. and 12° 3°, Canara; and only the southern part, as far as Cape Comorin, is named Malabar. The surface of this narrow tract is never entirely level, except along the sea-shore and to a distance at the utmost of five miles from it. But the low hills which are offsets from the Ghauts frequently approach nearer the sea. The level tract along the sea-shore is covered with sand, and overgrown with cocoa-palms; near the termination of the hills the soil is better, and planted with rice. The sandy coast is indented with numerous small inlets, which during the rainy season are the receptacles of torrents, most of which, as they flow only for a few months, have received no name. The small valleys which lie farther inland between the low ranges of hills are converted into swamps by the abundant rains, but when the water has run off they are cultivated, and give very rich crops of rice. On the sides of the hills which separate these valleys from one another are situated numerous villages, enclosed by extensive plantations of fruit-trees. The top of these ranges of hills is level, but dry and naked.

This coast experiences the full effects of the south-western monsoon, more especially in the southern part. It begins there at the end of May or the beginning of June, but commences somewhat later farther north, and sets in with tremendous thunder-storms. The rain pours down continually for several days in torrents, after which it decreases, and is occasionally interrupted by fine weather for about a month. In July it increases again, and then attains its maximum. It begins to decrease in August, but slowly, more rapidly so in September, and in October the rain and the monsoons depart with thunder-storms. The annual quantity of rain in Malabar amounts to 116 inches, of which 36 inches fall in July; at Bombay it does not exceed 64 inches; and farther north the quantity is still smaller. The mean annual temperature at Bombay is about 80°, but observations on that of Malabar are wanting. The climate of this coast is considered very healthy, notwithstanding the immense quantity of rain and the cultivation of rice.

No kind of grain is cultivated except rice, for the growth of which no artificial irrigation is required, as the soil is saturated by the abundant rains. This country contains a great variety of fruit-trees, especially different kinds of palms; the cocoa-palms cover an immense tract of land along the sea. The sugar-cane is also extensively cultivated. Cattle and buffaloes are the only domestic animals, and both are distinguished by their size. Fowls, geese, ducks, and turkeys are only raised by the Portuguese families which are settled along the coast. Wild elephants are numerous; and also tigers, leopards, hyænas, and jackals.

The whole of this maritime tract, as far south as 10°, is now in possession of the East India Company, with the exception of that portion which lies between 15° and 16°, which is nearly equally divided between the Portuguese and the raja of Sawunt Warree, and the towns of Mahé and Damaun, of which the first belongs to tho French, and the second to the Portuguese. The English possessions north of 16° N. lat. are annexed to the presidency of Bombay, and those south of 15° to that of Madras. Damaun, the Portuguese settlement (20° 22′ N. lat.), which was formerly more important, has lost much of its commerce since the rise of Bombay. It lies nearly halfway between Surat and Bombay, and has a safe harbour for vessels of small size, there being 17 feet water over the bar. Vessels of teak-timber are built here. Farther south (18° 56′) is Bombay [BOMBAY]; on the neighbouring islands of Salsette and Elephanta temples are excavated in the rocks. [ELEPHANTA.] Near Fort Victoria (18° N. lat.) is the town of Bancote, or Bancoot, with 14,000 inhabitants. It has a harbour for small vessels, and carries on a considerable commerce with Punah and Satara. Goa, the Portuguese settlement, is situate about 15° 30′, and consists properly of two towns. [GOA.] Mangalore (12° 50′), which is built on the banks of a salt lake, into which several rivers discharge their water, was destroyed by Tippoo in 1784, but has risen again since it came into the hands of the English. Ships drawing less than 10 feet water can enter the harbour at high tides. The town is thriving, and derives its importance from being situated not far from the Hosso Angady Ghaut and other mountain-passes, by which it carries on a considerable commerce with the table-land of the Deccan. Much teak is floated down from the mountains to tho town. It now contains more than 40,000 inhabitants. [CANARA.] Cananore (11° 52′) is built at tho bottom of a small lake, which is one of the best harbours on this coast. It has some commerce with Arabia and the harbours of Hindustan, and contains about 10,000 inhabitants. Tellicherry (11° 44′), which was long the chief settlement of the English on the coast of Malabar, but is much neglected at present, has about 5000 inhabitants; it has still a considerable commerce in the produce of the country, coir, sandal-wood, cardamoms, pepper, cassia, and cocoa-nuts; shark-fins and salangana-nests are also sent to China. Mahé (11° 42′), the only French settlement on this coast, has a harbour for small vessels, and 6000 inhabitants. It is rather well built, and principally exports pepper. Farther south is the town of Calicut. [CALICUT.]

We pass to the Southern Ghauts, a term not yet in use, but one which ought to be adopted to designate those mountain-ranges which support the table-land of the Deccan on the south, and have only been discovered within the last twenty years. They cover by far the greatest part of the space contained between 11° and 12° N. lat., and 76° and 79° E. long. The western portion of the Southern Ghauts is occupied by the Nilgherry Mountains, which are well known to Europeans resident in India as affording them the climate and productions of Europe at a distance of only 11 degrees from the equator. These mountains are connected with the southern extremity of the Western Ghauts extending between 76° 26′ and 77° 20′ E. long. and between 11° 10′ and 11° 35′ N. lat., so that their length from west to east is more than 60 miles, and their width about half as much. All this space is occupied by one mass of high land, unbroken by ravines or deep valleys. Its surface is not level, but a continual succession of ascents and descents, separated from one another by tracts of level ground. The lowest parts of these level tracts are estimated to have an elevation of from 5000 to 6000 feet. The hills by which they are overtopped are generally not high, but through the centre of this region there runs a more elevated ridge, containing various summits, the highest of which, nearly in the middle of the whole mountain-mass, the Dodabetta Peak, is 8429 feet above the level of the sea. The surface of this region is a fertile soil overgrown with a green sward of grass and several kinds of alpine herbs where it is not cultivated. Only one-thirtieth part of it is under cultivation. The excellent climate on these heights has led to the establishment of several sanatory stations, in which Europeans may re-establish their health, when impaired by a long residence in the hot countries. One of these European settlements is at Utakamund, 7000 feet above the sea, at the foot of the Dodabetta Peak; the other is at Dimhutty, 5785 feet above the sea. The mean annual temperature at Utakamund is 56°, and consequently 28° less than at Madras; that of Dimhutty 64°. At the former place the thermometer sometimes rises to 69°, and has been observed to descend as low as 20°, but only once in 12 years. The changes in the temperature are very slow, and the difference in 24 hours hardly exceeds two degrees. The effect of both monsoons is slightly felt; moderate rains occur all the year round, but more during the south-west than during the north-east monsoon. Frost occurs between September and April, but it is moderate; the thickest ice does not exceed 1½ inch in thickness. Agriculture is limited to wheat, barley, millet, peas, and pulse, to which of late years European vegetables have been added. The fruit-trees of England succeed everywhere, and are frequently seen covered with blossoms and fruits in all stages at the same time. Oranges grow only in the lower districts. No animals are kept, except cattle and buffaloes; sheep, goats, and dogs are found in a wild state. Some very large species of deer are common. Game abounds everywhere. To the south this hilly table-land descends with a steep slope to the Gap of Ponany and the plain of Coimbatore, from which it is divided by the river Bhovany. The deep valley through which the small river Moyar runs along its northern side separates it from the table-land of Mysore. The slopes on all sides are wooded, and it is only here that the animals of the tropical regions, as tigers, leopards, and elephants, are found.

North-east of the Nilgherry Mountains are the central Southern Ghauts, which occupy nearly the whole space between the Cavery and the Bhovany river, an affluent of the former, as far west as 77° E. long. Very little is known of these mountains, which occupy more than twice the space of the Nilgherry Mountains, though a mountain-road leads through the northern part of them, connecting the fortress of Satteagala with the small town of Caverypooram. We only know that this road passes over several high and steep ridges. The mountains in this region rise to a considerable elevation; Kumbetarine Peak, which is a short distance north of the town of Sattimungalum, attains the height of 5548 feet above the sea. To the east of the Cavery river the Southern Ghauts extend eastwards, and their southern declivity approaches the towns of Salem and Atoor; they terminate near the last-mentioned place. It is only their southern border that is known to any extent. On the banks of the Cavery, west of Salem, stands tho Paulamally Peak, which is 4955 feet high. North of Salem are the Sherwaray Mountains, whose highest summit, Mount Mutu (4935 feet) forms a table-land seven miles long and three wide, where Europeans whose health has been impaired seek the recovery of their strength.

The Southern Ghauts are broken through by the river Cavery, which for about one-fourth of its course drains the table-land of the Deccan, for nearly the same space winds between the high mountains of the Ghauts, and for the remainder runs through a level plain. It enters the mountains a little above the fortress of Satteagala, which is built on a rock a little above the cataracts of Sivanasamudra [CAVERY], and in this tract its course is extremely winding between high rocks, which approach so near its banks as not to leave space enough for a road: this part of the river has not been visited by any European. At Caverypooram the river issues from between the mountains, and enters a valley extending to the west of south. Where it receives the Bhovany river it has already entered the plain, and is a large river in the rainy season. For about one-half of its course in the plains it runs in one channel, but below the town of Trichinopoly it divides, and encloses the island of Seringham, famous for its two pagodas and as a place of pilgrimage. Below this island the river again unites for a short distance, and then divides again. The northern arm, called Coleroon, runs in an east-north-east direction, and falls into the Bay of Bengal between Deviacotta and Chillumbrun; but its waters have been so exhausted by irrigating the adjacent fields, that it carries only a small quantity to the sea. The water of the southern arm is employed in feeding a great number of canals which traverse the sandy alluvial plain extending on the coast between Cape Calymere and Deviacotta. The waters of these canals being conducted over the adjacent fields, convert them into one of the most fertile tracts in Hindustan, their crops of rice being only inferior to those of the district of Burdwan in Bengal. The principal of these canals terminate on the shore at Calymere, Negapatam, Nagore, Carrical, and Tranquebar. This extensive country is dotted with villages, each of which has a well-built pagoda, with architectural ornaments in a good style. The towns also are numerous, and each of them has a well-stocked bazaar. The Cavery river receives its principal supply of water from the south-west monsoon and the rain which during its continuance falls on the Western Ghauts. At Caverypooram it begins to rise at the end of May, and attains its greatest height from 13th of July to 13th of August; before the rains of the north-east monsoon set in, its waters begin to decrease, and after the 11th of January they are so low as to be fordable.

The delta of the Cavery and the level country along its lower course in the plain lie in the parallel of the Gap of Ponany, which may be considered as a prolongation of the plain to the Indian Ocean. That part of this plain which extends between the Gap and the delta, or between Trichinopoly and Coimbatore, contains many fertile tracts, some of which are cultivated; but the greatest portion is covered with forests, which however do not exhibit such a vigorous egetation as those in the Gap itself.

The countries extending along the Southern Ghauts and the lower course of the Cavery constitute a portion of the Carnatic, the principal division of the presidency of Madras. The most remarkable places in it are: Coimbatore [COIMBATORE], which is beginning to be a place of importance; Salem, a well-built thriving place, with some manufactures and a good deal of commerce, but unhealthy. Trichinopoly is a fortress built on a rock. Tanjore is a place of great strength. [TANJORE.] Negapatam, formerly a Portuguese and afterwards a Dutch settlement of importance, has lost its trade since it was united to the British dominions (1783). Carrical, a French settlement, built at one of the outlets of the Cavery, which is navigable for small river-boats, has a harbour, considerable commerce, and 15,000 inhabitants. Tranquebar, a Danish settlement, with a harbour, some commerce, and 20,000 inhabitants, is one of the principal stations of the Protestant missionaries in Hindustan. Chillambrum, or Chillumbrum, has an extensive and beautiful pagoda, one of the most antient in India.

The Eastern Ghauts, which separate the table-land of the Deccan from the low and level country extending along the Bay of Bengal, between 12° and 18° N. lat., occupy in width a much larger space than the other Ghauts. South of 13° 10′ N. lat., where their longitudinal direction is south-south-west and north-north-east, their average breadth is not less than fifty miles. Between 13° 30′ and 16° N. lat., where they are called Nella Malla Mountains, and, lying in a general northern direction, occupy the whole space between 78° and 79° E. long., they are probably nearly 80 miles across; between 16° and 18° N. lat. they run south-west and north-east, and here their breadth is probably somewhat less. These mountains consist of a number of mountain-ridges running parallel to one another in their general direction, and this peculiar feature is still more distinctly marked in the Nella Malla Mountains than in the southern portion of the Eastern Ghauts. The longitudinal valleys which separate the single ridges appear to be rather narrow. Their elevation has not been ascertained. It is stated that the most western range of the southern portion, which borders on the table-land about Bangalore, is about 500 or 700 feet above the plain, and may therefore attain an elevation of between 3500 and 4000 feet above the sea. In the Nella Malla Mountains the eastern range is said to be the most elevated; but its highest summits do not seem to exceed 3000 feet. The surface of the whole region is very stony, dry, and exceedingly broken, and presents very few spots fit for agricultural purposes. It is also nearly destitute of trees, with the exception of a few tracts covered with wild date-trees. In many places it is covered with bushes, and affords indifferent pasture-walks; but in general it is almost entirely without vegetation.

Three rivers, originating on the table-land, pass through this mountain-region in transverse valleys, so narrow, that they are, properly speaking, mere clefts. The most southern is the Pann-air, which runs about 250 miles. It enters the mountains between the fortresses of Raicotta and Kistnaghurry, and issues from them near Vaipoore. Its intermediate course is not known. The Pal-air, which flows about 220 miles, enters the mountains to the south-east of Colar, and from this point its course is not known to Antoor, from which place it traverses a fine and well-cultivated valley, passing near Vellore to Arcot. The most northern of these rivers is the Penn-air, whose course extends to 280 miles. It enters the mountains between Ooderpee Droog and Gooty Droog; but at Gandicotta its valley becomes exceedingly narrow, and admits no road along its banks. It enters the low land some distance below Sidhout. Though its course is long, it brings down a comparatively small volume of water, and is of little use for irrigating the low-lands; whilst the Pann-air and Pal-air fertilize the whole country which they traverse.

The mountain-passes through this region are as difficult as those over the Western Ghauts. As the rivers which traverse it flow through very narrow valleys, the roads have been conducted over the mountains. These roads are very little visited, and are nearly unknown, except the great military road which leads from Madras to the table-land. It runs over the plain to Arcot, on the Pal-air, and thence to Vellore, whence it begins to ascend the mountains, and runs to Santghur (1120 feet above the sea). Here it divides into two branches: the northern traverses Vencatagherry (2180 feet) and Pednadurgam (1907 feet), and terminates at Colar, on the table-land: the southern branch leads from Santghur to Kistnagherry, and thence over the Pann-air to Raicotta, whence it passes to Oossoor and Bangalore. The two last-mentioned places are on the table-land. The Malla Nella Mountains are rich in metals; iron is very abundant, and copper and lead are worked in several places. Diamonds are found, especially to the north of the river Penn-air; and most frequently near Cuddapah and at Banganpally, in the neighbourhood of Nandial.

The country which separates the Eastern Ghauts from the Bay of Bengal, and comprehends the central and northern Carnatic, with the Guntoor Circar, has a low sandy beach, from which the surface rises gradually, but slowly, to the foot of the mountains. Arcot, which is nearly 60 miles from the sea, is 490 feet above it. The surface of the whole is nearly level, but towards the mountains somewhat undulating. Near the coast the soil is a mixture of sea-sand and loam, with some remains of marine animals. In some parts it is covered with an efflorescence of common salt in dry weather. Towards the mountains, where the low hills commence, it consists chiefly of a mixture of loam and sand, with a considerable proportion of vegetable mould. This latter kind of soil is very fertile when irrigated, which is partly done by canals from the rivers, and partly by numerous tanks; but the upper part of the hills is dry and sterile. Along the sea-coast the country is less fertile, but produces good crops of rice when the rainy season has been abundant, or where it can be irrigated from tanks. Millet, maize, cotton, and indigo are also raised, with a few leguminous plants. Sugar is cultivated in small quantities. The southern portion, as far north as the lake of Pulicat, is much more fertile than the country which extends between the lake and the river Goondlagama; but the Guntoor Circar, which comprehends the tract between the Goondlagama and the Kistna rivers, is fertile, though perhaps less so than the country south of the lake of Pulicat. This lake appears to owe its existence to the sea breaking through a low sandy beach, and overflowing the land within. It extends 33 miles from north to south, and is 11 miles across in the broadest part. It contains several large islands. It communicates with the sea at three points, but the outlets are extremely narrow and shallow.

The rainy season is later here than on the western coast of the Deccan. When the south-west monsoon (June to August) is in full force, only moderate showers refresh the air and soil. They become more abundant at the end of the south-west monsoon in September, increase greatly in October, and are heaviest in November, when they descend in torrents, sometimes for several days together. The north-east monsoon sets in regularly at the same time. In December the rains decrease, and with the end of the year they cease entirely. During the dry season (from January to June), a few showers only occur. The annual quantity of rain at Madras is about 48 inches. The climate of the Carnatic is very hot. Its mean annual heat is stated to be between 82° and 84° Fahr. On the coast the heat is somewhat mitigated by the sea-breeze, which sets in between ten and eleven o'clock; but at a distance of from 10 to 12 miles inland this breeze has lost its cooling property by passing over a heated surface of sand. Sometimes the sea-breeze fails altogether, and then the thermometer rises to 130° in the shade.

The Carnatic, or the low country extending from Cape Comorin to the river Goondlagama, constitutes the main body of the presidency of Madras. Though exposed to a heavy surf from the sea, which renders landing very difficult and dangerous, and though destitute of harbours, it has been for a long time the favourite country for European settlements. The whole country is now under the dominion of the English, the Danes having preserved only their settlement at Tranquebar, and the French the towns of Carricall and Pondicherry. The towns of Madras, Arcot, Conjeveram, and Cuddalore are noticed under their respective articles. Near the small town of Sadras, 47 miles south of Madras, are the ruins of an extensive town, cut in the rock, called Mahâmalaipuram, or the Seven Pagodas.

The river Kistna or Krishna originates on the eastern declivity of the Western Ghauts. All the waters collected on the eastern side of that range, between 13° and 19° N. lat., unite successively in its channel. The source of the river, which is called Kistna, is near 18° N. lat., between Poonah and Satara, hardly more than 30 miles from Fort Victoria on the coast of Concan. The river runs for more than 100 miles south-south-east, receiving numerous small streams from the west, among which the Warna, which separates the territories of the rajas of Satara and Colapore, is the most considerable. Afterwards it flows south-east, and its waters are increased by the two rivers Gatpurba and Malpurba. The remainder of its course on the table-land is nearly east, with some great bends towards the north and south. Here it receives from the north the Beema, whose farthest branches rise north of 19° N. lat., and whose winding course through the table-land probably exceeds 300 miles. Where the Kistna approaches the Nella Malle mountains, it is joined from the south by the Toongabudra, whose upper branches, the Toonga and the Budra, originate near 13° N. lat. After entering the mountain-region it forms some considerable cataracts near Timoracotta, and rushes between Warapilly and Kondapilly through a narrow chasm in the mountains. Below Kondapilly it flows south-south-east through a low plain, in which it divides into several arms, embracing a small delta. Its whole course is about 650 miles. On the table-land, as well as in the low plain, the surface of the water is from 20 to 30 feet below the adjacent land, and consequently it cannot be used to irrigate the fields. This river brings down a comparatively small volume of water, and is not navigable in any part.

The mountain-region between the Kistna and Godavery, which separates the table-land of the Deccan from the low tract along the coast, and which may be considered as a continuation of the Nella Malle mountains, occupies nearly 60 miles from west to east. On the Kistna it begins in the neighbourhood of Timeracotta, and extends to Kondapilly; on the Godavery, its western border is at Mahadeopoor, near 80° E. long., whence it extends eastward to the east of Polenshaw (near 81°). We are almost entirely unacquainted with the character of this region. It seems however that the mountains are of inconsiderable height towards the Godavery, whose course is not interrupted by rapids and cataracts, like that of the Kistna. In these mountains, and near the banks of the Kistna, in the neighbourhood of the town of Kondapilly, are the diamond-mines of Mallavilly. They belong to the Nizam of Golconda, though they are situated within the British territory.

The low country between the lower course of the rivers Kistna and Godavery comprehends the Circar districts of Kondapilly and Ellore; and Rennell properly compares it with the delta of the Nile, though it is somewhat smaller. A considerable portion of it is annually inundated by the lake of Colair, which is a freshwater lake, situated in a deep depression, nearly in the centre of the low tract. It is about 24 miles long, and half as wide in the broadest part, and is connected with the Godavery and Kistna by channels which in the dry season contain no water, but from July to September convey a portion of the water of these rivers to the lake, which is then filled, and inundates the adjacent country, when it becomes from 40 to 50 miles long. During the dry season the water is conveyed by means of canals to a considerable distance from the lake. The lake covers 200 square miles, and contains fifteen islands, which, as well as the neighbouring country, are fertilized by the deposit of mud brought down by the rivers. The superfluous water is carried off by the river Oopatair, in which the tides ascend to the lake, but are prevented from entering it by embankments. This river is navigable for small vessels, and of great use for the export of produce. The soil of the whole tract is the black cotton ground, mixed with a rich vegetable mould. Besides rice, a great quantity of javary (*Holcus sorghum*) is raised. This tract, like the other Circars, is annexed to the presidency of Madras, and contains the large commercial town of Masulipatam.

The Godavery, the largest river of the Deccan, rises in the most north-western corner of the table-land, north of 20° N. lat., between the town of Nassuck and the fortress of Chandore, about 60 miles from the Indian Ocean. It flows about 150 miles east-south-east without receiving any great tributary; it then winds through the plain in a general eastern direction for 250 miles more, and in this space it is joined by the Manjera river from the south, and by the Poorna and Whurdha from the north. The Whurdha is a considerable river, which, together with its tributaries, drains a great extent of country extending along the southern declivity of the Northern Ghauts and the elevated table-land of Omercuntuc, between 76° and 80° E. long. Its principal affluents are the Pain Ganga from the west and the Bain or Wyne Ganga from the north. The last-named affluent receives the Nag Nadi, a small river, on which the town of Nagpoor, the capital of Berar, is built. After the junction with the Bain Ganga, the Whurdha is called by the natives Pranhceta, but the Europeans give it the name of Whurdha up to its junction with the Godavery. After this junction the Godavery is a mile wide, but at the end of the dry season it has only 15 inches of water. Soon afterwards it enters the mountain-region by the strait of Muticotta, near Mahadeopoor, and issues from it below Polenshaw. In the low country it is 4 miles wide, and has a great volume of water, but soon divides into two branches, which include a small delta. Where it approaches the sea it divides into many more branches, in which the tide ascends to some distance, and which admit vessels of considerable burden. On the most northern of these arms is the harbour of Coringa, the only smooth water on the coast between Cape Comorin and the Hoogly during the south-west monsoon. This is owing to Godavery Point, which projects to the northward and breaks the swell. A bar of mud lies across the entrance, through which ships must be forced. Coringa is a place of considerable traffic. The course of the river Godavery exceeds 700 miles, and as it presents no obstacles to navigation, it is thought that a water-communication might be established between Coringa and Nagpoor by means of the Godavery, Whurdha, Bain Ganga, and Nag Nadi, at least for some months in the year.

The north-eastern portion of the Deccan, extending along the Bay of Bengal, between the mouth of the Godavery and the Bay of Balasore, and from that coast westward into the interior, presents features very different from those of the remainder of the peninsula. Along the banks of the Godavery, from the neighbourhood of the town of Rajamundry as far inland as the junction of the Whurdha with the Godavery, high lands come close to the bed of the river, and only in a few places recede to the distance of some miles. When seen from the river they appear like a continuous mountain-range, with an elevation which probably nowhere exceeds 2000 feet. Along the western border of this region another tract of high land skirts the course of the Bain Ganga on the east, passing near the town of Wyragut, which remains on the west of it. This chain is very little known as to its elevation and width; but it seems to continue northward until it joins the table-land of Omercuntue, between 80° and 81° E. long. It must be considered as the natural boundary of the table-land of the Deccan in this part, which table-land to the west of it is not more than 1000 feet above the sea. Another range of high land runs along the Bay of Bengal, between 20 and 60 miles from the shore, beginning near Rajamundry on the Godavery, and terminating at the lake of Chilka, near 20° N. lat. It rises from 600 to 1200 feet above the sea. The whole tract of country included by these high lands, and extending as far north as 20° N. lat., must be considered as unexplored ground, having never been visited by Europeans, partly on account of the difficulties which the steep mountains oppose to such an attempt, and partly because the whole of it is inhabited by a race of barbarians, who are not inclined to permit the visits of foreigners. This people are called Gonds or Goands, and this extensive tract of country is called from them Gondwarra or Gandwana. It is only known that the whole surface of Gondwarra is covered with mountains and very thickly wooded, which latter circumstance distinguishes this tract from the Eastern Ghauts. The British government and the raja of Berar are considered as sovereigns of this country in nearly equal parts, but the authority of both is only nominal. The low tract however along the sea-coast which skirts the Gondwarra on the east belongs to the British, and is annexed to the presidency of Madras. It comprehends the Circars of Rajahmundry, Vizapatam, Cicacole, and Ganjam. [CIRCARS.]

The mountainous country of Gondwarra extends between 82° and 83° 40′ E. long., farther northward, even to 21° 40′ N. lat., but here it does not fill up the whole space between the Circars and the basin of the Godavery; for between this projection of the mountains and the ridge along the Bain Ganga lies a level country, whose width we are not acquainted with, but which in length from south to north extends from the neighbourhood of Konkeir (near 20° 10′ N. lat.) to Ruttenpoor (22° 20′) about 150 miles. This plain of Ruttenpoor is a fertile tract with fine rivers, tanks, fields, and villages, and produces wheat and other grain in abundance, but rice only in such places as can be irrigated by artificial means. It forms the eastern portion of the territories of the raja of Berar, but is rarely visited by Europeans.

The Mahanuddy, whose upper branches drain this plain, receives its principal supply of water from the unknown mountain-region of Gondwarra, and partly also from the range which skirts the Bain Ganga. It afterwards encircles the mountain-region which projects northward from Gondwarra, and in this part its course is in a wide valley. At Sumbhulpoor, where it is a mile across, it turns southward, but from the junction with the Kobrugur river at Sohnpoor to the sea its course lies to the east. At Cuttack, where it is 2 miles across, it enters a level plain, which is fertilized by its waters. Below Cuttack it divides into three branches, one of which, called the Cajori, runs directly southwards, and passes near the temple of Juggurnaut. The main body of the river, called Chittertola, continues eastward to the sea; and the northern arm, named Betoopa, runs north-east until it joins the Braminy river, and then runs eastward to the sea, into which it falls near Cape Palmyras. The whole course of the Mahanuddy is estimated at 500 miles: it is certainly the most important river of the Deccan, being navigable for vessels of 300 or 400 *maunds* (a maund is 82 pounds) burden as far as Sumbhulpoor, and for smaller river-boats to the mouth of its tributary the Hoostu, a distance of 380 miles. But during the dry season, from January to June, its waters decrease very much. The extent of country which is fertilized by its waters is only inferior to that drained by the Cavery.

The delta of the Mahanuddy extends along the sea from the lake of Chilka (19° 40′ N. lat) to the town of Balasore (21° 30′ N. lat.). The lake of Chilka, which forms the boundary between the Circars and the province of Cuttack, receives its waters partly by one or two channels which branch off from the Cajori, or southern arm of the Mahanuddy. The lake is about 35 miles long and 8 miles wide on an average. It is divided from the Bay of Bengal by a low and sandy tract, which is less than half a mile across. Its mean depth is only from 4 to 6 feet. Its banks are sandy and low, but a range of hills approaches its north-west corner. The islands of this lake are composed of large but rounded pieces of porphyritic granite. A great quantity of salt is prepared from the water of the lake by evaporation. The channel by which its waters are discharged into the sea has been filled up in modern times, and a new channel has been made north of Manickpatam, or Manickaputtun. The lake abounds in fish.

The delta of the Mahanuddy rather resembles that of the Ganges than that of the Cavery, being occupied along the shore by a swampy woody tract. But it is not covered with high forest-trees, like the Sunderbunds of Bengal; its swampy surface is only overgrown by jungle and low bushes, among which few trees rise to a great height. This tract, which extends from 5 to 20 miles inland, is more the habitation of tigers, leopards, wild buffaloes, and crocodiles, than of men. Great quantities of salt, of the finest quality, are made here. The most southern part of the coast, between the Chilka Lake and the Black Pagoda, has a dry sandy soil, and is destitute of trees. Contiguous to this woody tract, but farther inland, lies the fertile portion of the delta, called Mogulbundi, which is generally only from 10 to 15 miles across, but in some places 30 or 40 miles. Though its soil is not of the first quality, it produces, when irrigated, abundant crops of rice, sugar, and tobacco; in the less fertile tract millet is raised. It produces wild dates and mangoes. For particulars as to its climate and towns see CUTTACK. It forms, with the adjacent mountainous country, the province of Orissa, which is annexed to the presidency of Calcutta.

The middle course of the Mahanuddy lies through a valley, which is generally wide and covered with alluvium, and of great fertility, producing rice, wheat, and sugar in abundance, and of the first quality. At Sumbhulpoor this level tract is only 410 feet above the sea. But north-west of the delta of the Mahanuddy, and north of its valley, there spreads out an extensive mountain-region, whose southern declivity forms part of the Deccan, while the northern belongs to the mountain-region of Northern Hindustan. The highest portion of this mountain-tract lies in the line of the table-land of Omercuntue (between 22° and 23° N. lat.), and may be considered as its eastern continuation; whilst the Vindhya Mountains branch off from it on the west in the same direction from east to west. This mountain-tract, north of the valley of the Mahanuddy, seems to be a kind of mountainous table-land, whose mean elevation, according to estimation, is from 3000 to 4000 feet above the sea; while the ridges by which it is traversed, and which here run east and west, rise about 2000 feet higher. It is only at its most eastern extremity that a single range projects from it towards the Bay of Bengal, where it terminates west-south-west of Balasore, under the name of Nelligreen or Nila Ghira (Nilgherry Mountains). The whole region however does not rise abruptly from the plains which lie east and south of it, but gradually; the first ascent varies between 300 and 1200 feet; farther towards the interior it rises higher. Though the ridges which traverse it are numerous, a great portion of the region is occupied by level plains of considerable extent, which are partly covered with high grass and partly cultivated, especially along the foot of the ridges, where the soil is more fertile. As many of these level tracts have no slope, or only a very gentle one, the great quantity of water poured down during the rainy season cannot be carried off, and thus extensive swamps and lagunes, or *djils*, are formed, which however dry up at the end of the dry season. These temporary lakes are used by the inhabitants for irrigation. The climate is not so hot as on the low coast. The thermometer varies in the rainy season between 72° and 80°, in the cold season between 32° and 66°, and in the hot season between 75° and 98°. In the higher places, as in Sirgoojah, it falls in January even to 28° Fahr. The rainy season lasts from June to October, with prevailing north-eastern winds: the quantity of rain which descends in these months must be considerable, as the rivers, which are mere swamps or are entirely without water in the dry season, have then from 15 to 20 feet water. The dry season is divided into the cold and hot, the former comprehending the months between October and April, and the latter those between April and June. At the end of the rainy season the jungle-fever is very prevalent. The productions which are cultivated are chiefly rice and javary, but the greatest wealth of this region consists in its forests, which cover the ridges and valleys, and contain thirteen different kinds of trees useful as timber or for cabinet-work. A considerable portion of the population is employed in preparing these trees for the market, and in floating them down to Cuttack. These forests are inhabited by numerous wild animals, among which are wild buffaloes. Iron-ore is very abundant in this region, and diamonds are found in the tract which separates the valley of the Mahanuddy at Sumbhulpoor from the sources of the Braminy river. This country is a part of the province of Orissa, and annexed to the presidency of Calcutta.

The table-land of the Deccan is separated from the mountain-region of Northern Hindustan by the valleys of the parallel rivers Tapty and Nerbudda. The Tapty rises in the mountain-tract which joins the table-land of Omercuntuc on the south-west, with two branches, the Tapty and the Poorna; the former running west-south-west, and the second due west, till they unite, after a course of about 150 miles, near 76° E. long. The high mountain-range which separates these two rivers, and rises to 4000 feet, is called the Mahadeo Phar; it terminates on the west at their junction, and extends eastward to the sources of the Tapty and Whurdha, a distance of nearly 150 miles. Its average width may be 20 miles. Both declivities of this range are extremely steep, but partly covered with forests. After the junction of the upper branches the Tapty flows in a wide valley between the Sautpoora Mountains, on the north, and the Northern Ghauts on the south, for about 280 miles, until it enters the Indian Ocean by a wide æstuary below the town of Surat. The valley contains a broad tract of level ground along the banks of the river, which is well cultivated in the upper parts, but almost entirely covered with bushes and jungle along its middle course. In its lower course it flows 30 or 40 feet below the adjacent plain, which is covered with a deep black mould of great fertility, but traversed in a very remarkable manner by chasms 30 or 40 feet deep, and frequently several miles long. This plain is in a high state of cultivation. In the upper valley of the Tapty is the town of Burhampoor, situated on a fertile plain; it is of considerable size, though less extensive than formerly, and carries on an active commerce with the countries both to the north and south of it. Not far from the mouth of the river is the great emporium of Surat.

The Nerbudda rises on the table-land of Omorcuntuc, but its sources have not been seen by Europeans, though the temple of Omercuntuc, which is built close to them, is visited by crowds of Hindu pilgrims. It is said to wind slowly over the mountain-plain in a westerly direction until it is precipitated from its steep western declivity not far from the town of Mundlah. Thence it runs in a narrow valley and between masses of rocks with a rapid course past Jubbulpoor, below which town it forms a cataract at Bedaghur. Farther west the valley grows wide, the mountains to the south rise with a gentle declivity, and the river has a less rapid course. Thus it arrives at Hussingabad, or Hoshungabad, where it is 900 yards wide and from five to six feet deep, so as to become navigable for small vessels. It continues to be navigable as far west as ten miles below Chiculdah, near the town of Burwanee (west of 75° E. long.), a distance of between 130 and 140 miles, though there are two rapids in it, the first at Deyri, between Hindia and the island of Mundatta Unka, or Unkar Mandatta, on which there is a famous temple and place of pilgrimage; and the second at Sansadarah, below the town of Mheysir. About ten miles below Chiculdah is the Hurn Pahl (deer's leap), where the river, which at Mundleysir is 1200 yards wide, is narrowed to 200 yards, and basalt-rocks rising from 10 to 12 feet above its usual surface lie across its bed. The water of the river rushes with great violence through three openings. Farther downwards the river is still more narrowed by the rocks, which advance from the mountains on both sides to the water's edge; and thus the river becomes entirely unfit for navigation for a great distance. But about 10 miles above Tulluckwarra it enters the low lands of Gujerat, and is navigable from this place to its mouth for river-boats, a distance of about 90 miles, and for vessels of moderate size half that distance. Below the town of Baroach it forms a wide æstuary. The whole course of the river is about 600 miles. Neither the Nerbudda, nor any other of the rivers of the Deccan that empty themselves into the Indian Ocean, forms a delta at its mouth, as is the case with all the larger rivers which fall into the Bay of Bengal.

The valley of the Nerbudda extends mostly along the southern banks of the river, since the Vindhya Mountains, which enclose it on the north, often advance to the banks of the river or very near them. The upper part of the valley from Mundlah to Hoshungabad is comparatively narrow, and mostly filled up by low offsets from the mountains which lie farther south. When a level tract or a gentle declivity occurs, the surface is covered with a black mould of great fertility, but it is little cultivated, and the forests which cover the adjacent mountains frequently descend to the bed of the river. South of Hoshungabad, at the sources of the Tapty, the mountains take the form of a continuous chain, called the Sautpoora Mountains. This chain at its commencement runs nearly south-west, but by degrees turns westward and continues nearly parallel to the Vindhya Mountains, until it approaches that range, at about 76° E. long., but afterwards it resumes its western direction. These mountains are not very high, their mean elevation towards the east not exceeding 3000 feet, and farther westward they are somewhat lower. But both their declivities are steep, and the mountains are nearly inaccessible. They are rich in iron-ore, which is worked in several places; and at their western extremity, in the mountains of Raj Peepla, are mines of carnelians, which have been noted for their produce from antient times. The central portion of the valley of the Nerbudda from Hoshungabad to the Hurn Pahl, where the mountains approach the banks of the river, is called the valley of Nemaur or Nemawur. In length it extends about 130 or 140 miles, and its breadth varies between 24 and 32 miles. Its surface is undulating, and west of Mheysir nearly level; its soil is very fertile and was formerly well cultivated, but great part of it is now overgrown with jungle, the inhabitants having been obliged to abandon it during the continuous wars of the last century. A great portion of it is now used as pasture-ground. That portion of the valley which is situated between the Hurn Pahl and the issuing of the river from the chasm above Tulluckwarra has not been visited, and is unknown. It seems to be filled up by steep rocks. The lower part of the river runs through the plain of Gujerat. The most considerable places in the valley of the Nerbudda are Jubbulpoor, 1458 feet above the sea, whence a road leads over the Vindhya Mountains through Belhari to Pannah in Bundelcund; Hoshungabad, a large town with good buildings, and an important place for the communication between the plain of the Ganges and the western countries of the Deccan; Mundleysir, or Mundlesir, which, though not large, is an important place, because the most frequented pass leads from it northward over the Vindhya Mountains to Oujein; Mheysir, a little farther west, a large place, with good buildings and a well stocked bazar; and Burwanee, which is the most considerable town in Nemaur, and contains many good buildings and a large palace.

The upper portion of the valleys of the Tapty and Nerbudda are subject to the English, and annexed to the province of Allahabad, under the name of the Ceded Districts on the Nerbudda. The western districts on both rivers belong also to the English, with the exception of a tract in the middle, which is subject to the Guicowar. The British possessions in this part are annexed to the presidency of Bombay, forming a portion of the province of Khandeish, or Candeish. The country between Allahabad and the presidency of Bombay is partly subject to Maharaja Scindia, and partly to other Mahratta chiefs, especially to Holkar.

III.—*The Mountain-Region of Northern Hindustan* has nearly the form of a triangle, whose base is formed by the Vindhya Mountains, skirting the vale of the river Nerbudda on the north, and whose apex is at Rewarree, at no great distance from Delhi, on the Jumna, to the south-west. It contains a table-land of considerable extent, that of Malwa, which occupies its southern portion, and is everywhere enclosed by mountain-ranges, and also a mountain-region, called Uppermal, which extends on the north of the table-land. To these two extensive portions are to be added the peninsula of Gujerat and the island of Cutch, which ought to be considered as detached members of this mountain-region.

The Vindhya Mountains begin on the west between 73° and 74° E. long., about 10 or 15 miles from the north banks of the Nerbudda, with the high hill of Powaghur situated between the town of Dubhooee and Champaneer, and extend eastward along the vale of the Nerbudda. The western portion, as far east as Chiculdah on the Nerbudda, has not the appearance of a continuous range, being frequently broken into isolated groups and presenting many steep summits. So far its width is very considerable, its southern offsets approaching to the very banks of the river, and its northern declivity being intimately connected with the extensive mountain-tract which extends between 73° and 75° E. long. in a north-north-west direction on both sides of the river Mhye, and which unites the Vindhya Mountains with the Aravulli range. East of Chiculdah (near 75° E. long.) the range approaches the river Nerbudda and continues along it like a steep wall, with a broad-backed surface and without summits. Its upper line preserves nearly always the same elevation, and only slight changes are observable in it. On an average, it is about 1700 feet above the vale of the Nerbudda, and hardly more than 2200 feet above the level of the sea. As the table-land extending north of it, where it is contiguous to the range, has an elevation of 2000 feet above the sea-level, the mountainous character of the range disappears on that side. But towards the vale of the Nerbudda its declivity is exceedingly steep, and indented by short transverse cuts, which give to many of its single parts the appearance of projecting bastions: on many of them fortresses, or *ghurs*, of great extent were built, but they are rapidly going to decay. Such are the Vindhya Mountains as far east as the road which connects the town of Bhopal on the table-land of Malwa with that of Hoshungabad on the Nerbudda, and it is only to this portion of the range that the name of Vindhya Mountains is applied by the natives. But the range continues east of the road, with a slight inclination northward, is connected with the table-land of Omercuntuc (between 80° and 81°), and occupies farther east the greatest part of the tract between the Ganges and the river Sone, approaching the Ganges within a short distance between the towns of Mirzapoor and Chunarghur; it terminates on the banks of the Sone between Rotasghur and Sasseram. This eastern portion of the Vindhya Mountains is called by the natives the Kimoor range. It rises from both rivers with a steep acclivity, but its upper surface, where not deeply furrowed by water-courses, is rather a hilly plain, intersected with rocky eminences, and mostly covered with wood; cultivation is carried on in a few isolated spots. It may be, in general, 1000 feet or a little more above the sea-level, and about 700 feet above the plain of the Ganges near Patna.

The roads leading over the Vindhya mountains are few. The most frequented seem to be the following. The most western connects Burwanee in the vale of the Nerbudda with Oujein on the table-land of Malwa, passing the river at Chiculdah, and then ascending the mountains by the bed of a small river to Baug, in whose neighbourhood there are temples excavated in rocks; it afterwards traverses the Tanda Ghaut, and terminates on the table-land at Bhowapoor; whence it continues to Oujein or Oodipoor. Farther east is the Jaum Ghaut, which is more frequented than the others: it is in 22° 23′ N. lat. and 75° 49′ E. long., and rises to 2328 feet above the sea-level: it connects the towns of Mheysir and Mundleysir on the Nerbudda with Mow on the table-land, and thence leads to Indore and Oujein. A third road farther east connects the towns of Bhopal on the table-land with Hoshungabad. Where the Vindhya mountains approach the table-land of Omercuntuc, and the highest parts of the country extend in uneven and hilly plains, a road leads from Jubbulpoor in the vale of the Nerbudda, which is 1456 feet above the sea-level, to Belhari (about 2000 feet), and thence to Lohargong (1248) and Pauna. The Kimoor range is traversed by a road which runs from Chunarghur on the Ganges south through Suctasghur and Bilwanya, and terminates on the river Sone, at the small village of Selpy.

Between the Kimoor range and the mountains which divide the province of Orissa in the Deccan from the basin of the Ganges (between 23° and 24° 30′ N. lat.), extends a mountain-tract, comprehending all the countries between the numerous branches of the Upper Sone and the upper course of the rivers Dummooda, an affluent of the Ganges, and the Shubunrecka, which falls into the Bay of Bengal. A line, beginning on the south at Balasore and running north through Bishunpoor and Nagore to the Rajamahal hills divides this mountain-tract from the plain of the Ganges. Along this line of division lie the extensive coal beds which have recently been discovered in Bengal. This mountain-tract is not entirely covered with ridges, but includes numerous plains of considerable extent and elevation, some of which are fertile and well cultivated, especially along the foot of the ridges. The highest parts of the ridges are estimated to attain an elevation of 4000 feet, and some parts of the plain are as high as 2000. They seem to descend in terraces to the plain of the Ganges. The mountains are generally covered with high trees, useful both as timber and for cabinet-work. The northern portion of this region is occupied by a broad-backed range, called the Goomah Ghauts, or Rajamahal Hills, and sometimes, from a nation inhabiting it, the Pooharree Hills. They are divided from the Kimoor range by the narrow valley of the Sone, near Rotasghur, and may therefore be considered as the most eastern offsets of the Vindhya mountains. Between Boglipoor and Rajamahal these mountains advance so near the Ganges that there is hardly space enough to make a good road along the river. Recently however the East India Company has caused an excellent road to be made between Rajamahal and Colgong, which traverses the narrow pass of Sicligully on the banks of the river. It may be compared with the military roads of the Romans. These Goomah Ghauts have excellent pastures and a fertile soil, but cultivation is much neglected; wheat and barley are raised in no great quantities. The hills are mostly covered with wood, and are very picturesque.

We pass to the table-land of Malwa. The Vindhya mountains constitute its southern boundary. On the north it is enclosed by a chain of mountains, which Malcolm called the Mokundra range, but Ritter prefers the name of Harraouttee range. On its eastern extremity it is connected with the Vindhya mountains, near the sources of the river Sonar, at Chandpoor (79° E. long.). From this point it extends north-west to Saugur, then west-north-west to Seronge and Chuppra, and then westward to Rampoor on the Chumbul, and to Neemuch (75° E. long.), where it is connected with a mountain-region occupying the country south of Oodipoor, and joining the Aravulli range near 24° N. lat., and between 73° and 74° E. long. This range, which probably does not rise more than 500 or 600 feet above its base, is not a continuous chain, being at many places broken through by the rivers, which originate in the Vindhya mountains, and in their northern course traverse the table-land of Malwa, and afterwards force their course through the Harraouttee mountains, where they form numerous rapids and cataracts in the narrow valleys.

The table-land of Malwa extends from Dohud or Dowud on the west (near 74° 20′ E. long.) to Bhopal on the east (77° 20′ E. long.), about 170 miles, and its average width from south to north may be about 80 miles; its area consequently may be estimated at 13,600 square miles, or more than half the surface of Scotland. Malwa is a plain, gently inclined towards the north, with an elevation varying between 2000 and 1300 feet. Indore, near the Vindhya mountains, is 2000 feet high; Oujein, 1640 feet; Barode, near the junction of the Chota Sind with the Chumbul, 1520 feet; and Rampoor, near the Harraouttee mountains, 1276 feet above the sea-level. These towns, which are built on the banks of the Chumbul river, indicate the declivity of the table-land northward. On the plain itself no range of any extent appears: a few hills only occur, which do not rise more than from 100 to 200 feet above their base. Its soil is a black, soft, and rich loam, producing rich crops of rice, Indian corn, peas, beans, &c. Large quantities of sugar-cane, tobacco, cotton, linseed, and sesamum are also raised and exported. Two dye-stuffs, achu (Morinda citrifolia) and safflower (Carthamus tinctorius), are also cultivated on a large scale. But the most important of its productions is opium, of which 350,000 pounds are annually raised, and more than 200,000 exported. The cultivation of this article increases rapidly. There are three seasons. The rain falls during the south-west monsoon, from June to September; its annual quantity amounts to 50 inches. The thermometer never rises above 88°, and at the utmost 90° in the day, and falls in the night to 72°. Towards the end of the rainy season it becomes colder, and then the mean temperature of the day varies between 72° and 79°. The cold season comprehends the months of December, January, and February, during which the thermometer sometimes, though rarely, descends to 28°. During the hot season, from March to June, the north-western winds prevail; they are dry and frequently boisterous.

The thermometer sometimes attains 98°, but the nights are always cool and refreshing. Though the cholera is considered endemic on the table-land of Malwa, it is in general allowed to be a healthy country.

On this table-land are several towns of importance. Near the Vindhya mountains is Bhopal, a large town built near an extensive tank; it is of great antiquity, and carries on some commerce, being situated on one of the great roads which traverse this part of Hindustan. Indore, likewise near the Vindhya mountains, is the residence of the Mahratta prince Holkar. Dhar, once a very large place, has still a population of 38,000. Nearly in the centre of Malwa is Oujein, a very antient town, through which the first meridian of the Hindu astronomers is drawn; it was formerly the residence of Maharaja Scindia, is well built, full of temples and other buildings, and contains 150,000 inhabitants. Bhampoor (24° 31′ N. lat., 75° 50′ E. long.), on the river Chumbul, nearly opposite Rampoor, is a place of great commerce, being situated at the pass of Mokundra, which leads over the Harraouttee mountains to Uppermal; it contains 5000 houses. South of it is the town of Gurrote, with 1200 houses, and in its neighbourhood the temples of Dhumnar (24° 12′ N. lat., 75° 34′ E. long.), which are excavated in the rocks. In the north-western corner of the table-land is Pertabghur, a considerable place, situated on the great road which leads from the table-land to the plain of Gujerat and to Cutch; it is noted for its works in gold.

A line drawn from the last-mentioned town southward to Taundla, and hence to Dohud, marks the western boundary of the table-land of Malwa. West of this line is a mountain-tract, about 50 miles across from east to west, connecting the Vindhya mountains with the Aravulli range. The ridges which cover the greatest part of its surface run south and north, and are mostly connected with the western broken portion of the Vindhya mountains. The valleys between the ridges are not wide, but well watered; yet they are mostly uncultivated. The forests, which nearly cover all the ridges, are valuable for their timber, which consists of much teak and many other timber-trees. This region, called Kauntel, extends westward to the meridian of Lunawarra on the Mhye river.

West of this meridian lies the plain of Gnjerat, with an average breadth of about 45 miles, extending southward to the very banks of the Tapty at Surat, and northward to the river Subermatti, or Sabarmati, which enters the most northern corner of the Gulf of Cambay. It is one of the richest and most popnlous countries of Hindustan, having a good soil, and receiving the heavy rains brought on by the south-western monsoon. It is also well watered, though some of its rivers, especially the largest, Mhye, have furrowed out a deep bed, sometimes 200 feet below the surface of the plain. Rice is nearly the only grain which is cultivated; but the nnmerous villages are surrounded hy extensive plantations of cocoa, mango, and other fruit-trees, and full of tanks, temples, and choultries. The number of large towns is considerable. Among its harbours those of Baroach [Baroach] and Cambay [Cambay] have been noted since the oldest historical times. The latter, which was the seaport of Ahmedabad, has lost much of its importance, but still contains 30,000 inhabitants. In the interior is Baroda, the residence of the Guicowar, with 100,000 inhabitants [Baroda]; and on the banks of the Sabarmati is Ahmedabad, with its extensive ruins, occupying a space of 30 miles in circuit; it still contains a population of more than 100,000 souls. [Ahmedabad.]

The Gulf of Cambay, which divides the plain of Gujerat from the peninsula of the same name, is very difficult of navigation, on account of the violence with which the high tide enters it, and of the circumstance that at low tide the northern portion of it, as far south as 22° 3′, is left entirely dry, with the exception of a channel about three miles wide. If a vessel cannot reach Cambay in one tide, and sticks fast in the mud and quicksand, it is certain to be upset by the next flood-tide. For this reason vessels generally do not go farther with one tide than Gongway, at the mouth of the Mhye river, opposite Cambay, and the second tide carries them into Cambay creek. The violence with which the spring-tides enter the gulf and run up it is compared with that of the bore in the Ganges at Calcutta, and really seems to be still greater. This gulf extends in length about 72 miles, but its width varies between 32 and 8 miles. It is supposed that the depth of the gulf has progressively decreased for more than two centuries past.

At the most northern corner of the Gulf of Cambay, and on the western banks of the river Sabermati, lies a very flat tract, covered with an alluvial soil, which continues in a north-western direction until it meets that part of the Runn which forms the interior of the Gulf of Cutch. This tract is so low, that when the Runn is covered with water, it is likewise inundated, and the peninsula of Gujerat is changed into an island. It is only used as pasture-ground, and may be considered as a continuation of the Runn, which is nothing but a salt-morass, which during the dry season becomes dry in several places; but when the rains of the south-western monsoon set in, it is entirely covered with water, and forms an impenetrable swamp. When the water has been evaporated by the heat of the dry season, the Runn is covered with a layer of salt. This salt-marsh occupies the eastern part of the Gulf of Cutch, as far west as Mallia in Gujerat, but the greatest portion of it extends on the northern side of the island of Cutch, which is separated by it from the sandy desert lying east of the lower course of the Indus.

The peninsula of Gujerat, which is separated by the Gulf of Cutch from the island of that name, and by the Gulf of Cambay from the plain of Gujerat, but connected with the latter by the low swampy tract extending from the most northern corner of the Gulf of Cambay to the Gulf of Cutch, comprehends, according to a rough calculation, an area equal to that of England, or about 50,000 square miles. The greatest part of it is covered with mountains and hills, but a fertile plain extends along its northern shores from 15 to 20 miles inland, and the flat swampy tract along its eastern border continues along the Gulf of Cambay as far south as Bhownuggar. The mountains in the interior are very imperfectly known. They seem to extend in two continuous ridges, of which the northern, called the Mandva mountains, runs nearly north-east and south-west, beginning not far from the low swampy tract on the east, and terminating on the west near the harbour of Poor Bunder: the southern range, called the Joonaghur mountains, runs east and west at a distance of about 30 miles from the southern shores of the peninsula; its offsets however advance to the neighbourhood of the coast, and extend along it from Gopnath Point, at the entrance of the Bay of Cambay, to Puttun, and even farther. This part of the coast is rocky and high, but all the remainder low, and in many places swampy, and especially so between Nuvvee Bunder and Poor Bunder, where several lagunes occur. The mountains do not seem to attain a great elevation, but their declivities are steep. The northern range is mostly destitute of trees, but the southern is well wooded. The whole of the peninsula is well watered, and the rivers, with the exception of those which fall into the Gulf of Cutch, preserve their water all the year round: the Bhunder, which enters the sea at Nuvvee Bunder on the western coast, is even navigable for small river-boats during the greatest part of the year as far as Kotyana. In the lower country which separates the two mountain-ranges several extensive tracts occur which are cultivated, but the best cultivated district is the northern plain, where the common grains of Hindustan are raised in abundance, together with cotton. Here also is the principal commercial town, Nowannuggur, which carries on a considerable commerce with Arabia and the Persian Gulf. It is a large place, and has good manufactures of cotton and many dye-houses. The most western district, called Oka Mundal, is covered with low hills, and separated from the main body of the peninsula by a low swampy tract, similar in its character to the Runn. The most mountainous districts are inhabited by some savage tribes which live by the produce of their herds. The climate of Gujerat is rather mild, and not unhealthy even for Europeans. The highest point to which the thermometer has been observed to rise is 102°; in January it sinks as low as 45°. In December and January eastern and north-eastern winds prevail, and are accompanied by thick fogs, which however disappear at the rising of the sun. Dry and hot winds from the west are general in May and June, after which follows the south-west monsoon with its rains, which are rather abundant. At the most southern point of Gujerat the Portuguese are in possession of the small island of Diu, where there is a good harbour and a fort erected for its protection. It was formerly a considerable place, but has now little or no commerce.

The Gulf of Cutch, which lies between the peninsula of Gujorat and the island of Cutch, grows more shallow as it proceeds east. Large vessels can sail up to Nowannuggur, and small ones only to Jooria; at Mallia it is a swamp. The island of Cutch is only an island during the rainy season of the south-western monsoon, when the Runn enclosing it on the northern side is covered with water. The strong wind forces the sea-water through the Koree or eastern mouth of the Indus into the low plain, but at the same time the rivers which fall into the Runn, as the eastern branch of the Indus, the Loony river, and the Bunnass, which enter the eastern extremity of the Runn, bring down a great volume of fresh water, with which the Runn is partly covered. Those districts which are situated near the mouths of these rivers supply during the dry season much pasture-ground, whilst the remainder is an impassable swamp, or is covered with a saline incrustation. During this season Cutch is separated from the continent of India by a desert. This island extends from east to west about 140 miles; its greatest width is about 60, but in some places not more than 12 miles: its surface may cover about 10,000 square miles, or about the extent of Sicily.

Two ranges of low mountains traverse the island from one extremity to the other. The higher, called the Lunkhi or Lukbi Mountains, is the southern; its width does not exceed 8 or 10 miles, but it is a continuous chain, dry, without springs and destitute of wood, but broken by deep ravines on its declivities. Along the northern shores of the main body of the island there is another range, which constitutes the high coast of the Runn, but it is frequently broken by declivities, and appears in single peaks or in groups. It is connected by some transverse ridges with the Lukhi Mountains. The valleys between these two ranges constitute, with the southern plain, the cultivable portions of the island. The southern plain, which varies in width from 5 to 30 miles, is separated from the sea by a continuous series of sand-hills, which protect it against the fury of the sea during the south-west monsoon; and it seems that the low plain behind these hills is lower than the level of the sea. From the northern side of the main body of the island a remarkable tongue of land projects far into the Runn. It is about 60 miles long, but not more than 10 miles wide on an average. It is called the Bhunnee. Its surface is somewhat raised above the level of the Runn, but not sufficiently high to admit the cultivation of grain. It is consequently only used as pasture-ground for numerous herds of buffaloes and cattle; and the produce of their dairies, the ghee, is one of the most important articles of export from Cutch. The three islands situated within the Runn, Puchum, or Cowra, the most western, Khurur in the middle, and Charar, lying in what is called the Little Runn, farther east, are of the same description. In the last-mentioned island is the town of Sauntulpoor, a place of some trade, the great road between Cutch and Ahmedabad passing through it. Though no active volcano is known to exist at present on this island, a great portion of its surface consists of particles of lava and other volcanic products, and extinct volcanoes have been observed in some places. It is subject to earthquakes, and suffered much by one in the year 1819, in which many hundred persons lost their lives, and the mouth of the river Indus underwent some remarkable changes. The climate of this island, which is traversed by the tropic of Cancer, and is near the rainless region of the globe, is very dry and hot. The south-west monsoon brings rain from June to October, but as this island constitutes the most north-western boundary of its range, the rains are not copious, and it sometimes happens that they do not set in at all. This seems to be the principal reason why the cultivation of the ground is in a very backward state, and the produce not sufficient to supply the scanty population of 400,000 souls. The summers are hot, but the winters rather cold. In the former season the thermometer rises to 106°, and in the latter it sinks to 33°. The prevailing winds during ten months are from the west of the meridian. Respecting the productions and considerable towns see CUTCH. We shall only add, that, towards the northern extremity of the island, an excellent kind of alum is collected, of which nearly 100,000 maunds annually are exported to Bombay and Gujerat, where it is used in the dye-houses with great advantage. The first commercial town is Mandawce. [CUTCH, vol. viiii., p. 243.] The second is Moondra, farther within the Gulf of Cutch; it has 12,000 inhabitants, and a good deal of commerce.

We return to the continent of Northern India. On the north side of the table-land of Malwa, and separated from it only by the Harraouttee Mountains, lies a mountain-region called by the natives Upermal, or mountainous country. Its western boundary is well defined, and protected by the Aravulli range, which runs in a north-north-east direction between 24° and 28° N. lat. and 73° and 76° E. long., beginning on the south, near Edur or Eder, and terminating on the north to the south-west of Rewaree. [ARAVULLI.] The country between this range, the Harraouttee mountains and the Kimoor division of the Vindhya chain, is traversed by several ridges running nearly parallel to the Aravulli mountains. They decrease in elevation and width as they advance eastward, and the valleys which divide them are also comparatively more narrow. This country occupies nearly double the area of the table-land of Malwa.

The Chitore Mountains are nearest to the Aravulli, with whose southern extremity they are united by a kind of mountain-knot, in which the Harraouttee range also terminates on the west. They may be considered as beginning to form a separate range north of Neemuch, near Jawud, whence they proceed in a north-east direction towards Agra on the Jumna, where they terminate near Dholpoor Baree, in the plain of the Ganges, about 30 miles from the banks of the Jumna. Towards the south they are from 40 to 50 miles across, and fill up the whole tract between the Chumbul and the Bunnass rivers. Though of inconsiderable elevation, being only about 600 feet above their base, and 2000 feet above the sea-level, their steep declivities and extremely broken surface oppose great impediments to an easy communication between the two valleys which they separate. Among the difficult roads which traverse this range, the most frequented is that which, near its southern extremity, leads from Jawud to Chitore; and another farther north, which passes from Kotah on the Chumbul, through Boondeo to Jhaipoor on the Bunnass, and to Ajmeer; but the most noted is the mountain-pass of Lakhairi, through which the road runs near the fortress of Indurghur. At a considerable distance from this pass, to the north-east, the range is broken through by a narrow valley, which the Bunnass river traverses in an east and south-east direction, until it joins the Chumbul below Pally. That portion of the range which lies to the north-east of this transverse valley is less steep and broken.

The country between the Chitore Mountains and the Aravulli, which, on an average, is 60 miles across, but towards the north considerably wider, may be considered as a plain with an undulating surface, which becomes hilly towards the north. Its southern portion forms an inclined plain, descending gently to the east. Near the foot of the Aravulli it may be nearly 2000 feet above the sea-level; but on the banks of the Bunnass, which runs along the base of the Chitore Mountains, it is not more than 1500 feet high. The soil is pretty good, and produces wheat, barley, and javary in abundance; opium is also raised. The rains fall from June to September with western winds, and are abundant; but they are preceded by north-eastern winds, which last uninterruptedly for four months, and are extremely hot. During these months all vegetation disappears, with the exception of some evergreens. The northern portion of the plain, north of 26° N. lat., is much less favoured by nature. Its sandy soil gives it the appearance of a desert, from which isolated and strangely-formed rocks rise, generally to an elevation of 300, and rarely to 600 or 700 feet. On the highest of these isolated rocks is the town of Alwur, 1200 feet above the plain. During the winter months the air is cool, and sometimes it freezes during the night, though in the daytime the heat is insupportable. The rains are followed by the hot season, during which the winds blow from the east, and produce great storms. This stormy period generally occupies three weeks between the beginning of February and July, when the sand is raised in such quantities as to hide the sun. With all these disadvantages the climate is healthy, but the country is poor. Its principal production is javary; in a few places indigo, the sugar-cane, and cotton are raised. The most remarkable places in this wide and elevated valley are Oodipoor, the residence of the raja of Mewar, situated towards the southern extremity of the valley between mountains; and farther northward Ummerghur, Bhilwara, and Bunaira, three well-built and industrious towns. Farther north is Ajmeer, with the English military station of Nusseerabad: the town, which lies within the mountain-range of the Aravulli chain, is full of ruins; but it has improved since it came into the possession of the English (1817), and now contains more than 25,000 inhabitants. In the northern districts is the large and well-built town of Jypoor, the residence of the raja of Jypoor.

As to the country south-east of the Chitore Mountains, and between them and the Vindhya range, its western districts are known by the name of Harraouttee, and in the eastern are called Bundelcund. It is a succession of narrow valleys, separated from one another by broad-backed ranges, which, in their upper parts, extend in uneven plains. The only low and level plain of any extent occurs on the eastern banks of the Chumbul, between Kotah and Pally, where the river Parbutty joins the Chumbul. In climate and productions it resembles the valley east of the Chitore Mountains. The valleys are narrow, and produce only javary and other more coarse grains, no irrigation being possible, on account of the bed of the rivers being so deep. Cotton plantations however are numerous and extensive. The plains on the mountains, which rise from 1000 to 2000 feet above the sea-level, are still less productive, and mostly covered with bushes of a stunted growth. On the table-land of Pannah, between the Cane and Tonsa rivers, is the town of Pannah, or Punnah, a well-built place, perhaps 1800 feet above the sea, the neighbourhood of which contains the richest diamond-mines in Hindustan. North of Pannah, on the banks of the river Cane, is the town of Bandah, which is well built, has some manufactures, and carries on a considerable commerce, especially in cotton, from the valley south of it. This town is situated where the mountain-region borders on the plain of the Ganges. Another place, in a similar situation, is the fortress of Gwalior, which is built on a rock, having a tolerably level surface of considerable extent, and a steep descent on all sides. At the foot of the rock is the town of Gwalior, which contains 30,000 inhabitants. On the right bank of the Chumbul, in a very mountainous country, is the town of Kotah, the residence of the raja of Kotah, a well situated but unhealthy place. In the plain which extends between the last-mentioned place and Pally is Patun, a thriving commercial town, in which nearly the whole commerce between Malwa and the other parts of Northern Hindustan is now concentrated. In its neighbourhood are magnificent ruins.

All the rivers which traverse the table-land of Malwa and the mountain-region of Upermal fall into the Jumna or the Ganges, their course being north-east. The rivers which drain the western part of the table-land of Malwa with a slow current, break through the chain of the Harraouttee Mountains in very narrow valleys, where they form a series of rapids and cataracts. The largest is the Chumbul, which originates on the northern declivity of the Vindhya Mountains, in three branches, between which the towns of Dhar, Sagore, and Indore are built: it receives a great portion of the drainage of the table-land before it leaves it, and enters the Harraouttee range between Rampoor and Bhampoor. It then runs in a narrow cleft as far north as Kotah, and as there is no level land along its banks sufficient for a road for beasts of burden, the great thoroughfare in this part of India traverses the Harraouttee Mountains by the pass of Mokundra, which is some distance east of the Chumbul, and which keeps up the communication between the thriving commercial towns of Bhampoor in Malwa and Patun in Upermal. In the plain below Kotah it is joined by other rivers, especially the Newuj and Parbuttee, which bring to it the waters of the eastern districts of Malwa, and likewise traverse the Harraouttee Mountains in narrow glens. The Chumbul begins to be navigable only a short distance above its junction with the Jumna, which takes place between the great towns of Etawah and Calpee, after a course of about 400 miles. The other rivers of Upermal, the Sinde, Betwah, Cane, and Tonsa, which fall likewise into the Jumna, with the exception of the Tonsa, which empties itself in the Ganges, are all full of cataracts, cannot be used for irrigation, and are only navigable a short distance above their respective mouths. The most eastern of the rivers of the mountain-region of Northern Hindustan, the Sone, rises on the eastern declivity of the table-land of Omercuntuc, south of 23° N. lat., and near 82° E. long. It skirts that table-land on the east, flowing in a north-north-western direction to 24° N. lat., where it suddenly turns to the east-north-east, in which general direction it continues until it joins the Ganges above Patna. Its course is in a narrow valley as far as Ratasghur, below which fortress it enters the plain of the Ganges and becomes navigable.

The mountain-region of Northern Hindustan is for the most part in the possession of native princes. The British have however annexed the countries south of the Sone to the presidency of Calcutta, and the tract between the Sone and the Ganges to Allahabad. Between the territories of Calcutta and Allahabad the possessions of the raja of Rewah are enclosed, which comprehend a tract of mountainous country on the Upper Sone and on the Tonsa. The remainder is divided between the Mahratta princes, Scindia, Holkar, and the Guicowar, and the Rajpoots. The Rajpoots were formerly in possession of the whole of Upermal, including even Bundelcund, which country therefore frequently is called Rajastan, or Rajpootana; but as the Rajpoots extended and still extend their dominions on the western side of the Aravulli range over a great portion of the desert lying between the mountain-region of Northern Hindustan and the banks of the Indus river, the name of Rajastan is applied also to these countries. The Rajpoot princes of Oodipoor and Jypoor, with the raja of Kishnaghur, have their principal possessions in the flat country between the Aravulli and Chitore ranges; whilst the raja of Kotah is in possession of a considerable part of Harraouttee, and in Bundelcund are several small rajas, called the princes of Bundela. The remainder of these two countries, with by far the greatest part of Malwa, belongs to Maharaja Scindia. A small portion of Malwa is in the possession of the raja of Bhopal and the Mahratta chief Holkar. The plain of Gujerat is divided between the English and the Guicowar, a Mahratta chief, who also possesses nearly the whole of the peninsula of Gujerat. The English territory in this part is annexed to the presidency of Bombay. The island of Cutch is subject to the raja of that name.

IV. *The Plain of the Ganges.*—The Ganges, or Ganga, rises with its two principal branches in the highest elevation of the Himalaya Mountains, near 31° N. lat. and between 78° 30′ and 80° E. long. The most western branch, whose remotest sources lie on both sides of the mountain-pass of Gangtang Ghaut [HIMALAYA], is called Bhaghirettee. Between the higher masses of the Himalaya its general course is south-south-west, in a very narrow valley; but where it enters the lower mountains it turns south-east, and after passing Tiri, the capital of Ghurwal, it meets the other branch, the Alakananda, at Deoprang, or Deva Prayaga. This other branch, the Alakananda, rises in the immense snow masses which cover the Himalaya range near the mountain pass of Manah Ghaut, and flows south-south-west until it joins another mountain-stream, the Douli, which comes down from the Neetee Ghaut. After their junction at Josee Muth, which is still 6300 feet above the sea, the Alakananda flows in a west-south-western direction past Sireenaggar to Deoprang. The river formed by the junction of the Bhaghirettee and Alakananda is called the Ganges. Its course within the region of the Himalaya Mountains is not long, but very winding, until it entirely leaves it below Hurdwar, and enters the plain of the Ganges. The surface of the river at this point is hardly more than 1000 feet above the sea-level. The length of its course, including the Alakananda as the longer branch, does not fall short of 150 miles. In the plain it continues its course for a considerable distance due south, or nearly so, until it begins to decline imperceptibly to the south-south-east, in which direction it flows to its junction with the Jumna at Allahabad. In this part of its course, of more than 400 miles, it receives no considerable affluent, except the Ram Ganga, which, with its principal tributary, the Kosila, originates in the lower portion of the Himalaya range, runs south-south-east, and joins the Ganges above Canoge. The Jumna, or Yamuna, which joins the Ganges at Allahabad, rises west of the Ganges within the more elevated masses of the Himalaya range in two branches, of which the eastern soon takes the name of Jumna, whilst the western is called Supin, or Tonse. They unite near Kalsi, within the lower range of the Himalaya, and soon afterwards leave the mountain-region above Khiderabad. In the plain the surface of the river is about 1200 feet above the sea-level. Its course is parallel to that of the Ganges, being first south and afterwards south-east. By degrees it approaches nearer to that river until it joins it at Allahabad, at the Deva Prayaga. Its course within the mountains does not perhaps exceed 120 milos; but in the plain it runs nearly 150 miles more than tbe Ganges up to their junction. Though its waters during its course are increased by those of the mountain-region of Nortbern India, tbe Chumbul, Sinde, Betwah, and Cane, yet at the point of their confluence the Ganges is much larger, being a mile across, while the Jumna is only 1400 yards.

From Allahabad to below Boglipoor, situated at the foot of the Rajamahal hills, the Ganges runs with a winding course eastward, and in this part of its course it receives a great number of large streams. The Goomtee, rising near the foot of the Himalaya range, runs through the plain past Lucknow and joins the Ganges between Benares and Ghazepoor; its numerous bends have given it the name of Goomtee, which signifies 'the winding river.' Above the town of Chupra the Ganges is joined by the Gogra, the largest of its affluents from this side: it rises far within tbe highest portion of the Himalaya range near tho mountain-pass of Taklakot, and passes Fyzabad and Oude. Its course is hardly less than 600 miles, which is equal to that of the Rhine. Opposite Patna, near Hageepoor, the Ganges receives the Gbandaki Ganga, or Gunduck, wbose farthest source lies near the Mastang Pass, on the table-land of Tibet, and it is not much inferior in length to the Gogra. Farther down the waters of the Ganges are increased by those of the Bagmutty, which rises on the southern declivity of tbe higher Himalaya cbain, passes near Khatmandu, the capital of Nepaul, and entering the plain, changes its soutbern into a south-eastern course. Nearly opposite Boglipoor the Coosy falls into the Ganges, wbose farthest branches seem to originate on the table-land of Tibet, and whicb, like the Ghandaki Ganga and the Gogra, brings down the waters of a considerable area of the mountain-region of the Himalaya. At Sicligully, about 30 miles below Boglipoor and 10 miles above Rajamahal, the Ganges having passed the hills, which here approach its bed, turns soutbward, and here the great delta of the river may bo considered to begin. Though it does not at present divide at this place, it is evident that its waters formerly did, and that one arm passed near the extensive ruins of Gour, which at present are five miles distant from tbe river. At present the first bifurcation of the Ganges takes place at Sooty, about 20 miles below Rajamahal. Tho name of Ganges, or Ganga, continues in the eastern arm; the western is called Bhaghirettee by the natives, and Cossimbazar by the Europeans. The Ganges flows soutb-east, and the Bbagirettee south. The former divides again about 40 miles lower down, near Jellinghy, from wbich the western branch is called the Jellinghy river. It flows mostly in a southern direction, and joins the Bbaghirettee near Nuddea. The island thus enclosed is called the Cossimbazar Island. Another arm branches off from the Ganges a few miles from Jellinghy. This arm, called the Matabunga branch, runs likewise southward with many largo bends, and joins the Bhaghirettee nearly at an equal distance between Nuddea and Hoogly. After the junction of these three arms of the Ganges, the western branch of the Ganges is called the Hoogly, under which name it passes Calcutta and reacbes the Bay of Bengal near the island of Sagor. The principal branch of the Ganges, continuing its course to the south-east, sends off anotber arm near Custy, or Custea, whicb is called the Chundna river, and passes near Comercolly. The fifth great bifurcation takes place at no great distance lower down, near Maddapoor, and here the smaller or western branch is called the Gurroy river. These two great branches, the Chundna and Gurroy, unite again near Colna, and hence proceed southward to the Bay of Bengal under the namo of Boirub, or Horingotta river, which, like the Hoogly, forms a wide æstuary at its mouth. Whilst the Ganges loses a great deal of its waters by sending off so many large branches, besides several smaller ones, it receives new supplies from the Himalaya range and the Brahmapootra. The Mahanada and tho Teesta, wbich both run from 250 to 300 miles, rise on the southern declivity of tbe higher Himalayas in Nepaul and Bootan, and run southward. Tbey communicate by several branches with one another during the rainy season, but they join the Ganges at different points,—the Mahanada near Nabobgunge, and the Teesta below Jaffiergunge. At the last-mentioned place tbe Ganges receives the first supply of water from tbe Brahmapootra by the branch called the Jenye, which leaves its principal stream opposite the town of Sheerpoor, is very deep, and brings down a great volume of water. Where the Ganges is increased with the waters of the Jenye it divides again, and its eastern branch, called the Booree Ganga, passes Dacca at no great distance, and enters the wide bed of tbe Brahmapootra below Nurain-gunge. The Booree Ganga receives three other navigable branches of the Brahmapootra, the Bangs, or Bungs, the Banar, and the Lukbya. Tbe last is the most important, and joins the Booree Ganga near Nurain-gunge; it is joined higher up by the Banar. The Brahmapootra is so much drained of its waters by these different offsets tbat during the dry season it is not navigable between Sheerpoor and the moutb of the Booree Ganga. The principal branch of the Ganges flows nearly parallel to the Booree Ganga and tbe Brabmapootra, but falls into tbe sea by a separate embouchure between the continent and the island of Deccan Shabazpoor. The Ganges runs nearly 1500 miles.

All the affluents of the Ganges rising within the mountain-region of the Himalaya are navigable for smaller or larger river-boats to the very foot of the range for six months and longer. The Ganges itself and all its arms within the delta, and also the Jumna, are navigable all the year round, but not for vessels of the same size. The Bhaghirettee and the Jellinghy branches in the dry season are so shallow that only barges can pass drawing not more tban one foot of water; the Matabunga however admits always boats drawing two feet. The Horingottah river and its branches, tbe Chundna and Gurroy, may always be navigated by vessels of considerable size, and the same is said to be the case with the Jenye and Luckhya brancbes of the Brahmapootra and with the Boorree Ganga. Even before the river divides its waters are not very deep. As far upward as Allahabad it consists of a series of pools divided from each other by shallow tracts, by which navigation is rendered difficult and even dangerous. Above Allahabad numerous shallow places and rapids occur, which impedo navigation during the dry season, but disappear after the river is swollen by the rains. Two swellings of its waters are observed. The first begins in June, and attains its maximum in July or the beginning of August. It is followed by a depression which lasts for three or four weeks, when the waters again rise in September, and attain their maximum in October. The Hoogly can only be navigated as far up as Calcutta by vessels not drawing more than fifteen feet water, and all larger vessels are obliged to remain at the island of Sagor, where the unhealthy climate causes great loss among the crews. The tide at full and change causes a terrible boro in the Hoogly [Bore], and its ascent as far as Culna, and even Nuddea, is very perceptible; but though the bore in the Megna, or Brahmapootra, is said to be still greater, the tide does not ascend farther than the town of Dacca, on the Booree Ganga. In tbe Horingottah branch it is felt as far as Custy, where this river branches off from the principal body of tbe Ganges.

The great plain which is drained by the Ganges and its affluents may be divided into three parts:—the plain of Bengal, which comprehends the delta of the river and the country north of it as far as tbe lower range of the Himalaya mountains; tbe plain of Bahar, which is divided from Bengal by the river Coosy and the Rajamahal hills, and extends as far wost as the confluence of the Ganges with the Jumna; and the plain of the Doab, Oude, and Rohilcund. The first extends lengthwise from south to north, the second from east to west, and the third from south-east to north-west.

The plain of Bengal extends from the mouths of the Ganges to the Himalaya mountains, about 280 miles, and its widtb may perbaps exceed 180 miles; its surface is therefore equal to that of England without Wales. Its western boundary runs from Balasore on tbe Bay of Bengal, through Midnapoor, Bishunpoor, and Nagore to Rajamahal, and thence along the Coosy river to the mountains. On the east its border skirts the Tiporah bills, includes the province of Silhct in the form of a gulf, and follows here and farther north the southern and wostern declivity of the Garrow Hills, until in the meridian of Goyalpore it traverses the Brahmapootra, and attains in that direction tbe Himalaya Mountains. On this side the plain is connected with the maritime low tract of Chittagong and the valleys of Silhet and Asam, which differ considerably in their natural cbaracter from the plain of Bengal.

The Tiperah or Tripurah mountains, which cover a great space between Chittagong and Silhet, seem to form an extensive table-land with an uneven surface, but their interior is entirely unknown. They are probably connected with the mountain-region from which the great mountain-range of Aracan or the Yeomadong mountains run off to the southward. The Garrow hills are the continuation of that range of mountains which skirts the valley of Asam on the south, and is connected with the eastern extremity of the Himalaya range by the Langtan mountains at the sources of the Brahmapootra. The Garrow hills do not rise to a great elevation, their highest summits probably not exceeding 6000 feet above the sea-level; but the Brahmapootra running at their northern declivity is not more than 200 feet above that level. In these hills, at a place called Chirapoonje, north of Silhet, a sanatory station has been established for the presidency of Bengal.

The plain of Bengal comprehends four natural divisions: the Sunderbunds, the country subject to inundation, the country which is not inundated, and the Tarai. The Sunderbunds occupy the most southern part of the plain between the mouths of the Ganges and Brahmapootra, and as far north as the salt water of the sea is carried by the tides. This district extends farthest along the Horingottah branch, where it advances to the neighbourhood of Colna at the junction of the Chundna and Gurroy branches of the Ganges, a distance of 70 miles: the mean width may be about 50 miles. This tract is entirely uncultivated. The soil is extremely swampy all the year round, and overgrown with tall trees, which produce excellent timber; these thickets are inhabited by tigers, rhinoceroses, and other wild animals; while the numerous branches into which the different arms of the Ganges divide within this tract harbour gavials, and contain numerous kinds of fish. The inhabitants are few in number, owing to the great unhealthiness of the country. Their occupations are the cutting down of timber trees, and the preparation of salt from the sea-water, which enters these rivers and canals with the tides. It is only towards the two extremities, along the Hoogly and the principal branch of the Ganges, that some cultivated tracts occur within the Sunderbunds. The district of Backergunge on the last-mentioned river is noted for most abundant crops of rice, though the produce is of inferior quality.

The country subject to inundation comprehends not only what is called the delta, or the country between the branches of the Ganges, but also the country between that river and the Brahmapootra, as far north as 25°. The inundation is not equally spread over the whole surface; it is greatest in the eastern districts, especially where the waters of the Brahmapootra are connected with the Ganges, in which part an immense tract of country is covered for several months with water many feet deep, so that at the end of June the towns and villages, which are built on artificial mounds and protected by embankments, appear like islands. The river has then risen 15 feet above its level in the dry season, but it still continues to rise for several weeks, about 5 inches every day. At Custy, at the bifurcation of the Chundna branch, it rises between 31 and 32 feet; at Dacca, only 14 feet; and farther southward, at Luckipoor, not more than 6 feet. In the Sunderbunds themselves it is not perceptible. In October, when the water rapidly decreases, the country is sown with rice, and the produce of this tract is sufficient to furnish the whole plain of Bengal with this principal article of food. The western districts of the country subject to inundation are only slightly covered with water; and though they likewise produce rice, they are principally covered with plantations of mulberry-trees, especially towards the middle tracts; whilst in the northern parts indigo, sugar, cotton, and tobacco are raised in abundance. The plantations, with which the villages are surrounded, consist of mango-trees, jack-trees, cocoa-trees, and other kinds of palms. The whole of this plain is covered with several layers of alluvial earth, to a depth of 130 or 140 feet, and in spite of numerous attempts, no wells have been made in it. In this alluvial soil the rivers frequently change their course, furrowing new channels through it, and leaving the old channels dry. The banks of the old channels appear like low sandy hills, and these hills, together with the abandoned beds, constitute the waste land of the country, which frequently extends for 8 or 10, or even 15 miles from the present channel of the river. The best cultivated portion of this plain is the island of Cossimbazar, between the Bhaghirette and the Jellinghy branches of the Ganges. [BENGAL.]

The country not subject to inundation lies partly west of the Hoogly, and partly north of 25° N. lat. The district west of the Hoogly is of great fertility, especially Burdwan, which produces grain, sugar, cotton, silk, and indigo, in the greatest abundance and of excellent quality; it is the best cultivated, most populous, and most productive district in India. The country north of 25° N. lat. is fertile and well cultivated in its southern districts, as the lower tracts along the rivers are covered with water during the rainy season; and those which lie higher are partly irrigated by artificial means, and partly used for raising such kinds of grain as do not require irrigation. But farther north large tracts of waste land occur, which are covered with rank grass, reeds, and fern. These sterile tracts increase in number and extent as they approach the Tarai.

The Tarai (*i. e.* the swamp) divides the plain of the Ganges from the lower region of the Himalaya mountains, and extends from the banks of the Brahmapootra along the foot of the mountains to the place where the Ganges issues from them at Hurdwar. But it varies in width and also in its character, narrowing insensibly as it proceeds farther to the north-west. In Bengal it is from 20 to 25 miles across, but towards its north-western extremity only a few miles wide. Its soil is extremely soft, and as its slope is not sufficient to draw off the water of the numerous springs which issue from the mountains, it is converted into a deep swamp of great fertility, which is covered with a vigorous vegetation and large forest-trees. [HIMALAYA.] It is the haunt of elephants, rhinoceroses, wild buffaloes, tigers, monkeys, and other wild animals. But as the exhalations of the decaying vegetable matter and of the swampy ground, united to a great degree of heat, engender the most dangerous fevers, it is very thinly inhabited, and by a very miserable class of people, among whom goître is common. These people chiefly maintain themselves by cutting down the forest-trees, which are sent to Calcutta and other towns in Bengal, where they are used for constructing boats and for building purposes. No part of this tract is cultivated, nor does any portion of it serve as pasture-ground. Farther north, in Bahar, Oude, and Rohilcund, the underwood and the climbing plants disappear, and the ground between the trees is covered only with long coarse grass, which being destroyed by putting fire to it, herds of cattle pasture on the new grass which immediately springs up.

The plain of Bahar, which extends west of the river Coosy and the Rajamahal hills as far as the meridian of Allahabad, is divided by the Ganges into two regions. The southern, or Bahar Proper, has not a great width, being narrowed at both extremities by the Rajamahal hills and the projecting offsets of the Kimoor range. Its surface along the banks of the river is undulating, but farther south it rises into hills. The soil contains more sand than in Bengal, but water is found everywhere at no great distance from the surface, which gives it such a degree of fertility that even the few tracts which are not cultivated display a very vigorous vegetation. No part of it is inundated by the Ganges, which runs 30 feet below its general surface, but its waters present the means of abundant irrigation. By the industry of its inhabitants this country has attained such a degree of cultivation that it resembles a garden, and its crops are not inferior to those which are obtained in the inundated districts with less labour. Its principal products are opium, indigo, rice, and cotton. [BAHAR.]

The country north of the Ganges is called Tirhut or Trihuta. It is an inclined plain, near the Himalaya mountains, about 600 or 700 feet above the sea, and sloping towards the Ganges, where its mean elevation may be about 300 feet. Its surface is undulating, and the districts which border on the Ganges do not differ much from Bahar Proper in soil and cultivation. But about 30 or 40 miles from the river large tracts are covered with forest-trees, especially saul-trees, which increase in extent as the country approaches the Tarai. The great abundance of water which descends in the heavy rains and is brought down by the numerous rivers from the Himalaya, forms extensive lakes, or djils, which render this part of the Gangetic plain nearly as unhealthy as the Tarai, and prevent the extension of cultivation in a country distinguished by an extremely fertile soil. But with all these disadvantages its agriculture is on the increase, as no part of India is better adapted for the raising of indigo. The cultivation of opium is also on the increase. In no part of the great plain is saltpetre obtained in such abundance; indeed the ground seems to be generally impregnated by it. The large forests of saul furnish an article of export.

The portion of the Gangetic plain which extends west of the meridian of Allahabad, and comprehends the Doab, or country between the rivers Ganges and Jumna, together with Oude and Rohilcund, differs considerably from Bahar, and still more from Bengal, in its climate and productions. The soil between and on the banks of the rivers does not differ much from that of Bahar, being sandy and loamy, and having likewise water under it at no great distance from the surface; but it slopes with more rapidity, descending from north-west to south-east from 1200 feet to 300 or 400 feet, and consequently the running water is sooner drained off and the soil is much drier. As the heat of the summer, though excessive, lasts only a short time, and the cold in winter is considerable, the vegetation differs greatly from that of the lower plain. The winter crops resemble those of Europe, consisting chiefly of wheat, barley, oats, and millet, together with peas, beans, vetches; also tobacco, flax, and hemp. The summer crops, which grow during the rainy season, are rice, javary, cotton, indigo, &c. The palm-tree disappears; but the European fruit-trees grow together with bananas, custard-apples, and the fruits which have been transplanted from China. Almonds, peaches, nectarines, pomegranates, figs, and most of the fruits of England are cultivated with success. The number of evergreen trees is small; nearly all trees loose their leaves in December. Forests are rare in this plain, except towards the Himalaya mountains, where the level of the country is lower, and approaches the Tarai, which however is of small width in this part of the plain.

The country which lies to the west of the Jumna, and extends as far as the banks of the Sutlej and Gharra, constitutes the connecting link between the plains of the Ganges and the Indus. It is a level tract; no mountains or even high hills occur in its whole extent. The surface consists of a loose sand, and as the equatorial rains here begin to cease, and the winter rains of the northern latitudes do not extend so far south, it is nearly without cultivation. Where this plain borders on the Himalaya range, it is in some measure watered and fertilized by the numerous small rivers which originate along the declivity of the lower range and a short distance within it; and numerous villages, with some cultivated tracts, occur here. But the small volume of water brought down by these rivers is soon absorbed by the sandy soil, and some of them cease to flow at a distance of about 30 to 40 miles. The remainder unite in one somewhat larger stream, the Gagur, which continues to flow for about 100 miles, and then also is lost in the sand. It is said that it once joined the Indus, and that its antient bed can still be traced. With the decrease of the waters of these rivers the villages become fewer in number and smaller in extent, and the country gradually assumes the dismal aspect of the Indian desert. At the inhabited places fresh water can only be found at a depth of from 50 to 100 feet. Where this country borders on the Indian desert, it is chiefly covered with low sandy hills.

The climate of the Gangetic plain presents still more marked differences than its surface and soil. The rains are brought by the south-west monsoon. It commences in March, but in the beginning affects only the waters of the Bay of Bengal, which are raised by it several feet: the current, which during the dry season runs to Cape Comorin, being then directed to the interior angle of the Bay. This higher level of the Bay lasts to the end of the monsoon in October. The rains set in towards the end of April or in May: they are however not abundant in Calcutta before the beginning of June. In the countries farther east, as Chittagong, Silhet, and along the base of the Himalaya mountains, the abundant rains begin a month earlier, and therefore the rivers which drain these districts inundate the adjacent lands earlier. They are also more abundant than in the western districts of Bengal. At Calcutta the mean annual quantity of rain is 71 to 72 inches, but at Dacca it probably does not fall short of 100 inches. The heat is excessive all the year round, but especially so before the setting in of the rains. The mean annual temperature of Calcutta is 79° of Fahr.; that of the hottest month (May) 86°; and that of the coldest (January) 67°. The thermometer sometimes rises above 100°. The climate of Bengal, especially of the western districts, is not unhealthy for Europeans; but the excessive heat which prevails nearly all the year round gradually enfeebles the constitution. The eastern districts are less favourable to health. The climate changes greatly as soon as the hills of Rajamahal are passed in ascending the Ganges. In Bahar the difference between the hottest and coldest season is much greater. Though we are not acquainted with the fact by meteorological observations, it is certain that the greatest heat is not inferior to that of Bengal; but, on the other hand, in the month of December and January frost is experienced, and fire is kindled in the houses. This difference of cold cannot be ascribed to the difference in elevation of the two countries, as Bahar is only from 200 to 300 feet higher than Bengal. It probably has its cause in the direction of the Rajamahal hills, which break the force of the monsoons; and this conjecture seems to be confirmed by the smaller quantity of rain, which at Benares does not exceed 40½ inches annually. The rains set in here a month later. In June only a few showers occur, and the most abundant rains are in July. In Tirhut however the rains occur earlier, and they are also more abundant, and form the numerous rain-water lakes, or djils, which, with the forests, render that district rather unhealthy, whilst the countries along the banks of the Ganges in Bahar are considered very healthy. Before the rains commence, Bahar experiences strong western or north-western winds, which raise the thermometer considerably, and occasion an intense degree of heat. The difference between Bahar and the Doab, in respect of climate, is not so great as between Bengal and Bahar, though the difference of elevation is greater, a great portion of the Doab being more than 600 or 700 feet above Bahar. The winter months (from November to March) are somewhat colder. In January and February the thermometer sinks below the freezing-point, and stagnant waters are covered with thin ice. In the hot season (from April to June) the temperature rises gradually to 90°, and sometimes even to 105°. The difference between January and June is 68° Fahr. (between 37° and 105°). But both states of the air are of short duration, and do not much affect vegetation. The western districts of the Doab however are visited during the hot season by the scorching westerly winds which come from the Indian desert. The rains are abundant in the districts between the Himalaya mountains and the Ganges, but much less so in those farther west, and very moderate to the west of the Jumna. Farther to the west in the desert country between the last-mentioned river and the Sutlej they disappear entirely, or are only limited to a comparatively narrow tract along the Himalaya range.

The Gangetic plain is the most fertile, the best cultivated, and most thickly inhabited portion of Hindustan. It contains more than one half of all its population, and the number of inhabitants probably exceeds 60 millions. The number of large towns is considerable. The most important in the lower portion of the plain are enumerated with their population in the article BENGAL, and for a description of the largest see CALCUTTA, DACCA, &c. Colna, at the confluence of the Chundna and Gurroy branches of the Ganges, is a rapidly increasing place. In the middle plain of the Ganges, or Bahar, the large towns are also numerous; especially along the banks of the Ganges. Boglipore contains 30,000 inhabitants [BOGLIPORE], and Monghir, a fortress with an equal population, is noted for its manufactures of iron. Farther west, about the mouths of the river Sone and Gunduck, is a very populous district containing the great town of Patna, and near it the large towns of Bankipoor, Hajcepoor, and Dynapoor. Then follow the towns of Chupra, Buxar, and Gazipoor. Benares, farther west, is considered in some respect as the capital of this portion of India. [BENARES.] Between Benares and Allahabad are Chunarghur, a fortress with 15,000 inhabitants, and the great commercial town of Mirzapoor. At some distance from the Ganges on the south is the town of Gayah with 36,000 inhabitants and a famous temple of Vishnu, which is visited by a great number of pilgrims; and not far from it on the Sone is Daoudnaggur, with 18,000 inhabitants. The towns of the Tirhut have not yet risen to importance, but are rapidly increasing with the extension of cultivation in this fertile district. The largest towns are Mullye and Goruckpoor. The northern portion of the plain has from the earliest times been the seat of the most powerful empires in India, and it contains several towns which successively have been the capitals of this country. All of these are situated either on the Ganges or the Jumna. On the first-mentioned river are the antient capitals of Cawnpoor, or Caunpoor, Canoge and Furruckabad. Cawnpoor is still a large town, extending six miles along the river, but it is thinly peopled and the streets are intersected hy large orchards and gardens. Canogo, which once covered a surface equal to that of London, is now of very little importance. Furruckabad has still a population of 70 or 80,000, and is one of the most commercial towns of Northern Hindustan. On the Jumna are the antient capitals of Calpee, Etawah, Agra, Muttra, and Delhi. [Agra; Delhi.] Calpee is still a considerable place, and carries on an extensive trade in cotton. Etawah has also preserved a considerahle population, hut is not otherwise important. Muttra, or Mathura (the Methora of Arrian, *Indic.*, c. 8), is still a large town, and a sacred city, to which great numbers of pilgrims annually resort, as well as to the neighbouring town of Bindrabund. Among the antient capitals of this part of Hindustan, one of the oldest seems to be Hustanapoor, near 29° N. lat. and 78° E. long., north-east of Merut, whose ruins covered a great extent of ground. In the Doah, or country between the Ganges and Jumna, are the towns of Merut and Scharanpoor, which in latter times have risen to some importance. In Oude are Lucknow and Fyzabad. In Rohilcund are Shahjehanpoor with 50,000 inhabitants, Bareilly with 65,000 inhabitants, and Rampoor on the Kosila river, which is said to have a population of 100,000 inhahitants. Hurdwar, which is situated where the Ganges issues from the mountain-region of the Himalaya range, is a place of pilgrimage, and has a considerahle commerce.

The whole of the Gangetic plain is immediately subject to the government of the Company, with the exception of the kingdom of Oude, which occupies that portion of the plain which extends, between 80° and 82° E. long., from the banks of the Ganges to the Himalaya Mountains. Its area may he about 25,000 square miles, or half the extent of England. The British possessions are annexed to the presidency of Calcutta and to Allahabad, the river Sone constituting the boundary between them on the south of the Ganges, and the Gunduck for a great part of its course on the north. The arid plain lying between the Jumna and the Sutlej is possessed hy some chiefs of the Seiks, who are under the protection of the Company.

V. *The Plain of the Indus.*—The Indus, called in its southern course also Sinde, rises on the table-land of Tibet, hut its sources have not heen visited hy Europeans. It is supposed that they are situated at no great distance from the sacred lakes Rawan Hrad and Manas Sarowar, to the north-north-west in 31° 20 N. lat. and near 80° 30′ E. long., on the western declivity of one of the mountain-ranges which traverse the table-land of the south of Central Asia, called the Gangdiari or Kailasa Mountains. Hence it runs north-west passing the town of Ghertope to Leh in Ladakh, and it is called hy the Chinese, in this part of its course, Sing-he-tsiu. After a course of perhaps not less than 250 miles on a table-land from 12,000 to 15,000 feet above the sea, it is joined below Leh hy the Shayuk, which rises at a great distance north-east in the Karakorum Mountains, and prohahly exceeds the Sing-he-tsiu in the volume of water, if not in the length of its course. This affluent of the Indus has not been visited hy Europeans, and indeed it is only that portion of the Sing-he-tsiu which lies between Ghertope and Leh that has heen seen hy European travellers. Nothing is known of the Sanpoo, or Great River, as the Indus is called after its junction with the Shayuk, until it issues from the Himalaya range a few miles east of Attock. In this part of its course it gradually declines more to the west, and traverses the narrow valley hy which the north-western mountain-range of the Himalaya, the Gosseie Mountains, are separated from the elevated mountain-masses of the Hindu Coosh. Above Attock its course lies due west, and it is joined hy the river of Cahul, the only considerahle affluent which it receives from the west after it has left the mountains. After leaving the high mountains ahove Attock, it continues its course in a south-western direction for about 70 miles more between lower ranges, until at 33° 7′ N. lat. it enters the great plain. This plain however lies almost entirely on the eastern side of the river, as the mountain-ranges which support the table-lands of Afghanistan and Beloochistan accompany the river in its course as far south as 30° N. lat. South of this parallel the plain extends also on the west, hut only to a short distance. The Hala Mountains, which run along the eastern border of the table-land of Beloochistan, rise at a short distance from it, at some places within a few miles.

As soon as the Indus has left the mountains it divides into four arms, which run southward with great bends, and sometimes unite, hut separate again, so that the whole volume of its waters is seldom united in one hed. South of 29° N. lat., near the small town of Mittun Cote, it is joined on the east hy the united rivers of the Panjah, Penjâh, or Punjauh, and changes its southern course to a south-western. It is here 2000 yards wide. It continues its south-western course to Shidelkarpoor and Bukkur, and then turning to the south-east, it reaches Hyderahad, above which town it divides into two arms and encloses a delta. The most eastern of these arms, the Fulaili, passes the town of Hyderahad on the east, and flowing farther down in an east-south-eastern and southern direction, enters the Runn, out of which it flows hy the wide æstuary which separates the island of Cutch from the plains of Sinde. This hranch of the river has only a great volume of water during the inundation; the greatest part of the year it is dry. Where it approaches the Runn, a place called Sindree, with an extensive tract of land in its neighbourhood, was plunged into the water hy the frightful earthquake of 1819, and at present is a large lake, whose waters are discharged into the Koree, or eastern mouth of the Indus. The æstuary of the Koree has 12 feet of water as far as Busta, hut farther inland it is not so deep. The western and principal hranch of the Indus divides again south of 29° N. lat. near Jarruck; the smaller or eastern branch, called the Pinyari, runs nearly parallel to the Fulaili, and loses also a great part of its waters before it reaches the sea hy the mouth called Sir. It is navigahle however as far as Gunda for vessels of 38 tons hurthen, and it is much navigated, though the merchandise must be transferred into small river-boats at Gunda. Below Tatta, and about 60 miles from the sea, the principal hranch of the Indus separates again into two hranches, of which the smaller, called Buggaur, runs westward, and the larger, the Sata, continues in a south-south-western direction to the sea. The last-mentioned hranch is hy far the larger, being, after the hifurcation, still 1000 yards across, and carrying off the greatest volume of water. It divides into seven arms hefore it reaches the sea. The widest of its mouths, the Gora, is only accessible to small vessels on account of its shoals and rapid current. Another of its embouchures, called the Hujamri, lies farther west, and admits vessels of 50 tons burthen, which may sail as far up as Vikkur, more than 20 miles from the sea. The Mull mouth of the Sata, which is to the south-east of the Gora hranch, may be navigated hy vessels of 25 tons hurthen as far up as Shah-Bunder. Vikhur, as well as Shah-Bunder, exports great quantities of rice. The most western of the branches of the Indus, the Buggaur, divides again helow the town of Daraji into two arms, called Pittee and Pieteeanee, both of which are navigahle as far as their point of separation for small vessels. Daraji has some commerce, hut at present these two arms have less water than they had formerly.

The Indus receives only one great affluent in its extensive plain, hut this affluent unites all the rivers which drain the Panjab, or the Five Rivers, the Pentapotamia of the Greeks. These five rivers, enumerated from east to west, are the Sutlej or Satadru (the Zaradrus of Ptolemy), the Beeah or Beas (the Hyphasis of Arrian), the Ravee (the Hydraotes of Arrian), the Chenauh (the Acesines), and the Jhilum or Behut (the Hydaspes). The Sutlej has the longest course. It originates on the tahle-land of Tibet, in some mountains north of the sacred lake of Rawan Hrad, and it is even supposed that this lake discharges its waters into the Sutlej. Its course on the tahle-land, where it flows in some measure parallel to the Sing-he-tsiu, or Indus, amounts to more than 150 miles. At Shipkee, where it enters the territories of Bissahir, it is still 10,484 feet ahove the sea. So far it flows north-west. Changing its course to the south-west, it soon enters the Himalaya range, through which it runs in a narrow valley, with numerous hends, more than 100 miles. It enters the plain, near Ropur, whence it flows due west past Ludiana as far as Hurree, where it is joined hy the Beas. The Beas originates in the Paralasa range of the Himalaya mountains [Himalaya], traverses the mountain-region with two great bends to the south and north, and enters the plain ahove Nadaun after a course of less than 100 miles. Hence it flows west-south-west, gradually approaching the Sutlej, until it joins it. The united river then takes the name of Garra or Gharra, and continuing to flow in a south-western direction, unites with the Chenauh near Ooch, below Bhawulpoor. The

Ravee does not appear to rise in the highest range of the Himalaya, but on one of its intermediate parallel chains, called the Santch Mountains. Its upper course is not known, but it does not seem to be long. Above Kotoa or Kothua it enters the plain of the Panjah, where it flows in a south-west direction parallel to the Beas and Garra, until it joins the Chenaub at Fazilshab. The Chenauh, whose Sanscrit name Chandrabbága (*i. e.* moon-river) was not adopted by the followers of Alexander, because it sounded like Sandaro-phagos (*i. e.* Alexander-eater), rises in the Paralasa range of the Himalaya, near the sources of the Beas and the mountain-pass of Para-Laha, and runs for about 100 miles in a longitudinal valley of the mountain-region to the north-west; it afterwards turns gradually to the west, passes the town of Kishtawar, and inclining by degrees more to the soutb, leaves the Himalaya mountains above Jommu, after a course of perhaps not much less than 200 miles. In the plain of the Panjab its course is west-south-west until it has joined the Ravee, when it declines to the soutb-south-west. The last of the rivers of the Panjab, the Jhilum, rises in the Tibet Panjahl range of tbo Himalaya mountains [HIMALAYA], not far from tho high peaks of Mer and Ser. Like the Chenaub, it flows first in a longitudinal valley of the mountain-region [CASHMERE] in a north-north-west direction, traverses the lake of Wooler, and issues from the valley hy the narrow valley of the Baramule pass. Within the mountain-range it passes near Mozufferabad, up to which place its course is to the west. Soon afterwards it turns by a bold hend to the south, in which direction it reaches tbe plain, where it again takes a western course above Pindee Dader Khan. Its course within the range of the Himalaya exceeds 200 miles. The remainder of its course, somewhat more than 100 miles, is mostly directed towards tbe south, until it joins the Chenaub at Trimo, below Jung. After the five rivers have united, tbey still flow between 40 and 50 miles until they fall into the Indus at Mittun Cote. The natives call the united river Chenaub, but in the other countries of India it is known hy the name of Punjund. All the rivers of the Panjab are in general navigable up to tbe place where they issue from the mountains, and the Indus itself to Attock, hut above that placo tbere is a whirlpool which cannot be passed hy boats.

The northern portion of tho plain of the Indus, the Panjab, or country of tho five rivers, extends from the lower ranges of tbe Himalaya mountains to tbe confluence of the Chenaub with tbe Indus, between 34° and 29° N. lat., and has the form of an isosceles triangle, whose sbortest line, or base, which is about 450 miles in length, lies along the Himalaya, and the equal sides, each about 600 miles, unite at the confluence of the Indus and Chenauh. Its surface may be on an average about 1000 feet above the sea; tbe Ravee at Lahore is 900 feet above it, and 100 feet bigher than tbe Ganges at Delhi. This immense tract of country varies considerably in soil and surface. It contains very fertile and very sterile tracts. Perbaps not moro than one-fourtb of its surface is under cultivation. Tbe country along the foot of tbe Himalaya range, and to a distance of ahout 100 miles from it, has an undulating surface; it is well supplied with water, and has the advantage of more abundant rains, and of a plentiful irrigation. It is well cultivated, and contains a greater portion of cultivated land than the remainder. The Julinder Doab, or country between the Sutlej and Beas, is very populous, and so likewise is the Barri Doab, between the Beas and Ravee as far as Amritsir. But in the Richna and Chinut Doab, hetween the Ravee, Chenauh, and Jbilum, tbe waste lands are more extensive. The remainder of tbe three last-mentioned doabs, or the country west of a line drawn from Hurree at the confluence of the Sutlej and Beas, through Lahore, and hence to Pindee Daden Khan, bas a much smaller portion of cultivated land. It is only found along the rivers to a distance of 5 or 15 miles. This narrow tract is level, and not much elevated above the surface of the rivers, so that it is either inundated when the rivers are swollen, or may easily be irrigated. The villages are commonly built at tho place where the inundation ceases, or the farthest edge of tbe cultivated ground. Those parts of the country which are beyond the reach of irrigation and inundation are considerably more elevated, and tbeir surface towards the Indus is generally covered witb low sand-hills; but hetween the Chenaub and Gbarra it is level, and tho soil is a hard loam. These tracts are not cultivated, and serve only as pasture-ground during and after the rainy season. The soil is extremely dry, and water can only he found at a depth of between 50 and 100 feet, and it is often salt. The cultivated tracts along the rivers are of great fertility. Rice is the principal object of agriculture all over tbe Panjab, hut wheat is also raised in sufficient quantity for the consumption. Other kinds of grain, as javary, gram, and several kinds of legumes, are imported. The sugar-cane is cultivated with great care, and much sugar is made. Wine and different kinds of fruits are produced in many places. The date-tree gives very good fruit south of Lahore. Other fruits are mangoes, guavas, and jamhu, and also those of Europe, as peaches, apricots, figs, pomegranates, quinces, oranges, lemons, almonds, and apples. There is a good hreed of horses in the tracts between the Indus and Jhilum, and there are also good and strong mules reared. Cattle are very numerous, though commonly of small size. Melons constitute the principal food of the lower classes.

We are very imperfectly acquainted with the climate of the Panjab, no series of meteorological observations having yet been made there. In Lahore the maximum of beat in July was 102°, and tbe minimum in January 24°. In Multan it seems to rise still higher; at other places even to 110°. The highest degree of heat is generally accompanied by violent nortb-western winds or tornados, which sometimes occur several days successively, but do not last more than an bour. Rain seems to fall all tbe year round, but not in equal proportions: in July a greater quantity falls than in other months.

The country south of the Panjab is occupied by the great sandy desert of Hindustan, wbicb extends southward to the Aravulli range and the salt-morass of the Runn. Its western border approaches the banks of the Indus, from whicb it is only divided by a fertile tract of land, from 10 to 15 miles in width. But as the Indus is almost always divided into several channels in this part of its course, of which some penetrate farther into tbe country east of it, the cultivated tracts extend in some places to 20 miles and more from its principal channel. This country resembles in fertility and productions tbe cultivated tracts in the soutbern Panjab, hut its seasons seem to he more regular: several months pass without rain, and in others the rains are more abundant.

The Desert of Sinde, or the Thurr, which on the north-east is connected with the sterile country which separates tbe plain of the Ganges from that of the Indus, does not present so dreary an aspect as the Sahara or the deserts of Western Asia. Its surface is covered with ridges of sand-hills, generally extending from soutb-west to north-east. In some places these hills, called *tibas*, are overgrown with coarse grass or low bushes, but tbey cbiefly consist of loose sand witbout any vegetation on it. Even on tbose tibas where grass and bushes grow, this scanty vegetation lasts only for two montbs, and the remainder of the year their surface is bare, and exposed to great changes from the winds. Between these ridges occur some lower tracts, whicb have a bard, loamy, or stony soil, and on these the vegetation lasts much longer. They are however generally of very small extent, and rarely contain a tract whicb can be cultivated; yet tbey are used as pasture-ground for camels and sheep, and for a small race of cattle, tbe only domestic animals which are kept here. Tbese small oases, called *dehris*, are not numerous in the neighbourhood of the Indus, but they increase in number and extent as wo approach the Aravulli range. In the middle of the desert is tbe more extensive oasis of Jessulmer, and along the Aravulli mountains are the still larger oases of Bikanair, Nagore, Jboudpoor, and Sirohi, which contain a considerable extent of cultivated land. Their principal agricultural products aro bajery and javary. A little cotton is raised. No fruit-trees grow, but melons are abundant. Irrigation from wells is impossiblo; soon after the rains, water is found near tbe surface, but at all other seasons only at a depth of 180 feet or even more. In some places it occurs only at tbe depth of 480 feet. A small quantity of rain falls during the south-west monsoon, but sometimes tbere is none. The daily variations of heat aro very great in winter: at two o'clock the thermometer rises to 75°, but at sunrise it is as low as 30°, and tbe water of some lakes is covered with ice. In summer the heat is oppressive.

The desert of Sinde may be considered as extending over the greater part of the delta of the Indus. All the eastern part of the delta resembles the desert in sterility of soil, though its surface is a perfect level, and so low that it is frequently inundated to a great extent. But the water of the Indus does not carry down such fertilizing soil as that of the Ganges. Though the inundated country is covered with grass after the inundation ceases, its soil is not adapted to the production of corn, and it offers only pasture-ground for the numerous herds of cattle, and especially buffaloes, which, as well as their herdsmen, are continually moving from one place to another. Such is the condition of the whole country east of the Sata branch of the Indus, with the exception of a narrow tract along the banks of the river where the fields can be irrigated. A great part of the interior between the Fulaili and Pinyari branches is covered by a salt marsh. The best part of the delta lies between the Sata branch and the Buggaur, where a considerable portion of the country is cultivated and produces rich crops; yet it does not extend over more than one-fourth of its surface. The cultivated lands do not reach the shores of the sea, being separated from them by a broad belt of country covered with bushes and entirely unproductive. The navigation along the delta is very dangerous. The bottom of the sea slopes very regularly from the shore, and at a distance of one mile and a balf from it the sea is only from 12 to 15 feet deep. Farther from the shore are numerous sandbanks, against which the water when agitated by heavy storms breaks with great violence. The spring-tides rise 9 feet in the mouths of the Indus. In the river the tide ascends only 75 miles, and is not perceptible at Tatta. Besides rice, which is the principal object of cultivation, the other dry grains of Hindustan are raised. There are also considerable plantations of sugar-cane; but fruit-trees, except dates, are rare: and timber is imported from the coast of Malabar. Besides cattle, buffaloes, and sheep, the extensive pastures support numerous horses and camels, both of good breeds, though the horses are small. Only a few showers of rain fall during the year, and sometimes none at all. The rising of the river is only caused by the melting of the snow in the Himalaya, and by the rains which fall along its southern declivity. It begins at the end of April, increases up to July, and in September the river returns to its usual bed. The heat is great all the year round. In March the thermometer has been observed to rise to 90°; but the climate is considered healthy.

The plain of the Indus probably does not contain one-tenth of the population of that of the Ganges; and the number of considerable towns is very small. The most populous portion is the Panjab. Its present capital, Amritsir, which has a population of 100,000 souls, is situated in a fertile country, between the Beas and Ravee, and carries on a considerable trade with Cashmere and Tibet. Lahore on the Ravee has 80,000 inhabitants, but its commerce is not so great as that of Amritsir. Mooltan on the Chenaub has 60,000 inhabitants, and considerable manufactures of silk and cotton. These fabrics go to other parts of India, and to Cabul and Persia. The commerce of this place is considerable. In the southern part of the plain of the Indus is Shikarpoor, 32 miles from the banks of the river to the west, near 28° N. lat., a town with an extensive commerce, being situated not far from one of the most frequented roads which leads from the plain of the Indus to the table-land of Persia. Hyderabad on the Indus, the capital of Sinde, contains 20,000 inhabitants; Tatta contains 15,000, and Curachee about the same number. The last-mentioned town, which lies west of the most western arm of the river, has a good harbour, and, like Tatta, carries on a considerable trade. In the Thurr, or desert, are several large towns, as Jessulmer, with 20,000 inhabitants; Jhoudpoor, the capital of Marwar, with 60,000; Palli, a commercial town, with 50,000; Mairta, with 20,000; and Nagore, with 40,000 inhabitants.

The Panjab is subject to Runjit Singh, the great chief of the Seiks, whose dominions extend likewise over the whole of the Himalaya range which lies north of the Sutlej river, including Cashmere. Along the southern banks of the Gharra is Daoudpotra, which is subject to an independent Afghan chief or khan, be resides in Bhawulpoor on the Gharra. The southern portion of the plain of the Indus is possessed by the Amirs or Emirs, the descendents of a chief of Beloochistan, who conquered this country towards the end of the last century; their country is called Sinde. The desert is divided between several Rajpoot princes, who are protected by the East India Company. The principal are the rajas of Bikanir, Marwar, Jessulmer, and Sirohi. Along the northern banks of the Runn lies the small and isolated country of Parkur, which has an independent raja.

People of Hindustan.—The population of Hindustan amounts, according to a probable estimate, to between 110,000,000 and 120,000,000. More than 100,000,000 may be considered as aborigines; for though it is supposed that the Hindus came from another country into Hindustan, this supposition rests on a very slender foundation. The circumstance of their being nearly exclusively in possession of all the districts which are adapted to agricultural purposes renders it very probable that they were the first inhabitants who introduced agriculture into this country.

The aboriginal tribes, besides the Hindus, who are spoken of in a subsequent part of this article, are at present only found in the mountainous parts of the country, where they live chiefly on the produce of the chase and their cattle, though they also cultivate some kinds of grain in the more level parts of the districts occupied by them. Many of them consist of a comparatively small number of families. In the Nilgherry mountains alone five small aboriginal tribes exist even now, the Erular, the Kurumbar, the Gohata, the Buddagur, and the Tudas, and many others are found in the Ghauts. We shall only mention those which occupy a considerable extent of country. These larger tribes are dispersed over the countries which extend on the east between the river Godavery and the plain of the Ganges, and on the west enclose the valleys of the Tapty and Nerbudda. The most widely dispersed of these tribes are the Gonds or Goands. They occupy the whole of the mountains extending from the Circars in a north-western direction over the higher branches of the Mahanuddy river to the table-land of Omercuntuc, which is in their possession, and west of it to the sources of the Tapty and Whurdha. In this immense tract of country they have only been obliged to leave entirely the plain of Ruttunpoor, which extends from that town southward to Konkair, and which is inhabited by Hindus. The Gonds are in a very low state of civilization compared with the Hindus; they live in a state of independence of the governments whose territories they inhabit, and rarely permit foreigners to traverse their country. Their country, as already observed, is called Gondwarra or Gondwana, by which name however at present that part only of their country is generally understood which lies about the table-land of Omercuntuc. The western neighbours of the Gonds are the Bhils, or Bhilla, who occupy the northern Ghauts and the Vindhya range, together with the mountain-region connecting the last-mentioned chain with the Aravulli mountains. Southward they extend to Poonah, and they are also in possession of the northern portion of the Western Ghauts as far south as the parallel of Damaun. They are not more advanced in civilization than the Gonds, though they are more intermixed with Hindus, and less independent of their masters. The neighbours of the Bhils, the Coulies and Ramusis, are dispersed over a comparatively small tract of country. The Coulies occupy the Western Ghauts south of the Bhils, and as far as Bombay, and even farther. They enjoy no independence, are a laborious people, and at Bombay and other places serve as labourers, and especially as porters. Hence porters in Hindustan are commonly called Coulies by Europeans. The Ramusis are dispersed over the Western Ghauts, south of the Coulies, and even partly over the table-land of the Deccan as far as Bejapoor; they are more advanced in civilization, and partly agriculturists. Of the smaller tribes we shall only mention the Puharrees, who inhabit the hills of Rajamahal, and the Katti and Coalies on the peninsula of Gujerat. The Katti, from whom that country has also obtained the name of Kattiwarra, are settled in the mountains which extend over the north-east of the peninsula, and the Coalies in those along the southern coast above Diu. Both tribes are little known, and seem to be in a low state of civilization.

The foreigners settled in Hindustan are partly Asiatics and partly Europeans. The Asiatics have come both by sea and by land. To the former class belong the Arabs, who are very numerous on the coast of Malabar, a circumstance which shows that their commerce with that coast must date from a very early period. There are also some Syrian Christians (Suriani) and Jews settled on the same coast. Some Parsees, or Guebres, are dispersed in the cities on the coast between Bombay and Surat. The Asiatics who entered India by land are chiefly settled in the plains of the Ganges and Indus. They came to these countries with the conquerors, who at several epochs have established their empires here. They are mostly Afghans, and commonly called Patans. Their number is considerable and said to amount to ten millions. But many, if not the greater part of them, are of Hindu origin, as the Mohamedans used to buy children from their parents in times of great dearth for the purpose of educating them in their own creed. In Sinde, and especially in the delta of the Indus, there are many families which emigrated to that country from Beloochistan with the family of the Amirs.

The Europeans in Hindustan are chiefly descendants of the Portuguese, who being rather conquerors than merchants, established themselves permanently in the places where they settled. But they are only numerous along the western coast, where their whole population is said to be two millions, an estimate which however seems exaggerated. Next to the Portuguese the British are the most numerous, but though they are at present in possession of nearly one half of the country, and dictate to more than three-fourths of it, their number is stated not to exceed 60,000.

For statistical details relating to Hindustan see EAST INDIA COMPANY. See also BOMBAY, CALCUTTA, &c.

Antient India as known to the Western Nations.—Commerce between India and the western nations of Asia appears to have been carried on from the earliest historical times. The spicery, which the company of Ishmaelites mentioned in *Genesis* (xxxvii. 25) were carrying into Egypt, must in all probability have been the produce of India; and in the 30th chapter of *Exodus*, where an enumeration is made of various spices and perfumes, cinnamon and cassia are expressly mentioned, which must have come from India or the islands in the Indian Archipelago. It has been thought by many that the Egyptians must have used Indian spices in embalming their dead; and Diodorus Siculus says (i. 91) that cinnamon was employed by the Egyptians for that purpose. This trade appears to have been carried on by means of the Arabs, who brought the produce of India from the modern Sinde or the Malabar coast to Hadramaut in the south-western part of Arabia, or to Gerra on the Persian Gulf, from which places it was carried by means of caravans to Petra, where it was purchased by Phœnician merchants. A great quantity of Indian articles was also brought from the Persian Gulf up the Euphrates as far as Circesium or Thapsacus, and thence carried across the Syrian desert into Phœnicia. Europe was thus supplied with the produce of India entirely by means of the Phœnicians; but we cannot assent to the opinion of Robertson (*Historical Disquisition on India*) that Phœnician ships sailed to India; for there is no reason for believing that the Phœnicians had any harbours at the head of the Red Sea, as Robertson supposes, but, on the contrary, the Idumæans remained independent till the time of David and Solomon; and in the 27th chapter of *Ezekiel*, which contains a list of the nations that traded with Tyre, we can discover none of an Indian origin; but the names of the Arabian tribes are specified which supplied the Phœnicians with the products of India (v. 19, 22).

The conquest of Idumæa by David gave the Jews possession of the harbour of Ezion-geber on the Red Sea, from which ships sailed to Ophir, bringing 'gold and silver, ivory, apes, and peacocks.' (1 *Kings*, ii. 28, x. 11, 22.) Considerable variety of opinion prevails concerning the situation of Ophir [ARABIA, vol. ii., p. 214); but we are inclined to consider it as an emporium of the African and Indian trade in Arabia. The Arabian merchants procured the gold from Africa, and the ivory, apes, and peacocks from India. The Hebrew words in this passage appear to be derived from the Sanskrit (see Gesenius' *Hebrew Lexicon*, under קוֹף, תֻּכִּיִּים, שֶׁנְהַבִּים). In the troubles which followed the death of Solomon the trade with Ophir was probably neglected; and till the foundation of Alexandria the trade with India was carried on by the Arabs in the way already mentioned.

The produce of India was also imported into Greece by the Phœnicians in very early times. Many of the Greek names of the Indian articles are evidently derived from the Sanskrit. Thus the Greek word for pepper, *pepperi* (πίπερι), comes from the Sanskrit pippalî; the Greek word for emerald is *smaragdo-s* or *maragdo-s* (σμάραγδο-ς or μάραγδο-ς), from the Sanskrit *marakata*. The *bussinê sindôn* (βυσσίνη σινδὼν), 'fine linen' or 'muslin,' mentioned by Herodotus (ii. 86; vii. 181), seems to be derived from *Sindhu*, the Sanskrit name of the river Indus. The produce of the cotton plant, called in Greek *karpaso-s* (κάρπασο-ς), comes from the Sanskrit *karpâsa;* this word we also find in Hebrew (*Esther*, i. 6) *karpās* (כַּרְפַּס); and it was probably introduced into Greece together with the commodity by the Phœnicians. That this was the case with the word cinnamon, Herodotus (iii. 111) informs us. The word cinnamon (Greek, *kinnamômon* or *kinnamon*, κιννάμωμον, κίνναμον; Hebrew, *kinnamon*, קִנָּמוֹן) is not found in Sanskrit; the Sanskrit word for cinnamon is *gudha tvach*, 'sweet bark.' The word cinnamon appears to be derived from the Singalese *kakyn nama*, 'sweet wood,' of which the Sanskrit is probably a translation. We are not however surprised at missing the Sanskrit word for this article, since the languages in southern India have no affinity with the Sanskrit. Tin also appears to have been from early times an article of exportation from India; the Greek word for tin, *kassitero-s* (κασσίτερο-ς), which occurs even in Homer, is evidently the same as the Sanskrit *kastîra*.

It is usually considered that the Greeks obtained their tin, by means of the Phœnicians, from the Scilly Islands or Cornwall; but there is no direct proof of this; and it appears probable, from the Sanskrit derivation of the word, that the Greeks originally obtained their tin from India. The islands Cassiterides however, the position of which was unknown to Herodotus (iii. 115), are supposed to be the Scilly Islands or the peninsula of Cornwall, though their position is not very exactly defined by Strabo (iii. 175). Still there can be little doubt that the 'Cassiterides' to which the Phœnicians from Gades (Cadiz) went for tin, and the Romans afterwards traded for the same commodity, were on the south-western angle of Great Britain.

The western nations of Asia appear to have had no connection with India, except in the way of commerce, till the time of Darius Hystaspes, B.C. 521. The tales which Diodorus relates respecting the invasion of India by Sesostris and Semiramis (i., p. 50; ii. 103, ed. Rhodoman) cannot be estimated as historical facts. The same remark may perhaps apply to the alliance which, according to Xenophon in his 'Cyropædeia' (vi. 2, 1), Cyrus made with a king of the Indians. But in the reign of Darius Hystaspes, Herodotus informs us (iv. 44) that Scylax of Caryanda was sent by the Persians to explore the course of the Indus; that he set out from the city Caspatyrus and the Pactyican country (Pakali?), in the northern part of India; that he sailed down the Indus till he arrived at its mouth, and thence across the Indian sea to the Arabian Gulf, and that this voyage occupied 30 months. Darius also, it is said, subdued the Indians, and formed them into a satrapy, the tribute of which amounted to 360 talents in gold. (Herodot., iii. 94.) The extent of the Persian dominions in India cannot be ascertained with any certainty. The Persians appear to have included under the name of Indians many tribes dwelling to the west of the Indus; it seems doubtful whether they ever had any dominion east of the Indus; and it is nearly certain that their authority did not extend beyond the Panjab.

The knowledge which the Greeks possessed respecting India, previous to the time of Alexander, was derived from the Persians. We do not find the name of Indian or Hindu in antient Sanskrit works; but the country east of the Indus has been known under this name by the western nations of Asia from the earliest times. In the Zend and Pehlvi languages it is called *Heando*, and in the Hebrew *Hoddu* (הֹדּוּ, *Esther*, i. 1), which is evidently the same as the *Hend* of the Persian and Arabic geographers. The first mention of the Indians in a Greek author is in the 'Supplices' of Æschylus (l. 287); but no Greek writer gives us any information concerning them till the time of Herodotus. We may collect from the account of Herodotus a description of three distinct tribes of Indians: one dwelling in the north near the city Caspatyrus and the Pactyican territory, resembling the Bactrians in their customs and manners of life. The second tribe or tribes evidently did not live under Brâhmanical law; some of them dwelt in the marshes formed by the Indus, and subsisted by fishing; others, called Padæi, with whom we may probably class the Calantiæ, or Calatiæ, were wild and barbarous tribes, such as exist at present in the mountains of the Deccan. The third class, who are described as subsisting on the spontaneous produce of the earth and never killing any living thing, are more likely to have been genuine Hindus. (Herodot., iii. 98-105.) Herodotus had heard of some of the natural productions of Hindustan, such as the cotton plant and the bamboo; but his knowledge was very limited.

Ctesias, who lived at the court of Artaxerxes Mnemon for many years, has given us a fuller account than Herodotus of the manners and customs of the Indians and of the natural productions of the country. He had heard of the war elephants, and describes the parrot, the monkey, the cochineal, &c.

The expedition of Alexander into India (ALEXANDER, vol. i., p. 300), B.C. 326, first gave the Greeks a correct idea of the western parts of India. Alexander did not advance farther east than the Hyphasis; but he followed the course of the Indus to the ocean, and afterwards sent Nearchus to explore the coast of the Indian Ocean as far as the Persian Gulf. The Panjab was inhabited at the time of Alexander's invasion by many independent nations, who were as distinguished for their courage as their descendants the Rajpoots. Though the Macedonians did not penetrate farther east than the Hyphasis, report reached them of the Prasii, a powerful people on the banks of the Ganges, whose king was prepared to resist Alexander with an immense army. After the death of Alexander, Seleucus made war against Sandracottus, king of the Prasii, and was the first Greek who advanced as far as the Ganges. This Sandracottus, called Sandracoptus by Athenæus (*Epit.*, i. 32), is probably the same as the Chandragupta of the Hindus. (See Sir W. Jones in *Asiatic Researches*, vol. iv., p. 11; Wilson's *Theatre of the Hindus*, vol. ii., pp. 127-150, 2nd ed.; Schlegel's *Indische Bibliothek*, vol. i., p. 246.) Sandracottus is represented as king of the Gangaridæ and Prasii, who are probably the same people; Gangaridæ being the name given to them by the Greeks, and signifying merely the people in the neighbourhood of the Ganges; and Prasii being the Hindu name, the same as the Prachi (*i. e.* 'eastern country') of Sanskrit writers. Seleucus remained only a short time in the country of the Prasii; but his expedition was the means of giving the Greeks a more correct knowledge of the eastern parts of India than they had hitherto possessed; since Megasthenes and afterwards Daimachus resided for many years as ambassadors of the Syrian monarchs at Palibothra* (Sanskrit, Pataliputra), the capital of the Prasii. From the work which Megasthenes wrote on India later writers, even in the time of the Roman empire, such as Strabo and Arrian, appear to have derived their principal knowledge of the country. The Seleucidæ probably lost all influence at Palibothra after the death of Seleucus Nicator, B.C. 281; though we have a brief notice in Polybius (xi. p. 652, ed. Casaubon) of an expedition which Antiochus the Great made into India, and of a treaty which he concluded with a king Sophagasenus (Sanskrit, Subhagasêna? *i. e.* 'the leader of a fortunate army'), whereby the Indian king was bound to supply him with a certain number of war-elephants. The Greek kingdom of Bactria, which was founded by Theodotus, or Diodotus, a lieutenant of the Syrian monarchs, and which lasted about 120 years (B.C. 256—134), appears to have comprised a considerable part of northern India.

After the foundation of Alexandria, the Indian trade was almost entirely carried on by the merchants of that city; but few ships appear to have sailed from Alexandria to India till the discovery of the monsoons by Hippalus; and the Arabians supplied Alexandria, as they had formerly done the Phœnicians, with the produce of India. The monsoons must have become known to European navigators about the middle of the first century of our æra, since they are not mentioned by Strabo, but in the time of Pliny were well known. Pliny has given us (*Nat. Hist.*, vi. 23) an interesting account of the trade between India and Alexandria, as it existed in his own time. We learn from him that the ships of the Alexandrine merchants set sail from Berenice, a port of the Red Sea, and arrived in about 30 days at Ocelis, or Cane, in Arabia. Thence they sailed by the wind Hippalus (south-west monsoon) in 40 days to Muziris (Mangalore), the first emporium in India, which was not much frequented on account of the pirates in the neighbourhood. The port at which the ships usually stayed was that of Barace (at the mouth of the Nelisuram river?). After remaining in India till the beginning of December or January, they sailed back to the Red Sea with the wind Vulturnus (north-east monsoon); and after entering the Red Sea, met with the wind Africus or Auster (south or south-west wind), and thus arrived at Berenice in less than a twelvemonth from the time they set out. The same author informs us that the Indian articles were carried from Berenice to Koptos, a distance of 258 Roman miles, on camels; and that the different halting-places were determined by the wells. From Koptos, which was united to the Nile by a canal, the goods were conveyed down the river to Alexandria.

We have another account of the Indian trade written by Arrian, who lived in all probability in the first century of the Christian æra, and certainly not later than the second. Arrian had been to India himself, and describes, in a small Greek treatise entitled 'The Periplus of the Erythrean Sea,' the coast from the Red Sea to the western parts of India; and also gives a list of the most important exports and imports. According to his account, the two principal ports in India were Barygaza on the north-western, and Barace or Nelcynda on the south-western coast. To Barygaza (the modern Baroach on the river Nerbudda), goods were brought from Ozene (Oujein), Plithana (Pultaneh), and Tagara (Deoghur). But Barace or Nelcynda seems, from the account of Pliny and Arrian, to have been the principal emporium of the Indian trade. The Roman ships appear to have seldom sailed beyond this point; and the produce of the countries farther east was brought to Barace by the native merchants.

The knowledge which the Romans possessed of India beyond Cape Comorin was exceedingly vague and defective. Strabo describes the Ganges as flowing into the sea by one mouth; and though Pliny gives a long list of Indian nations which had not previously been mentioned by any Greek or Roman writer, we have no satisfactory account of any part of India except the description of the western coast by Arrian. Ptolemy, who lived about 100 years later than Pliny, gives us the names of many towns on the Coromandel coast and the Bay of Bengal, and is the earliest writer who attempts to describe the countries east of the Ganges; but there is great difficulty in determining the position of any of the places enumerated by him, in consequence of the great error he made in the form of the peninsula, which he has made to stretch in its length from west to east instead of from north to south, a mistake the more extraordinary since all preceding writers on India with whom we are acquainted had given the general shape of the peninsula with tolerable accuracy. In addition to which, Ptolemy appears to have derived his information from the Alexandrine merchants, who only sailed to the Malabar coast, and could not therefore have any accurate knowledge of the eastern parts of India, and still less of the countries beyond the Ganges. The Aurea Chersonesus of Ptolemy represents the peninsula of Malacca, on which the port of Zaba was situated, probably in the neighbourhood of Singapore. The Sinus Magnus is considered the same as the Gulf of Siam, and the Thinæ Metropolis is probably Canton. [ASIA, vol. ii., p. 456.] The Romans never extended their conquests as far as India, nor visited the country except for the purposes of commerce. But the increase of the trade between Alexandria and India seems to have produced in the Indian princes a desire to obtain some further information concerning the western nations.

* The position of Palibothra has been much disputed. Robertson places it at Allahabad; but the opinion of Major Rennell, who places it in the neighbourhood of Patna, near the confluence of the Ganges and the Sone, appears more correct. Strabo says (xvi., vol. 6, p. 79, ed. Siebenkees) that it is at the confluence of the Ganges with another river, but he does not mention the name. Arrian (*Ind.* c. 10) says that it is at the confluence of the Ganges with the Erannoboas; this Sir W. Jones remarks is evidently the Sanskrit Hiranyavâha. The Amara Kosha, an antient Sanskrit Dictionary, gives this river as synonymous with Sone. (See Schlegel's *Réflexions sur l'Etude des Langues Asiatiques*, p. 100; *Indische Bibliothek*, v. ii., p. 394; Wilson's *Theatre of the Hindus*, ii., p. 135, 2nd ed.)

We read of embassies to Augustus Cæsar, sent by Pandion and Porus, and also of an embassy from the island of Ceylon to the Emperor Claudius. Bohlen, in his work on the Indians (i. 70), doubts whether these embassies were sent; but as they are both mentioned by contemporary writers, the former by Strabo, and the latter by Pliny, we can hardly question the truth of their statements.

We may form some idea of the magnitude of the Indian trade under the emperors by the account of Pliny (vi. 23), who informs us that the Roman world was drained every year of at least fifty millions of sesterces (upwards of 400,000*l.*) for the purchase of Indian commodities. The profit upon this trade must have been immense, if we are to believe the statement of Pliny that Indian articles were sold at Rome at 100 per cent. above their cost price. The articles imported by the Alexandrian merchants were chiefly precious stones, spices and perfumes, and silk. It has usually been considered that the last article was imported into India from China; but there are strong reasons for believing that the silkworm has been reared in India from very early times. Mr. Colebrooke, in his 'Essay on Hindu Classes' (*Miscellaneous Essays*, vol. ii., p. 185), informs us that the class of silk twisters and feeders of silkworms is mentioned in an antient Sanskrit work; in addition to which it may be remarked that silk is known throughout the Indian archipelago by its Sanskrit name, *Sûtra.* (Marsden's *Malay Dictionary*, under *sûtra.*) Those who wish for further information on the articles of commerce both imported and exported by the Alexandrian merchants, may consult with advantage the Appendix to Dr. Vincent's 'Periplus of the Erythrean Sea;' in which he has given an alphabetical list, accompanied with many explanations, of the exports and imports of the Indian trade, which are enumerated in the Digest, and in Arrian's 'Periplus of the Erythrean Sea.'

We have no further account of the trade between Alexandria and India till the time of the Emperor Justinian, during whose reign an Alexandrine merchant of the name of Cosmas, who had made several voyages to India, but who afterwards turned monk, wrote a work, still extant, entitled 'Christian Topography,' in which he gives us several particulars respecting the Indian trade. But his knowledge of India is not more extensive than that of Arrian, for the Alexandrine merchants continued only to visit the Malabar coast, to which the produce of the country farther east was brought by native merchants, as in the time of Arrian. Alexandria continued to supply the nations of Europe with Indian articles till the discovery of the passage round the Cape of Good Hope by Vasco de Gama in 1498. But the western nations of Asia were principally supplied by the merchants of Basra, which was founded by the caliph Omar near the mouth of the Euphrates, and which soon became one of the most flourishing commercial cities in the East. In addition to which, it must be recollected that a land trade, conducted by means of caravans which passed through the central countries of Asia, existed from very early times between India and the western nations of Asia.

History.—First period: From the earliest times to the Mohammedan Conquest.—The materials for the history of this period are very few and unsatisfactory. The only antient history written in the Sanskrit language which the researches of modern scholars have been able to obtain is a chronicle of the kings of Cashmere, entitled 'Raja Taringini,' of which an abstract was given by Abulfazl in the 'Ayin-i-Akbery.' The original Sanskrit was obtained for the first time by English scholars in the present century, and was published at Calcutta in the year 1835: an interesting account of the work is given by Professor Wilson in the fifteenth volume of the 'Asiatic Researches.' But though this chronicle throws considerable light upon the early history of Cashmere, it gives us little information respecting other parts of Hindustan. The existence of this chronicle is sufficient to disprove the assertion which some persons have made, that the Hindus possessed no native history prior to the Mohammedan conquest; and it may be hoped that similar works may be recovered by the researches of modern scholars. We may also expect to obtain further information by a more diligent examination of the various inscriptions which exist on public buildings in all parts of Hindustan, though the majority of such inscriptions relate to a period subsequent to the Mohammedan conquest. The Brâhmans profess to give a history of the antient kingdoms of Hindustan, with the names of the monarchs who successively reigned over them, and the principal events of their reigns. But their accounts are derived from the legendary tales of the Puranas, a class of compositions very similar to the Greek theogonies; and although these, and especially the two great epic poems, the 'Ramayana' and 'Mahabbarata,' are exceedingly valuable in an historical point of view for the information they give us respecting the religion, civilization, and customs of the antient Hindus, they cannot be regarded as authorities for historical events.

The invariable tradition of the Hindus points to the northern part of Hindustan as the original abode of their race, and of the Brahmanical faith and laws. It appears probable, both from the tradition of the Hindus and from the similarity of the Sanskrit to the Zend, Greek, and Latin languages, that the nation from which the genuine Hindus are descended must at some period have inhabited the central plains of Asia, from which they emigrated into the northern part of Hindustan. Heeren and other writers have supposed that the Brahmans, and perhaps the Kshatriyas and Vaisyas, were a race of northern conquerors, who subdued the Sudras, the original inhabitants of the country. But whatever opinion may be entertained respecting the origin of the Hindus, it is evident that the Hindus never regarded the southern part of the peninsula as forming part of *Aryavarta*, or 'holy land,' the name of the country inhabited by genuine Hindus. Aryavarta was bounded on the north by the Himalaya, and on the south by the Vindhya mountains (*Manu*, vi., 21-24); the boundaries on the east and west cannot be so easily ascertained. In this country, and especially in the eastern part, there existed great and powerful empires at least a thousand years before the Christian æra (the probable date of the Ramayana and Mahabbarata), which had made great progress in knowledge, civilization, and the fine arts, and of which the antient literature of the Sanskrit language is an imperishable memorial. According to Hindu tradition, two empires only existed in the most antient times, of which the capitals were Ayodhya, or Oude, and Pratisbthana, or Vitora. The kings of these cities, who are respectively denominated children of the Sun and of the Moon, are supposed to have been the lineal descendants of Satyavrata, the seventh Manu, during whose life all living creatures, with the exception of himself and his family, were destroyed by a general deluge. Another kingdom was afterwards established at Magadha, or Bahar, by Jarasandha, appointed governor of the province by a sovereign of the Lunar race. A list of these kings is given by Sir William Jones in his 'Essay on the Chronology of the Hindus.' (*As. Res.*, ii., pp. 111-146, 8vo. ed.)

The kings of Ayodhya appear to have conquered the Deccan, and to have introduced the Brahmanical faith and laws into the southern part of the peninsula. Such at least appears to be the meaning of the Ramayana, according to which Rama, an incarnation of Vishnu, and the son of the king of Ayodhya, penetrates to the extremity of the peninsula, and conquers the giants of Lanka (Ceylon). This is in accordance with all the traditions of the peninsula, which recognise a period when the inhabitants were not Hindus. We have no means of ascertaining whether these conquests by the monarchs of Ayodhya were permanent, but we know that in the time of Arrian and Pliny the Brahmanical faith prevailed in the southern part of the peninsula, since all the principal places mentioned by these writers have Sanskrit names. We learn from tradition and from historical records extant in the Tamul language (Wilson's *Descriptive Catalogue of the Oriental MSS. collected by the late Lt.-Col. Mackenzie*, and Taylor's *Oriental Historical MSS. in the Tamil Language*, 2 vols. 4to., Madras, 1835) that three kingdoms acquired in early times great political importance in the southern part of the Deccan. These were named Pandya, Chola, and Chera, and are all said to have been founded by natives of Ayodhya, who colonized the Deccan with Hindus from the north. Pandya was the most powerful of these kingdoms: it was bounded on the north by the river Velar, on the west by the Ghauts, though in early times it extended as far as the Malabar coast, and on the south and east by the sea: its principal town was Madura. The antiquity of this kingdom is confirmed by Pliny, Arrian, and Ptolemy, who all mention Pandion as a king who reigned in the south of the peninsula. Chola was bounded on the south by the territories of Pandya, and did not extend farther north than the town of Pulicat; its western boundary is uncertain. The kingdom of Chera was of small extent: its northern limit was originally at Palini, near Dharapur: it was bounded on the east by Pandya and Chola, and on the west by the kingdom of Kerala, or Malabar, which extended along the western coast. This last kingdom was probably founded in later times, since, in the time of Arrian the Malabar coast is said to have belonged to the Pandya kings. The Brahmanical colonists appear to have settled principally in the southern parts of the Deccan: the native traditions represent the northern parts as inhabited by savage races till a much later period. This is in accordance with the accounts of the Greek writers. The names of the places on the upper part of the eastern and western coasts are not Sanskrit. The modern Concan is described both by Arrian and Pliny as the pirate coast; and the coast of the modern Orissa is said by Arrian to be inhabited by a savage race called Kirrhadæ, who appear to be identical with the Kiratas of Sanskrit writers, who are represented as a race of savage foresters.

The accounts of the Greeks who accompanied Alexander, and more particularly that of Megasthenes, give us, as we have already shown, some information respecting the northern part of Hindustan in the third and fourth centuries before the Christian æra. But hardly anything is known of the history of Hindustan from this period to the time of the Mohammedan conquest. There are only a very few historical events of which we can speak with any degree of certainty. After the overthrow of the Greek kingdom of Bactria by the Tartars, B.C. 126, the Tartars (called by the Greeks Scythians, and by the Hindus Sakas) overrun the greater part of the north-western provinces of Hindustan, which remained in their possession till the reign of Vicramaditya I., B.C. 56, who, after adding numerous provinces to his empire, drove the Tartars beyond the Indus. This sovereign, whose date is pretty well ascertained, since the years of the Samvat æra are counted from his reign, resided at Ayodhya and Canoj, and had dominion over almost the whole of northern Hindustan from Cashmere to the Ganges. He gave great encouragement to learning and the fine arts, and his name is still cherished by the Hindus as one of their greatest and wisest princes. He fell in a battle against Salivahana, raja of the Deccan. We also read of two other sovereigns of the same name, Vicramaditya II., A.D. 191, and Vicramaditya III., A.D. 441. The most interesting event in this period of Hindu history is the persecution of the Buddhists and their final expulsion from Hindustan. It is difficult to conceive the reasons that induced the Hindu sovereigns, after so long a period of toleration, to aid the Brahmans in this persecution; more especially as the Jains, a sect strikingly resembling the Buddhists, were tolerated in all parts of Hindustan. But this portion of Hindu history has already been discussed in another part of this work. [BUDDHA, vol. v., pp. 526-532.] During this period many of the islands of the Indian Archipelago were colonized both by Brahmans and Buddhists; for though the Brahmans were finally successful, yet at first they appear to have been overcome by the Buddhists in some parts of Hindustan, and to have been obliged to emigrate to foreign countries. (Crawford, in *Asiatic Res.*, vol. xiii., p. 154.) Sir Stamford Raffles, in his 'History of Java,' ii., pp. 1-65, describes the splendid remains of Hindu art which are still to be seen in that island; and a recent traveller in Borneo remarks that 'in the very inmost recesses of the mountains, as well as over the face of the country, the remains of temples and pagodas are to be seen similar to those found on the continent of India, bearing all the traits of Hindu mythology; and that in the country of Waaho, at least 400 miles from the coast, there are several of very superior workmanship, with all the emblematical figures so common in Hindu places of worship.' (Dalton, in *Asiatic Journal*, N.S., vol. vii., p. 153.)

Christianity is said to have been introduced into Hindustan in the first century; according to some accounts, by the Apostle Thomas; and, according to others, by the Apostle Bartholomew. But there is very little dependence to be placed upon these statements. The first Christians who settled in any number in Hindustan appear to have been Nestorians, who settled on the Malabar coast for the purposes of commerce. Nestorius lived in the middle of the fifth century; and in the sixth century we learn from Cosmas that Christian churches were established in the most important cities on the Malabar coast, and that the priests were ordained by the archbishop of Seleucia, and were subject to his jurisdiction. When Vasco de Gama arrived at Cochin, on the Malabar coast, he was surprised to find a great number of Christians, who inhabited the interior of Travancore and Malabar, and who had more than a hundred churches. But these Christians appear to have been the descendants of those Nestorians who emigrated to Hindustan in the fifth and sixth centuries, for there is no reason for believing that any Hindus were converted by their means to the Christian religion.

Second Period: History of the Mohammedan States.—Some Arabian historians pretend that part of Hindustan was conquered by the Mohammedans as early as the eighth century; but the earliest invasion of the country by the Mohammedans, of which we can speak with any degree of certainty, was made in the latter part of the tenth century by Sabuktaghin, a Tartar soldier, who had been proclaimed by the army monarch of Ghizni. He passed the Indus at least twice, laid waste the province of Lahore, and returned to Ghizni laden with plunder. But he made no permanent conquests. He died A.D. 997, and was succeeded by his son, the celebrated Sultan Mahmud, who is usually regarded as the first Mohammedan conqueror of Hindustan. The Mohammedan historians celebrate the twelve expeditions which he undertook against the Hindus, and extol the religious zeal which prompted him to destroy the idols and temples of the inhabitants. He died A.D. 1028, and was succeeded by his son Massud. Though Mahmud had conquered the northern part of Hindustan from the Indus to the Ganges, yet regular government had only been established in Lahore and the north-western provinces. Massud and his successors were unable to prosecute their conquests in the country, in consequence of the formidable enemies they possessed at home. Several Tartar tribes, denominated Seljukides, from the name of their leader, had been invited by Mahmud to settle in Khorasan. After his death they seized upon Bokhara and Samarcand, and threatened the destruction of the empire of Ghizni. In the year 1171 Yeasuddin, king of Gaur in Khorasan, conquered all the countries west of the Indus which were subject to the monarchs of Ghizni, and compelled the reigning sultan to take refuge in Lahore. Lahore was taken by Mohammed, brother of Yeasuddin, in 1184, and Khosrou II., the last monarch of the house of Sabuktaghin, was put to death.

The Hindus however received no benefit from this change of dynasty. In 1191 Mohammed marched farther east, and though he was at first defeated by the Hindu rajas, he finally conquered the greater part of the northern provinces. He appointed Kuttub, a favourite slave, governor of the newly-conquered provinces, who continued to prosecute the conquests of Mohammed; and in 1193 took Delhi, and made it the seat of government, whence he has frequently been called the founder of the Mohammedan empire in Hindustan. During the life of Mohammed, who succeeded his brother Yeasuddin, the northern provinces of Hindustan formed part of the empire of Ghizni; but after the assassination of Mohammed, in 1206, Kuttub became independent, and left his dominions to his son Aram, who succeeded to the throne in 1210. Aram was obliged to surrender the power to Altumsh, the son-in-law of Kuttub, a prince of great courage and vigour, who extended the Mohammedan conquests still farther. He died 1235. During this reign Genghis Khan conquered the greater part of Asia, but did not penetrate into Hindustan. But the Moguls were soon tempted by the riches and fertility of the country, and the successors of Altumsh were engaged in constant wars in order to repel their invasions. Mahmud II., who ascended the throne in 1244, and his successor Balin (1266), were two able princes, who frequently defeated the Moguls; but Kai-Kobad, the successor of Balin, was a weak prince, who was murdered in 1289. By his death the Gaurian dynasty ended, after having reigned for 117 years.

The dominion now passed into the hands of the Afghans. During the reign of Firoz II., who succeeded Kai-Kobad, the Mohammedans first undertook the conquest of the Deccan. Deoghir was taken by Alâ, the nephew of Firoz; but the entire subjection of the northern part of the Deccan was not effected till the following reign. Firoz II. was succeeded by Alâ, in 1295, who, though a cruel, was an able and powerful monarch. He defeated the Moguls, subdued the Rajpoots, and, by means of his general Kafoor, added the greater part of the Deccan to his dominions. But with his death in 1316 the prosperity of the Mohammedan empire in Hindustan rapidly declined. A succession of weak princes followed, during whose reigns many Hindu rajas in Bengal and the Deccan recovered their independence. The invasion of Timur (Tamerlane) in 1398 overturned the already tottering power of the monarchs of Delhi. Timur did not remain in Hindustan more than a few months; but after his departure the country became divided into a number of small independent states governed by Mohammedan chiefs, which were nominally subject to the emperor of Delhi. Confusion prevailed in every department of the government, till at length, in the reign of Ibrahim II., Baber, a descendant of Timur, invaded Hindustan, and put an end to the Afghan dynasty. In 1526 he took Delhi, and was the founder of the Tartar, or as it is more usually but erroneously called, the Mogul dynasty. He extended his dominions as far as the Ganges; and though constantly engaged in military expeditions, he found time to cultivate the arts of peace, and devoted his attention to whatever appeared calculated to promote the prosperity of his empire. The troubles of Humaiun's reign, who succeeded Baber in 1530, prevented him from attending to the internal organization of the empire; and it was not till the accession of Akbar in 1556 that the Tartar (or Mogul) dominion in Hindustan was placed upon a firm basis. During his reign the Hindus appear to have enjoyed greater prosperity than they had ever experienced since the invasion of the Mohammedans. Akbar was distinguished by a spirit of toleration and a love of justice; and the memory of his virtues still survives among the Hindu as well as the Mohammedan population of the country. An excellent political and statistical account of the Mogul empire was written during his reign by his vizir Abul Fazl. [AYEEN AKBERY.] Akbar died in 1605, and was succeeded by his son Selim, who took the title of Jehanghir, *i.e.* 'conqueror of the world.' His reign was troubled by foreign and intestine enemies. The Uzbeks obtained possession of Cabul; the king of Persia took Candabar; the Rajpoots again commenced their struggles for independence; the Afghans revolted in the north; and his son Shah Jehân rebelled against him. But notwithstanding these troubles, the country appears upon the whole to have enjoyed considerable prosperity; literature was extensively cultivated; many new cities were built, and the Hindu religion experienced even greater toleration than in the reign of Akbar. During the reign of Jehanghir, Sir Thomas Roe arrived at the court of Agra, and obtained from the emperor many advantageous grants to the East India Company. Jehanghir was succeeded in 1627 by Shah Jehân, during whose reign a great part of the Deccan, which had not been subdued by Kafoor, was conquered by his son Aurungzebe. The ingratitude which Shah Jehân had shown to his father he was destined to experience from his own sons. He was thrown into prison by Aurungzebe, in which he died at the age of 74, on the 21st January, 1666. He was succeeded by Aurungzebe, who had been proclaimed emperor in 1659. Aurungzebe was the last powerful sovereign that ruled over the Mogul empire of Hindustan. He took the cities of Hyderabad, Bejapore, and Golconda, and extended his dominions nearly to the limits of the Carnatic. During his reign the Mahrattas first rose into power, and rapidly extended their conquests over the greater part of the Deccan. They were frequently defeated in the plain by the troops of Aurungzebe; but all the efforts of this powerful prince were unable to subdue the country of these mountaineers. Sevajee, the founder of the Mahratta empire, died in 1682, and was succeeded by his son Sambajee, who was taken prisoner by Aurungzebe, and put to a cruel death in 1689. After the death of Aurungzebe in 1707, the Mogul dominion rapidly declined.

He was succeeded by Shah Alum, who died, after a short reign, in 1712. New enemies arose on every side. The Mahrattas extended their conquests in the south; the Rajpoots, who had never been entirely subdued by the Mogul princes, again asserted their independence; and the Sikhs, who first rose into power in the reign of Shah Alum, ravaged the provinces of Lahore and Delhi. The Sikhs now form a powerful nation in India, and occupy a great portion of the western provinces of the antient Mogul empire. Their origin and early progress belong to the religious history of the Hindus, of which an account is given in this article. The Mogul power was still further weakened by intestine commotions. Each of the four sons of Shah Alum contended for the throne, which was obtained after a severe struggle by the eldest brother Moez-eddin. He was dethroned at the end of a few months by his nephew Farrukhsir (1713), who was succeeded in 1720 by Mohammed Shah, a grandson of Shah Alum. During his reign the Moguls lost all real dominion in Hindustan. The Deccan became virtually independent of their authority under the viceroyalty of Nizam-al-Mulk, tho vizir of Mohammed; and a considerable portion of the northern provinces was wrested from them by the Rohillas (an Afghan race), who established themselves in that part of the country, which was afterwards known by the name of Rohilla-khand (Rohilcund). The sanguinary invasion of Nadir Shah in 1739, and tho massacre of the inhabitants of Delhi by his troops, tended still further to weaken the Mogul empire.

Mohammed was succeeded in 1747 by his son Ahmed Shah. During his reign, which lasted six years, the dissolution of the Mogul empire may be said to have taken place. The northern and north-western provinces were seized upon by the Afghans and the Sikhs, and the Rajpoots extended their dominions as far as Ajmeer. Ahmed Shah was dethroned in 1753 by Alamghir, a grandson of Moez-eddin. Alamghir was assassinated after a reign of seven years; and the nominal sovereignty devolved upon Shah Alum II., who, after undergoing many vicissitudes, at last became the pensioner of the East India Company, which succeeded to the power of the Mogul emperors.

Third Period: History of the European Conquests.—The Portuguese were the first nation of Europe that obtained any dominion in Hindustan. Vasco de Gama landed with three ships at Calicut on the Malabar coast, on the 20th of May, 1498. The Portuguese rapidly acquired extensive power in the country. By the possession of Malacca, which fell into their hands twenty-four years after the voyage of Gama, they commanded the trade of the Indian Archipelago; and by their numerous settlements along the Malabar coast, especially at Goa and Diu, they monopolized the commerce with Europe. In the beginning of the seventeenth century, the English, Dutch, and French began to make settlements along the coast; and the Portuguese lost their dominions almost as rapidly as they had acquired them.

The Dutch never acquired much political power in Hindustan; though at one time they carried on the greater part of the Indian trade. The French on the contrary obtained extensive possessions in the Deccan. Their principal settlement was at Pondicherry, of which they acquired possession in the latter part of the seventeenth century, and which soon became one of the most splendid European establishments in the country. But their power in the Deccan was principally owing to the wise and vigorous government of Dupleix in 1749. Under his administration the Northern Circars were occupied by the French, and the English power was almost destroyed. Dupleix was succeeded by Count de Lally, who was sent from France with a large fleet in 1756; but this expedition entirely failed; and Pondicherry was taken by the English in 1761. At present the French possessions consist only of Pondicherry, which was restored, and a fow other places.

The commencement and early progress of the political power of the British in Hindustan have already been described. [BENGAL.] An account of the British government, revenues, &c., together with a list of the British possessions, is given under EAST INDIA COMPANY

Languages.—The numerous languages spoken in Hindustan at the present time may be divided into two great classes; the one consisting of those languages which are derived from the Sanskrit, and which are spoken in the northern and central provinces; and the other comprising those languages which are unconnected with the Sanskrit, and which are spoken in the southern parts of the peninsula.

Languages derived from the Sanskrit.—The groundwork of these languages is altogether Sanskrit, such as that of the Italian or Spanish is Latin, with a comparatively small addition of words which cannot be traced to that source. They are not however derived immediately from the Sanskrit, but through the medium of the Prakrit, which is still more akin to the Sanskrit than the vernacular languages of Hindustan, and which became the modern language of the people when the Sanskrit ceased to be spoken. None of the dialects of the Prakrit are spoken at the present day; but several works, especially parts of dramatic poems, are preserved in these languages. It is therefore evident that a knowledge of Sanskrit is not alone sufficient for an accurate investigation of the history and structure of the modern languages spoken in the northern provinces, since these languages are immediately derived from the Prakrit, as the Prakrit was from the Sanskrit. An account of the Prakrit, and of the Pali, the sacred language of the Buddhists, which is also immediately derived from the Sanskrit, is given in another part of this work. [SANSKRIT LANGUAGE.]

The languages derived from the Sanskrit may be said in general terms to be spoken in the provinces which lie between the Himalaya and Vindhya Mountains; which, as has been already remarked, is the proper country of the Hindus. But this definition is not sufficiently accurate; since the Sanskrit appears to have been also spoken to a considerable extent in the northern part of the Deccan. Lassen, who has investigated this subject with great accuracy, remarks (*Institutiones Linguæ Pracriticæ*, Excursus, ii., p. 12) that the most southerly languages derived from the Sanskrit are the Kunkunan, spoken on the western coast, the Orissan, on the eastern coast, and the Mahratta, in the central parts; and he thinks that a line drawn from Chicacole on the Bay of Bengal towards the sources of the river Tapty, passing by the city of Beder near the sources of the river Kistna, and thence across the Ghauts to Goa on the western coast, would separate the northern languages from those which are unconnected with the Sanskrit.

The languages spoken in the countries bordering on the northern and north-eastern provinces of Hindustan have no connexion with the Sanskrit, but belong to an entirely different family of languages. Those which are spoken in the countries watered by the Indus are closely related to the Sanskrit. It is almost impossible to draw any line which shall separate the languages of Sanskrit origin from those which are derived from the Zend, the antient language of Persia.

The following list contains an account of the modern languages derived from the Sanskrit. The arrangement is taken, with a slight alteration, from Lassen's 'Prakrit Grammar.'

I. Languages spoken in the eastern provinces.

1. *Bengálí*. [BENGALI LANGUAGE.]

2. *Asamese*, spoken in Asam. This language has no literature; the New Testament was translated into it in 1819.

3. *Maithila*, or *Tirhutíya*, is 'the language used in Mithila (that is, in the Sircar of Tirhut) and in some adjoining districts, limited however by the rivers Cusi (Causici) and Ghandac (Ghandaci), and by the mountains of Nepaul. It has great affinity with Bengali; and the character in which it is written differs little from that which is employed throughout Bengal. In Tirhut too the learned write Sanskrit in the Tirhutiya character, and pronounce it after their own inelegant manner. This dialect has no extensive use, and does not appear at any time to have been cultivated by elegant poets.' (Colebrooke, *On the Sanskrit and Prakrit Languages; As. Res.*, vol. vii.; and *Miscellaneous Essays*, vol. ii., pp. 27, 28.)

4. *Orissan*, or *Uriyan*, spoken in Orissa Proper, or Cuttack, has a great resemblance to the Bengali, but is not much cultivated. We know of no original composition of importance in this language, except the epic poem called 'Kanji Kaviri Pothi,' which celebrates the conquest of Anjeveram; one of the most striking events in the modern history of the country. In Wilson's 'Descriptive Catalogue of the MSS. of Col. Mackenzie,' there is a list of several tales in this language relating principally to the passionate and mystical worship of Krishna. The whole Bible has been translated into the Orissan language, in 5 vols. 8vo. (Stirling on *Orissa Proper*, in *As. Res.*, vol. xv.)

II. Languages spoken in tho northern provinces.

5. *Népálese*, spoken in Nepaul. 6. *Kosalese*, spoken in Northern Kosal. 7. *Doguri*, spoken in the Himalaya Mountains between Cashmere and Almora. 8. *Cáshmírí*, spoken in Cashmere. Our knowledge of these languages is very limited. They do not appear to have auy literature. The New Testament has been translated into the Nepalese and Cashmiri.

III. Languages spoken in the western provinces.

9. *Panjabí*, spoken in the Panjab. 'The songs entitled Khéâls and Teppas, which are no doubt familiar to all who have a taste for the vocal music of India, are composed almost entirely in this dialect.' (Colebrooke's *Miscell. Essays*, ii., p. 33.) A Grammar of this language has been published by Dr. Carey, 8vo., Serampore, 1812.

10. *The Wuchí*, or *Multaní*, spoken in the provinces of the same name.

11. *Sindhí*, spoken in Sinde as far as the mouths of the Indus. A Grammar of this language has lately been published by W. H. Wathen, which we have not yet seen; but of which there is an account in No. 65 of the 'Journal of the Asiatic Society of Bengal,' May, 1837. The Sindhí is divided into two dialects, northern and southern.

IV. Languages spoken on the western coast.

12. *Kutchí*, spoken in the peninsula of Kutch, or Cutch.

13. *Gurjaratí*, or *Guzeratí*, spoken in Gujerat, and along the coast as far as Bombay. (See Drummond's *Illustrations of the Grammatical Parts of the Guzerattee, Mahratta, and English Languages*, fol., Bombay, 1808.)

14. *Kunkuna* begins where the Gurjaratí ceases to be vernacular: it is spoken at Bombay, and thence up the coast as far as Goa, where the Tuluva language begins.

V. Languages spoken in the central provinces.

15. *Bikanera*, or *Vikanera*; 16, *Marwar*; 17, *Jayapura*; 18, *Udayapura*. These four are the languages spoken by the Râjpoots. 19, *Hâruti*, called by the antient writers Sârasvatî, which was a dialect of the Prakrit. [SANSKRIT LANGUAGE.] 20, *Brâja Bhâkâ*, or *Vraja bhâshâ*, spoken in the Doab on the banks of the Yamuna (Jumna). This language is derived from the Sâurasení, one of the Prakrit dialects. The Brâja Bhâkâ contains a more than ordinary number of Sanskrit words, and appears to have been one of the dialects from which the Hindûstaní was formed. Mr. Colebrooke (*Misc. Ess.*, ii. p. 34) says that 'it derives its name from the cow-pens (*vraja*) and dairies in the forest of Vrindâ, where Krishna was educated among the wives and daughters of the cowherds. His amorous adventures with Râdhâ and the Gopis furnish the subject of many favourite songs in this language.' A Grammar of this language has been published under the title of 'General Principles of Inflection and Conjugation in the Brij Bhakha; composed by Shree Lulloo Lal Kuvi, Moonshee,' 4to., Calcutta, 1811. Some works in the Brâja Bhâkhâ have been published at the Education Press in Calcutta; and a translation into English of several tales in this language, entitled 'Bytal-Puchisi, or the Twenty-five Tales of Bytal,' was published at Calcutta in 1834.

21. *Malâví*, spoken in *Malwá*. 22, *Bundelakhandí*, spoken in Bundelcund. 23, *Mâgadha*, spoken in the southern part of Bahar.

24. *Mahârâshtra*, or *Mahrâtta*. The districts in which this language is spoken are accurately defined by Carey in the preface to his Mahratta Grammar: 'A line drawn across the peninsula in the latitude of Visiapore (Bejapore) will nearly express the southern limit of this language, and another at a small distance from Ujjayin (Oujein) about 24° N. lat. will nearly mark its northern limits. From east to west its extent is various, but it may in general be reckoned to be spoken from the mountains which separate Bengal, Bihar, and Orissa from the countries immediately west of them, to the western side of the peninsula and the province of Guzerate.' Colebrooke (*Miscell. Essays*, ii. p. 30) remarks, 'that the Mahrâtta, like other Indian tongues, contains much pure Sanscrit, and more corruptions of that language, intermixed with words borrowed from Persian and Arabic, and with others derived from an unknown source. The Mahrâttas possess many poems in their own dialect, either translated from the Sanscrit, or original compositions, in honour of Krishna, Rama, and other deified heroes. Treatises in prose too, on subjects of logic and philosophy, have been composed in the Mahrâtta dialect.' The political importance which the Mahratta nation once possessed rendered the study of their language important to Europeans. The first Grammar was published at Rome in 1778, under the title of 'Grammatica Marastta à mais vulgar, que se practica nos Reinos do Nizamaxà e Idalxà; Offerecida aos mintos reverendos padres missionarios dos dittos reinos;' another edition of this work appeared at Lisbon in 1805. See also Carey's *Grammar of the Mahratta Language*, 8vo., Scrampore, 1805; Carey's *Dictionary of the Mahratta Language*, 8vo., Serampore, 1810; *Dictionary, Murathee and English, compiled for the Government of Bombay*, by J. T. Molesworth, assisted by Thomas and George Candy, 4to., Bombay, 1831.

VI. *Hindustâní* is not limited to any particular district, but is spoken by almost all the natives in addition to their own dialects in the northern and central provinces of Hindustan. This language appeared to have been formed from the Brâja Bhâkâ and the Prakrit, which was spoken in the extensive empire in northern India, of which Kânyâkubja, or Canoj, was the capital. After the conquest of Mahmud this language was adopted as the means of communication between the Mohammedans and Hindus, in consequence of which a considerable number of Persian and Arabic words was introduced into the language. It was called by the Mohammedans *Urdû Zabân*, or 'camp-language,' and by the poets *Rekhta*, 'scattered,' on account of the variety of languages interspersed in it. The Hindustânî was very much cultivated under Akbar and the following emperors, and numerous poems, by Mohammedans as well as Hindus, were composed in this language. It was spoken at Delhi and Agra with the greatest purity, but since the downfal of the Mogul empire it has been principally cultivated at Lucknow. The Hindî is the same language as Hindustânî, but differs from it chiefly in retaining Sanskrit words, while the Hindustani substitutes for them words of Persian and Arabic origin. The Hindi is the dialect which is chiefly cultivated by Hindu poets. The intercourse of Europeans with uneducated natives has tended to corrupt the Hindustani, and thus a barbarous dialect has been produced which is commonly called Moorish or Moors. Grammars of this dialect have been published by Lebedeff, 'Grammar of the Mixed Indian Dialects, erroneously called Moorish or Moors,' 4to., Lond., 1801: and Hadley, 'Grammar of the Corrupt Dialect of the Jargon of Hindustan (commonly called Moors),' 8vo., Lond., 1809. The Mohammedans adopt the Arabic, but the Hindus generally prefer the Devanagari characters in writing Hindustani. 'The affinity of Hindi with the Sanscrit language is peculiarly striking; and no person acquainted with both can hesitate in affirming that Hindi is chiefly borrowed from the Sanscrit. Many words, of which the etymology shows them to be the purest Sanscrit, are received unaltered; many more undergo no change but that of making the final vowel silent; a still greater number exhibits no other difference than what arises from the uniform permutation of certain letters; the rest too, with comparatively few exceptions, may be easily traced to a Sanscrit origin.' (Colebrooke's *Miscell. Essays*, ii. p. 23.)

To Europeans who wish to commence the study of Hindustani the following works may be recommended:—'Grammar of the Hindustani Language,' by Shakespear, 4to., London, 1826; 'Rudimens de la Langue Hindoustani,' by Garcin de Tassy, 4to., Paris, 1829; 'Hindoostanee Interpreter, containing the Rudiments of Hindoostanee Grammar,' by W. C. Smyth, 8vo., London, 1824; 'Introduction to the Hindoostanee Language,' by W. Yates, 8vo., Calcutta, 1827; 'Muntakhabat-i-Hindi, or Selections in Hindustani, with Verbal Translations and a Grammatical Analysis,' by Shakespear, 2 vols. 4to., London, 1834—35; 'Les Adventures de Kamrup, par Tahcin-Uddi; publiées en Hindoustani,' par Garcin de Tassy, 8vo., Paris, 1835; 'Intikhab-i-Ikwan-us-Suffa, or Hindi Selections,' by J. Michael, 4to., London, 1829; 'Naklat-i-Hindi, or Hindi Stories,' by J. Michael, 4to., London, 1829; and the various elementary works published by Gilchrist. Dictionaries in Hindustani and English have been published by W. Hunter, originally compiled by J. Taylor, 2 vols. 4to., Calcutta, 1808; W. C. Smyth, abridged from Taylor and Hunter's work, 8vo., London, 1820: and Shakespear, 4to., London, 1834. An English and Hindustani Dictionary has been published by Gilchrist, under the title of 'Hindoostanee Philology,' 4to., Lond., 1825.

There are also many mountainous parts and forests in the northern provinces of Hindustan inhabited by numerous tribes, which do not profess the Brahmanical faith and which speak a language entirely unconnected with Sanskrit. These tribes, which are known by the names of Bhils, Gondas, and Puharees, inhabit the mountainous tracts in Candeish, Malwa, Rajpootana, Gondwana, and the Rajmahal hills in Bengal. See Sir J. Malcolm, in 'Transactions of Asiatic Society,' i. 65-91; 'Asiatic Researches,' iv. 31-108; v. 127-130; Heber's 'Journal,' i. 211, 257, 493; ii. 71. It is remarked by Ellis, in the preface to Campbell's 'Teloogoo Grammar,' that 'it is extraordinary that the uncivilized races of the north of India should in this respect bear any resemblance to the Hindus of the south: it is nevertheless the fact, that, if not of the same radical derivation, the language of the mountaineers of Rajmahal abounds in terms common to Tamul and Telinga.' If this be true, it would afford a strong presumption that the whole of Hindustan was inhabited, before the introduction of the Brahmanical faith and the Sanskrit language, by one race, which spoke a common language, and that the Bhils and other uncivilized tribes which are found in northern Hindustan are the descendants of the original inhabitants of the country.
